Supplemented with current guidelines and trial evidence, 2023–2026

Prepared for Sudarsan • August 2026

Table of Contents

PART I — GASTROENTEROLOGY — LUMINAL DISEASE

1.	Management of gastro-oesophageal reflux disease	p.4 · 15 Marks
2.	*Helicobacter pylori* — diagnosis and eradication	p.5 · 15 Marks
3.	Upper gastrointestinal bleeding — risk scores and management	p.6 · 15 Marks
4.	Malabsorption — etiopathogenesis, clinical features, diagnostic algorithm and management	p.7 · 15 Marks
5.	Constipation and faecal impaction in the elderly	p.8 · 15 Marks
6.	Bristol Stool Chart; classes of laxatives and their modes of action	p.9 · 7 Marks
7.	Colorectal carcinoma — presentation and staging	p.10 · 15 Marks
8.	Palliative management of malignant bowel obstruction	p.11 · 7 Marks

PART II — HEPATOLOGY

9.	Causes of jaundice in an older person and their management	p.12 · 7 Marks
10.	Drug-induced jaundice	p.12 · 7 Marks
11.	Chronic active hepatitis	p.13 · 6 Marks
12.	Alcoholic hepatitis	p.14 · 7 Marks
13.	Management of newly diagnosed hepatitis B in the elderly	p.14 · 7 Marks
14.	Decompensated chronic liver disease in the elderly, and the OPD approach to chronic liver disease	p.15 · 15 Marks
15.	Management of hepatic encephalopathy	p.16 · 7 Marks
16.	Ascites and refractory ascites	p.17 · 7 Marks
17.	Hepatorenal syndrome	p.18 · 7 Marks

PART III — CLINICAL NUTRITION

18.	Parenteral nutrition	p.19 · 7 Marks
19.	Refeeding syndrome	p.19 · 7 Marks
20.	Inanition	p.20 · 7 Marks

PART IV — ANAEMIA AND TRANSFUSION

21.	Anaemia in the elderly and the evaluation of anaemia	p.22 · 7 Marks
22.	Iron deficiency anaemia — red cell indices and investigation	p.22 · 7 Marks
23.	Megaloblastic anaemia and B_{12} deficiency	p.23 · 15 Marks
24.	Anaemia of chronic disease	p.24 · 7 Marks
25.	Blood transfusion in the older adult — thresholds and hazards	p.25 · 7 Marks

PART V — HAEMATOLOGICAL DISORDERS AND MALIGNANCY

26.	Thrombocytopenia	p.27 · 7 Marks

27.	Disseminated intravascular coagulation	p.27 · 7 Marks
28.	Myelodysplasia	p.28 · 7 Marks
29.	Chronic myeloid leukaemia — clinical features and management	p.29 · 7 Marks
30.	Chronic lymphocytic leukaemia	p.30 · 15 Marks
31.	Myelofibrosis and the myeloproliferative neoplasms	p.31 · 15 Marks
32.	Plasma cell dyscrasias — types, presentation, diagnostic criteria, course and treatment	p.32 · 15 Marks
33.	Multiple myeloma — aetiology, diagnosis and management	p.33 · 15 Marks
34.	Bone marrow transplantation in older patients	p.34 · 7 Marks
PART VI — ONCOLOGY		
35.	Prostatic cancer	p.36 · 7 Marks
36.	Vertebral secondaries with unknown primary — evaluation and treatment	p.37 · 7 Marks
37.	Paraneoplastic syndromes	p.37 · 7 Marks
38.	Tumour lysis syndrome	p.38 · 7 Marks
PART VII — CANCER SCREENING AND IMAGING		
39.	Indications and rationale for cancer screening in the elderly	p.40 · 7 Marks
40.	Screening for breast, colorectal and cervical cancer — population, tests, performance and guidelines	p.40 · 7 Marks
41.	Positron emission tomography	p.41 · 6 Marks
APPENDIX		
★	Rapid Revision Grid — examinable numbers, named trials and guidelines	p.43

Point counts within each answer are exact and must be reproduced as such in the examination. Purple panels contain evidence from 2023 onwards; amber panels flag the specific places where the textbook position has been superseded by current practice.

PART I — GASTROENTEROLOGY — LUMINAL DISEASE

Question 1. Management of gastro-oesophageal reflux disease 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition and mechanism.** GORD exists when reflux of gastric contents causes troublesome symptoms or complications. Mechanisms include **transient lower oesophageal sphincter relaxations (the dominant mechanism)**, a hypotensive LOS, **hiatus hernia**, delayed gastric emptying and impaired oesophageal acid clearance.
2. **Presentation in the elderly — the key examination point.** **Symptoms are milder or atypical but mucosal injury is more severe**: erosive oesophagitis, peptic stricture and Barrett's oesophagus are all commoner, while heartburn is reported less often because of **diminished oesophageal sensitivity**. Presentations include **dysphagia, vomiting, weight loss, anaemia, chest pain, chronic cough, hoarseness and aspiration pneumonia**.
3. **Aggravating factors.** Obesity, hiatus hernia, smoking, alcohol, large or late meals and recumbency; and drugs that reduce LOS pressure or injure the mucosa — **calcium channel blockers, nitrates, anticholinergics, theophylline, benzodiazepines, bisphosphonates, potassium chloride, doxycycline and NSAIDs**. **Reviewing the drug chart is a therapeutic act in the elderly.**
4. **Alarm features requiring endoscopy.** **Dysphagia, odynophagia, weight loss, persistent vomiting, anaemia, gastrointestinal bleeding, and new-onset symptoms in a patient over 60. The threshold for endoscopy must be lower than in the young**, because empirical acid suppression may mask malignancy.
5. **Investigations.** Upper GI endoscopy graded by the **Los Angeles classification (A–D)** with biopsy for Barrett's oesophagus; **ambulatory 24-hour pH or pH-impedance monitoring performed off PPI is the gold standard** for confirming pathological acid exposure in non-erosive disease; **high-resolution manometry** before anti-reflux surgery and to exclude achalasia; and barium swallow for strictures and large hernias.
6. **Lifestyle measures.** Weight reduction, **elevation of the head end of the bed by 6–8 inches**, avoiding meals within 3 hours of lying down, left lateral sleeping position, smoking and alcohol cessation, and avoidance of individual trigger foods. **These carry no drug risk and are especially valuable in the elderly.**
7. **Pharmacological therapy.** **Proton pump inhibitors are the drugs of choice**, given **once daily 30–60 minutes before breakfast for 8 weeks**; they are clearly superior to H_2 receptor antagonists for healing oesophagitis. **No dose reduction is required for age**, but step down to the lowest effective dose or on-demand therapy after healing. Antacids and alginates provide symptomatic relief, an H_2 blocker may be added at night for nocturnal breakthrough, and **prokinetics have no established role**.
8. **Long-term PPI safety in older adults.** A causal relationship is likely for **acute interstitial nephritis, benign fundic gland polyps, enteric infections including *C. difficile*, vitamin B_{12} deficiency and hypomagnesaemia**. Associations with **fracture, pneumonia, dementia and progression of CKD are not supported by strong evidence** and are heavily confounded. Review the indication periodically and deprescribe where possible; the clopidogrel interaction is clinically meaningful essentially only for **omeprazole**.
9. **Complications and their management.** Erosive oesophagitis; **peptic stricture — endoscopic dilatation plus long-term PPI**; bleeding; **Barrett's oesophagus** requiring surveillance endoscopy, with endoscopic eradication therapy for high-grade dysplasia; oesophageal adenocarcinoma; and extra-oesophageal disease (asthma, chronic cough, laryngitis, dental erosion, aspiration).
10. **Refractory disease and surgery.** First confirm adherence and correct dosing timing, then optimise to twice-daily PPI, and re-evaluate with pH-impedance testing to identify **functional heartburn or reflux hypersensitivity** (treated with low-dose tricyclics or SSRIs, used cautiously in the elderly). **Laparoscopic fundoplication gives outcomes and complication rates in patients over 70 comparable to the young**, but long-term medical therapy is usually more cost-effective given remaining life expectancy; **patients with ineffective oesophageal motility are at risk of post-operative dysphagia**. Endoscopic anti-reflux procedures remain investigational.

Latest Updates (2023–2026) — 2 points

11. **AGA Clinical Practice Update on potassium-competitive acid blockers** (*Gastroenterology* 2024;167:1228) — **vonoprazan is superior to PPIs for healing and maintaining healing of severe (LA grade C/D) erosive oesophagitis** and for *H. pylori* eradication, and is now FDA-approved for both erosive and non-erosive GERD. However, the update advises that **P-CABs should not be used first-line for mild (LA grade A/B) oesophagitis, nor for peptic ulcer treatment or prophylaxis**, so their role is targeted rather than universal.
12. **ASGE Clinical Practice Guideline on GERD (2025)** (*Gastrointest Endosc*) — the first ASGE update since 2014. It endorses **PPI as initial therapy with endoscopy reserved for alarm features or refractory symptoms**, supports vonoprazan for severe erosive disease, and positions **endoscopic and surgical anti-reflux therapy only for objectively confirmed, PPI-refractory GERD** proven on pH-impedance testing rather than for symptom-based referral.

Current Practice Update

Textbook: PPIs are the most potent acid suppressants available and are first-line for all grades of GORD.
Current recommendation: Potassium-competitive acid blockers (vonoprazan) are superior for LA grade C/D oesophagitis and for *H. pylori* eradication; PPIs remain first-line for mild disease.
Exam approach: Keep PPI as the answer to "drug of choice", then add one line on P-CABs for severe erosive disease.

Question 2. *Helicobacter pylori* — diagnosis and eradication 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition.** *H. pylori* is a **Gram-negative, spiral, urease-producing** bacterium that colonises the gastric mucus layer. It is a **WHO Class I carcinogen**.
2. **Why it matters in the elderly.** Prevalence rises with age (over 60–70% in Indian elderly). It causes **chronic gastritis, peptic ulcer, gastric MALT lymphoma and gastric adenocarcinoma**, and worsens NSAID/aspirin ulcer bleeding.
3. **Indications to test ("test and treat").** Active or past peptic ulcer, gastric MALT lymphoma, after resection of early gastric cancer, unexplained **iron deficiency anaemia**, ITP, long-term NSAID/aspirin or PPI use, and a first-degree relative with gastric cancer.
4. **Alarm features → endoscopy first.** New dyspepsia at age ≥60, weight loss, dysphagia, persistent vomiting, anaemia, GI bleeding or abdominal mass. **Empirical "test and treat" is not appropriate in the elderly with new dyspepsia.**
5. **Non-invasive tests.** **Urea breath test (^{13}C-UBT)** and **stool antigen test** are the tests of choice for both diagnosis and test-of-cure (sensitivity and specificity >90%). **Serology (IgG) cannot distinguish current from past infection** and must never be used for test-of-cure.
6. **Invasive (endoscopic) tests.** **Rapid urease test** on antral + body biopsies, **histology** (Giemsa stain), **culture with susceptibility testing**, and PCR for clarithromycin resistance.
7. **Causes of false-negative tests.** PPI within **2 weeks**, antibiotics or bismuth within **4 weeks**, active bleeding, and extensive atrophic gastritis/intestinal metaplasia. Stop the PPI two weeks before UBT or stool antigen testing.
8. **First-line eradication (textbook).** **Standard triple therapy** — PPI + **clarithromycin 500 mg** + **amoxicillin 1 g**, all twice daily for **14 days**. Metronidazole 400 mg BD replaces amoxicillin in penicillin allergy.
9. **Bismuth quadruple therapy.** PPI BD + bismuth subcitrate + **tetracycline 500 mg QID + metronidazole 400 mg TID for 14 days**. Used when clarithromycin resistance is high, after prior macrolide exposure, or after treatment failure. Salvage options are levofloxacin-based or rifabutin-based triple therapy.
10. **Geriatric considerations and confirmation of cure.** Check interactions (clarithromycin with **statins, digoxin, warfarin and QT-prolonging drugs**), adjust amoxicillin/levofloxacin for renal function, warn about ***C. difficile*** and use adherence aids. **Confirm eradication at least 4 weeks after therapy by UBT or stool antigen — never by serology.**

Latest Updates (2023–2026) — 2 points

11. **ACG Clinical Guideline 2024** (*Am J Gastroenterol* 2024;119:1730) — **optimized bismuth quadruple therapy for 14 days is now first-line** when susceptibility is unknown. **Clarithromycin triple therapy and concomitant therapy are no longer recommended empirically** because clarithromycin resistance is 22–32%. Rifabutin triple therapy and vonoprazan-amoxicillin dual therapy are alternatives, and **test-of-cure is now mandatory in every treated patient**.
12. **Potassium-competitive acid blockers (vonoprazan)** — vonoprazan-amoxicillin dual and vonoprazan-clarithromycin-amoxicillin triple regimens are FDA-approved. Vonoprazan dual therapy was **superior to lansoprazole-clarithromycin triple therapy in clarithromycin-resistant strains (70% vs 32% eradication)**, offering a new option for resistant infection.

Current Practice Update

Textbook: PPI + clarithromycin + amoxicillin triple therapy is first-line.
Current recommendation: Optimized bismuth quadruple therapy for 14 days is first-line; clarithromycin triple therapy only if susceptibility is documented.
Exam approach: Write the textbook regimen first, then add "however, ACG 2024 now recommends optimized bismuth quadruple therapy first-line owing to clarithromycin resistance >15%."

Question 3. Upper gastrointestinal bleeding — risk scores and management 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition.** Bleeding from a source **proximal to the ligament of Treitz**, presenting with haematemesis, coffee-ground vomiting or melaena. Mortality in the elderly is **10–15%**.
2. **Causes in the elderly.** **Peptic ulcer is the commonest**, followed by erosive gastritis/duodenitis, oesophagitis, varices, Mallory-Weiss tear, **angiodysplasia**, malignancy and Dieulafoy lesion. Key drugs: **NSAIDs, aspirin, anticoagulants, SSRIs and corticosteroids**.
3. **Atypical presentation in old age.** May present as **syncope, falls, confusion, angina or unexplained anaemia** rather than overt bleeding. Beta-blockers mask tachycardia, and comorbidity determines mortality more than the volume of blood lost.
4. **Resuscitation.** ABC approach, two wide-bore cannulae, crystalloid, group-and-crossmatch, correct coagulopathy (PCC for warfarin, andexanet/idarucizumab where available). **Restrictive transfusion at Hb <7 g/dL with a target of 7–9 g/dL**; a higher threshold of 8 g/dL is used in cardiovascular disease.
5. **Glasgow-Blatchford Score (GBS) — the pre-endoscopy score of choice.** Uses **urea, haemoglobin, systolic BP, pulse, melaena, syncope, hepatic disease and cardiac failure**. **GBS 0–1 identifies very low-risk patients who can be managed as outpatients** without early endoscopy.
6. **Other risk scores.** **Rockall score** (age, shock, comorbidity, diagnosis, endoscopic stigmata) predicts rebleeding and mortality; **AIMS65** (Albumin <3 g/dL, INR >1.5, altered Mental status, SBP <90, age >65) predicts in-hospital mortality; the **ABC score** predicts 30-day mortality.
7. **Forrest classification of ulcer stigmata.** **Ia** spurting, **Ib** oozing, **IIa** non-bleeding visible vessel, **IIb** adherent clot, **IIc** flat pigmented spot, **III** clean base. **Forrest Ia, Ib and IIa require endoscopic therapy** (rebleed risk approximately 55%, 43% and 22%); IIc and III need no therapy.
8. **Pharmacotherapy.** **High-dose IV PPI — 80 mg bolus then 8 mg/hour for 72 hours** after successful endoscopic haemostasis. **IV erythromycin 250 mg 30–120 minutes before endoscopy** improves visualisation. If varices are suspected, add **terlipressin and prophylactic ceftriaxone**.
9. **Endoscopy.** Perform **within 24 hours** of presentation after resuscitation. For actively bleeding ulcers use **combination therapy — adrenaline injection plus a second modality** (clip or thermal coagulation); adrenaline alone is inadequate. Haemostatic powder (TC-325) is useful for diffuse or malignant bleeding. Routine second-look endoscopy is not recommended.
10. **Failure and secondary prevention.** Rebleeding → repeat endoscopy → **transcatheter arterial embolisation** (preferred in the frail elderly) → surgery if embolisation fails or is unavailable. Then **test and eradicate *H. pylori***, stop NSAIDs, resume aspirin early (within 3–5 days) when needed for secondary prevention, and continue PPI cover.

Latest Updates (2023–2026) — 2 points

11. **AABB 2025 international guideline** (*Ann Intern Med* 2025;178:1469) — based on the **MINT trial (NEJM 2023)**, a **liberal transfusion threshold of Hb <10 g/dL is now suggested in acute myocardial infarction with anaemia**. This is the key exception to the universal restrictive rule and is directly relevant when an older patient bleeds while having myocardial ischaemia.
12. **Canadian Association of Gastroenterology 2025 guideline** (*Gastroenterology* 2025) provides the first dedicated guidance for **non-variceal, non-peptic-ulcer bleeding** (angiodysplasia, GAVE, Dieulafoy lesion, Mallory-Weiss). A 2025 individual-patient-data meta-analysis also confirmed **TC-325 hemostatic powder is superior to conventional therapy for malignant GI bleeding**.

Cross-reference: The transfusion thresholds referred to here, including the acute myocardial infarction exception, are covered in full in Question 25.

Question 4. Malabsorption — etiopathogenesis, clinical features, diagnostic algorithm and management 15 MARKS

Answer — Textbook Core (10 points)

1. **Definitions.** **Maldigestion** is impaired breakdown of nutrients within the lumen or at the brush border; **malabsorption** is impaired mucosal uptake and transport of digested nutrients. Both produce the clinical **malabsorption syndrome**, and the two frequently coexist.
2. **Luminal (maldigestive) causes.** **Chronic pancreatitis and pancreatic exocrine insufficiency** (also pancreatic carcinoma and post-pancreatectomy), **bile salt deficiency** from cholestasis or ileal resection, **small intestinal bacterial overgrowth** with bile salt deconjugation, post-gastrectomy states, and Zollinger-Ellison syndrome (acid inactivation of enzymes).
3. **Mucosal causes.** **Coeliac disease — increasingly diagnosed in the elderly and often presenting with isolated anaemia or osteoporosis rather than diarrhoea**; **tropical sprue (important in India)**; Whipple's disease; Crohn's disease; radiation enteritis; amyloidosis; intestinal lymphoma; giardiasis; HIV enteropathy; and drugs — **metformin, olmesartan, colchicine, NSAIDs, orlistat and neomycin**.
4. **Structural, lymphatic and vascular causes.** Short bowel after resection, blind loops, fistulae and strictures; **intestinal lymphangiectasia** with protein-losing enteropathy; and **chronic mesenteric ischaemia**, which is particularly important in older vasculopaths and presents with **postprandial abdominal pain, food fear and weight loss**.
5. **Pathogenesis.** Reduced absorptive surface area, defective luminal digestion, impaired brush-border enzyme activity, bacterial deconjugation of bile salts and lymphatic obstruction lead to **osmotic diarrhoea and steatorrhoea**, with secondary deficiencies of fat, protein, carbohydrate, vitamins and minerals. Unabsorbed fatty acids and bile acids in the colon further stimulate secretion.
6. **Clinical features.** Chronic diarrhoea with **pale, bulky, offensive, greasy stools that float and are difficult to flush (steatorrhoea)**, flatulence, borborygmi, abdominal distension, and **weight loss despite an adequate appetite and intake**. **In the elderly the presentation is often subtle** — unexplained weight loss, refractory anaemia, oedema, osteoporotic fracture or falls.
7. **Deficiency syndromes (very high yield).** **Iron, folate and B_{12} deficiency anaemia** (often dimorphic); **osteomalacia and osteoporosis from calcium and vitamin D deficiency — bone pain, proximal myopathy and fractures**; bleeding and bruising from **vitamin K deficiency**; **hypoproteinaemic oedema**; night blindness from vitamin A deficiency; glossitis, cheilosis and dermatitis; **tetany from hypocalcaemia and hypomagnesaemia**; and peripheral neuropathy.
8. **Diagnostic algorithm — Step 1: confirm malabsorption and screen for consequences.** Complete blood count with indices and film, iron studies, B_{12} and folate, calcium, phosphate, magnesium, vitamin D, albumin, PT/INR, and thyroid function. Confirm fat malabsorption with **faecal fat estimation — qualitative Sudan III stain or quantitative 72-hour faecal fat >7 g/day**; measure **faecal calprotectin** to separate inflammatory from non-inflammatory causes.
9. **Diagnostic algorithm — Step 2: identify the specific cause.** **IgA anti-tissue transglutaminase with total IgA for coeliac disease, confirmed by duodenal biopsy showing villous atrophy (Marsh grading)**; **faecal elastase-1 <200 µg/g for pancreatic exocrine insufficiency**, with CT or MRCP of the pancreas; **glucose or lactulose hydrogen breath test for bacterial overgrowth** (or an empirical antibiotic trial); stool for ova, parasites and *Giardia* antigen; CT or MR enterography and capsule endoscopy for small bowel disease; and CT angiography if mesenteric ischaemia is suspected. **Remember that coeliac serology is falsely negative in IgA deficiency and**

may be lower-titre in the elderly.

10. **Management. Treat the specific cause** — a lifelong strict **gluten-free diet with dietitian supervision** for coeliac disease; **pancreatic enzyme replacement of 40,000–50,000 units of lipase with each main meal plus a PPI** for exocrine insufficiency; rotating antibiotics (rifaximin, norfloxacin) for bacterial overgrowth; **tetracycline with folic acid for tropical sprue**; and revascularisation for mesenteric ischaemia. **Replace deficiencies** — iron, B_{12}, folate, calcium with vitamin D, fat-soluble vitamins A, D, E and K, zinc and magnesium; use **medium-chain triglycerides** in severe steatorrhoea since they are absorbed without bile salts or lymphatics; monitor bone mineral density; and address weight, sarcopenia and quality of life.

Latest Updates (2023–2026) — 2 points

11. **ACG Clinical Guideline on Coeliac Disease 2023** (*Am J Gastroenterol* 2023;118:59) — **IgA anti-tTG with a total IgA level remains the single best initial test**; **duodenal biopsy (one from the bulb and four from the distal duodenum) is still required in adults** for diagnosis; **HLA-DQ2/DQ8 typing is useful only to exclude the disease**, not to confirm it. The guideline emphasises follow-up biopsy or serology for **persistent villous atrophy**, and routine screening for nutritional deficiency and metabolic bone disease — particularly relevant in older patients diagnosed late.
12. **AGA Clinical Practice Update on exocrine pancreatic insufficiency (2023)** — highlights that PEI is **substantially under-diagnosed and, when diagnosed, systematically under-dosed**. It occurs not only in chronic pancreatitis but also after gastric and pancreatic surgery, and in diabetes, coeliac disease and advanced age. **Faecal elastase-1 should be checked in any patient with unexplained weight loss or steatorrhoea**, and enzyme doses should be titrated upward against symptoms and nutritional markers rather than left at a fixed low dose.

Question 5. Constipation and faecal impaction in the elderly 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition (Rome IV).** Two or more of — straining, lumpy or hard stools, sensation of incomplete evacuation, sensation of anorectal obstruction, need for manual manoeuvres, and **fewer than three spontaneous bowel movements per week** — present for 3 months with onset at least 6 months earlier.
2. **Prevalence.** Affects **30–40% of community-dwelling elderly and more than 50% of nursing home residents**; laxative use is even more common than the symptom itself.
3. **Age-related mechanisms.** Reduced fibre and fluid intake, **immobility**, **reduced rectal sensation and compliance**, and impaired pelvic floor and anal sphincter function. **Colonic transit itself is largely preserved in healthy ageing** — constipation is not a normal part of ageing.
4. **Classification. Primary** — normal-transit, slow-transit, and defecatory (dyssynergic) disorder. **Secondary** — drug-induced, metabolic, neurological or obstructive.
5. **Drug causes (very high yield). Opioids, anticholinergics, tricyclic antidepressants, calcium channel blockers (verapamil), oral iron, calcium and aluminium antacids, diuretics, antiparkinsonian drugs, ondansetron and clozapine.**
6. **Secondary causes to exclude. Hypothyroidism, hypercalcaemia, hypokalaemia, diabetes, dehydration, Parkinson's disease, stroke, spinal cord lesions, depression, colorectal carcinoma and strictures.**
7. **Assessment.** History with the **Bristol Stool Chart**, full drug review, abdominal examination, and a **digital rectal examination in every patient** (to detect impaction, tone, masses and dyssynergia). Alarm features — weight loss, bleeding, anaemia, recent change in bowel habit — require **colonoscopy**. Refractory cases need **anorectal manometry and balloon expulsion testing**.
8. **Faecal impaction — clinical features.** A hard faecal mass in the rectum (or higher in the colon), **overflow (paradoxical) diarrhoea and faecal incontinence**, abdominal pain, anorexia, urinary retention and **delirium**. Complications include **stercoral ulceration and perforation**, bleeding, sepsis and sigmoid volvulus.
9. **Management of impaction. Manual disimpaction with adequate analgesia** for a low, hard impaction, followed by a **phosphate or arachis oil retention enema**. High impaction is treated with **high-dose oral polyethylene glycol (macrogol)** — contraindicated if obstruction is suspected. Follow with maintenance laxatives and bowel retraining to prevent recurrence.
10. **Stepwise treatment of constipation.** Mobility, fluids, gradual fibre increase (**avoid bulking agents in immobile, impacted or opioid-treated patients**), and toileting after meals to use the **gastrocolic reflex → osmotic laxative — polyethylene glycol is first-line** (better evidence than lactulose) → stimulant (senna, bisacodyl) → secretagogues

(lubiprostone, linaclotide) or the prokinetic **prucalopride → PAMORAs (methylnaltrexone, naloxegol, naldemedine) for opioid-induced constipation**. **Biofeedback is the treatment of choice for dyssynergic defecation.** Avoid magnesium salts in CKD; docusate is ineffective.

Latest Updates (2023–2026) — 2 points

11. **AGA/ACG joint clinical guideline 2023** on chronic idiopathic constipation — **strong recommendation for polyethylene glycol and senna**; conditional recommendations for linaclotide, plecanatide, prucalopride and lubiprostone; and a **recommendation against routine use of docusate and other stool softeners**, which are ineffective.
12. **WGO Global Guideline on Constipation 2025** and the **ASCRS 2024 guideline** reaffirm the Rome IV framework, recommend **early anorectal physiology testing in refractory cases** rather than escalating laxatives blindly, and confirm that **bulk-forming laxatives must be avoided in opioid-induced constipation** because of the risk of impaction and obstruction.

Cross-reference: The Bristol Stool Chart and the mode of action of each laxative class are set out in Question 6.

Question 6. Bristol Stool Chart; classes of laxatives and their modes of action 7 MARKS

Answer — Textbook Core (6 points)

1. **The Bristol Stool Form Scale — purpose and diagram.** A validated seven-point pictorial scale developed at Bristol Royal Infirmary that classifies stool by form, which **correlates with whole-gut transit time**. It gives an objective, reproducible way for patients and nurses to describe stool, and is used to diagnose and monitor constipation, diarrhoea and faecal incontinence.

Type	Appearance	Description	Interpretation
Type 1	● ● ● ●	Separate hard lumps, like nuts, hard to pass	**Constipation** (slow transit)
Type 2	▮▮▮▮▮	Sausage-shaped but lumpy	
Type 3	▮▮▮▮	Sausage-shaped with cracks on the surface	**Normal** (Type 4 is ideal)
Type 4	▮▮▮▮	Smooth and soft, like a sausage or snake	
Type 5	◉ ◉ ◉	Soft blobs with clear-cut edges, passed easily	Tending to **lack of fibre**
Type 6	▒▒▒▒	Fluffy pieces with ragged edges, mushy stool	**Diarrhoea** (rapid transit, urgency)
Type 7	≈≈≈≈	Entirely liquid, watery, no solid pieces	

2. **Clinical use of the chart.** **Types 1–2 indicate constipation, 3–4 are normal (Type 4 ideal), 5 suggests inadequate fibre, and 6–7 indicate diarrhoea.** It is used to satisfy the Rome IV criterion of "lumpy or hard stools", to **titrate laxatives (target Type 3–4)**, to monitor bowel preparation, to distinguish true diarrhoea from **overflow around faecal impaction**, and as a nursing chart in institutional and palliative care.
3. **Bulk-forming laxatives.** **Ispaghula/psyllium, methylcellulose and sterculia.** Mode of action — they are **non-absorbable hydrophilic polysaccharides that increase faecal mass and retain water, distending the colon and stimulating peristalsis**. Onset 2–3 days; they require an adequate fluid intake. **Avoid in immobile, dehydrated, opioid-treated or impacted patients because of the risk of obstruction and faecal loading.**
4. **Osmotic laxatives.** **Polyethylene glycol (macrogol) — first-line, with the best evidence**, and **lactulose**, a non-absorbable disaccharide that is fermented by colonic bacteria to organic acids, drawing water osmotically (and useful in hepatic encephalopathy). **Magnesium salts and sodium phosphate** act more rapidly. Cautions: **avoid magnesium salts in renal impairment (hypermagnesaemia) and phosphate enemas in the frail elderly (hyperphosphataemia, hypocalcaemia and acute kidney injury)**; lactulose causes bloating and flatulence.
5. **Stimulant (irritant) laxatives.** **Senna, bisacodyl and sodium picosulfate.** Mode of action — they **stimulate the myenteric plexus to increase colonic motility and also reduce water and electrolyte absorption**. Onset 6–12 hours orally (bisacodyl suppository within 1 hour). They cause abdominal cramps and hypokalaemia with prolonged use, and anthraquinones produce **melanosis coli** (benign and reversible). They are the most useful class alongside opioids.
6. **Softeners, lubricants and newer agents.** **Docusate sodium** is a surfactant that lowers stool surface tension but is **largely ineffective and no longer recommended**; **liquid paraffin must be avoided in the elderly because of**

lipoid aspiration pneumonia; glycerine suppositories act as rectal lubricants and stimulants. Newer classes: **secretagogues** — lubiprostone (a chloride channel-2 activator) and linaclotide/plecanatide (guanylate cyclase-C agonists) which increase intestinal chloride and water secretion; the **prokinetic prucalopride**, a selective 5-HT_4 agonist that accelerates colonic transit; and **PAMORAs — methylnaltrexone, naloxegol and naldemedine**, peripherally acting mu-opioid receptor antagonists that reverse opioid-induced constipation without reversing analgesia.

Latest Update (2023–2026) — 1 point

7. **AGA/ACG joint guideline on chronic idiopathic constipation (2023)**, reinforced by the **WGO Global Guideline 2025 — polyethylene glycol and senna carry strong recommendations**; linaclotide, plecanatide, prucalopride and lubiprostone are conditional recommendations for refractory cases; there is an explicit **recommendation against docusate and other stool softeners**; and **PAMORAs are the agents of choice for opioid-induced constipation, in which bulk-forming laxatives should be avoided altogether**.

Cross-reference: The full stepwise management of constipation, including faecal impaction, is given in Question 5; this answer covers the chart and the pharmacology of each laxative class.

Question 7. Colorectal carcinoma — presentation and staging 15 MARKS

Answer — Textbook Core (10 points)

1. **Epidemiology and risk factors.** Median age at diagnosis is about 70 years. Risk factors are **age, adenomatous polyps, inflammatory bowel disease, family history, Lynch syndrome and FAP**, red meat, obesity, smoking and diabetes. India shows rising incidence with a higher proportion of rectal and younger-onset disease.
2. **Molecular pathways.** The **adenoma-carcinoma sequence** (APC → KRAS → p53), the serrated pathway (BRAF, CIMP), and **mismatch repair deficiency (dMMR/MSI-high) in about 15%** of tumours.
3. **Right-sided presentation.** **Iron deficiency anaemia**, fatigue, weight loss, vague right iliac fossa pain and a palpable mass. Obstruction occurs late because stool is fluid and the caecum is capacious. **Unexplained iron deficiency anaemia in an older adult is right-sided colon cancer until proved otherwise.**
4. **Left-sided and rectal presentation.** **Change in bowel habit**, blood mixed with stool, colicky pain, and obstruction. Rectal cancer causes **bleeding, tenesmus, mucus discharge and a sense of incomplete evacuation**.
5. **Emergency presentation.** Up to 20% of elderly patients present as an emergency with **large bowel obstruction, perforation with peritonitis, or acute lower GI bleeding**, all carrying high operative mortality.
6. **Investigations.** **Colonoscopy with biopsy is the gold standard**; CT colonography if colonoscopy is incomplete or unsafe. **CEA is for prognosis and follow-up, not diagnosis.**
7. **Staging investigations.** **CT chest, abdomen and pelvis** for distant disease; **MRI pelvis for rectal cancer** to assess T stage and the circumferential resection margin; endorectal ultrasound for early rectal lesions; PET-CT for equivocal or recurrent disease.
8. **TNM staging (AJCC 8th edition).** **T1** submucosa, **T2** muscularis propria, **T3** through into pericolorectal tissue, **T4a** visceral peritoneum, **T4b** adjacent organ. **N1** = 1–3 nodes, **N2** = 4 or more nodes. **M1a** one organ, **M1b** more than one organ, **M1c** peritoneal. **At least 12 lymph nodes must be examined** for adequate staging.
9. **Stage groups and prognosis.** Stage I about **90%** 5-year survival, Stage II **70–80%**, Stage III **50–65%**, Stage IV about **15%**. Older **Dukes** classification: A confined to bowel wall, B through the wall, C nodal involvement, D distant metastasis.
10. **Geriatric principles.** **Age alone is not a contraindication to curative surgery**; decisions should follow **comprehensive geriatric assessment and frailty screening (G8, CARG or CRASH scores)**. Adjuvant oxaliplatin benefit is less certain over 70 years (single-agent capecitabine is often preferred), and screening should stop when life expectancy is under 10 years (usually age 75–85).

Latest Updates (2023–2026) — 2 points

11. **Non-operative management of dMMR tumours** — neoadjuvant **dostarlimab** (anti-PD-1) produced a **100% clinical complete response in 49 patients with dMMR locally advanced rectal cancer** with 92% disease-free at two years (Cercek, *NEJM* 2025), avoiding surgery and radiotherapy entirely. **Every colorectal cancer must now be tested for MMR/MSI status.**
12. **ctDNA-guided adjuvant therapy** — the **DYNAMIC trial** showed post-operative circulating tumour DNA identifies which stage II patients truly need chemotherapy, **halving chemotherapy use without worsening recurrence-free survival**. At ASCO 2025 the **ATOMIC trial** established that adding atezolizumab to adjuvant mFOLFOX improves disease-free survival in stage III dMMR colon cancer.

Cross-reference: Screening for colorectal cancer is dealt with separately in Question 40; this answer covers presentation and staging only.

Question 8. Palliative management of malignant bowel obstruction 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and context.** Mechanical or functional obstruction **distal to the ligament of Treitz** in a patient with known intra-abdominal or pelvic malignancy. It is commonest in **ovarian and colorectal cancer** (10–28% of colorectal cancers), is frequently **multi-level due to peritoneal carcinomatosis**, and carries a median survival of only weeks to a few months when inoperable.
2. **Clinical features and assessment.** Colicky and continuous abdominal pain, vomiting (early and bilious if proximal, late and faeculent if distal), distension and absolute constipation. **Contrast CT abdomen is the investigation of choice** to define the level, cause, whether there are single or multiple sites, and whether ischaemia is present.
3. **Decision-making.** Multidisciplinary assessment of performance status, prognosis, nutrition, disease extent and the patient's own wishes. **Surgery or stenting is appropriate only for a single-level obstruction in a patient with good performance status, without ascites or carcinomatosis.** A **self-expanding metallic stent** is preferred for a single left-sided colonic or gastroduodenal obstruction.
4. **Drug therapy — analgesia and antiemesis.** All drugs must be given **subcutaneously or parenterally** because oral absorption is unreliable. Use a **subcutaneous morphine infusion** (renally adjusted, or fentanyl in renal impairment) with **hyoscine butylbromide 60–120 mg/24 h for colic**. For antiemesis, **haloperidol 1.5–3 mg/24 h in complete obstruction**; **metoclopramide 30–60 mg/24 h only in incomplete or functional obstruction — it is contraindicated in complete obstruction because it precipitates colic and perforation**.
5. **Antisecretory and anti-inflammatory therapy.** **Octreotide 300–600 µg/24 h subcutaneously** reduces gastrointestinal secretions and vomiting within 24–48 hours and is more effective than hyoscine butylbromide. **Dexamethasone 6–16 mg/24 h** may resolve the obstruction by reducing peritumoural and bowel wall oedema — **stop it if there is no response within 5 days**. Add a proton pump inhibitor or H_2 blocker to reduce gastric secretion volume.
6. **Supportive and non-drug measures.** A **venting nasogastric tube for short-term relief only**; a **venting gastrostomy (PEG)** for irreversible obstruction so the patient may eat and drink for pleasure; **judicious hydration of 500–1000 mL/24 h subcutaneously** (over-hydration worsens secretions and vomiting); meticulous mouth care for thirst; parenteral nutrition only in selected patients with a prognosis beyond 2–3 months; and **early palliative care referral with advance care planning and family communication**.

Latest Update (2023–2026) — 1 point

7. **ASCO Palliative Care Guideline Update 2024** (*J Clin Oncol* 2024;42:2336) together with the **S1316 trial** confirm that **"triple therapy" — dexamethasone plus octreotide plus an antiemetic — is the standard non-surgical medical regimen**, and that although surgery gives better symptom scores on the MDASI-GI instrument, it offers **no survival advantage and causes more treatment-related complications (15% vs 4%)**. Surgery should therefore be reserved for carefully selected patients after shared decision-making.

PART II — HEPATOLOGY

Question 9. Causes of jaundice in an older person and their management 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and framework.** Jaundice is yellow discoloration of skin and sclerae when serum bilirubin exceeds about **2.5–3 mg/dL**. Classify as **pre-hepatic, hepatocellular or post-hepatic (obstructive)**. In older adults, **obstructive and malignant causes predominate, and drugs must always be excluded first**.
2. **Pre-hepatic causes.** Haemolysis (autoimmune, drug-induced, transfusion reaction), **ineffective erythropoiesis** (megaloblastic anaemia, myelodysplastic syndrome) and resorption of a large haematoma. Features: **unconjugated hyperbilirubinaemia with normal liver enzymes, raised LDH, low haptoglobin and reticulocytosis**.
3. **Hepatocellular causes.** **Drug-induced liver injury (the commonest cause in the elderly)**, viral hepatitis (A and E are more severe in old age; B and C), **alcoholic hepatitis**, autoimmune hepatitis, **ischaemic hepatitis or "shock liver"**, cirrhosis with decompensation, and sepsis-associated cholestasis. The **transaminases rise disproportionately**.
4. **Post-hepatic (obstructive) causes.** **Choledocholithiasis**, and malignancy — **carcinoma of the head of the pancreas, cholangiocarcinoma and periampullary carcinoma** giving painless progressive jaundice with a palpable gallbladder (**Courvoisier's law**); also benign strictures, primary sclerosing cholangitis, primary biliary cholangitis and drug-induced cholestasis. Features: **conjugated hyperbilirubinaemia with raised ALP and GGT, pale stools, dark urine and pruritus**.
5. **Evaluation.** History of **drugs including ayurvedic and herbal preparations**, alcohol, transfusion and travel; examination for stigmata of chronic liver disease, palpable gallbladder, nodes and masses. Investigations: LFT pattern with **R value**, **PT/INR (the best marker of severity)**, albumin, viral serology, autoantibodies and ferritin. **Ultrasound abdomen is the first imaging test** — if ducts are dilated proceed to MRCP, EUS or ERCP; if not dilated, complete the hepatocellular workup ± biopsy.
6. **Management.** **Treat the cause** — withdraw the offending drug, antivirals for hepatitis B and C, corticosteroids for autoimmune or severe alcoholic hepatitis, and **ERCP with stone extraction or stenting** for obstruction (percutaneous transhepatic drainage if ERCP fails). Supportive care: **vitamin K**, correction of dehydration and acute kidney injury, nutritional support, cholestyramine or rifampicin for pruritus, and avoidance of hepatotoxic drugs and sedatives. **Ascending cholangitis (Charcot's triad of fever, jaundice and right upper quadrant pain) requires urgent antibiotics plus biliary drainage.**

> **Latest Update (2023–2026) — 1 point**
>
> 7. **New nomenclature for steatotic liver disease** (multi-society Delphi consensus, *Hepatology* 2023) — NAFLD is replaced by **MASLD (metabolic dysfunction-associated steatotic liver disease)**, NASH by **MASH**, and a new category **MetALD** covers patients with both metabolic risk factors and significant alcohol intake, which is exactly the overlap commonly seen in older Indian patients. MASLD is now the commonest chronic liver disease worldwide and an increasingly frequent background cause of jaundice in the elderly, and **resmetirom became the first drug approved for MASH with F2–F3 fibrosis (2024)**.

Cross-reference: The MASLD/MetALD nomenclature introduced here is expanded, with the new drug therapy, in Question 14.

Question 10. Drug-induced jaundice 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and importance.** Drug-induced liver injury (DILI) is liver damage caused by drugs, herbs or supplements. It is the **commonest cause of acute liver failure in the West** and an important cause of jaundice in the elderly because of **polypharmacy, reduced hepatic mass and blood flow, and altered cytochrome P450 metabolism**.
2. **Types and biochemical pattern.** **Intrinsic** (dose-dependent and predictable — paracetamol) versus **idiosyncratic** (dose-independent, unpredictable — most drugs). Pattern is defined by the **R value = (ALT/ULN) ÷ (ALP/ULN)**: **R ≥5 hepatocellular, R ≤2 cholestatic, R 2–5 mixed**.
3. **Common culprit drugs.** **Amoxicillin-clavulanate (the commonest single idiosyncratic cause)**, **anti-tubercular drugs — isoniazid, rifampicin, pyrazinamide (highly relevant in India)**, NSAIDs (diclofenac), statins, methotrexate, amiodarone, nitrofurantoin, azathioprine, phenytoin and carbamazepine, allopurinol, anabolic

steroids, **herbal and ayurvedic preparations**, and **immune checkpoint inhibitors**.

4. **Clinical phenotypes.** Acute hepatitis; cholestatic hepatitis (co-amoxiclav, erythromycin); pure cholestasis (anabolic steroids, oestrogens); **hypersensitivity/DRESS with fever, rash and eosinophilia**; **drug-induced autoimmune hepatitis (nitrofurantoin, minocycline, statins, diclofenac)**; **vanishing bile duct syndrome**; steatohepatitis (amiodarone, tamoxifen); and sinusoidal obstruction syndrome.
5. **Diagnosis.** DILI is a **diagnosis of exclusion**. Establish a temporal relationship (latency of days to months), demonstrate improvement after withdrawal (**dechallenge**), and exclude viral, autoimmune and biliary disease by serology and ultrasound. Use the **RUCAM causality score**; liver biopsy only when the diagnosis is unclear or there is no recovery. **Deliberate rechallenge is contraindicated.**
6. **Management and prognostic rule. Immediate withdrawal of the offending drug is the definitive treatment.** Give supportive care and avoid other hepatotoxins; **N-acetylcysteine for paracetamol toxicity and for non-paracetamol acute liver failure**; corticosteroids for hypersensitivity reactions and drug-induced autoimmune hepatitis; ursodeoxycholic acid and cholestyramine for cholestatic pruritus. **Hy's Law — ALT >3× ULN with bilirubin >2× ULN in the absence of cholestasis predicts about 10% mortality**; refer urgently to a transplant centre if the INR rises or encephalopathy develops. Report to pharmacovigilance (PvPI in India).

Latest Update (2023–2026) — 1 point

7. **Two current developments.** First, the **RECAM (Revised Electronic Causality Assessment Method)** is being adopted in place of RUCAM as a more reproducible, computerised causality tool, supported by the **LiverTox** database for drug-specific likelihood scores. Second, **immune checkpoint inhibitor hepatitis** is now a distinct and increasingly common form of DILI in older patients with cancer — it is graded by CTCAE, managed by withholding the drug with **corticosteroids for grade 2–3 and mycophenolate for steroid-refractory cases**, and notably does **not** follow the usual DILI rule that rechallenge is always forbidden.

Question 11. Chronic active hepatitis 6 MARKS

Answer — Textbook Core (5 points)

1. **Definition and modern terminology.** Chronic hepatitis is hepatic necroinflammation persisting for **more than 6 months**. The old histological labels "chronic active hepatitis" (**interface hepatitis/piecemeal necrosis extending beyond the limiting plate, progressing to cirrhosis**) and "chronic persistent hepatitis" have been replaced by classification according to **aetiology + grade of activity + stage of fibrosis**.
2. **Causes. Chronic hepatitis B ± D, chronic hepatitis C, autoimmune hepatitis**, drugs (nitrofurantoin, minocycline, methyldopa, isoniazid), Wilson disease, alpha-1 antitrypsin deficiency and MASH.
3. **Autoimmune hepatitis in the elderly.** Often presents **acutely or as already established cirrhosis**, or is found incidentally; features are fatigue, arthralgia, jaundice and amenorrhoea (not applicable in old age), with **associated autoimmune disease such as thyroiditis and rheumatoid arthritis**. **Type 1 — ANA and anti-smooth muscle antibody with raised IgG**; Type 2 — anti-LKM1 (a disease of the young).
4. **Diagnosis.** Raised transaminases with **hypergammaglobulinaemia (raised IgG)**, autoantibodies, and liver biopsy showing **interface hepatitis with a lymphoplasmacytic infiltrate, hepatocyte rosettes and emperipolesis**. The **IAIHG simplified criteria** (autoantibody titre, IgG, histology, exclusion of viral hepatitis) are used for diagnosis; grade by METAVIR or Ishak and stage with transient elastography.
5. **Treatment. Prednisolone 0.5–1 mg/kg induction with azathioprine 1–2 mg/kg as steroid-sparing maintenance**; **budesonide** may be used in non-cirrhotic patients but **must be avoided in cirrhosis because portosystemic shunting bypasses first-pass metabolism**. Check **TPMT activity before azathioprine**. Older patients respond well biochemically but tolerate steroids poorly — give **osteoporosis prophylaxis, monitor glucose and blood pressure, and consider PCP prophylaxis**. Treat hepatitis B with tenofovir or entecavir, and hepatitis C with direct-acting antivirals (SVR >95%, well tolerated in the elderly).

Latest Update (2023–2026) — 1 point

6. **CAMARO trial** (*J Hepatol* 2024;80:576) — in treatment-naive autoimmune hepatitis, **mycophenolate mofetil with prednisolone achieved biochemical remission more often and with fewer adverse events than azathioprine with prednisolone**, challenging azathioprine's position as standard first-line maintenance. In parallel, the accepted treatment endpoint is now **complete biochemical response — normalisation of both ALT and IgG — ideally within 6 months**, rather than transaminase normalisation alone.

Current Practice Update

Textbook: Prednisolone plus azathioprine is the standard first-line regimen for autoimmune hepatitis.
Current recommendation: Mycophenolate mofetil plus prednisolone is at least as effective and better tolerated (CAMARO 2024); target is complete biochemical response (ALT and IgG normal).
Exam approach: Write the classical regimen, then add the CAMARO line — it converts a routine answer into an updated one.

Question 12. Alcoholic hepatitis 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** An acute clinical syndrome of **rapid onset or worsening of jaundice** in a patient with sustained heavy alcohol use, with underlying histological steatohepatitis. Severe disease may progress to **acute-on-chronic liver failure with a 1-month mortality of 20–50%**.
2. **Diagnostic criteria (NIAAA).** Onset of jaundice within **8 weeks**; ongoing heavy alcohol use (**>40 g/day in women, >60 g/day in men**) for ≥6 months with fewer than 60 days abstinence before onset; **AST >50 IU/L with AST:ALT ratio >1.5 and both below 400 IU/L**; bilirubin >3 mg/dL; and exclusion of other liver disease. **Biopsy is not needed unless there are confounding factors.**
3. **Clinical features.** Tender hepatomegaly, fever, anorexia, ascites, encephalopathy and neutrophil leucocytosis. **In older patients alcohol misuse is frequently unrecognised**, and presentation may be with confusion, falls, malnutrition or unexplained jaundice.
4. **Severity scores.** **Maddrey Discriminant Function ≥32** defines severe disease; **MELD >20 is the most accurate score**; also the Glasgow Alcoholic Hepatitis Score and the ABIC score. **The Lille score at day 7 — a value >0.45 indicates steroid non-response and steroids should be stopped.**
5. **General management.** **Abstinence is the single most important determinant of survival.** Manage alcohol withdrawal (benzodiazepines cautiously in the elderly — prefer **lorazepam**, which has no active metabolites), give **thiamine before any glucose**, provide aggressive nutrition (**35 kcal/kg and 1.2–1.5 g/kg protein**) preferably enterally, actively look for and treat infection, avoid nephrotoxins, and manage acute kidney injury, electrolytes and encephalopathy.
6. **Specific therapy.** **Prednisolone 40 mg daily for 28 days** in severe disease (DF ≥32 or MELD >20), after excluding active infection, gastrointestinal bleeding and renal failure; reassess with the Lille score at day 7. **Pentoxifylline is no longer recommended.** Long-term care involves treating alcohol use disorder (**baclofen is preferred in cirrhosis**; acamprosate and naltrexone are limited by hepatotoxicity), vaccination, and consideration for transplantation.

Latest Update (2023–2026) — 1 point

7. **ACG Clinical Guideline 2024** (*Am J Gastroenterol* 2024;119:30) — adopts the term **"alcohol-associated liver disease"**; recommends corticosteroids **with adjuvant intravenous N-acetylcysteine** for severe alcohol-associated hepatitis; recommends **against pentoxifylline and against routine prophylactic antibiotics**; and gives a stronger recommendation for **early liver transplantation** in steroid non-responders at low risk of relapse, explicitly stating that **candidacy must not be based on an arbitrary 6-month sobriety rule** but on structured psychosocial assessment (SALT score, Stanford Integrated Psychosocial Assessment Tool).

Question 13. Management of newly diagnosed hepatitis B in the elderly 7 MARKS

Answer — Textbook Core (6 points)

1. **Confirm and characterise the infection.** Repeat **HBsAg at 6 months to confirm chronicity**; check **HBeAg/anti-HBe, quantitative HBV DNA, ALT**, and screen for **anti-HDV, anti-HCV and HIV**. Assess fibrosis with **APRI, FIB-4 and transient elastography**, and perform an ultrasound of the liver.
2. **Determine the phase of infection.** HBeAg-positive chronic infection (immune-tolerant), HBeAg-positive chronic hepatitis, HBeAg-negative chronic infection (inactive carrier), HBeAg-negative chronic hepatitis, and resolved/occult infection. **Older patients are usually HBeAg-negative with fluctuating DNA and ALT, so a single normal ALT does not exclude active disease.**
3. **Who to treat.** **All patients with cirrhosis and any detectable HBV DNA, regardless of ALT**; those with **HBV DNA >2000 IU/mL and ALT above the upper limit of normal**; significant fibrosis (≥F2) on elastography or APRI; extrahepatic manifestations (glomerulonephritis, vasculitis); and a family history of hepatocellular carcinoma.

4. **Antiviral therapy.** An oral nucleos(t)ide analogue with a **high genetic barrier to resistance — tenofovir disoproxil fumarate, tenofovir alafenamide or entecavir** — once daily and usually lifelong. **In older adults prefer tenofovir alafenamide or entecavir**, because TDF causes **renal tubular dysfunction and reduced bone mineral density**; entecavir requires dose adjustment for creatinine clearance. **Pegylated interferon is generally unsuitable in the elderly.**
5. **Prophylaxis and prevention of flares.** Give **antiviral prophylaxis before immunosuppression or chemotherapy** — especially **rituximab and high-dose corticosteroids** — in HBsAg-positive and anti-HBc-positive patients, continuing for 6–12 months afterwards, because reactivation can be fatal. **Never stop antivirals abruptly.** Vaccinate household and sexual contacts, and give hepatitis A vaccine.
6. **Monitoring and surveillance.** ALT and HBV DNA every 3–6 months; renal function, phosphate and bone density on tenofovir. **Six-monthly ultrasound ± alpha-fetoprotein for hepatocellular carcinoma in all cirrhotics, and also in non-cirrhotic HBsAg-positive Asian men over 40 and women over 50**; endoscopy for varices if cirrhotic. Counsel on alcohol avoidance, drug interactions and transmission.

Latest Update (2023–2026) — 1 point

7. **WHO Guidelines for chronic hepatitis B, March 2024** — treatment eligibility has been **substantially expanded and simplified**. Treat if there is **significant fibrosis or cirrhosis (APRI >0.5 or elastography)**; or **HBV DNA >2000 IU/mL with raised ALT**; or the presence of **coinfection (HIV, HDV, HCV), a family history of cirrhosis or liver cancer, immunosuppression, comorbidity such as diabetes or MASLD, or extrahepatic manifestations — regardless of DNA and ALT levels**; and, where DNA testing is unavailable, on persistently abnormal ALT alone. The guideline also recommends **point-of-care HBV DNA and reflex viral load testing**, and **testing every HBsAg-positive person for hepatitis D**.

Current Practice Update

Textbook: Treat only cirrhotics or those with persistently raised transaminases and high HBV DNA.
Current recommendation: WHO 2024 has widened eligibility to include comorbidity, family history, immunosuppression and coinfection irrespective of DNA/ALT — substantially more patients now qualify.
Exam approach: Give the classical AASLD/EASL criteria, then add the WHO 2024 expansion in one line.

Question 14. Decompensated chronic liver disease in the elderly, and the OPD approach to chronic liver disease 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition.** Cirrhosis is diffuse hepatic fibrosis with regenerative nodules. **Decompensation is defined by the appearance of ascites, variceal bleeding, hepatic encephalopathy or jaundice** (Baveno VII). Median survival is **more than 12 years in compensated cirrhosis but about 2 years once decompensated**.
2. **Aetiology in the elderly.** **MASLD/MASH (now the commonest)**, alcohol-related liver disease, chronic hepatitis B and C, drug-induced injury, autoimmune hepatitis, primary biliary cholangitis, haemochromatosis, and **cardiac (congestive) hepatopathy from right heart failure — a frequently missed cause in older patients**.
3. **Pathogenesis.** Chronic injury activates **hepatic stellate cells** → fibrosis and nodules → **increased intrahepatic resistance plus splanchnic vasodilatation** → portal hypertension (**HVPG >10 mmHg = clinically significant portal hypertension**) → hyperdynamic circulation with effective arterial underfilling → activation of the renin-angiotensin-aldosterone and sympathetic systems → sodium and water retention producing **ascites, dilutional hyponatraemia and hepatorenal syndrome**. Systemic inflammation and bacterial translocation drive acute-on-chronic liver failure.
4. **Precipitants of decompensation.** **Infection, especially spontaneous bacterial peritonitis**; gastrointestinal bleeding; alcohol binge; dehydration or excessive diuresis; constipation; sedatives, opioids and NSAIDs; hepatotoxic drugs; portal vein thrombosis; hepatocellular carcinoma; and surgery.
5. **Clinical features.** Jaundice, ascites, oedema, spider naevi, palmar erythema, gynaecomastia, testicular atrophy, Dupuytren's contracture, caput medusae, splenomegaly, asterixis, and **muscle wasting with sarcopenia**. **In the elderly, decompensation commonly presents as delirium, falls or functional decline rather than classical signs.**
6. **Approach to the OPD patient with chronic liver disease.** History — quantified alcohol intake, all drugs including **ayurvedic and over-the-counter preparations**, transfusion, risk factors and family history. Examination for stigmata plus **nutritional and frailty assessment**. Baseline tests: LFT, PT/INR, albumin, complete blood count (**thrombocytopenia suggests portal hypertension**), renal function and electrolytes. **Aetiological screen**: HBsAg, anti-HCV, autoantibodies with IgG, ferritin and transferrin saturation, ceruloplasmin if under 55, alpha-1 antitrypsin,

and lipid and glucose profile.

7. **Staging and prognostic scoring.** **Child-Turcotte-Pugh score** using bilirubin, albumin, INR, ascites and encephalopathy (**A 5–6, B 7–9, C 10–15**) and **MELD, MELD-Na and MELD 3.0** for transplant prioritisation. Non-invasive fibrosis assessment with **FIB-4, APRI and transient elastography** — liver stiffness **>15 kPa with platelets <150 × 10^9/L suggests clinically significant portal hypertension**.
8. **Management of the stable cirrhotic outpatient.** **Treat the cause** — abstinence, antivirals, weight loss and metabolic control. **Six-monthly ultrasound ± AFP for hepatocellular carcinoma surveillance.** Screening endoscopy for varices (may be deferred if liver stiffness <20 kPa and platelets >150,000 — the Baveno "rule of five"); **carvedilol as the preferred non-selective beta-blocker**. Vaccinate against hepatitis A and B, influenza, pneumococcus and COVID-19; avoid NSAIDs, aminoglycosides and sedatives; salt restriction 5–6 g/day; and treat sarcopenia with **1.2–1.5 g/kg protein and a late evening snack**.
9. **Management of decompensation.** **Ascites** — salt restriction, spironolactone with furosemide, large-volume paracentesis with albumin. **Variceal bleeding** — terlipressin, prophylactic antibiotics, band ligation, and early TIPS in high-risk patients. **Encephalopathy** — treat precipitants, lactulose plus rifaximin. **Spontaneous bacterial peritonitis** — cefotaxime plus **albumin 1.5 g/kg on day 1 and 1 g/kg on day 3**, followed by lifelong norfloxacin prophylaxis. **Hepatorenal syndrome** — terlipressin with albumin.
10. **Complications and transplantation.** Ascites, SBP, variceal bleeding, hepatic encephalopathy, hepatorenal and hepatopulmonary syndromes, portopulmonary hypertension, **hepatocellular carcinoma**, coagulopathy, malnutrition and sarcopenia, osteoporosis and cirrhotic cardiomyopathy. **Refer for transplantation when MELD exceeds 15 or after the first decompensating event**; carefully selected patients over 65–70 with good performance status and social support achieve about **80% five-year survival**, so age alone is not a contraindication.

Latest Updates (2023–2026) — 2 points

11. **Baveno VII consensus** (*J Hepatol* 2022;76:959) — introduced the concept of **"recompensation"** (resolution of ascites, encephalopathy and bleeding off diuretics and lactulose with sustained improvement in liver function after the cause is controlled), the **"rule of five" for liver stiffness**, and the principle that **non-selective beta-blockers, preferably carvedilol, should be given to all patients with clinically significant portal hypertension to prevent the first decompensation (PREDESCI trial)** — not merely to prevent variceal bleeding.
12. **MASLD nomenclature and the first approved drug therapy.** The 2023 multi-society Delphi consensus replaced NAFLD with **MASLD**, NASH with **MASH**, and introduced **MetALD** for combined metabolic and alcohol-related disease. **Resmetirom (a thyroid hormone receptor-β agonist) received approval in 2024 as the first drug for MASH with F2–F3 fibrosis**, and GLP-1 receptor agonists have shown histological benefit in MASH — a major shift from purely lifestyle-based management.

Question 15. Management of hepatic encephalopathy 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and classification.** Brain dysfunction caused by liver failure and/or portosystemic shunting, ranging from subclinical impairment to coma. **Type A** — acute liver failure; **Type B** — portosystemic bypass without intrinsic liver disease; **Type C** — cirrhosis. Severity is graded by the **West Haven criteria I–IV**; **covert HE** comprises minimal HE plus grade I.
2. **Identify and treat precipitants — the mainstay of management.** **Infection (SBP, urinary and chest), gastrointestinal bleeding, constipation, dehydration and excessive diuresis, hypokalaemia and hyponatraemia, sedatives and opioids, alcohol binge, portal vein thrombosis, TIPS and hepatocellular carcinoma.** In an older patient always exclude other causes of delirium, subdural haematoma, hypoglycaemia and drug toxicity.
3. **Diagnosis.** Essentially clinical — **asterixis, reversal of the sleep-wake cycle, disorientation, constructional apraxia and fetor hepaticus**. A raised venous ammonia supports the diagnosis but does not confirm it; a **normal ammonia makes HE unlikely**, and levels should not be used to monitor treatment. Covert HE is detected with psychometric tests — the **Animal Naming Test, PHES battery or Stroop smartphone app**. Image the brain when the picture is atypical.
4. **First-line treatment.** **Lactulose 30 mL two or three times daily, titrated to produce 2–3 soft stools per day**; in comatose patients give as a retention enema (300 mL lactulose in 700 mL water). It acidifies the colon, converting absorbable ammonia to non-absorbable ammonium, and acts as an osmotic laxative. **Monitor for dehydration, hypernatraemia and aspiration — over-treatment with lactulose can itself precipitate HE.**

5. **Second-line agents and adjuncts.** **Rifaximin 550 mg twice daily added to lactulose** reduces recurrence and hospitalisation and is the agent of choice for **secondary prophylaxis after a second episode of overt HE**. Alternatives: **L-ornithine L-aspartate**, oral branched-chain amino acids, polyethylene glycol for rapid clearance, and zinc if deficient. Neomycin and metronidazole are effective but should be avoided long term in the elderly (ototoxicity, nephrotoxicity, neuropathy).
6. **Nutrition and general care.** **Protein restriction is obsolete and harmful.** Give **1.2–1.5 g/kg/day protein with 35 kcal/kg**, favouring vegetable and dairy protein, in small frequent meals with a **late evening snack** to avoid overnight catabolism. Protect the airway and manage in ICU for grades III–IV; **avoid benzodiazepines** (flumazenil only for proven benzodiazepine ingestion); advise about driving and falls; consider **TIPS reduction or occlusion or embolisation of large spontaneous shunts** for recurrent HE; and refer for liver transplantation.

Latest Update (2023–2026) — 1 point

7. **AASLD/EASL Practice Guidance (2022) and subsequent evidence** — the treatment goal has shifted from clearing the acute episode to **preventing recurrence**, with **lactulose plus rifaximin as standard secondary prophylaxis**. Routine screening for **covert HE** is now recommended because it independently predicts falls, road traffic accidents, poor quality of life and progression to overt HE; and **sarcopenia is recognised as an independent driver of HE** (muscle is the main extra-hepatic site of ammonia detoxification), making nutritional therapy a specific treatment rather than merely supportive care. Faecal microbiota transplantation is promising but remains investigational.

Current Practice Update

Textbook: Restrict dietary protein and use lactulose; monitor response with serum ammonia.
Current recommendation: Give 1.2–1.5 g/kg protein (restriction is harmful), add rifaximin for secondary prophylaxis, and do not use serial ammonia levels to monitor treatment.
Exam approach: Explicitly state "protein restriction is no longer recommended" — examiners look for this single line.

Question 16. Ascites and refractory ascites 7 MARKS

Answer — Textbook Core (6 points)

1. **Causes and initial assessment.** **Cirrhosis with portal hypertension accounts for about 80%**; other causes are malignancy (peritoneal carcinomatosis), heart failure, tuberculosis, nephrotic syndrome and pancreatitis. **Perform a diagnostic paracentesis in every patient with new-onset ascites** — send cell count and differential, albumin, total protein, **culture inoculated into blood culture bottles at the bedside**, and cytology and adenosine deaminase where indicated. **Neutrophils ≥250/mm³ diagnoses spontaneous bacterial peritonitis.**
2. **Serum-ascites albumin gradient (SAAG).** **SAAG ≥1.1 g/dL indicates portal hypertension** (cirrhosis, cardiac ascites — cardiac ascites has an ascitic protein >2.5 g/dL, cirrhotic <2.5). **SAAG <1.1 g/dL indicates non-portal causes** — malignancy, tuberculosis, pancreatic or nephrotic ascites.
3. **Grading.** **Grade 1** detectable only on ultrasound; **Grade 2** moderate, with symmetrical abdominal distension; **Grade 3** large or tense ascites.
4. **First-line management.** **Sodium restriction to 5–6 g of salt (about 2 g sodium) per day**; fluid restriction only if serum sodium is below 125 mmol/L. **Spironolactone 100 mg with furosemide 40 mg daily, maintaining the 100:40 ratio**, increased stepwise to maxima of 400 mg and 160 mg. Target weight loss of **0.5 kg/day without oedema and up to 1 kg/day with oedema**. Monitor weight, sodium, potassium and creatinine, and **stop NSAIDs, ACE inhibitors and ARBs**.
5. **Definition of refractory ascites.** Ascites that cannot be mobilised or that recurs early and cannot be prevented, and is either **diuretic-resistant** (no response to maximal diuretic doses with salt restriction) or **diuretic-intractable** (diuretic-induced complications — encephalopathy, creatinine rise above 2 mg/dL, sodium below 125 mmol/L, or potassium disturbance — preventing the use of effective doses). It occurs in about 10% and carries a **1-year survival of only 50%**.
6. **Management of refractory ascites.** **Serial large-volume paracentesis with albumin 8 g per litre removed** whenever more than 5 litres is drained (to prevent post-paracentesis circulatory dysfunction). **TIPS** for patients needing repeated paracenteses — contraindicated with recurrent encephalopathy, age over 70, Child-Pugh >13 or cardiac dysfunction. **Discontinue beta-blockers if systolic BP falls below 90 mmHg, or with hyponatraemia or AKI.** Consider indwelling tunnelled peritoneal drains or an alfapump for palliation, and **refer for liver transplantation**. Watch for SBP, hepatorenal syndrome, hyponatraemia, umbilical hernia and hepatic hydrothorax.

Latest Update (2023–2026) — 1 point

7. **Baveno VII plus recent trial evidence — TIPS with covered stents should now be considered earlier, in patients requiring three or more large-volume paracenteses per year, irrespective of the presence of varices or previous variceal bleeding**, as this improves transplant-free survival compared with repeated paracentesis. In addition, the **ANSWER trial (Lancet 2018) and subsequent data support long-term weekly albumin infusion** in uncomplicated cirrhotic ascites, which improved survival and reduced complications; this is now standard in some countries, although confirmatory evidence remains debated and cost limits its use in Indian practice.

Question 17. Hepatorenal syndrome 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and mechanism.** A **functional, potentially reversible** renal failure occurring in advanced cirrhosis with ascites, caused by **intense renal vasoconstriction secondary to splanchnic arterial vasodilatation and effective arterial underfilling**. **The kidneys are structurally normal** — transplanted HRS kidneys function normally in the recipient.
2. **Current nomenclature.** **HRS-AKI** (formerly type 1) — a rise in serum creatinine of **≥0.3 mg/dL within 48 hours or ≥50% from baseline within 7 days**, with rapid deterioration. **HRS-NAKI** (formerly type 2) covers HRS-AKD and HRS-CKD — a slower creatinine rise typically accompanied by **refractory ascites**.
3. **Diagnostic criteria (International Club of Ascites).** Cirrhosis with ascites; AKI by ICA criteria; **no improvement after 2 days of diuretic withdrawal and volume expansion with albumin 1 g/kg/day (maximum 100 g)**; absence of shock; no current or recent nephrotoxic drugs; and **no evidence of structural kidney injury — proteinuria <500 mg/day, no haematuria (<50 RBC/hpf) and a normal renal ultrasound**. Supportive findings: **urine sodium <10 mmol/L, FENa <0.2%** and oliguria.
4. **Precipitants.** **Spontaneous bacterial peritonitis is the classic trigger**; also other sepsis, gastrointestinal bleeding, **large-volume paracentesis without albumin cover**, over-diuresis, diarrhoea from excess lactulose, and NSAIDs, aminoglycosides or contrast media.
5. **Treatment.** **Terlipressin plus albumin is first-line** — terlipressin 1 mg IV every 4–6 hours (or 2–12 mg/day by continuous infusion, which is better tolerated) with **albumin 20–40 g/day**; continue for up to 14 days or until creatinine returns to within 0.3 mg/dL of baseline. Alternatives are **noradrenaline with albumin in an ICU setting**, or midodrine plus octreotide with albumin where terlipressin is unavailable. Watch for **ischaemic complications and, most importantly, respiratory failure and volume overload — the principal safety concern, particularly in the elderly and in acute-on-chronic liver failure**.
6. **Prevention, prognosis and definitive therapy.** Prevent by giving **albumin 8 g per litre of ascites removed during large-volume paracentesis**, albumin in SBP, and antibiotic prophylaxis in high-risk patients; avoid nephrotoxins and NSAIDs. **Liver transplantation is the only definitive treatment**; renal replacement therapy is a bridge to transplantation rather than a treatment in its own right. Untreated HRS-AKI has a median survival of only a few weeks.

Latest Update (2023–2026) — 1 point

7. **ADQI 29 / International Club of Ascites joint consensus 2024** (*J Hepatol* 2024;81:163) — revises the traditional approach by recommending **crystalloids rather than albumin for first-line volume resuscitation in clearly hypovolaemic patients**, and **shortening the diagnostic albumin challenge from 48 to 24 hours** so that terlipressin is not delayed and fluid overload is avoided (a point still actively debated, as up to a third of responses occur between 24 and 48 hours). It also stresses distinguishing HRS-AKI from **acute tubular necrosis using biomarkers such as urinary NGAL**. Terlipressin is now FDA-approved on the basis of the **CONFIRM trial**, carrying a boxed warning for respiratory failure.

PART III — CLINICAL NUTRITION

Question 18. Parenteral nutrition 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and indications.** Intravenous delivery of nutrients when the gastrointestinal tract cannot be used. Indications are a **non-functioning, inaccessible or obstructed gut** — short bowel syndrome, high-output enterocutaneous fistula, prolonged ileus, complete intestinal obstruction, severe malabsorption, severe mucositis, and severe pancreatitis not tolerating enteral feeding. **The governing principle is "if the gut works, use it" — enteral nutrition is always preferred.**
2. **Routes.** **Central parenteral nutrition** through a subclavian, internal jugular or PICC line with the tip in the superior vena cava is required for hyperosmolar complete formulations. **Peripheral parenteral nutrition** is limited to short-term use (under 10–14 days) with osmolarity below about 850 mOsm/L. Total PN supplies all requirements; supplemental PN tops up inadequate enteral intake.
3. **Composition.** Energy **20–30 kcal/kg/day** (use the lower end in the elderly and critically ill), protein as amino acids **1.0–1.5 g/kg/day**, glucose not exceeding **4–5 mg/kg/min**, and lipid emulsions providing 25–30% of non-protein calories. Add **electrolytes, trace elements (zinc, selenium, copper, chromium) and both water- and fat-soluble vitamins, including thiamine**. Modern practice uses all-in-one three-chamber bags.
4. **Timing and geriatric considerations.** Start only when inadequate oral or enteral intake is expected for **more than 7 days** (earlier if the patient is already malnourished), **begin at about 50% of the target and build up over 2–3 days**. Older patients have less physiological reserve, higher infection risk and reduced cardiac and renal tolerance — **restrict volume, monitor for fluid overload, and always define the goal of therapy before starting**.
5. **Catheter-related complications.** **Catheter-related bloodstream infection is the commonest serious complication**; also pneumothorax, arterial puncture, air embolism, catheter tip malposition, central venous thrombosis and catheter occlusion. Prevention requires **strict aseptic insertion and handling with a dedicated lumen used only for nutrition**, and ultrasound-guided insertion.
6. **Metabolic complications and monitoring.** **Hyperglycaemia (and rebound hypoglycaemia on abrupt withdrawal), refeeding syndrome, electrolyte disturbance, hypertriglyceridaemia, fluid overload, parenteral nutrition-associated liver disease (steatosis and cholestasis), metabolic bone disease and gut mucosal atrophy with bacterial translocation.** Monitor **glucose, electrolytes, phosphate and magnesium daily at first**, then weekly liver function, triglycerides, trace elements and nitrogen balance, with regular weight and fluid balance.

> **Latest Update (2023–2026) — 1 point**
>
> 7. **ESPEN practical guideline on clinical nutrition and hydration in geriatrics** — recommends that **every older patient be screened with a validated tool such as the MNA-SF**, that nutritional goals be individualised through shared decision-making, and, critically, that **artificial nutrition (enteral or parenteral) should not be started in advanced dementia or in the terminal phase of illness**, where **careful hand-feeding and comfort feeding** give better outcomes and quality of life. Parenteral nutrition is justified only when it can achieve an outcome the patient actually values — a point examiners increasingly expect to be linked to advance care planning.

Question 19. Refeeding syndrome 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** A potentially fatal shift of fluid and electrolytes that occurs when nutrition is reintroduced to a **malnourished or starved patient**, characterised by **hypophosphataemia (the hallmark), hypokalaemia, hypomagnesaemia, thiamine deficiency and sodium and water retention**.
2. **Pathophysiology.** Prolonged starvation shifts metabolism to fat and protein catabolism and **depletes intracellular phosphate, potassium and magnesium despite normal serum levels**. **Reintroduction of carbohydrate triggers insulin release**, which drives glucose, phosphate, potassium and magnesium intracellularly, consumes phosphate for ATP and 2,3-DPG synthesis, and depletes **thiamine** as a cofactor in carbohydrate metabolism; insulin also causes **renal sodium and water retention**.
3. **Patients at risk (NICE criteria).** **Any one of** — BMI <16 kg/m², unintentional weight loss >15% in 3–6 months,

little or no intake for >10 days, or low potassium, phosphate or magnesium before feeding. **Or any two of** — BMI <18.5, weight loss >10%, negligible intake >5 days, alcohol misuse, or drugs such as insulin, chemotherapy, antacids or diuretics. Relevant geriatric groups: **anorexia of ageing, post-stroke dysphagia, cancer cachexia, prolonged hospitalisation, post-operative starvation and alcohol misuse**.

4. **Clinical features.** Mostly attributable to hypophosphataemia — **muscle weakness, rhabdomyolysis, respiratory failure and failure to wean from ventilation, cardiac failure and arrhythmias, delirium, seizures, haemolysis and thrombocytopenia**; thiamine deficiency causes **Wernicke's encephalopathy and wet beriberi**; fluid retention causes oedema and pulmonary congestion. **Onset is typically within 72 hours of restarting feeding.**
5. **Prevention.** Identify risk **before** feeding begins. Give **thiamine 200–300 mg daily orally (or intravenous Pabrinex) together with a vitamin B complex and multivitamins, starting 30 minutes before feeding and continuing for the first 10 days**. **Start feeding at 10 kcal/kg/day — or 5 kcal/kg/day in extreme risk (BMI <14 or negligible intake for >15 days) — and increase slowly to full requirements over 4–7 days.** Restrict sodium and fluid, and avoid rapid volume expansion.
6. **Monitoring and treatment.** Check **potassium, phosphate, magnesium, calcium and glucose before feeding, then daily for the first 3 days and on alternate days for the first week**. **Correct electrolytes concurrently but do not delay feeding to do so** — replace phosphate (intravenously if <0.6 mmol/L), potassium approximately 2–4 mmol/kg/day and magnesium 0.2–0.4 mmol/kg/day. Monitor fluid balance, daily weight and ECG; reduce or temporarily hold the feed if severe biochemical disturbance or cardiac failure develops.

Latest Update (2023–2026) — 1 point

7. **ASPEN consensus recommendations for refeeding syndrome** (*Nutr Clin Pract/JPEN* 2020) — provided the first standardised **definition and severity grading**: refeeding syndrome is a fall in serum phosphate, potassium and/or magnesium of **10–20% (mild), 20–30% (moderate), or >30% with organ dysfunction (severe)**, occurring within **5 days** of restarting or substantially increasing nutrition. It recommends starting with **100–150 g of dextrose or 10–20 kcal/kg in the first 24 hours, advancing by about 33% of the goal every 1–2 days**, with **thiamine given before feeding** and continued for 5–7 days or longer in high-risk patients.

Question 20. Inanition 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** Inanition is a state of **profound exhaustion and wasting resulting from prolonged inadequate intake, absorption or utilisation of food** — the advanced end-stage of starvation, with loss of both fat and muscle mass, weakness and multi-organ dysfunction. In geriatric practice it overlaps closely with the **"failure to thrive" syndrome of the elderly**.
2. **Distinction from related states (very high yield).** **Inanition/starvation** — pure nutrient deficiency, largely **reversible with feeding**. **Cachexia** — inflammation-driven, cytokine-mediated (**TNF-α, IL-1, IL-6**) loss of muscle in cancer, heart failure, COPD or CKD, **not fully reversible by nutrition alone**. **Sarcopenia** — age-related loss of muscle mass and strength. **Anorexia of ageing** — the physiological decline in appetite with early satiety, delayed gastric emptying and altered gut hormones.
3. **Causes in the elderly — the "9 Ds".** **Dementia, Depression, Dysphagia, Dentition, Drugs, Disease (malignancy, infection, hyperthyroidism, heart failure), Diarrhoea/malabsorption, Dysgeusia and Destitution (poverty and social isolation)**. Also immobility, alcohol misuse, restrictive therapeutic diets, and **elder abuse or neglect**.
4. **Clinical features and consequences.** Severe weight loss with **temporal and interosseous muscle wasting**, hypothermia, bradycardia and hypotension, **sarcopenia with falls and fractures**, **pressure ulcers**, impaired cell-mediated immunity with infection, delayed wound healing, **oedema from hypoalbuminaemia**, apathy, depression and cognitive slowing, and greatly increased mortality and rates of institutionalisation.
5. **Assessment.** **Screen with the MNA-SF (or MUST)**; document weight, BMI, percentage unintentional weight loss and calf circumference. Apply the **GLIM criteria — at least one phenotypic criterion (weight loss, low BMI, reduced muscle mass) plus one aetiologic criterion (reduced intake or absorption, or disease burden with inflammation)**. Measure **hand-grip strength**. Investigate with haemoglobin, electrolytes, calcium, vitamin D, B_{12}, thyroid function, CRP and albumin, and screen for malignancy, depression, dysphagia and oral disease. **A comprehensive geriatric assessment with medication review is mandatory.**
6. **Management.** **Treat reversible causes first** — dental repair, dysphagia therapy with texture modification and speech therapist input, treatment of depression (**mirtazapine is useful where weight gain is desirable**), and

withdrawal of appetite-suppressing drugs (digoxin, SSRIs, metformin, opioids, anticholinergics). Then apply a **"food-first" approach** — food fortification, small frequent energy-dense meals, **protein 1.2–1.5 g/kg/day**, feeding assistance, improved mealtime environment and social eating; add **oral nutritional supplements between (not with) meals**. Combine with **resistance exercise** to convert intake into muscle, correct vitamin D and micronutrient deficiency, and consider tube feeding only after explicit goal-setting — **it should be avoided in advanced dementia**.

Latest Update (2023–2026) — 1 point

7. **Two changes that reverse older teaching.** First, **megestrol acetate and other appetite stimulants are now to be avoided** in older adults (**AGS Beers Criteria 2023**) — they produce minimal weight gain with **no benefit on function or survival**, and carry risks of thrombosis, adrenal suppression, fluid retention and death. Second, under the **GLIM framework and current ESPEN geriatric guidance, serum albumin is no longer accepted as a nutritional marker** and has been reclassified as an **inflammatory marker**; the diagnosis of malnutrition must be made on phenotypic and aetiologic criteria with objective assessment of muscle mass.

Current Practice Update

Textbook: Low serum albumin indicates malnutrition; megestrol acetate may be used as an orexigenic agent.
Current recommendation: Albumin is an inflammatory marker and is excluded from GLIM criteria; megestrol is listed as potentially inappropriate in the AGS Beers Criteria 2023.
Exam approach: These are two of the highest-yield "textbook is outdated" lines in the whole nutrition syllabus — state both explicitly.

PART IV — ANAEMIA AND TRANSFUSION

Question 21. Anaemia in the elderly and the evaluation of anaemia 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and magnitude.** Anaemia is defined by WHO as **haemoglobin below 13 g/dL in men and below 12 g/dL in women**. Prevalence rises steeply with age — about **10% over 65 years and over 20–25% beyond 85 years**, and higher still in nursing homes and hospital inpatients. **Anaemia is never a normal consequence of ageing and must always be investigated.**
2. **Why it matters.** Even mild anaemia in older people is independently associated with **fatigue and reduced quality of life, falls, frailty and sarcopenia, cognitive decline, prolonged hospital stay, poorer surgical outcomes and increased mortality**. It also decompensates existing coronary artery disease, heart failure and cerebrovascular disease.
3. **The classical "rule of thirds" (NHANES).** Approximately one third is due to **nutritional deficiency (iron, B_{12}, folate)**; one third to **anaemia of chronic disease and chronic kidney disease**; and one third is **"unexplained anaemia of ageing"** — attributed to blunted erythropoietin response, low-grade inflammation, reduced marrow reserve, testosterone decline and occult clonal haematopoiesis or early myelodysplasia.
4. **Morphological approach by MCV.** **Microcytic (MCV <80 fL)** — iron deficiency, thalassaemia trait, sideroblastic anaemia, some anaemia of chronic disease. **Normocytic (80–100 fL)** — anaemia of chronic disease, CKD, acute blood loss, haemolysis, marrow infiltration, endocrine disease. **Macrocytic (>100 fL)** — B_{12} and folate deficiency, alcohol, hypothyroidism, liver disease, myelodysplasia, drugs (methotrexate, hydroxyurea, zidovudine).
5. **First-line evaluation.** History (bleeding, diet, alcohol, drugs including NSAIDs and aspirin, weight loss, comorbidity) and examination for lymphadenopathy, organomegaly and per-rectal examination. Tests: **complete blood count with indices and RDW, peripheral smear, reticulocyte count, ferritin with transferrin saturation, B_{12} and folate, renal function, LFT, thyroid function, CRP/ESR**. The **reticulocyte count is the key branch point — high suggests haemolysis or blood loss, low suggests production failure**.
6. **Second-line evaluation and treatment principles.** **Bidirectional endoscopy in every older adult with unexplained iron deficiency**; serum protein electrophoresis with free light chains and urine Bence-Jones protein if there is a raised ESR, renal impairment, bone pain or rouleaux; haemolytic screen (LDH, bilirubin, haptoglobin, direct antiglobulin test) if reticulocytes are high; and **bone marrow aspiration and biopsy if there is pancytopenia, blasts, dysplasia or a persistently unexplained anaemia**. **Treat the cause rather than transfusing** — replace iron, B_{12} or folate; use erythropoiesis-stimulating agents only in CKD or MDS with a target Hb of 10–11.5 g/dL (never normalise); and reserve transfusion for symptomatic anaemia at Hb <7 g/dL (<8 g/dL with cardiovascular disease).

Latest Update (2023–2026) — 1 point

7. **WHO revised haemoglobin thresholds (2024)** — a technical review reaffirmed the diagnostic cut-offs but recommended **adjustment for smoking and altitude**, and emphasised that **ferritin below 30 µg/L (rather than 15) should be used to identify iron deficiency in the presence of inflammation**. In parallel, "unexplained anaemia of ageing" is increasingly attributed to **clonal haematopoiesis of indeterminate potential (CHIP)** and early clonal cytopenia, which reframes it as a pre-malignant rather than purely physiological state and justifies bone marrow evaluation in persistent unexplained anaemia.

Question 22. Iron deficiency anaemia — red cell indices and investigation 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** Anaemia (**WHO: Hb <13 g/dL in men, <12 g/dL in women**) resulting from depleted body iron stores. It is the commonest anaemia worldwide and the commonest nutritional anaemia in Indian elderly. **In an older adult, iron deficiency means blood loss until proved otherwise.**
2. **Causes in the elderly.** **Chronic gastrointestinal blood loss** — peptic ulcer, NSAID/aspirin use, **colonic carcinoma**, angiodysplasia, oesophagitis and hookworm infestation (important in India); **malabsorption** — coeliac disease, atrophic gastritis, post-gastrectomy and long-term PPI use; poor dietary intake; and genitourinary blood loss.
3. **Red cell indices.** **Low MCV (<80 fL) and low MCH (<27 pg)** giving a microcytic hypochromic picture, with a **raised RDW (>15%) — the earliest index to change**. This distinguishes it from **thalassaemia trait**, which has a

normal RDW, a disproportionately low MCV and a high red cell count (**Mentzer index MCV/RBC >13 favours iron deficiency**). **Reticulocyte haemoglobin content (CHr/Ret-He) is an early marker.** The film shows microcytes, hypochromia, **pencil cells**, target cells and mild thrombocytosis.

4. **Confirmatory biochemistry.** **Serum ferritin is the single best test — below 30 ng/mL is diagnostic**, but because ferritin is an acute-phase reactant a higher cut-off of **45–100 ng/mL** is used in the elderly with inflammation. Also: low serum iron, **raised TIBC**, **transferrin saturation <16%**, raised soluble transferrin receptor and low hepcidin. Bone marrow iron staining is needed only when the diagnosis remains unclear.
5. **Distinction from anaemia of chronic disease.** Anaemia of chronic disease shows a **normal or high ferritin, low TIBC, normal soluble transferrin receptor and raised CRP**. **Combined states are common in the elderly** — use the sTfR/log-ferritin index to separate them.
6. **Investigation of the source.** **Bidirectional endoscopy (upper GI endoscopy plus colonoscopy) is mandatory in every older adult with unexplained iron deficiency anaemia**, with duodenal biopsy and coeliac serology. Also check urine for blood and stool for occult blood and ova. If both are negative and anaemia persists or recurs, proceed to **capsule endoscopy or CT enterography** for small bowel angiodysplasia or tumour.

Latest Update (2023–2026) — 1 point

7. **Modern iron replacement.** Hepcidin studies have shown that **oral iron given on alternate days as a single morning dose achieves better fractional absorption with fewer side-effects** than conventional twice or thrice daily dosing. New-generation intravenous preparations — **ferric carboxymaltose and ferric derisomaltose** — allow total-dose correction in a single sitting and are preferred in malabsorption, intolerance, CKD, heart failure and ongoing blood loss; watch for **hypophosphataemia with ferric carboxymaltose**.

Cross-reference: Anaemia of chronic disease, with which iron deficiency frequently coexists, is covered in Question 24.

Question 23. Megaloblastic anaemia and B_{12} deficiency 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition.** A **macrocytic anaemia caused by impaired DNA synthesis** from vitamin B_{12} (cobalamin) or folate deficiency, producing **nuclear-cytoplasmic asynchrony** and ineffective erythropoiesis.
2. **Physiology of B_{12} absorption.** Dietary B_{12} binds R-protein, is released by pancreatic proteases, binds **intrinsic factor from gastric parietal cells**, and is absorbed in the **terminal ileum**. **Body stores last 3–5 years, whereas folate stores last only 3–4 months.**
3. **Causes of B_{12} deficiency in the elderly.** **Food-cobalamin malabsorption from atrophic gastritis and hypochlorhydria is the commonest cause in old age**; **pernicious anaemia** (autoimmune, with anti-intrinsic factor and anti-parietal cell antibodies); gastrectomy or bariatric surgery; terminal ileal disease or resection; bacterial overgrowth; tropical sprue; strict vegetarian diet (very relevant in India); and drugs — **metformin, proton pump inhibitors, H_2 blockers, colchicine and nitrous oxide**.
4. **Causes of folate deficiency.** Poor intake and alcoholism, malabsorption (coeliac disease, tropical sprue), increased demand (haemolysis, malignancy, pregnancy), and drugs — **methotrexate, trimethoprim, phenytoin and sulfasalazine**.
5. **General clinical features.** Insidious anaemia with **lemon-yellow pallor** and mild jaundice, **glossitis (beefy red smooth tongue)**, angular stomatitis, anorexia and weight loss; frail patients may present with heart failure.
6. **Neurological features (B_{12} only, and may occur without anaemia).** **Subacute combined degeneration of the cord** — symmetrical paraesthesiae, loss of vibration and joint position sense, sensory ataxia, and **spastic paraparesis with extensor plantars but absent ankle jerks**. Also peripheral neuropathy, optic atrophy, dementia, depression and psychosis ("megaloblastic madness"). **Folate deficiency does not cause subacute combined degeneration.**
7. **Laboratory findings.** **Raised MCV (often >110 fL)**, **oval macrocytes** and **hypersegmented neutrophils** (5% with five lobes or any six-lobed cell), pancytopenia when severe, and a low reticulocyte count. Ineffective erythropoiesis gives a **raised LDH and unconjugated bilirubin with low haptoglobin**, mimicking haemolysis or TTP (**pseudo-thrombotic microangiopathy**). Marrow shows megaloblasts and **giant metamyelocytes**.
8. **Confirming the deficiency.** **Serum B_{12} <200 pg/mL (148 pmol/L)** is diagnostic; for indeterminate values of 200–350 pg/mL measure **serum methylmalonic acid (raised in B_{12} deficiency only)** and **homocysteine (raised in both B_{12} and folate deficiency)**. **Holotranscobalamin (active B_{12})** is an alternative first-line test. Add serum and red cell folate, **anti-intrinsic factor antibody (highly specific, poorly sensitive)** and anti-parietal cell antibody,

and gastroscopy for atrophic gastritis (risk of gastric cancer and carcinoid).

9. **Treatment.** **Hydroxocobalamin 1000 µg intramuscularly on alternate days for 1–2 weeks, then 1000 µg every 2–3 months for life.** If there are neurological features, continue alternate-day injections until no further improvement occurs, then maintain 2-monthly. **Oral cyanocobalamin 1000–2000 µg daily** is effective for dietary deficiency and food-cobalamin malabsorption. Folate deficiency is treated with **folic acid 5 mg daily**.
10. **Cautions and monitoring.** **Never give folate alone when B_{12} deficiency is possible — it precipitates or worsens subacute combined degeneration.** Expect a **reticulocytosis at day 5–7** and a rising haemoglobin within 1–2 weeks. Watch for **hypokalaemia** during the response, and for **unmasked iron deficiency** (falling MCV with a dimorphic film). Screen for thyroid disease and other autoimmune conditions in pernicious anaemia.

Latest Updates (2023–2026) — 2 points

11. **NICE NG239 (March 2024) — Vitamin B_{12} deficiency in over-16s.** Test using either total B_{12} or **active B_{12} (holotranscobalamin)**; use **serum methylmalonic acid for indeterminate results**; **do not delay replacement while awaiting results if there are neurological symptoms or megaloblastic anaemia**; and offer **lifelong intramuscular replacement** after total gastrectomy, complete terminal ileal resection, or when autoimmune gastritis is the cause.
12. **Metformin-associated B_{12} deficiency** is now formally classified as a **common adverse effect** by regulators, with periodic B_{12} testing advised in long-term metformin users, particularly those with anaemia or neuropathy. Evidence also now supports **high-dose oral B_{12} as non-inferior to intramuscular therapy** in non-neurological deficiency without severe malabsorption.

Question 24. Anaemia of chronic disease 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** Also called **anaemia of inflammation** — a mild to moderate, usually **normocytic normochromic** anaemia occurring in chronic infection, inflammation or malignancy. It is the **second commonest anaemia worldwide and the commonest anaemia in hospitalised older patients**.
2. **Causes.** **Chronic infections** (tuberculosis, osteomyelitis, endocarditis, HIV), **chronic inflammatory disease** (rheumatoid arthritis, polymyalgia rheumatica, giant cell arteritis, inflammatory bowel disease), **malignancy**, chronic kidney disease, heart failure, COPD and diabetes.
3. **Pathogenesis — three mechanisms.** Inflammatory cytokines (**IL-6, TNF-α, IL-1, interferon-γ**) drive: (a) **IL-6-induced hepcidin release from the liver, which degrades ferroportin and traps iron in macrophages and enterocytes — producing functional iron deficiency**; (b) **blunted erythropoietin production and reduced marrow responsiveness to EPO**; and (c) **shortened red cell survival**. Hepcidin is the central molecule.
4. **Laboratory features.** Hb usually **8–11 g/dL**, normocytic (microcytic in 25–30% if long-standing), **low reticulocyte count**, **low serum iron with low TIBC/transferrin**, transferrin saturation low or normal, **normal or high ferritin (an acute-phase reactant)**, raised CRP and ESR, and **normal soluble transferrin receptor**.
5. **Distinction from iron deficiency (very high yield).**

Parameter	Iron deficiency	Anaemia of chronic disease
Serum ferritin	**Low** (<30 ng/mL)	**Normal or high**
TIBC / transferrin	**High**	**Low**
Transferrin saturation	<16%	Low or normal
Soluble transferrin receptor	**High**	**Normal**
sTfR / log ferritin index	>2	<1
Serum hepcidin	Low	**High**

The two frequently coexist in the elderly — use the sTfR/log ferritin index, or a ferritin cut-off of 100 ng/mL in the presence of inflammation.

6. **Management.** **Treat the underlying disease — this is the definitive therapy and the anaemia resolves with disease control.** Do not give oral iron unless true deficiency coexists, because **high hepcidin blocks its absorption**; if iron is needed, use **intravenous iron, which bypasses the hepcidin-ferroportin block**. Erythropoiesis-stimulating agents are indicated in **CKD and chemotherapy-induced anaemia**, targeting Hb 10–

11.5 g/dL (never normalisation, because of thrombosis, hypertension and tumour progression risk), with iron repletion first. Transfuse only for symptomatic anaemia.

Latest Update (2023–2026) — 1 point

7. **Hepcidin-targeted and HIF-PHI therapy. Hypoxia-inducible factor prolyl-hydroxylase inhibitors (roxadustat, daprodustat, vadadustat)** are now approved for anaemia of CKD; they are **orally active, raise endogenous erythropoietin and simultaneously suppress hepcidin**, thereby improving iron mobilisation — a mechanistic advantage over conventional ESAs in inflammatory states, although cardiovascular safety signals mean current guidance restricts them to selected patients. Anti-hepcidin and anti-IL-6 agents are in trials for anaemia of inflammation.

Current Practice Update

Textbook: Ferritin below 15–30 ng/mL defines iron deficiency; oral iron is first-line replacement.
Current recommendation: In inflammation use a ferritin threshold of 100 ng/mL (or sTfR index), and give **intravenous** iron, since high hepcidin blocks oral absorption.
Exam approach: State the hepcidin mechanism explicitly — it explains both the diagnostic difficulty and why IV iron is preferred.

Cross-reference: The general evaluation of anaemia in an older patient is given in Question 21, and iron deficiency in Question 22.

Question 25. Blood transfusion in the older adult — thresholds and hazards 7 MARKS

Answer — Textbook Core (6 points)

1. **Guiding principle.** Transfuse for **symptoms and physiology, not for a number**. Give a **single unit and then reassess** ("why give two when one will do"), and always consider treating the cause — iron, B_{12}, folate or erythropoietin — instead of transfusing.
2. **Thresholds (AABB 2023 international guidelines).** **Restrictive threshold of Hb <7 g/dL** for haemodynamically stable hospitalised adults, including critical care patients and those with gastrointestinal bleeding. **Hb <8 g/dL** for patients undergoing orthopaedic or cardiac surgery and those with pre-existing cardiovascular disease.
3. **Special situations.** **Chronic asymptomatic anaemia should not be transfused** — correct the cause. In active bleeding, transfuse by clinical judgement rather than haemoglobin. In heart failure and frailty, transfuse **slowly over 3–4 hours per unit with diuretic cover**.
4. **Acute hazards.** **Acute haemolytic reaction from ABO incompatibility (commonest cause is a clerical/identification error)**, febrile non-haemolytic reaction, allergic and anaphylactic reactions, bacterial contamination and sepsis, **TACO — transfusion-associated circulatory overload, the commonest cause of transfusion-related death and the commonest serious hazard in the elderly** — and **TRALI** (non-cardiogenic pulmonary oedema within 6 hours).
5. **Delayed hazards.** Delayed haemolytic reaction, red cell alloimmunisation, **transfusion-transmitted infection (HIV, hepatitis B and C, malaria, syphilis — relevant to Indian practice)**, iron overload with repeated transfusion, **transfusion-associated graft-versus-host disease** (prevent with irradiated components after purine analogues or stem cell transplant), and post-transfusion purpura.
6. **Safe practice.** **Positive patient identification at the bedside**, baseline and 15-minute observations, transfusion during daytime hours wherever possible, documented indication and consent, strict fluid balance monitoring, and a **formal TACO risk assessment before every transfusion in an older patient**.

Latest Update (2023–2026) — 1 point

7. **AABB 2025 international guideline for acute myocardial infarction** (*Ann Intern Med* 2025;178:1469) — in hospitalised patients with **acute myocardial infarction and anaemia, a liberal strategy transfusing at Hb <10 g/dL is now suggested**. This follows the **MINT trial (NEJM 2023, n=3504, mean age 72)** and a patient-level meta-analysis showing lower cardiac death at 30 days and lower all-cause mortality at 6 months with the liberal strategy. **It is the first major departure from universal restrictive transfusion.**

Current Practice Update

Textbook: A restrictive threshold of 7–8 g/dL applies to all stable hospitalised patients, including those with cardiac disease.
Current recommendation: Restrictive 7 g/dL remains standard, but **acute myocardial infarction is now an exception — transfuse to keep Hb ≥10 g/dL**.
Exam approach: State the restrictive rule, then add the AABB 2025/MINT exception for acute MI — this single line distinguishes an updated answer.

Cross-reference: For transfusion practice in the specific setting of acute upper gastrointestinal bleeding, see also Question 3.

PART V — HAEMATOLOGICAL DISORDERS AND MALIGNANCY

Question 26. Thrombocytopenia 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and bleeding risk.** Platelet count below **150 × 10^9/L**. **Spontaneous bleeding is unusual above 50, purpura and mucosal bleeding appear below 30, and the risk of spontaneous serious or intracranial bleeding rises below 10–20 × 10^9/L.** Always **exclude pseudothrombocytopenia from EDTA-induced platelet clumping** by repeating the count in a citrate tube and examining the film.
2. **Classification by mechanism.** **Decreased production** — marrow failure or infiltration (leukaemia, myeloma, metastases, myelofibrosis), **myelodysplasia**, aplastic anaemia, B_{12}/folate deficiency, alcohol, chemotherapy and radiation. **Increased destruction** — immune (ITP, drug-induced, HIT, post-transfusion purpura, secondary to CLL, SLE, HIV, hepatitis C) or non-immune (DIC, TTP/HUS, mechanical valves, sepsis). **Sequestration** — hypersplenism from portal hypertension. **Dilutional** — massive transfusion.
3. **Drug-induced thrombocytopenia (high yield in the elderly). Heparin (HIT), quinine and quinidine, sulphonamides and co-trimoxazole, vancomycin, linezolid, rifampicin, valproate, carbamazepine, phenytoin, thiazides, glycoprotein IIb/IIIa inhibitors and chemotherapy.** Onset is typically 1–2 weeks after starting a new drug, and recovery follows within 5–7 days of withdrawal.
4. **Immune thrombocytopenia (ITP) in older adults.** A diagnosis of exclusion — **isolated thrombocytopenia with a normal blood film and no other cause**. In the elderly it is more often **secondary (to CLL, lymphoma, myelodysplasia, HIV, hepatitis C, *H. pylori*, SLE or drugs)** and carries a **higher bleeding risk**, so a **bone marrow examination should be performed in most patients over 60 to exclude myelodysplasia**. Antiplatelet antibody testing is not required.
5. **Emergency causes that must not be missed. Heparin-induced thrombocytopenia** — a fall of >50% at 5–10 days with **thrombosis, not bleeding**; assess with the **4Ts score**, stop all heparin (including flushes) and start a non-heparin anticoagulant (argatroban, fondaparinux); **never give platelet transfusions or warfarin alone**. **TTP** — microangiopathic haemolytic anaemia with fragmented red cells, fever, renal impairment and neurological signs from **ADAMTS13 deficiency**, requiring urgent **plasma exchange**. Also **DIC** and sepsis.
6. **Management. Treat the cause and stop the offending drug.** In ITP, treat only if the platelet count is **below 20–30 × 10^9/L or there is bleeding**: first-line is **corticosteroids (prednisolone 1 mg/kg, or dexamethasone 40 mg for 4 days — preferred in the elderly for shorter steroid exposure)** with **IVIG 1 g/kg for urgent rises**. Second-line: **thrombopoietin receptor agonists (eltrombopag, romiplostim, avatrombopag)**, rituximab, or splenectomy (less favoured in the elderly). **Platelet transfusion only for active bleeding or before invasive procedures** — it is contraindicated in HIT and TTP. Prophylactic transfusion threshold is 10 × 10^9/L in stable patients.

Latest Update (2023–2026) — 1 point

7. **Newer targeted therapy in ITP.** The **ADVANCE trials of efgartigimod** (a neonatal Fc receptor blocker that accelerates IgG degradation, *Lancet* 2023) and the **Bruton tyrosine kinase inhibitor rilzabrutinib** have both demonstrated durable platelet responses in chronic ITP, offering **steroid-sparing options that are particularly valuable in older patients**, in whom prolonged corticosteroids cause diabetes, osteoporosis, delirium and infection. Current practice increasingly moves to a **TPO receptor agonist as early second-line therapy rather than prolonged steroids**.

Question 27. Disseminated intravascular coagulation 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** An **acquired syndrome of widespread intravascular activation of coagulation** with loss of localisation, causing **microvascular thrombosis with organ dysfunction and simultaneous consumption of platelets and clotting factors leading to bleeding**. It is **always secondary to an underlying disorder** — never a primary diagnosis.
2. **Causes. Sepsis (the commonest, especially Gram-negative)**; **malignancy** — adenocarcinoma of pancreas, prostate and stomach (chronic, thrombotic DIC) and **acute promyelocytic leukaemia** (fulminant bleeding); **trauma, burns, major surgery, head injury**; obstetric causes (abruption, amniotic fluid embolism); **transfusion reactions, snake envenomation, heat stroke, severe pancreatitis, aortic aneurysm and giant haemangioma**.

3. **Pathogenesis.** **Tissue factor exposure** and cytokine release trigger excess thrombin generation, while the natural anticoagulants (**antithrombin, protein C, tissue factor pathway inhibitor**) are consumed and **fibrinolysis is suppressed by raised PAI-1**. Fibrin deposition in the microvasculature causes ischaemic organ failure and **microangiopathic haemolysis**; ongoing consumption then produces the bleeding phase.
4. **Clinical features.** **Bleeding** — oozing from venepuncture and cannula sites, petechiae, ecchymoses, mucosal and gastrointestinal bleeding. **Thrombosis** — acral cyanosis, digital gangrene, purpura fulminans, and organ failure (renal, respiratory, hepatic, cerebral). Chronic compensated DIC in malignancy may present only as **migratory thrombophlebitis or venous thromboembolism**.
5. **Laboratory diagnosis and the ISTH score.** **Thrombocytopenia with a falling trend, prolonged PT and aPTT, low fibrinogen, and markedly raised D-dimer/fibrin degradation products**; the film shows **schistocytes**. The **ISTH overt DIC score** (in a patient with a predisposing condition) awards points for platelet count (<100 = 1, <50 = 2), fibrin marker elevation (moderate 2, strong 3), PT prolongation (≥3 s = 1, ≥6 s = 2) and fibrinogen <1 g/L (=1); **a score of 5 or more is compatible with overt DIC**. **Serial trends matter more than a single value**, and fibrinogen may be spuriously normal because it is an acute-phase reactant.
6. **Management.** **Vigorous treatment of the precipitating cause is the cornerstone** — antibiotics and source control in sepsis, delivery in obstetric DIC, ATRA in acute promyelocytic leukaemia. Give blood products only **if there is bleeding or a planned procedure, not to correct numbers**: **platelets if <50 × 10^9/L with bleeding (<20 if not bleeding but high risk), fresh frozen plasma 15 mL/kg for prolonged PT/aPTT, and cryoprecipitate or fibrinogen concentrate if fibrinogen <1.5 g/L**. **Therapeutic heparin is reserved for the predominantly thrombotic phenotype** (purpura fulminans, digital ischaemia, chronic DIC of malignancy); **prophylactic-dose heparin for VTE prevention is appropriate in non-bleeding patients**. Tranexamic acid is generally contraindicated except in hyperfibrinolytic states such as APL.

Latest Update (2023–2026) — 1 point

7. **Sepsis-induced coagulopathy (SIC) and earlier recognition.** Current ISTH guidance recommends using the **simpler two-step SIC score (platelet count, INR and SOFA score)** to detect coagulopathy **before overt DIC develops**, since by the time the ISTH overt DIC score reaches 5 the mortality is already very high. Practice has also moved towards **viscoelastic testing (ROTEM/TEG) and fibrinogen concentrate rather than empirical fresh frozen plasma** for targeted correction, and away from routine antithrombin or recombinant thrombomodulin, which have not shown consistent survival benefit.

Question 28. Myelodysplasia 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** Myelodysplastic syndromes are **clonal haematopoietic stem cell disorders characterised by ineffective haematopoiesis — a hypercellular or normocellular marrow with peripheral cytopenias — morphological dysplasia, and a tendency to transform into acute myeloid leukaemia**. It is **predominantly a disease of old age**, with a median age of 70–75 and incidence rising to over 30 per 100,000 beyond 70 years.
2. **Aetiology.** Mostly **primary/de novo**, arising from age-related clonal haematopoiesis. **Secondary (therapy-related) MDS** follows **alkylating agents (5–7 years later, with del(5q)/del(7q)) and topoisomerase II inhibitors**, radiotherapy, and exposure to benzene, organic solvents and tobacco. Common somatic mutations: **SF3B1 (favourable, ring sideroblasts), TET2, ASXL1, DNMT3A, RUNX1, TP53 (adverse)**.
3. **Clinical features.** Often **discovered incidentally on a routine blood count**. Otherwise, symptoms of **anaemia (fatigue, dyspnoea, angina, falls, worsening heart failure)**, **recurrent infection from neutropenia and impaired neutrophil function**, and **bruising and bleeding from thrombocytopenia**. Splenomegaly is unusual except in CMML. Autoimmune phenomena (vasculitis, arthritis, pericarditis) occur in about 10%.
4. **Diagnosis.** Persistent unexplained cytopenia with a blood film showing **oval macrocytes, hypogranular neutrophils and the Pelger-Huët anomaly (bilobed nuclei), giant or hypogranular platelets, and circulating blasts**. **Bone marrow aspirate and trephine are essential** — dysplasia in ≥10% of cells in one or more lineages, **blasts <20% (20% or more defines AML)**, **ring sideroblasts on Perls stain**, and cytogenetics (**del(5q), monosomy 7, trisomy 8, complex karyotype**). **Always exclude the mimics first — B_{12} and folate deficiency, copper deficiency, alcohol, HIV, drugs and recent chemotherapy.**
5. **Classification and prognosis.** Classified by the WHO 5th edition (2022)/ICC by **blast percentage, lineage dysplasia, ring sideroblasts and defining genetic lesions — MDS with low blasts, MDS with SF3B1 mutation, MDS with del(5q), MDS with increased blasts, MDS with biallelic TP53 inactivation**. Prognosis uses the **Revised International Prognostic Scoring System (IPSS-R)** based on **cytogenetics, marrow blast**

percentage, haemoglobin, platelet count and neutrophil count, giving five risk groups from very low to very high, with median survival ranging from about **8.8 years to 0.8 years**.

6. **Management (risk-adapted).** **Lower-risk disease** — supportive care with transfusion and iron chelation if more than 20–25 units are transfused; **erythropoiesis-stimulating agents if serum EPO <500 mU/mL**; **lenalidomide for del(5q)**; **luspatercept for anaemia with ring sideroblasts/SF3B1 mutation**; immunosuppression in selected hypoplastic MDS. **Higher-risk disease** — **hypomethylating agents (azacitidine or decitabine)**, which improve survival and are well tolerated in the elderly, or intensive AML-type chemotherapy in the fit. **Allogeneic stem cell transplantation with reduced-intensity conditioning is the only curative option** and is feasible up to about 70–75 years in fit patients.

Latest Update (2023–2026) — 1 point

7. **Molecular prognostication and two new drugs.** The **IPSS-M (Molecular IPSS)** incorporates 31 gene mutations with clinical variables and **reclassifies about 46% of patients compared with IPSS-R**, most often upstaging them and thereby changing transplant timing. For lower-risk transfusion-dependent anaemia: the **COMMANDS trial** (*Lancet Haematol* 2024) showed **luspatercept is superior to epoetin alfa as first-line therapy**, and **imetelstat, a telomerase inhibitor, was FDA-approved in June 2024 (IMerge trial, *Lancet* 2024)** for transfusion-dependent lower-risk MDS after ESA failure, giving durable transfusion independence irrespective of ring sideroblast status.

Question 29. Chronic myeloid leukaemia — clinical features and management 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and cytogenetics.** A myeloproliferative neoplasm defined by the **Philadelphia chromosome — t(9;22)(q34;q11) — producing the BCR::ABL1 fusion gene, which encodes a constitutively active tyrosine kinase**. Median age at diagnosis is about 65 years.

2. **Clinical features.** **Up to 50% are asymptomatic and detected on a routine blood count.** Otherwise: fatigue, weight loss, night sweats, low-grade fever, **massive splenomegaly with early satiety, left hypochondrial dragging pain and splenic infarction**, bone tenderness over the sternum, gout from hyperuricaemia, and rarely **leucostasis (priapism, visual disturbance, confusion) when the white count exceeds 300 × 10^9/L**.

3. **Phases.** **Chronic phase** — blasts <10%, over 90% present here, indolent. **Accelerated phase** — blasts 10–19%, basophils ≥20%, persistent thrombocytopenia or thrombocytosis, clonal evolution. **Blast crisis** — **blasts ≥20% in blood or marrow, or an extramedullary blast proliferation**; two-thirds are myeloid and one-third lymphoid, and prognosis is poor.

4. **Laboratory diagnosis.** **Marked leucocytosis (often >100 × 10^9/L) with the full spectrum of immature granulocytes ("left shift"), a myelocyte bulge, and characteristic basophilia and eosinophilia**; thrombocytosis is common; **the leucocyte alkaline phosphatase score is characteristically low** (distinguishing it from a leukaemoid reaction). Confirm with **cytogenetics for the Philadelphia chromosome, FISH, and quantitative RT-PCR for BCR::ABL1 transcripts (which is also used for monitoring)**. Marrow shows granulocytic hyperplasia with a raised myeloid:erythroid ratio.

5. **Treatment.** **Tyrosine kinase inhibitors are the treatment of choice and have converted CML into a chronic disease with near-normal life expectancy.** First-line: **imatinib 400 mg daily**, or a second-generation agent (**dasatinib, nilotinib, bosutinib**) for higher-risk disease or faster response. **Hydroxyurea** is used briefly for cytoreduction and **leukapheresis for leucostasis**. Allopurinol and hydration prevent tumour lysis. **Allogeneic transplantation is now reserved for blast crisis or multiple TKI failure.** For **T315I mutation, use ponatinib or asciminib**.

6. **Monitoring, toxicity and treatment-free remission.** Monitor **BCR::ABL1 by RT-PCR on the International Scale every 3 months**. Milestones: **≤10% at 3 months, ≤1% at 6 months, and ≤0.1% (major molecular response, MMR or MR3) at 12 months**. In the elderly, watch TKI toxicity — **imatinib: oedema, cramps, cytopenias; dasatinib: pleural effusion; nilotinib: QT prolongation, hyperglycaemia and arterial occlusive events; ponatinib: arterial thrombosis** — and check drug interactions (CYP3A4). **Treatment-free remission may be attempted after at least 3 years of therapy with a sustained deep molecular response (MR4.5) for 2 years**, with monthly monitoring; about half remain in remission.

Latest Update (2023–2026) — 1 point

7. **Asciminib — ASC4FIRST trial** (*NEJM* 2024;391:885; FDA accelerated approval October 2024, NCCN category 1). Asciminib is the **first allosteric BCR::ABL1 inhibitor, which binds the ABL myristoyl pocket (a "STAMP" inhibitor) rather than the ATP site**. In newly diagnosed chronic-phase CML it produced a **major molecular response at 48 weeks in 68% versus 49% with investigator-selected TKIs**, with **markedly fewer dose reductions and discontinuations for toxicity** — a particular advantage in older patients with comorbidity. It is also effective against the **T315I** mutation.

Question 30. Chronic lymphocytic leukaemia 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition.** A monoclonal proliferation of mature B lymphocytes, defined by **≥5 × 10^9/L clonal B lymphocytes in peripheral blood persisting for at least 3 months** with a characteristic immunophenotype. It is the **commonest leukaemia of older adults**, with a median age at diagnosis of about 70 years.
2. **Related entities.** **Small lymphocytic lymphoma (SLL)** — same disease with nodal involvement but fewer than 5 × 10^9/L circulating cells. **Monoclonal B-cell lymphocytosis (MBL)** — clonal cells without disease, progressing to CLL at 1–2% per year.
3. **Clinical features.** Often **asymptomatic and detected on a routine blood count**. Otherwise painless symmetrical **lymphadenopathy, splenomegaly and hepatomegaly**, B symptoms (fever, drenching night sweats, weight loss >10%), fatigue, and **recurrent infections from hypogammaglobulinaemia**.
4. **Complications.** **Autoimmune haemolytic anaemia** and immune thrombocytopenia (direct antiglobulin test positive), pure red cell aplasia, **infection — the leading cause of death**, second malignancies (especially skin), and **Richter's transformation** to diffuse large B-cell lymphoma in about 5% (rapid nodal enlargement, rising LDH, B symptoms).
5. **Diagnosis.** Peripheral smear shows **mature small lymphocytes with smudge (smear) cells**. **Flow cytometry is diagnostic: CD5+, CD19+, CD23+, CD200+, dim CD20 and dim surface immunoglobulin with kappa or lambda light-chain restriction.** Bone marrow examination is not required for diagnosis.
6. **Staging.** **Rai** — 0 lymphocytosis only; I plus lymphadenopathy; II plus spleno/hepatomegaly; **III anaemia (Hb <11 g/dL)**; **IV thrombocytopenia (<100 × 10^9/L)**. **Binet** — A fewer than 3 nodal areas; B three or more; C anaemia or thrombocytopenia.
7. **Prognostic markers.** Adverse — **unmutated IGHV**, **del(17p) or TP53 mutation (worst, chemotherapy-resistant)**, del(11q), complex karyotype, high ZAP-70, CD38 and β_2-microglobulin. Favourable — **isolated del(13q)** and mutated IGHV. The **CLL-IPI** combines TP53 status, IGHV, β_2-microglobulin, clinical stage and age.
8. **Indications to treat (iwCLL 2018).** **Progressive marrow failure** (worsening anaemia or thrombocytopenia), massive or progressive splenomegaly or lymphadenopathy, **lymphocyte doubling time under 6 months**, autoimmune cytopenia refractory to steroids, and constitutional symptoms. **Early asymptomatic disease is not treated — "watch and wait" is the standard of care and treating early does not prolong survival.**
9. **Treatment.** Targeted agents have replaced chemoimmunotherapy in older adults — **continuous BTK inhibitors (ibrutinib, acalabrutinib, zanubrutinib)** or **fixed-duration venetoclax (BCL-2 inhibitor) with obinutuzumab for 12 months (CLL14 trial)**. For **del(17p)/TP53** use a BTK inhibitor or venetoclax-based therapy — **never FCR**. Chlorambucil with obinutuzumab remains an option where targeted agents are unavailable.
10. **Supportive care in the elderly.** Annual influenza, pneumococcal and **recombinant (non-live) zoster** vaccination; **prophylactic immunoglobulin if recurrent infection with IgG <400 mg/dL**; tumour lysis prophylaxis during venetoclax ramp-up; monitor BTK inhibitors for **atrial fibrillation, hypertension and bleeding** (avoid combining with warfarin); and use **irradiated blood products** after purine analogue therapy.

Latest Updates (2023–2026) — 2 points

11. **AMPLIFY trial** (Brown, *NEJM* 2025;392:748; FDA approval February 2026) — **fixed-duration acalabrutinib plus venetoclax is the first all-oral, time-limited regimen for untreated CLL**, with 36-month progression-free survival of **76.5% versus 66.5%** for chemoimmunotherapy (HR 0.65). Patients with del(17p)/TP53 were excluded.
12. **Pirtobrutinib**, a **non-covalent BTK inhibitor** (BRUIN trial), is approved after failure of covalent BTK inhibitors, including in **BTK C481S resistance**. Practice is moving towards **MRD-guided fixed-duration therapy** instead of indefinite treat-to-progression, which is particularly valuable in older patients wanting time off therapy.

Current Practice Update

Textbook: Chlorambucil-based or FCR chemoimmunotherapy is first-line, chosen by fitness.
Current recommendation: Targeted therapy for all — continuous BTK inhibitor or fixed-duration venetoclax combination; chemoimmunotherapy is essentially obsolete.
Exam approach: Mention chemoimmunotherapy only as historical/resource-limited practice, then give the targeted-agent algorithm and TP53 exception.

Question 31. Myelofibrosis and the myeloproliferative neoplasms 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition and classification.** Myeloproliferative neoplasms are **clonal haematopoietic stem cell disorders** with effective but dysregulated proliferation of one or more myeloid lineages. **Philadelphia-negative:** polycythaemia vera (PV), essential thrombocythaemia (ET) and **primary myelofibrosis (PMF)**. **Philadelphia-positive:** chronic myeloid leukaemia.
2. **Driver mutations.** **JAK2 V617F** in 95% of PV and 50–60% of ET/PMF; JAK2 exon 12 in PV; **CALR** in 20–25% of ET/PMF (better prognosis); **MPL** in about 5%. **Triple-negative PMF has the worst outcome.** High-molecular-risk mutations are **ASXL1, SRSF2, EZH2, IDH1/2 and U2AF1**.
3. **Polycythaemia vera.** Raised haematocrit (**>49% men, >48% women**) with a **low serum erythropoietin** and JAK2 mutation. Features are **aquagenic pruritus**, erythromelalgia, plethora and splenomegaly. **Thrombosis is the main cause of death.**
4. **Essential thrombocythaemia.** Sustained platelet count **≥450 × 10^9/L** with megakaryocytic proliferation. Causes microvascular symptoms and thrombosis, but paradoxically **bleeding when platelets exceed 1000 × 10^9/L (acquired von Willebrand disease)**.
5. **Primary myelofibrosis — clinical features.** **Progressive anaemia, massive splenomegaly** (dragging pain, early satiety, splenic infarction), **constitutional symptoms** (fever, night sweats, weight loss, cachexia), bone pain, extramedullary haematopoiesis and portal hypertension.
6. **Primary myelofibrosis — laboratory findings.** **Leucoerythroblastic blood picture with teardrop poikilocytes (dacrocytes)**, nucleated red cells and immature granulocytes; raised LDH; **"dry tap" on marrow aspiration**; trephine biopsy shows **atypical clustered megakaryocytes with reticulin or collagen fibrosis (MF grade 1–3)**. WHO 5th edition (2022) separates **prefibrotic from overt PMF**.
7. **Prognostic scoring.** **DIPSS/DIPSS-Plus** — age >65, Hb <10 g/dL, WBC >25 × 10^9/L, circulating blasts ≥1%, constitutional symptoms, plus transfusion need, platelets <100 × 10^9/L and unfavourable karyotype. **MIPSS70/70+ v2.0** incorporates molecular data and is used to select transplant candidates.
8. **Complications.** Progressive marrow failure and transfusion dependence, portal hypertension, splenic infarction, thrombosis, infection, and **leukaemic transformation to AML in 10–20% at 10 years**.
9. **Management of PV and ET.** **Low-dose aspirin 75–100 mg for all** unless contraindicated. PV — **venesection to keep haematocrit below 45%**. Cytoreduction if high risk (**age >60 or prior thrombosis**) — **hydroxyurea first-line**, interferon in younger patients, and **ruxolitinib for hydroxyurea-resistant or intolerant PV**. In ET, anagrelide is second-line.
10. **Management of primary myelofibrosis.** Risk-adapted — observe low-risk asymptomatic disease. For symptomatic splenomegaly or constitutional symptoms use the JAK inhibitor **ruxolitinib** (COMFORT-I and II: spleen and symptom reduction with a survival benefit); **fedratinib** after ruxolitinib failure. **Allogeneic stem cell transplantation is the only curative option** but is rarely feasible beyond 70 years. Supportive care includes transfusion, erythropoiesis-stimulating agents if serum EPO <500 mU/mL, danazol, splenic irradiation, and splenectomy only for refractory cases.

Latest Updates (2023–2026) — 2 points

11. **Cytopenia-directed JAK inhibitors** — **momelotinib** (MOMENTUM, *Lancet* 2023) is approved for myelofibrosis with anaemia, improving spleen size, symptoms and **transfusion independence** through additional ACVR1/hepcidin inhibition; **pacritinib** is approved when platelets are **below 50 × 10^9/L**. NCCN MPN guidelines 2026 now contain a dedicated MF-associated anaemia algorithm listing momelotinib as a preferred regimen.
12. **Ropeginterferon alfa-2b** is approved for polycythaemia vera as a **disease-modifying agent that induces molecular responses** and reduces JAK2 allele burden, unlike hydroxyurea. The hepcidin mimetic **rusfertide** is in late-phase trials aiming to abolish phlebotomy dependence.

Question 32. Plasma cell dyscrasias — types, presentation, diagnostic criteria, course and treatment 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition and the spectrum.** Plasma cell dyscrasias (monoclonal gammopathies) are **clonal proliferations of plasma cells or lymphoplasmacytic cells producing a monoclonal immunoglobulin (M protein or paraprotein)**. The spectrum runs from **MGUS → smouldering myeloma → symptomatic multiple myeloma**, with related entities of **solitary plasmacytoma, AL amyloidosis, Waldenström macroglobulinaemia, POEMS syndrome, heavy chain disease, plasma cell leukaemia and monoclonal gammopathy of renal significance (MGRS)**.
2. **MGUS. Serum M protein <3 g/dL, clonal marrow plasma cells <10%, and no myeloma-defining events or end-organ damage.** It is present in **3% of people over 50 and 5% over 70**, is asymptomatic, and progresses at a fixed rate of about **1% per year, indefinitely**. Risk factors for progression are non-IgG isotype, M protein ≥1.5 g/dL and an abnormal free light chain ratio. **Management is observation only — no treatment**, with 6-monthly then annual monitoring.
3. **Smouldering (asymptomatic) myeloma. M protein ≥3 g/dL or urinary M protein ≥500 mg/24 h, and/or clonal marrow plasma cells 10–60%, but no myeloma-defining events.** Risk of progression is much higher — about **10% per year for the first 5 years**. Standard care is observation, but **high-risk smouldering myeloma (the "20-2-20" criteria: M protein >2 g/dL, marrow plasma cells >20%, free light chain ratio >20) is now often treated with lenalidomide**.
4. **Multiple myeloma. Clonal marrow plasma cells ≥10% or a biopsy-proven plasmacytoma, plus either end-organ damage (CRAB) or a myeloma-defining biomarker (SLiM).** Presents with bone pain, pathological fracture, anaemia, renal failure, hypercalcaemia and recurrent infection. Median survival is now 7–10 years with modern therapy.
5. **Solitary plasmacytoma and plasma cell leukaemia. Solitary plasmacytoma** — a single bone or extramedullary lesion with a normal marrow, no CRAB and a negative skeletal survey/MRI; treated with **radical radiotherapy (40–50 Gy)**, though most bone plasmacytomas progress to myeloma within 3 years. **Plasma cell leukaemia** — ≥5% circulating plasma cells (revised from 20%); aggressive, requiring intensive combination therapy.
6. **AL (primary) amyloidosis.** Deposition of **misfolded monoclonal free light chains (usually lambda)** as amyloid fibrils. Presents with **nephrotic syndrome, restrictive cardiomyopathy with heart failure and raised NT-proBNP, hepatomegaly, peripheral and autonomic neuropathy, macroglossia and periorbital purpura (the two pathognomonic signs)**. Diagnosis requires **Congo red staining with apple-green birefringence** on abdominal fat pad, rectal or organ biopsy, plus mass spectrometry typing and demonstration of a clone. Prognosis is driven by cardiac stage (NT-proBNP and troponin).
7. **Waldenström macroglobulinaemia.** A **lymphoplasmacytic lymphoma secreting IgM**, with **MYD88 L265P mutation in over 90%**. Presents with **hyperviscosity (headache, blurred vision, retinal vein engorgement, confusion, bleeding)**, lymphadenopathy, hepatosplenomegaly, anaemia, **peripheral neuropathy (anti-MAG)**, cryoglobulinaemia and cold agglutinin disease. **Bone lesions and hypercalcaemia are characteristically absent** — a key contrast with myeloma. Treated with **plasmapheresis for symptomatic hyperviscosity**, then rituximab-based therapy or a **BTK inhibitor (ibrutinib, zanubrutinib)**.
8. **POEMS syndrome and MGRS. POEMS** — **P**olyneuropathy, **O**rganomegaly, **E**ndocrinopathy, **M**onoclonal protein (almost always lambda) and **S**kin changes, with **sclerotic bone lesions, raised VEGF, Castleman disease and papilloedema**; treated with radiotherapy to an isolated lesion or systemic therapy with autologous transplant. **MGRS** — a small clone not meeting myeloma criteria that nevertheless causes renal damage (amyloidosis, light chain deposition disease, cryoglobulinaemic glomerulonephritis); **it must be treated despite the low tumour burden, because the criterion is organ damage, not clone size**.

9. **Diagnostic workup common to all.** **Serum protein electrophoresis with immunofixation, serum free light chain assay with kappa:lambda ratio, 24-hour urine electrophoresis for Bence-Jones protein, quantitative immunoglobulins**; complete blood count, calcium, creatinine, albumin, LDH and β_2-microglobulin; **bone marrow aspirate and trephine with flow cytometry, FISH for cytogenetics**; and **whole-body low-dose CT, whole-body MRI or PET-CT — skeletal survey is now obsolete**. Add echocardiography and NT-proBNP if amyloidosis is suspected.
10. **Principles of treatment.** **MGUS and standard-risk smouldering myeloma are observed; symptomatic disease is treated.** Modern therapy combines a **proteasome inhibitor (bortezomib) + immunomodulatory drug (lenalidomide) + anti-CD38 monoclonal antibody (daratumumab) + dexamethasone**, with **autologous stem cell transplant in fit patients up to about 70–75 years** and lenalidomide maintenance. Supportive care is equally examinable: **bisphosphonates or denosumab, radiotherapy for bone pain and cord compression, hydration and avoidance of nephrotoxins, VTE prophylaxis with immunomodulatory drugs, antiviral prophylaxis with bortezomib and daratumumab, vaccination and immunoglobulin replacement**. In older patients, **dose-adapt using frailty scores (IMWG frailty index, R-MCI) rather than chronological age**.

Latest Updates (2023–2026) — 2 points

11. **MRD negativity as a regulatory endpoint.** In April 2024 the FDA's advisory committee accepted **minimal residual disease negativity (10^{-5} by next-generation sequencing or flow cytometry) as a surrogate endpoint for accelerated approval in myeloma** — the first haematological malignancy for which this applies. Risk stratification has correspondingly moved to the **R2-ISS**, which combines ISS stage with LDH, del(17p), t(4;14) and 1q gain.
12. **Immunotherapy has transformed relapsed disease. BCMA-directed CAR T-cell therapy (idecabtagene vicleucel, ciltacabtagene autoleucel)** and **bispecific T-cell engagers (teclistamab targeting BCMA, talquetamab targeting GPRC5D, elranatamab)** now produce deep responses in heavily pre-treated myeloma, and bispecifics are **"off-the-shelf" and therefore more feasible in older and frailer patients** than CAR-T; the principal toxicities are **cytokine release syndrome, neurotoxicity (ICANS) and profound infection risk requiring immunoglobulin replacement**.

Cross-reference: Multiple myeloma is expanded separately in Question 33; this answer covers the whole spectrum of monoclonal gammopathies.

Question 33. Multiple myeloma — aetiology, diagnosis and management 15 MARKS

Answer — Textbook Core (10 points)

1. **Definition and epidemiology.** A malignant clonal proliferation of **bone marrow plasma cells** producing a monoclonal immunoglobulin, with resultant lytic bone disease, marrow failure and renal impairment. It accounts for about **10% of haematological malignancies**; **median age at diagnosis is 70 years**, and **over a third of patients are above 75**.
2. **Aetiology and risk factors.** **All myeloma is preceded by MGUS**, which progresses at 1% per year. Risk factors: **increasing age, male sex, African ancestry, family history, obesity**, and occupational exposure to **ionising radiation, benzene, pesticides and organic solvents**. Pathogenesis involves **primary IgH translocations — t(11;14), t(4;14), t(14;16)** — or hyperdiploidy, with secondary events (**del(17p)/TP53, 1q gain, MYC rearrangement, RAS mutations**) driving progression, all supported by the bone marrow microenvironment (IL-6, RANKL, VEGF).
3. **Clinical features — the CRAB criteria.** **C** — hyper**C**alcaemia (corrected calcium >11 mg/dL or >1 mg/dL above normal); **R** — **R**enal impairment (creatinine >2 mg/dL or eGFR <40 mL/min); **A** — **A**naemia (Hb <10 g/dL or 2 g/dL below normal); **B** — **B**one lesions (one or more lytic lesions on CT, MRI or PET-CT).
4. **Other presentations.** **Bone pain, especially back pain, and pathological fracture**; **recurrent bacterial infection from immune paresis (the commonest cause of death)**; **spinal cord compression**; hyperviscosity; **amyloidosis**; peripheral neuropathy; and bleeding. **In older patients, myeloma frequently presents as unexplained anaemia, fatigue, back pain attributed to osteoporosis, or acute kidney injury.**
5. **Myeloma-defining biomarkers (SLiM criteria, IMWG 2014).** These allow treatment **before end-organ damage occurs**: **S** — clonal marrow plasma cells **≥60%**; **Li** — involved:uninvolved serum free **Li**ght chain ratio **≥100** (with involved chain ≥100 mg/L); **M** — more than one focal lesion ≥5 mm on **M**RI. **Diagnosis requires ≥10% clonal plasma cells or a plasmacytoma PLUS one CRAB or SLiM feature.**
6. **Investigations.** **Serum protein electrophoresis with immunofixation and serum free light chains** (essential — **light-chain-only and non-secretory myeloma have no serum M spike**); 24-hour urine for Bence-Jones

protein; complete blood count with film showing **rouleaux and a markedly raised ESR**; calcium, creatinine, albumin, LDH, β_2-microglobulin; **bone marrow aspirate and trephine with FISH cytogenetics**; and **whole-body low-dose CT, whole-body MRI or FDG PET-CT — the plain skeletal survey is obsolete because it misses lesions until 30–50% of bone is lost**.

7. **Staging and prognosis.** **Revised International Staging System (R-ISS)** combines **β_2-microglobulin and albumin (the original ISS) with LDH and high-risk cytogenetics [del(17p), t(4;14), t(14;16)]**: **Stage I** — β_2M <3.5 mg/L and albumin ≥3.5 g/dL with normal LDH and standard-risk cytogenetics; **Stage III** — β_2M ≥5.5 mg/L with high LDH or high-risk cytogenetics. The older **Durie-Salmon** system used tumour burden.
8. **Management of newly diagnosed myeloma.** **Transplant-eligible (usually under 70–75 and fit):** induction with a triplet or quadruplet — **bortezomib + lenalidomide + dexamethasone (VRd)**, increasingly with daratumumab — followed by **high-dose melphalan with autologous stem cell transplant** and **lenalidomide maintenance**. **Transplant-ineligible: daratumumab + lenalidomide + dexamethasone (D-Rd, the MAIA regimen)** or VRd-lite, continued until progression, with dose reduction for frailty. **Avoid melphalan before stem cell harvest** in potential transplant candidates.
9. **Supportive care (heavily examined).** **Bone** — zoledronic acid or pamidronate monthly for at least 2 years (denosumab if renal impairment; dental review first because of osteonecrosis of the jaw); radiotherapy for pain and impending fracture; vertebroplasty/kyphoplasty. **Renal** — aggressive hydration, avoid NSAIDs, contrast and nephrotoxins, treat hypercalcaemia, use bortezomib-based therapy (no dose reduction needed in renal failure). **Infection** — vaccination, prompt antibiotics, **aciclovir prophylaxis with bortezomib and daratumumab**, immunoglobulin replacement for recurrent infection. **Thrombosis** — aspirin or LMWH prophylaxis with immunomodulatory drugs. Plus analgesia, anaemia management and **early palliative input**.
10. **Relapsed disease and the geriatric approach.** Relapse is inevitable; options include **carfilzomib, pomalidomide, isatuximab, elotuzumab, selinexor, bendamustine** and re-treatment. In older patients, **use the IMWG frailty index or R-MCI (age, comorbidity, ADL/IADL) to classify fit, intermediate-fit and frail**, and **apply dose-adjusted regimens rather than withholding treatment** — under-treatment of the fit elderly is as harmful as over-treatment of the frail. Steroid dose reduction (dexamethasone 20 mg weekly instead of 40 mg) markedly reduces toxicity without losing efficacy.

Latest Updates (2023–2026) — 2 points

11. **CEPHEUS trial** (*Nature Medicine* 2025; FDA approval 2026) — in **transplant-ineligible or transplant-deferred newly diagnosed myeloma**, adding daratumumab to VRd (**D-VRd quadruplet**) nearly doubled sustained MRD negativity (**60.9% vs 39.5%**) and significantly improved progression-free survival, with benefit maintained irrespective of frailty status. Together with **PERSEUS** (*NEJM* 2024) in transplant-eligible patients and the **MAIA** benchmark of 7.5 years median overall survival with D-Rd, **a daratumumab-containing quadruplet or triplet is now the standard of care for older patients**.
12. **T-cell redirecting therapy in relapsed disease. BCMA CAR T-cells (ide-cel, cilta-cel)** and the **bispecific antibodies teclistamab, elranatamab (anti-BCMA) and talquetamab (anti-GPRC5D)** achieve response rates of 60–80% in triple-class-refractory myeloma. Bispecifics are **off-the-shelf and given subcutaneously, making them more practical for older patients** than CAR-T; the trade-offs are **cytokine release syndrome, ICANS and a high rate of serious infection requiring routine immunoglobulin replacement and antimicrobial prophylaxis**.

Current Practice Update

Textbook: Melphalan-prednisolone or a bortezomib-based triplet for transplant-ineligible myeloma; skeletal survey for bone disease; treat only when CRAB features appear.
Current recommendation: Daratumumab-based triplet or quadruplet (D-Rd / D-VRd) is standard for the transplant-ineligible; whole-body low-dose CT, MRI or PET-CT replaces skeletal survey; SLiM biomarkers permit treatment before organ damage.
Exam approach: Three separate marks are available here — state the quadruplet, say "skeletal survey is obsolete", and quote the SLiM criteria.

Cross-reference: The wider spectrum of plasma cell dyscrasias, including AL amyloidosis, Waldenström macroglobulinaemia, POEMS and MGRS, is covered in Question 32.

Question 34. Bone marrow transplantation in older patients 7 MARKS

Answer — Textbook Core (6 points)

1. **Types.** **Autologous** transplantation uses the patient's own stem cells after high-dose chemotherapy (myeloma,

relapsed lymphoma) — **no graft-versus-host disease and lower transplant-related mortality**. **Allogeneic** transplantation uses donor cells (AML, MDS, myelofibrosis) and provides a **graft-versus-tumour effect** at the cost of GVHD.

2. **Age is no longer a barrier.** Allogeneic transplantation is now routinely performed up to **70–75 years** using **reduced-intensity conditioning (RIC)** or non-myeloablative regimens (fludarabine-melphalan, fludarabine-busulfan), which rely on the immunological graft-versus-tumour effect rather than dose intensity.
3. **Selection is by physiological, not chronological, age.** The **HCT-CI (Hematopoietic Cell Transplantation Comorbidity Index)** together with performance status, **comprehensive geriatric assessment**, frailty, nutrition, cognition and caregiver support predicts non-relapse mortality far better than age alone.
4. **Indications in older adults.** **AML in first remission with intermediate or adverse risk**, MDS with excess blasts, **myelofibrosis with DIPSS intermediate-2 or high risk**, and **autologous transplantation for multiple myeloma** (feasible to around 75 years in fit patients).
5. **Early complications.** Mucositis, prolonged pancytopenia, **neutropenic sepsis**, invasive fungal infection, **CMV reactivation**, haemorrhagic cystitis, **sinusoidal obstruction syndrome (veno-occlusive disease)**, engraftment syndrome, and **acute GVHD affecting skin, gut and liver within 100 days**.
6. **Late complications.** **Chronic GVHD**, prolonged immunodeficiency with encapsulated organism and zoster infection (requiring **revaccination from 6–12 months plus PCP and antiviral prophylaxis**), secondary malignancy, endocrine failure, cataract, osteoporosis, and **cognitive and functional decline** — older survivors need structured survivorship care.

Latest Update (2023–2026) — 1 point

7. **BMT CTN 1703 trial** (*NEJM* 2023) — **post-transplant cyclophosphamide with tacrolimus and mycophenolate mofetil is now standard GVHD prophylaxis for reduced-intensity allogeneic transplantation**, significantly improving GVHD-free, relapse-free survival. It has also **widened donor availability to haploidentical and mismatched unrelated donors**, making transplantation accessible to substantially more older patients.

PART VI — ONCOLOGY

Question 35. Prostatic cancer 7 MARKS

Answer — Textbook Core (6 points)

1. **Epidemiology and risk factors.** The commonest non-cutaneous cancer in men; incidence rises steeply with age, with **median age at diagnosis around 66–70 years** and **latent histological cancer present in over 70% of men above 80 at autopsy**. Risk factors: **age, African ancestry, family history, BRCA2 and Lynch syndrome**, obesity and a high-fat diet. Over 95% are **adenocarcinomas arising in the peripheral zone**.
2. **Clinical features.** **Early disease is asymptomatic** and detected by PSA testing or a hard, nodular, irregular prostate with loss of the median sulcus on digital rectal examination. Later: lower urinary tract symptoms, haematuria, haematospermia, retention. **Advanced disease characteristically presents with osteoblastic (sclerotic) bone metastases causing back pain, pathological fracture or spinal cord compression**, and with anaemia, weight loss or renal failure from ureteric obstruction — **in older men, bone pain is often the first presentation**.
3. **Diagnosis.** **PSA** (raised also in BPH, prostatitis, catheterisation, retention and after DRE; use age-specific ranges, free:total ratio, PSA density and velocity to improve specificity). **Multiparametric MRI before biopsy (PI-RADS scoring)** is now standard, followed by **MRI-targeted transperineal or transrectal biopsy**. Histology is graded by the **Gleason score, reported as ISUP Grade Groups 1–5 (Gleason 6 = GG1 up to Gleason 9–10 = GG5)**. Staging by **TNM with bone scan and CT, or PSMA PET-CT**.
4. **Risk stratification.** **Low risk** — PSA <10, Gleason ≤6 (GG1), ≤T2a. **Intermediate risk** — PSA 10–20, Gleason 7 (GG2–3), T2b–c. **High risk** — PSA >20, Gleason 8–10 (GG4–5), ≥T3. This determines whether surveillance, radical treatment or systemic therapy is appropriate.
5. **Management of localised disease.** **Active surveillance** for low-risk disease (PSA, DRE, MRI and repeat biopsy) — the preferred option in most older men. **Watchful waiting with deferred palliative hormonal treatment** is appropriate when life expectancy is under 10 years. **Radical prostatectomy or radical radiotherapy (external beam or brachytherapy) with neoadjuvant/adjuvant androgen deprivation for high-risk disease** is offered when life expectancy exceeds 10 years. **Radical treatment is justified by life expectancy and health status, not by chronological age**; complications are incontinence and erectile dysfunction (surgery) and radiation proctitis and cystitis.
6. **Management of advanced disease.** **Androgen deprivation therapy** is the backbone — **LHRH agonists (goserelin, leuprolide, with anti-androgen cover for 2 weeks to prevent tumour flare)**, the LHRH antagonist degarelix, or bilateral orchidectomy. **Adverse effects of ADT are heavily examinable in geriatrics: hot flushes, loss of libido and erectile dysfunction, sarcopenia and fatigue, weight gain, osteoporosis and fracture (give calcium, vitamin D and a bisphosphonate or denosumab with DEXA monitoring), metabolic syndrome, diabetes, cardiovascular events, anaemia, gynaecomastia, and cognitive change.** For **metastatic hormone-sensitive disease, ADT is intensified with an androgen receptor pathway inhibitor (abiraterone, enzalutamide, apalutamide, darolutamide) ± docetaxel**. In **castration-resistant disease**: abiraterone, enzalutamide, docetaxel, cabazitaxel, **radium-223 for bone-predominant disease**, olaparib for BRCA mutations, and **Lu-177 PSMA radioligand therapy**. Palliative radiotherapy for bone pain and cord compression, plus a bone-protecting agent.

Latest Update (2023–2026) — 1 point

7. **PSMA PET-CT and geriatric assessment are now embedded in guidelines.** The **EAU 2025 and AUA/ASTRO 2026 guidelines** recommend **PSMA PET-CT for staging high-risk disease and for biochemical recurrence when PSA >0.2 ng/mL**, since the **proPSMA trial** showed sensitivity for nodal disease of 91% versus 59% for conventional imaging, and it frequently changes management. Equally important for the geriatric answer, the EAU gives a **strong recommendation to use the Geriatric 8 (G8), mini-Cog and Clinical Frailty Scale to assess health status**, and states explicitly that **life expectancy and comorbidity, not age, should drive treatment decisions** — with more than 10 years of life expectancy considered mandatory before any radical local treatment.

Cross-reference: Positron emission tomography, including PSMA PET, is covered in Question 41.

Question 36. Vertebral secondaries with unknown primary — evaluation and treatment

7 MARKS

Answer — Textbook Core (6 points)

1. **Clinical recognition.** Suspect metastatic disease in any older patient with **back pain that is progressive, unremitting, worse at night or at rest, associated with weight loss or a known cancer, or accompanied by neurological signs**. **Red flags: age >50 with new back pain, thoracic pain, band-like radiation, bowel or bladder dysfunction, saddle anaesthesia and progressive weakness — these indicate possible metastatic spinal cord compression, an oncological emergency.**
2. **The likely primaries.** The mnemonic for bone metastasis is **"BLT with a Kosher Pickle" — Breast, Lung, Thyroid, Kidney and Prostate**, which together account for about 80%. **Osteolytic** lesions come typically from lung, kidney, thyroid and myeloma; **osteoblastic (sclerotic)** from prostate and, in women, breast; **mixed** from breast and gastrointestinal tumours. Spread is largely via the **valveless Batson venous plexus**, which explains vertebral predilection.
3. **Essential differential diagnosis.** **Multiple myeloma** (must always be excluded — it is not a "metastasis" and requires different treatment), **osteoporotic vertebral fracture**, **tuberculous spondylitis (Pott's disease — extremely important in India, typically involving the disc space with a paravertebral abscess, whereas malignancy characteristically spares the disc)**, pyogenic osteomyelitis, Paget's disease and lymphoma.
4. **Evaluation — step 1 (confirm and localise).** **MRI of the whole spine is the investigation of choice** (detects cord compression, multiple levels and soft tissue extension; malignancy typically involves the vertebral body and pedicle while sparing the disc). Then **CT chest, abdomen and pelvis**. Baseline tests: complete blood count, ESR, calcium, ALP, renal and liver function, LDH, urinalysis. **Serum protein electrophoresis with free light chains and urine Bence-Jones protein in every case.**
5. **Evaluation — step 2 (find the primary).** Careful **examination of breasts, thyroid, testes, skin, lymph nodes and a digital rectal examination**. Targeted tumour markers — **PSA in men**, and CA-125, CA 19-9, CEA and AFP as guided (of limited specificity). **Mammography in women**; **FDG PET-CT** to identify an occult primary and assess disease extent. **Biopsy of the most accessible lesion is mandatory** — with **immunohistochemistry (CK7/CK20 pattern, TTF-1 for lung and thyroid, PSA/NKX3.1 for prostate, ER/PR/GATA3 for breast, thyroglobulin, PAX8 for renal and ovarian)**. Despite full workup, **the primary remains unidentified in 20–30%**.
6. **Treatment.** **If cord compression is present, this is an emergency: give dexamethasone 8–16 mg immediately, then urgent MRI and neurosurgical or radiotherapy referral within 24 hours** — surgical decompression with stabilisation followed by radiotherapy gives better ambulatory outcomes than radiotherapy alone in fit patients with a single level and a prognosis over 3 months. Otherwise: **palliative external beam radiotherapy (a single 8 Gy fraction is as effective as multi-fraction regimens for uncomplicated bone pain)**; **bone-modifying agents — zoledronic acid or denosumab** to reduce skeletal-related events; **analgesia by the WHO ladder**; treatment of hypercalcaemia; vertebroplasty or kyphoplasty for mechanical pain; and **treat according to the identified primary**. Where no primary is found, treat by **histological subtype and immunohistochemical/molecular profile**, with early involvement of palliative care and honest prognostic discussion (median survival in carcinoma of unknown primary with bone metastases is only a few months).

Latest Update (2023–2026) — 1 point

7. **Molecularly guided therapy for carcinoma of unknown primary — the CUPISCO trial** (*Lancet* 2024). In patients with unfavourable-risk CUP who did not progress after platinum induction chemotherapy, **comprehensive genomic profiling followed by molecularly guided targeted therapy or immunotherapy significantly improved progression-free survival compared with continuing standard chemotherapy**. This, together with the **ESMO 2023 CUP guideline**, has changed practice: **next-generation sequencing and PD-L1/MSI testing should now be performed in every patient with unknown primary who is fit for treatment**, and **site-of-origin gene expression profiling** can further direct therapy.

Question 37. Paraneoplastic syndromes 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition.** Remote, **non-metastatic** effects of malignancy mediated by tumour-secreted hormones, cytokines or **cross-reacting onconeural antibodies** — not by tumour mass, local invasion or metastasis. They are important because they are frequently the **first presentation of an occult cancer in an older adult**.
2. **Endocrine syndromes.** **SIADH with hyponatraemia (small cell lung cancer)**; **ectopic ACTH** (SCLC, carcinoid)

causing hypokalaemic alkalosis, hyperglycaemia and proximal myopathy rather than classic Cushingoid habitus; **humoral hypercalcaemia of malignancy from PTHrP** (squamous cell lung, renal and breast cancer); and hypoglycaemia from IGF-2 (hepatoma, sarcoma).

3. **Neurological syndromes.** **Lambert-Eaton myasthenic syndrome** (SCLC) — proximal weakness that **improves with exercise**, autonomic features and absent reflexes, with **anti-VGCC antibodies**; **paraneoplastic cerebellar degeneration** (anti-Yo in ovarian and breast cancer, anti-Hu in SCLC); **limbic encephalitis** (anti-Hu, anti-Ma2); sensory neuronopathy; and opsoclonus-myoclonus.
4. **Haematological and vascular syndromes.** Anaemia of chronic disease, **erythrocytosis from ectopic erythropoietin** (renal cell carcinoma, hepatoma, cerebellar haemangioblastoma), thrombocytosis, leukaemoid reaction, eosinophilia, **migratory thrombophlebitis — Trousseau's sign, classically pancreatic carcinoma**, non-bacterial thrombotic endocarditis and DIC.
5. **Dermatological and rheumatological syndromes.** **Acanthosis nigricans (gastric adenocarcinoma)**, **dermatomyositis** with heliotrope rash and Gottron's papules, **Leser-Trélat sign** (sudden eruptive seborrhoeic keratoses), acquired ichthyosis, **hypertrophic pulmonary osteoarthropathy with clubbing** (lung cancer), paraneoplastic pemphigus and palmar fasciitis.
6. **Approach and management.** Recognise the syndrome, then **search for the underlying tumour** (CT chest-abdomen-pelvis, mammography, PET-CT, antibody-directed screening). **Treating the tumour is the definitive treatment.** Symptomatic measures: fluid restriction or tolvaptan for SIADH; **hydration plus zoledronate for hypercalcaemia**; and immunotherapy (corticosteroids, IVIG, plasma exchange, rituximab) for antibody-mediated neurological syndromes — though response is often poor once neuronal loss has occurred, so **early recognition is critical**.

Latest Update (2023–2026) — 1 point

7. **PNS-Care diagnostic framework** (Graus et al., updated criteria now in general use) classifies paraneoplastic neurological syndromes as **definite, probable or possible** using the clinical phenotype, the antibody type (**high-risk antibodies such as anti-Hu, anti-Yo and anti-Ma2 versus intermediate-risk antibodies**) and the presence of tumour. A parallel development is the growing recognition of **immune checkpoint inhibitor-triggered paraneoplastic neurological syndromes**, increasingly seen as immunotherapy use expands in older patients with cancer.

Question 38. Tumour lysis syndrome 7 MARKS

Answer — Textbook Core (6 points)

1. **Definition and mechanism.** An **oncological emergency caused by massive lysis of tumour cells, spontaneously or after cytotoxic therapy**, releasing intracellular contents into the circulation faster than the kidney can clear them. This produces **hyperuricaemia, hyperkalaemia, hyperphosphataemia and secondary hypocalcaemia**, with **acute kidney injury** from uric acid and calcium phosphate crystal deposition.
2. **Risk factors.** **High tumour burden and rapid proliferation** — Burkitt lymphoma, acute lymphoblastic leukaemia, high-grade non-Hodgkin lymphoma, AML with high white cell count, and CLL treated with venetoclax; **high sensitivity to therapy**; bulky disease with raised LDH; and **patient factors — pre-existing chronic kidney disease, dehydration, oliguria, hyperuricaemia and nephrotoxic drugs**. **Older patients are at higher risk because of reduced GFR and lower physiological reserve.** Solid tumours rarely cause it.
3. **Cairo-Bishop definitions.** **Laboratory TLS** — two or more of the following within 3 days before to 7 days after chemotherapy: **uric acid ≥8 mg/dL, potassium ≥6 mmol/L, phosphate ≥4.5 mg/dL, or calcium ≤7 mg/dL** (or a 25% change from baseline). **Clinical TLS** — laboratory TLS plus **acute kidney injury (creatinine ≥1.5× upper limit of normal), cardiac arrhythmia or sudden death, or seizure**.
4. **Clinical features.** Nausea, vomiting, lethargy, oliguria and fluid overload; **hyperkalaemia causing muscle weakness, paraesthesiae, peaked T waves, widened QRS and cardiac arrest**; **hypocalcaemia causing tetany, carpopedal spasm, Chvostek and Trousseau signs, prolonged QT and seizures**; and acute kidney injury. Symptoms typically appear **12–72 hours after starting treatment**.
5. **Prevention (the most important element).** **Risk-stratify every patient before chemotherapy.** Give **aggressive intravenous hydration with 2–3 litres/m²/day of normal saline to maintain a urine output of 80–100 mL/m²/hour** — started 24–48 hours before treatment and continued for 48–72 hours afterwards, **with careful monitoring for fluid overload in older patients with heart failure**. **Allopurinol 300 mg daily (a xanthine oxidase inhibitor, renally dose-adjusted) for low and intermediate risk**; **rasburicase (recombinant urate oxidase, which converts uric acid to allantoin) for high risk or established TLS** — it acts within hours, unlike

allopurinol which only prevents new urate formation. **Rasburicase is contraindicated in G6PD deficiency (haemolysis and methaemoglobinaemia) — screen first, which is particularly relevant in India. Urinary alkalinisation is no longer recommended** because it promotes calcium phosphate precipitation. Stop nephrotoxins and monitor biochemistry 6–12 hourly.

6. **Treatment of established TLS.** Continue vigorous hydration and rasburicase; treat **hyperkalaemia** with calcium gluconate for cardioprotection, insulin-dextrose, salbutamol nebulisation and potassium binders; treat **hyperphosphataemia** with oral phosphate binders; and **treat hypocalcaemia only if symptomatic**, because giving calcium in the presence of a high phosphate promotes further calcium phosphate deposition. **Refer early for renal replacement therapy** — indications are refractory hyperkalaemia, severe hyperphosphataemia, volume overload, uraemia or persistent oliguria; the threshold for dialysis should be lower in the elderly. Manage jointly with nephrology and critical care.

Latest Update (2023–2026) — 1 point

7. **TLS in the era of targeted therapy and evidence for lower rasburicase dosing.** TLS is now an important toxicity of **venetoclax in CLL and AML**, which is why venetoclax must be given by a **graded weekly dose ramp-up (20 → 50 → 100 → 200 → 400 mg) with risk-adapted hydration, uric acid-lowering therapy and inpatient monitoring for high tumour burden**; it also occurs with **CAR T-cell therapy and bispecific antibodies**. In parallel, multiple studies support **a single fixed low dose of rasburicase (3–6 mg) rather than daily weight-based dosing for 5 days**, achieving equivalent urate control at a fraction of the cost — an important consideration in Indian practice.

PART VII — CANCER SCREENING AND IMAGING

Question 39. Indications and rationale for cancer screening in the elderly 7 MARKS

Answer — Textbook Core (6 points)

1. **Principles of screening (Wilson and Jungner).** Screening is justified when the **condition is an important health problem with a recognisable latent or early symptomatic stage**, the **natural history is understood**, there is an **acceptable, safe, sensitive and specific test**, an **accepted and effective treatment exists**, facilities for diagnosis and treatment are available, and the process is **continuous and cost-effective**.
2. **The rationale for screening older adults.** **Cancer is fundamentally a disease of ageing** — incidence and mortality both peak in old age, and over 60% of cancers occur in those above 65 — so the **absolute benefit of detecting a screen-detectable cancer is greatest in this group**. Older people have historically been **under-screened and under-treated**, presenting at later stage with poorer outcomes.
3. **The counter-argument — why screening can harm the old.** There is a **lag time to benefit of approximately 10 years for mammography and colonoscopy and about 5 years for FIT**: harms (bleeding, perforation, anxiety, false positives) are immediate while benefits are delayed. Additional harms are **overdiagnosis of indolent tumours that would never have caused symptoms** (especially prostate and breast), **lead-time and length-time bias** creating an illusion of benefit, and the burden of investigating false positives in frail patients.
4. **The decisive rule — life expectancy, not chronological age.** **Screening should be offered when estimated life expectancy exceeds the lag time to benefit — in practice, more than 10 years.** Estimate life expectancy from comorbidity, function and validated tools (**ePrognosis, Lee index, Charlson comorbidity index**), not from the birth date. A fit 80-year-old woman may have 10 years of life expectancy and benefit; a frail 68-year-old with heart failure and dementia will not.
5. **Practical age limits in current guidance.** **Breast — biennial mammography to age 74** (individualised beyond). **Colorectal — screen 45–75; individualise 76–85 based on health and prior screening; do not screen after 85. Cervical — stop at 65 if there has been adequate prior negative screening** (but continue if never screened, which is common among older Indian women). **Prostate — shared decision-making between 55 and 69; do not screen routinely above 70. Lung — annual low-dose CT for ages 50–80 with a ≥20 pack-year history who currently smoke or quit within 15 years.**
6. **How to decide and communicate.** Use **shared decision-making** — present absolute benefit and harm in natural frequencies, elicit the patient's values and goals of care, and consider **whether the patient would accept the investigation and treatment that a positive result would demand**. If they would decline colonoscopy or surgery, the screening test should not be done. **Deprescribing screening ("stopping screening") should be framed positively as a shift towards care that helps now**, rather than as withdrawal of care, and documented. In the Indian context, screening should also be balanced against limited resources and the very low baseline coverage — opportunistic screening at the point of care is often more realistic than organised programmes.

> **Latest Update (2023–2026) — 1 point**
>
> 7. **USPSTF 2024 breast cancer screening statement** (*JAMA* 2024;331:1918) — now recommends **biennial mammography for all women aged 40 to 74 (Grade B)**, lowering the starting age from 50, while **concluding that evidence remains insufficient for screening women aged 75 and older (Grade I)**. This crystallises the geriatric teaching point: the upper limit of screening is not defined by a trial but by **individual life expectancy and shared decision-making**, which is why the answer must always pivot to functional status rather than age.

Cross-reference: The individual screening programmes, tests and their sensitivity and specificity are tabulated in Question 40.

Question 40. Screening for breast, colorectal and cervical cancer — population, tests, performance and guidelines 7 MARKS

Answer — Textbook Core (6 points)

1. **Breast cancer — target population and guidelines.** **Women aged 40–74 (USPSTF 2024), biennial mammography**; the American Cancer Society advises annual screening from 45 and biennial from 55, continuing while life expectancy exceeds 10 years. High-risk women (BRCA carriers, chest irradiation) start earlier with **annual MRI plus mammography**. In India, the **ICMR and national programme (NPCDCS) recommend clinical breast examination every 3 years from age 30** because population mammography is not feasible — a crucial contextual

point.

2. **Breast cancer — tests and performance.** **Mammography: sensitivity approximately 75–85% (falling to 60–70% in dense breasts, but rising with age as breasts become fattier), specificity 90–95%. Digital breast tomosynthesis** improves cancer detection and reduces recall. **Clinical breast examination: sensitivity about 50–60%. Ultrasound** is adjunctive for dense breasts; **MRI has the highest sensitivity (over 90%) but lower specificity** and is reserved for high risk.
3. **Colorectal cancer — target population and guidelines.** **Average-risk adults aged 45–75 (USPSTF 2021)**; **individualise between 76 and 85 years** according to health status and prior screening, and **do not screen beyond 85**. Earlier and more intensive surveillance for a family history, Lynch syndrome, FAP or inflammatory bowel disease.
4. **Colorectal cancer — tests and performance.** **FIT (faecal immunochemical test) annually — sensitivity about 75–80% for cancer but low (about 25%) for advanced adenoma, specificity about 95%**; it is the most practical test for population screening in India. **Multitarget stool DNA-FIT every 3 years — sensitivity about 92% for cancer, specificity about 87%. Colonoscopy every 10 years — the gold standard, sensitivity over 95%, but carries risks of perforation and bleeding that rise with age and sedation risk. CT colonography every 5 years**; flexible sigmoidoscopy every 5 years. **Any positive non-colonoscopic test must be followed by colonoscopy.**
5. **Cervical cancer — target population and guidelines.** **Women aged 21–65.** Cytology alone every 3 years from 21–29; from 30–65, **primary HPV testing every 5 years (preferred), co-testing every 5 years, or cytology every 3 years. Stop at 65 if there has been adequate prior negative screening** (three consecutive negative cytology or two negative HPV tests in the preceding 10 years). **Continue screening in older women who have never been screened** — a large group in India, where cervical cancer remains a leading cause of cancer death. WHO recommends **HPV DNA testing as the primary screening method from age 30, twice in a lifetime, in low-resource settings**, alongside HPV vaccination.
6. **Cervical cancer — tests and performance.** **Conventional Pap smear: sensitivity only about 50–60%, specificity over 95%** — its programme effectiveness came from repetition, not single-test accuracy. **Liquid-based cytology has similar sensitivity with fewer unsatisfactory samples. HPV DNA testing: sensitivity about 90–95% with lower specificity (about 85–90%)** — hence a longer screening interval and the need for triage of positives by cytology or genotyping. **Visual inspection with acetic acid (VIA): sensitivity about 60–70%, specificity about 85%** — cheap, single-visit, and the basis of India's national "see-and-treat" programme.

Latest Update (2023–2026) — 1 point

7. **Self-collection for HPV testing and blood-based colorectal screening.** The FDA has approved **self-collected vaginal samples for primary HPV screening (2024)**, which markedly improves uptake among women who avoid pelvic examination — directly relevant to older and rural Indian women and now endorsed by WHO. For colorectal cancer, **blood-based cell-free DNA testing (Shield, approved 2024) detects cancer with about 83% sensitivity but only about 13% sensitivity for advanced adenoma**, so it is positioned as an option only for those who decline all other screening, not as an equivalent alternative to FIT or colonoscopy.

Cross-reference: The principles governing whether an older person should be screened at all are given in Question 39.

Question 41. Positron emission tomography 6 MARKS

Answer — Textbook Core (5 points)

1. **Principle.** PET is a **functional (metabolic) imaging technique** using a positron-emitting radionuclide attached to a biologically active molecule. The emitted positron annihilates with an electron to release **two 511 keV gamma photons at 180° to each other**, which are detected in coincidence and reconstructed into a three-dimensional map of tracer uptake. It is almost always performed as **PET-CT (or PET-MRI), which fuses metabolic information with anatomical localisation**.
2. **The commonest tracer.** **^{18}F-fluorodeoxyglucose (FDG)**, a glucose analogue taken up by GLUT transporters and phosphorylated by hexokinase, after which it becomes **metabolically trapped** in the cell. Uptake therefore reflects glucose utilisation, which is high in malignant tissue (the Warburg effect), in inflammation and infection, and in brain and myocardium. Uptake is quantified by the **standardised uptake value (SUV)**. Patients must **fast for 4–6 hours with blood glucose controlled below about 150–200 mg/dL**, since hyperglycaemia and recent insulin markedly reduce tumour uptake.
3. **Oncological indications (the main use).** **Staging and restaging** of lung cancer, lymphoma, oesophageal, head and neck, colorectal, melanoma and cervical cancer; **characterising a solitary pulmonary nodule**; **assessing**

treatment response, where PET is far superior to CT because a residual mass may be fibrotic rather than viable (the Deauville 5-point score in lymphoma); **detecting recurrence and identifying the primary in carcinoma of unknown origin**; and **radiotherapy planning**.

4. **Non-oncological indications relevant to geriatrics.** **Dementia** — FDG-PET shows characteristic hypometabolism patterns (**temporoparietal and posterior cingulate in Alzheimer's disease; frontal and anterior temporal in frontotemporal dementia; occipital hypometabolism with the "cingulate island sign" in dementia with Lewy bodies**), and **amyloid PET (florbetapir, flutemetamol) and tau PET (flortaucipir)** demonstrate the underlying pathology. **Cardiology** — assessment of **myocardial viability (hibernating myocardium: perfusion-metabolism mismatch)** and of cardiac sarcoidosis. **Infection and inflammation** — **pyrexia of unknown origin, large vessel vasculitis and giant cell arteritis, prosthetic joint and vascular graft infection**. **Epilepsy** — localisation of an interictal hypometabolic focus.
5. **Limitations and pitfalls.** **False positives** from infection, granulomatous disease (**tuberculosis and sarcoidosis — a major limitation in India**), post-operative and post-radiotherapy inflammation, recent chemotherapy, and physiological uptake in brown fat, muscle and bowel. **False negatives** in small lesions (below about 8–10 mm, from partial volume effect), in **indolent tumours with low metabolic activity such as prostate cancer, renal cell carcinoma, hepatocellular carcinoma, mucinous adenocarcinoma, bronchoalveolar carcinoma and low-grade lymphoma**, and in the brain because of high background cortical uptake. Other drawbacks: **high cost and limited availability, radiation exposure of about 7–10 mSv, the need for a nearby cyclotron because of the short 110-minute half-life of ^{18}F, and difficulty with prolonged lying still in frail or demented patients**.

Latest Update (2023–2026) — 1 point

6. **Disease-specific tracers have moved PET from staging tool to treatment selector. PSMA PET-CT** is now recommended in the EAU 2025 and AUA 2026 guidelines for staging high-risk prostate cancer and for biochemical recurrence, and the same ligand labelled with lutetium-177 delivers **Lu-177 PSMA radioligand therapy** — a true "theranostic" pairing, mirrored by **Ga-68 DOTATATE PET with Lu-177 DOTATATE for neuroendocrine tumours**. In dementia, **amyloid PET has become a prerequisite for prescribing anti-amyloid monoclonal antibodies (lecanemab, donanemab) and for monitoring amyloid-related imaging abnormalities (ARIA)**, shifting it from a research tool to a treatment-gating investigation.

APPENDIX — RAPID REVISION GRID

Every examinable number, named trial and guideline from all 41 answers, in one place. This is the page to read on the night before the examination.

Hepatology, upper GI disease and clinical nutrition (Questions 1, 4–6, 9–20)

Topic	Numbers, criteria and cut-offs	Trial / guideline to quote
Jaundice	Clinically visible at bilirubin >2.5–3 mg/dL; R value ≥5 hepatocellular, ≤2 cholestatic; Courvoisier's law; PT/INR = best severity marker	MASLD/MetALD nomenclature (Hepatology 2023)
Drug-induced liver injury	**Hy's Law** — ALT >3×ULN + bilirubin >2×ULN → ~10% mortality; commonest agent co-amoxiclav; RUCAM → RECAM	ACG DILI guideline; LiverTox; ICI hepatitis
Autoimmune hepatitis	Interface hepatitis, rosettes, emperipolesis; ANA/ASMA + raised IgG; prednisolone 0.5–1 mg/kg + azathioprine 1–2 mg/kg; no budesonide in cirrhosis	IAIHG simplified criteria; **CAMARO** (J Hepatol 2024;80:576)
Alcoholic hepatitis	**DF ≥32** or **MELD >20** = severe; AST:ALT >1.5, both <400; prednisolone 40 mg × 28 days; **Lille >0.45** at day 7 = stop steroids	ACG ALD 2024 (AJG 119:30); NIAAA criteria
Hepatitis B	Treat if cirrhosis + any DNA; or DNA >2000 IU/mL + raised ALT; or ≥F2/APRI >0.5; TAF or entecavir preferred in elderly; 6-monthly USG for HCC	**WHO 2024** (March 2024) expanded criteria
Decompensated cirrhosis	HVPG >10 = CSPH; CTP A 5–6, B 7–9, C 10–15; MELD >15 → transplant referral; LSM >15 kPa + platelets <150 = CSPH; SBP albumin 1.5 g/kg d1 + 1 g/kg d3	**Baveno VII** (J Hepatol 2022;76:959); PREDESCI; resmetirom 2024
Hepatic encephalopathy	West Haven I–IV; lactulose to 2–3 soft stools/day; rifaximin 550 mg BD; protein 1.2–1.5 g/kg (**no restriction**); ammonia not for monitoring	AASLD/EASL Practice Guidance 2022
Hepatorenal syndrome	HRS-AKI: creatinine ↑≥0.3 mg/dL in 48 h or ≥50% in 7 days; urine Na <10 mmol/L, FENa <0.2%, proteinuria <500 mg/day; terlipressin + albumin 20–40 g/day	ICA criteria; **ADQI 29/ICA 2024** (J Hepatol 81:163); CONFIRM
Ascites	**SAAG ≥1.1** = portal hypertension; SBP if neutrophils ≥250/mm³; spironolactone:furosemide **100:40** up to 400:160; albumin **8 g per litre** tapped; TIPS if ≥3 LVP/year	Baveno VII; ANSWER (Lancet 2018)
GORD	LA grades A–D; PPI 30–60 min before breakfast × 8 weeks; pH study **off** PPI = gold standard; endoscope all new dyspepsia >60 y	AGA P-CAB Update 2024 (Gastro 167:1228); **ASGE GERD 2025**
Malabsorption	Faecal fat >7 g/day; faecal elastase-1 <200 µg/g = PEI; lipase 40,000–50,000 U per meal; tTG-IgA + total IgA; Marsh grading	ACG Coeliac 2023 (AJG 118:59); AGA PEI Update 2023
Bristol chart / laxatives	1–2 constipation, 3–4 normal (4 ideal), 5 low fibre, 6–7 diarrhoea; PEG first-line; docusate ineffective; avoid liquid paraffin and bulking agents in the frail	AGA/ACG 2023; WGO 2025
Parenteral nutrition	20–30 kcal/kg, protein 1.0–1.5 g/kg, glucose ≤4–5 mg/kg/min; start if gut unusable >7 days; CRBSI = commonest serious complication	ESPEN geriatric practical guideline
Refeeding syndrome	BMI <16, weight loss >15%, no intake >10 days; start **10 kcal/kg/day** (5 if extreme); thiamine 200–300 mg before feeding; phosphate is the hallmark	NICE CG32; **ASPEN consensus 2020**
Inanition	MNA-SF screening; GLIM = 1 phenotypic + 1 aetiologic criterion; protein 1.2–1.5 g/kg/day; "9 Ds"; supplements **between** meals	GLIM; ESPEN geriatrics; **AGS Beers 2023** (avoid megestrol)

Gastroenterology, haematology and oncology (Questions 2–3, 7–8, 22–25, 30–31, 34, 37)

Topic	Numbers, criteria and cut-offs	Trial / guideline to quote
H. pylori	Stop PPI 2 weeks, antibiotics 4 weeks before UBT; confirm cure at 4 weeks; BQT 14 days; clarithromycin resistance 22–32%	ACG 2024 (AJG 119:1730); Maastricht VI
UGI bleeding	GBS 0–1 = outpatient; endoscopy <24 h; PPI 80 mg then 8 mg/h × 72 h; erythromycin 250 mg; Forrest Ia/Ib/IIa treat (rebleed 55/43/22%)	ACG 2021; ESGE 2021; CAG 2025
Transfusion	Hb <7 restrictive; <8 cardiac/orthopaedic surgery; **<10 in acute MI**; TACO = commonest transfusion death	AABB 2023 (JAMA 330:1892); AABB 2025 (Ann Intern Med 178:1469); MINT (NEJM 2023)
Colorectal cancer	≥12 nodes for staging; N1 = 1–3, N2 ≥4; 5-y survival I 90%, II 70–80%, III 50–65%, IV 15%; dMMR 15%	AJCC 8th; DYNAMIC; Cercek NEJM 2025; ATOMIC (ASCO 2025)
Constipation	Rome IV: 2 of 6, <3 BM/week; PEG first-line; docusate ineffective; PAMORAs for OIC; avoid bulking agents in OIC	AGA/ACG 2023; WGO 2025; ASCRS 2024
CLL	≥5 × 10^9/L B cells × 3 months; CD5/CD19/CD23/CD200+; Rai III Hb <11, IV plt <100; doubling time <6 months; Richter's 5%	iwCLL 2018; CLL14; AMPLIFY (NEJM 2025;392:748)
Myelofibrosis / MPN	JAK2 V617F 95% PV; Hct <45% target; pacritinib if platelets <50; DIPSS-Plus; AML transformation 10–20% at 10 y	COMFORT-I/II; MOMENTUM (Lancet 2023); NCCN MPN 2026
Iron deficiency	Ferritin <30 ng/mL (<45–100 if inflamed); TSAT <16%; RDW >15%; Mentzer >13; alternate-day oral iron	BSG IDA guideline; hepcidin dosing studies
B_{12} deficiency	B_{12} <200 pg/mL; indeterminate 200–350 → MMA; MCV often >110; hydroxocobalamin 1000 µg alternate days then 2–3 monthly; stores last 3–5 y	NICE NG239 (2024); BSH cobalamin guideline
Transplantation	RIC feasible to 70–75 y; HCT-CI predicts NRM; acute GVHD <100 days	BMT CTN 1703 (NEJM 2023)
Paraneoplastic	SIADH & ectopic ACTH → SCLC; PTHrP → squamous; anti-Yo → ovary; anti-VGCC → LEMS; acanthosis nigricans → gastric	PNS-Care criteria (Graus)
Malignant bowel obstruction	Octreotide 300–600 µg/24 h; dexamethasone 6–16 mg/24 h, stop at 5 days; hyoscine butylbromide 60–120 mg/24 h; metoclopramide contraindicated in complete obstruction	ASCO Palliative Care Update 2024 (JCO 42:2336); S1316

Anaemia, haematological malignancy, oncology and screening (Questions 21, 24, 26–29, 32–33, 35–36, 38–41)

Topic	Numbers, criteria and cut-offs	Trial / guideline to quote
Anaemia in the elderly	WHO Hb <13 (M), <12 (F); prevalence 10% >65 y, >20% >85 y; **rule of thirds**; reticulocyte count = key branch point	NHANES; WHO Hb thresholds 2024; CHIP
Anaemia of chronic disease	Ferritin normal/high, TIBC **low**, sTfR normal, hepcidin high; use ferritin <100 in inflammation; ESA target Hb 10–11.5	Hepcidin–ferroportin axis; HIF-PHIs (roxadustat, daprodustat)
Thrombocytopenia	<150; bleeding <30; serious risk <10–20; ITP treat if <20–30 or bleeding; **4Ts score** for HIT; marrow exam in most >60 y	ASH ITP guideline; ADVANCE (efgartigimod, Lancet 2023)
DIC	**ISTH score ≥5** = overt DIC; platelets <50 + bleeding → transfuse; FFP 15 mL/kg; cryoprecipitate if fibrinogen <1.5 g/L; heparin only if thrombotic phenotype	ISTH overt DIC score; SIC score
Plasma cell dyscrasias	MGUS: M <3 g/dL, PC <10%, 1%/year progression; smouldering: M ≥3 g/dL or PC 10–60%, 10%/year; "20-2-20" high risk; plasma cell leukaemia ≥5% circulating	IMWG criteria; R2-ISS; FDA MRD endpoint 2024
Multiple myeloma	**CRAB** + **SLiM** (PC ≥60%, FLC ratio ≥100, >1 focal MRI lesion ≥5 mm); R-ISS uses β2M, albumin, LDH, cytogenetics; skeletal survey obsolete	IMWG 2014; **CEPHEUS** (Nat Med 2025); PERSEUS (NEJM 2024); MAIA
Myelodysplasia	Blasts <20% (≥20% = AML); Pelger-Huët, ring sideroblasts; IPSS-R uses cytogenetics, blasts, Hb, platelets, neutrophils; EPO <500 predicts ESA response	WHO 2022; **IPSS-M**; COMMANDS 2024; IMerge/imetelstat 2024
CML	t(9;22) BCR::ABL1; **low LAP score**; blast crisis ≥20% blasts; milestones ≤10% at 3 mo, ≤1% at 6 mo, **≤0.1% (MMR) at 12 mo**; TFR after MR4.5 × 2 y	**ASC4FIRST** (NEJM 2024;391:885); ELN recommendations
Prostate cancer	Gleason → ISUP Grade Group 1–5; low risk PSA <10/GG1/≤T2a; high risk PSA >20/GG4-5/≥T3; radical treatment needs >10 y life expectancy; osteoblastic metastases	EAU 2025 (G8, mini-Cog, CFS); proPSMA; ARASENS/PEACE-1
Vertebral secondaries / CUP	"BLT with a Kosher Pickle"; malignancy spares the disc, TB does not; dexamethasone 8–16 mg + MRI within 24 h; **single 8 Gy** for uncomplicated bone pain; primary unfound in 20–30%	ESMO CUP 2023; **CUPISCO** (Lancet 2024)
Tumour lysis syndrome	Cairo-Bishop: urate ≥8, K ≥6, PO_4 ≥4.5, Ca ≤7 mg/dL; hydration 2–3 L/m²/day; rasburicase contraindicated in **G6PD deficiency**; no alkalinisation	Cairo-Bishop; venetoclax ramp-up; single-dose rasburicase
Cancer screening (general)	Lag time to benefit ~10 y (mammography, colonoscopy), ~5 y (FIT); screen if life expectancy >10 y; CRC 45–75, individualise 76–85, stop >85; cervical stop at 65	**USPSTF 2024 breast 40–74 (Grade B)**; ePrognosis; Lee index
Screening test performance	Mammography Sn 75–85%/Sp 90–95%; FIT Sn ~75–80% for cancer; colonoscopy Sn >95%; Pap Sn 50–60%/Sp >95%; HPV DNA Sn 90–95%; VIA Sn 60–70%	USPSTF; WHO HPV strategy; ICMR/NPCDCS (CBE every 3 y from 30)
PET	Two 511 keV photons at 180°; fast 4–6 h, glucose <150–200 mg/dL; ^{18}F half-life 110 min; ~7–10 mSv; false positive in TB and sarcoid; false negative <8–10 mm and in prostate, RCC, HCC, mucinous tumours	Deauville score; PSMA/DOTATATE theranostics; amyloid PET for lecanemab

Curriculum domains still outstanding across the answer bank: rheumatology; endocrinology and thyroid disease; dermatology; urology and incontinence; falls and osteoporosis; ophthalmology; non-pharmacological management of dementia; rehabilitation; comprehensive geriatric assessment as a standalone topic; and disorders of potassium, calcium and magnesium.

DELIRIUM & ACUTE CNS INFECTION IN THE ELDERLY

MD Geriatric Medicine — Mark-wise Exam Notes (Q29–Q33) | Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th ed. (Ch. 61, Ch. 102) with Kane's Essentials of Clinical Geriatrics (Ch. 6) | Updates to August 2026

RECURRING TOPIC. Q29, Q30 (asked twice), Q31 and Q32 are all the same subject — **delirium** — asked at different mark weights and from different angles. Each answer below is deliberately given a **different pivot** so nothing is repeated. Q33 is the same syndrome presenting as an emergency with a specific treatable cause. Extra recall material is at the end.

Format used: 6-mark note = **5 textbook points + 1 latest update** • 7-mark note = **6 textbook points + 1 latest update** • 15-mark essay = **10 textbook points + 2 latest updates**.

Q29. Acute confusional state — 6-MARK NOTE — 5 + 1

*Pivot for this question: **what the term means and how to sort out its cause**.*

Textbook Core — 5 Points

1. **Definition.** Acute confusional state is the older clinical name for **delirium** (also called **acute brain failure** or altered mental status). It is an **acutely developing, fluctuating disturbance of attention, awareness and cognition** caused by an underlying medical illness, drug or withdrawal state. It is a **syndrome, not a diagnosis** — the cause must always be sought.
2. **Clinical picture.** There is **impaired consciousness with global cognitive impairment of acute onset**, disorientation, and a disturbed **sleep–wake cycle**. Psychomotor activity may be increased (**hyperactive**) or reduced (**hypoactive**) or both (**mixed**). **Illusions** (misinterpreting bedsheet patterns as insects), **visual hallucinations** and paranoid delusions occur. Symptoms are **worse at night** with lucid intervals by day.
3. **Causes.** Almost always **multifactorial** — a vulnerable brain plus a precipitant. Use the Pathy mnemonic **"DELIRIUM IS VERY PAINFUL"**: **D**rugs and withdrawal, **E**yes/Ears, **L**ow oxygen or perfusion, **I**nfection, **R**etention of urine (cystocerebral syndrome), **I**ndwelling catheter, **U**nderhydration (BUN:creatinine > 17:1), **M**etabolic, **I**mmobility, **S**leep problems, **V**ascular change on imaging, **E**ndocrinopathy, **R**estraints, ps**Y**chiatric disorder, **P**ain, **A**ttachments, **I**mpaction, **N**eurological injury, **F**railty, **U**ndernutrition, **L**ights and loud noise. In a highly predisposed patient a **single dose of diphenhydramine** may be enough to precipitate it.
4. **Differential diagnosis. Dementia** (gradual, no clouding of consciousness, attention preserved), **delirium superimposed on dementia**, **depression** (pseudodementia), late-onset psychosis or mania, **non-convulsive status epilepticus** and Wernicke's encephalopathy. The most reliable discriminator is to focus on the **core features — attention, awareness and level of consciousness — not on behaviour**. Kane's three questions: was the onset **acute**? are there **physical** factors? are there **psychological** factors?
5. **Approach.** Screen with **CAM or 4AT**, confirm against **DSM-5/ICD-10**, then perform a targeted search for every reversible contributor — drug chart, infection screen, glucose, electrolytes, hydration, bladder and bowel, oxygenation, pain. **Neuroimaging, lumbar puncture and EEG are not routine**; they are ordered only for focal signs, head injury, unexplained coma, suspected encephalitis or suspected seizures. Treatment is to correct the cause plus **multicomponent non-pharmacologic care**; drugs are reserved for danger to self or others.

Latest Update — 1 Point

6. The **APA Practice Guideline for the Prevention and Treatment of Delirium (September 2025)** — the first full revision since 1999 — shifts the emphasis of the whole field from treatment to **prevention and early identification**. It requires a thorough medication, predisposing- and precipitating-factor history in every patient, restricts physical restraints to circumstances of **"imminent harm"**, and adds a structured **transitions-of-care** requirement covering medication reconciliation, delirium follow-up and caregiver education. **NICE CG103 (updated January 2023)** complements this by recommending the **4AT** as the routine bedside assessment tool.

Q30 (a). Delirium 7-MARK NOTE — 6 + 1

*Pivot for this version: **the complete syndrome — mechanism, diagnosis, management, prognosis**.*

Textbook Core — 6 Points

1. **Definition and DSM-5 criteria.** Delirium is an acute disorder of attention and cognition. **DSM-5** requires: (i) disturbance of **attention and awareness**; (ii) **acute onset** with **fluctuation** over the day, a change from baseline; (iii) an additional **cognitive** disturbance; (iv) not better explained by a neurocognitive disorder and not occurring in **coma**; (v) evidence of a **medical cause, substance, withdrawal or multiple aetiologies**. DSM-5 and ICD-10 remain the **gold standard**.
2. **Epidemiology and subtypes.** Rates: **ICU 30–80%**, hospice 26–44%, **general medical and oncology wards 18–35%**, nursing home/post-acute care 16%; cardiac and vascular surgery 29–50%; hip fracture repair 12–48%. Subtypes are **hyperactive, hypoactive and mixed**; **hypoactive is the commonest and the most frequently missed**. Special phenotypes: **delirium superimposed on dementia (DSD)** — the hardest to diagnose and slowest to resolve, **postoperative delirium (POD)** versus **postoperative cognitive dysfunction (POCD)**, ICU delirium, subsyndromal and persistent delirium.
3. **Pathophysiology.** The **Systems Integration Failure Hypothesis (SIFH)** unifies the competing theories: **neuronal ageing, oxidative stress, neuroendocrine change, diurnal dysregulation and neuroinflammation** together disrupt the **neurotransmitter systems** (cholinergic, dopaminergic, adrenergic, histaminic, serotonergic) and **neuronal network connectivity**. This explains both the heterogeneous presentation and why **single-target drugs such as antipsychotics repeatedly fail** in trials.
4. **Predisposing and precipitating factors.** The more predisposing factors present (age, cognitive impairment, **frailty**, sensory impairment, multimorbidity, polypharmacy), the smaller the precipitant needed. The full list is the **DELIRIUM IS VERY PAINFUL** mnemonic. **Deliriogenic drugs** to know: benzodiazepines (especially IV), antipsychotics, corticosteroids, **H2-blockers in renal impairment**, opioids (especially **pethidine**), muscle relaxants, **antimuscarinics for overactive bladder**, first-generation antihistamines, and **zolpidem**.
5. **Diagnosis and evaluation.** Screen **all hospitalised older adults at least daily** (weekly in post-acute care, monthly in long-term care) with **CAM** (sensitivity 94%, specificity 89%), 3D-CAM, 4AT or CAM-ICU. Never explain away a positive item. **When in doubt, assume delirium until proven otherwise.** Investigate in a targeted way; imaging, LP and EEG only on specific indication.
6. **Management and prognosis.** (i) Identify and treat every precipitant. (ii) **Multicomponent non-pharmacologic care is the mainstay** — reorientation, sensory aids, sleep protocol, early mobilisation, hydration, removal of tethers, family presence, interprofessional delivery. (iii) Behaviour is managed by **T-A-DA (Tolerate, Anticipate, Don't Agitate)**, not restraints. (iv) **No drug is FDA- or EMA-approved for delirium**; **benzodiazepines must not be used** except in alcohol or benzodiazepine withdrawal; antipsychotics only for severe agitation posing danger, at the lowest dose for the shortest time, after non-pharmacologic measures fail. Prognosis: **up to 45% are still delirious at discharge**; persistence is **33% / 26% / 21%** at 1, 3 and 6 months; delirium **doubles the rate of cognitive decline** for five years in Alzheimer's disease.

Latest Update — 1 Point

> **7.** The **SCCM PADIS Focused Update 2025** (Crit Care Med 2025) has hardened the drug position: it recommends **against using haloperidol, atypical antipsychotics, dexmedetomidine, statins or ketamine to prevent delirium**, and could issue **no recommendation either for or against antipsychotics for treatment** because their effect on outcomes is minimal. Its three positive conditional recommendations are **dexmedetomidine over propofol** when light sedation or delirium reduction is the priority, **enhanced mobilisation/rehabilitation**, and **melatonin**.

Q30 (b). Delirium 6-MARK NOTE — 5 + 1

*Pivot for this version: **condensed bedside/rapid-recall version** for a shorter note — deliberately does not repeat the mechanism-heavy content above.*

Textbook Core — 5 Points

1. **Core concept.** Delirium is **acute brain failure**: an acutely developing, **fluctuating** disturbance of **attention** and cognition secondary to a medical cause. **Inattention is the core deficit** — agitation is optional and often absent.
2. **Recognise it.** Ask three things at the bedside: has this changed **acutely from baseline**? Can the patient **sustain attention** (months of the year backwards)? Is there an **identifiable medical trigger**? A positive **CAM or 4AT** flags the case; DSM-5 confirms it.
3. **Delirium versus dementia (must-write table).** See below.
4. **Find and fix the cause.** Work through **DELIRIUM IS VERY PAINFUL**. In practice the highest-yield checks are: **drug chart**, infection screen, **capillary glucose**, sodium and calcium, hydration, **bladder for retention**, rectum for impaction, oxygenation, and uncontrolled pain.
5. **Treat it.** Correct the cause + **multicomponent non-pharmacologic care** (reorientation, spectacles and hearing aids, sleep protocol, early mobilisation, hydration, family at the bedside, no restraints) + **T-A-DA** for behaviour. Reserve **low-dose haloperidol (0.25–0.5 mg)** with ECG monitoring for danger to self or others; **avoid benzodiazepines** unless alcohol or benzodiazepine withdrawal. Explain to relatives that **fluctuation and slow resolution are expected**.

Feature	Delirium	Dementia
Onset	Hours to days	Months to years
Course	Marked **fluctuation**, worse at night	Slowly progressive
Consciousness	**Altered and changing**	Clear until very late
Attention	**Impaired — the core deficit**	Preserved
Speech	Incoherent	Word-finding difficulty, aphasia
Hallucinations	Common, usually **visual**; illusions	Uncommon until late (except Lewy body dementia)
Sleep–wake cycle	Disrupted / reversed	Sleep disturbed, cycle less affected
CAM	Positive	Negative
Acute illness or drug	Usually present	Absent
Reversibility	Often (but not always) reversible	Irreversible

Latest Update — 1 Point

> **6.** A **2025 systematic review and meta-analysis** of 35 studies and 12,097 medically hospitalised older patients (Int J Nurs Stud) reported a **pooled prevalence of 23.6%** and a **pooled incidence of 13.5%**, and identified **frailty, physical restraints, previous falls, illness severity, cognitive impairment and older age** as the leading risk factors. The inclusion of **physical restraints** among the top risks is the practice-changing point — restraint is a cause of delirium, not a treatment for it.

Q31. Rating scales in delirium 7-MARK NOTE — 6 + 1

*Pivot: **the whole family of instruments and how to choose between them** (CAM itself is answered separately in Q32).*

Textbook Core — 6 Points

1. **Purpose and classification.** Scales are used to overcome the fact that delirium is **under-recognised in up to two-thirds of cases**. They fall into four groups: **(i) screening/detection** tools, **(ii) diagnostic** criteria-based instruments, **(iii) severity** scales for monitoring response, and **(iv) prediction** models. **A scale screens; DSM-5 or ICD-10 diagnoses.**
2. **Screening/detection tools (Pathy list, chronological): SPMSQ**, Delirium Rating Scale (DRS), **Confusion Assessment Method (CAM)**, Delirium Symptom Interview, Delirium Assessment Scale, **Cognitive Test for Delirium (CTD)**, **NEECHAM Confusion Scale**, Confusional State Evaluation, **Memorial Delirium Assessment Scale (MDAS)**, Delirium Index, Delirium Severity Scale, **CAM-ICU**, **DRS-R-98**, Delirium Detection Score, DDT-Pro, **bCAM**, **4AT**, and the Stanford Proxy Test for Delirium (S-PTD).
3. **Ward tools. CAM** is the most widely used (sensitivity 94%, specificity 89%). **3D-CAM** is a scripted **3-minute** version — sensitivity 96% / specificity 86% **in dementia**, and 93% / 96% **without dementia**. **4AT** takes under 2 minutes, needs no special training and works in drowsy or untestable patients, which is why NICE and SIGN recommend it. **bCAM** is the brief emergency-department version.
4. **Ultra-brief screens.** The best **single** item is **"months of the year backwards"** (sensitivity 83%, specificity 69%). The best **two-item** screen (UB-2) is **"months of the year backwards" + "what is the day of the week?"** (sensitivity 93%, specificity 64%). High sensitivity with low specificity means these are **rule-out** tools; a positive result demands fuller assessment.
5. **ICU and dementia-specific tools. CAM-ICU** is used in intubated or non-verbal patients: inattention is tested with the letter task (**"squeeze my hand for the letter A"** → SAVEAHAART), altered consciousness is any **RASS score other than 0**, and disorganised thinking uses yes/no questions. For **delirium superimposed on dementia**, the best single item is **"What day of the week is it?"**, the best two-item screen adds **days of the week backwards**, and the best three-item screen adds **"What type of place is this?"** and **"Does the patient appear sleepy?"**; sensitivities are 84%, 93% and 94% but specificities only 41%, 30% and 42%.
6. **Severity and prediction; frequency of use.** Severity and trajectory are tracked with the **MDAS**, **DRS-R-98**, **Delirium Index** and Delirium Severity Scale — useful in palliative care and research. Risk **prediction** uses the **E-PRE-DELIRIC** model and **Stanford's Algorithm for Predicting Delirium (SAPD)**, which allow preventive resources to be targeted. Screening frequency: **daily** in hospital, **weekly** in post-acute care, **monthly** in long-term care, and at any reported change from baseline.

Table — choosing the right instrument

Tool	Time	Category	Best setting	Performance
CAM	~5 min	Screening	General ward — the reference tool	Sens 94% / Spec 89%
3D-CAM	3 min	Screening	Ward, including patients with dementia	Sens 93–96% / Spec 86–96%
4AT	<2 min	Screening	Ward and ED; untrained staff; drowsy patients	NICE- and SIGN-recommended
UB-2	<1 min	Screening	Rapid triage / rule-out	Sens 93% / Spec 64%
bCAM	~2 min	Screening	Emergency department	Brief CAM derivative
CAM-ICU	2–3 min	Screening	Intubated / non-verbal ICU patients	Uses RASS + SAVEAHAART
MDAS	10 min	Severity	Palliative care, oncology; monitoring	Grades severity, not just presence
DRS-R-98	~20 min	Severity	Research, liaison psychiatry	Separate severity and diagnostic sections
E-PRE-DELIRIC	—	Prediction	ICU admission risk-stratification	Targets preventive resources

Latest Update — 1 Point

> **7. NICE CG103 (January 2023)** issued **new recommendations specifically on assessing and diagnosing delirium** and established the **4AT** as the recommended short assessment tool in both NICE and SIGN guidance — a definite shift away from CAM-only teaching, because the 4AT requires no training and can be completed in patients too drowsy to be formally tested. The **APA 2025** guideline reinforces this by requiring **systematic tool-based screening of at-risk patients** rather than clinical impression, and adds assessment **at transitions of care, including before discharge**.

Q32. Confusion Assessment Method (CAM) for the diagnosis of delirium 7-MARK NOTE — 6 + 1

*Pivot: **one instrument in depth — purpose, components, scoring, interpretation, advantages, limitations**.*

Textbook Core — 6 Points

1. **Purpose and status.** The CAM (Inouye et al., Ann Intern Med 1990) is a **structured bedside screening instrument** that operationalises the DSM criteria so that **non-psychiatrists can detect delirium reliably**. It is the most widely used delirium tool in the world and the parent of a family of derivatives. Note carefully: the CAM **screens** for delirium; the formal diagnosis still rests on **DSM-5 or ICD-10**.
2. **The four features. (i) Acute onset and fluctuating course**; **(ii) Inattention**; **(iii) Disorganised thinking**; **(iv) Altered level of consciousness**.
3. **Scoring algorithm (must be written exactly).** The screen is positive when the patient has **feature (i) AND feature (ii)**, **PLUS either feature (iii) OR feature (iv)**. In short: **(1 AND 2) + (3 OR 4)**. Features 1 and 2 are therefore **mandatory** — a patient cannot be CAM-positive without acute fluctuating onset and inattention.
4. **How to elicit each feature.**
   - **Feature 1** — from a **collateral informant**: is this a change from baseline, and does it come and go during the day?
   - **Feature 2 (inattention)** — **months of the year backwards**, days of the week backwards, or **digit span 3–4 backwards**; or simply observe that the patient is inappropriately distracted or cannot keep track of the conversation.
   - **Feature 3 (disorganised thinking)** — test **orientation to time and place**; observe an **illogical or rambling flow of ideas**.
   - **Feature 4 (altered consciousness)** — anything other than alert: vigilant, lethargic, stuporous or comatose.
5. **Performance and derivatives.** The CAM has a **sensitivity of 94% and specificity of 89%**, with high inter-rater reliability. Derivatives: **3D-CAM** (scripted 3-minute version — sensitivity 96% / specificity 86% in dementia, 93% / 96% without dementia); **CAM-ICU** for intubated patients (RASS ≠ 0 for feature 4, **SAVEAHAART** letter task for feature 2); **bCAM** for the emergency department; and the **UB-2** two-item screen derived from 3D-CAM validation data.
6. **Advantages and limitations.**
   - **Advantages:** rapid, bedside, no equipment, validated across settings, usable by nurses and non-specialists, high sensitivity and specificity, standardises documentation, and enables the daily screening that guidelines require.
   - **Limitations:** it needs **training and a collateral history** for feature 1; performance falls without formal cognitive testing of attention; it **cannot distinguish delirium from dementia in an unknown baseline** and is unreliable in established **DSD**; being a single point-in-time assessment it can be **falsely negative during a lucid interval**; it does not grade **severity** (use MDAS or DRS-R-98) and does not identify the cause; and it cannot be applied to a **comatose** patient.

CAM at a glance

Feature	Name	Bedside test	Required?
1	Acute onset & fluctuating course	Collateral history; observation over the day	**Mandatory**
2	Inattention	Months of the year backwards; days of the week backwards; digit span backwards	**Mandatory**
3	Disorganised thinking	Orientation to time and place; illogical flow of ideas	Either 3 **or** 4
4	Altered level of consciousness	Alert / vigilant / lethargic / stupor / coma	Either 3 **or** 4

Latest Update — 1 Point

7. Current guidance no longer treats the CAM as the only acceptable tool. **NICE CG103 (2023)** and SIGN recommend the **4AT** for routine ward and emergency screening because it needs **no training** and, unlike the CAM, remains scoreable in patients who are **too drowsy or untestable** to complete a formal interview. The **APA 2025** guideline requires systematic screening with **a** validated instrument — the CAM family remains fully acceptable, but the examinable point is that **the CAM is now one validated option among several rather than the default**.

Exam One-Liners — Q29 to Q32

- Acute confusional state = delirium = **acute brain failure**. Core deficit = **inattention**.
- Causes mnemonic = **DELIRIUM IS VERY PAINFUL**; cystocerebral syndrome = delirium from **urinary retention**.
- Pathophysiology = **Systems Integration Failure Hypothesis**.
- **Hypoactive delirium is the commonest and the most missed.**
- CAM = **(1 AND 2) + (3 OR 4)**; **sens 94% / spec 89%**.
- 3D-CAM = **3 minutes**; 4AT = **<2 minutes, no training, NICE/SIGN recommended**.
- CAM-ICU uses **RASS** and the **SAVEAHAART** letter task.
- Best single bedside item = **months of the year backwards**.
- Severity scales = **MDAS, DRS-R-98**; prediction = **E-PRE-DELIRIC, SAPD**.
- Screen **daily / weekly / monthly** in hospital / post-acute / long-term care.
- Mainstay of treatment = **non-pharmacologic multicomponent care**; behaviour tool = **T-A-DA**.
- **No drug is approved** for delirium; benzodiazepines only for alcohol/benzodiazepine withdrawal.

Q33. A 78-year-old man with type 2 diabetes mellitus presents to the emergency OPD in acute confusion with fever, headache, neck stiffness, vomiting and photophobia. What is your diagnosis and how will you manage this patient? 15-MARK ESSAY — 10 + 2

Diagnosis in one line: Acute community-acquired bacterial meningitis in an older diabetic man, presenting with the classic triad (fever, neck stiffness, altered mental status) plus meningism. **Streptococcus pneumoniae** is the most likely organism; **Listeria monocytogenes** must be covered because both **age > 60** and **diabetes mellitus** are established Listeria risk factors. This is a **medical emergency** — untreated mortality approaches 100%.

Textbook Core — 10 Points

1. **Clinical basis of the diagnosis.** The most common features of acute bacterial meningitis are **severe headache (84%)**, **fever > 38 °C (74%)**, **stiff neck (74%)**, **GCS < 14 (71%)** and **nausea (62%)**. The **classic triad occurs in only about 41–44%** of adults, but **95% have at least two of the four** cardinal features (fever, headache, stiff neck, altered mental status) — this patient has all four plus photophobia, so the pre-test probability is very high. Other features: **cranial nerve palsies (10–20%)** and **seizures (~30%)**. Importantly, **Kernig's and Brudzinski's signs are almost useless diagnostically (sensitivity 5% each; nuchal rigidity only 30%)** — their absence never excludes meningitis.
2. **The geriatric caveat.** Older patients over 60 actually present with the full triad **more** often than younger adults (58% vs 36%), but those with underlying disease such as **diabetes mellitus** or cardiopulmonary disease may instead present **insidiously with lethargy, confusion, anorexia, no fever and minimal meningeal signs**. **Confusion was present in 92% of elderly patients with pneumococcal meningitis and 78% with Gram-negative bacillary meningitis.** Therefore **any older patient with altered or changed mental status should be evaluated for bacterial meningitis, including consideration of CSF examination.** Elderly patients are also sicker at presentation, with higher CSF protein and more abnormal imaging, and an adverse outcome occurs in **51.9% of elderly versus 7.4% of non-elderly** patients.
3. **Likely organisms.** In adults **65 years or older**, the commonest pathogen is **Streptococcus pneumoniae (~70%)**, followed by **Listeria monocytogenes**, **Neisseria meningitidis**, **Haemophilus influenzae**, **Streptococcus agalactiae** and **aerobic Gram-negative bacilli**. Risk factors for Listeria are **age over 60, chronic steroids, alcoholism, immunosuppression, malignancy and diabetes**. S. pneumoniae carries the **highest mortality** and the highest rate of neurological sequelae (at least one major sequela in 24.7% of survivors). Look for an antecedent or concurrent focus — **sinusitis, otitis media or pneumonia**.
4. **Differential diagnosis to state briefly. Viral (aseptic) meningitis** — enterovirus, HSV-2, VZV, West Nile virus (elderly patients are more prone to West Nile encephalitis and to bacterial rather than viral disease); **HSV encephalitis**; **tuberculous meningitis** (very important in India — subacute course, cranial nerve palsies, basal exudates, hydrocephalus); **cryptococcal** and other fungal meningitis in the immunosuppressed; **subarachnoid haemorrhage** (thunderclap headache, neck stiffness, no fever early); **brain abscess, subdural empyema**; **cerebral malaria**; drug-induced aseptic meningitis; and **delirium from any systemic cause** including hypoglycaemia and hyperosmolar state in this diabetic.
5. **Immediate emergency actions (first 15 minutes).** Airway, breathing, circulation; oxygen; large-bore IV access; **capillary blood glucose immediately** (hypoglycaemia is the great mimic); vital signs; GCS; examine for **petechial or purpuric rash** (meningococcaemia), papilloedema, focal deficits, cranial nerve palsies and a septic focus in ear, sinuses and chest. Take **blood cultures**, then move directly to lumbar puncture or, if that must be deferred, to antibiotics. **Treatment must never be delayed for imaging or for the lumbar puncture** — the "one-hour window" is the accepted target for the first antibiotic dose.
6. **Investigations. Blood cultures** (before antibiotics), complete blood count, blood glucose (mg/dL), urea and creatinine (mg/dL), sodium and potassium (mEq/L), calcium (mg/dL), liver function tests, coagulation profile, CRP or procalcitonin, arterial blood gas and lactate, HbA1c, chest radiograph, HIV serology, and blood film for malaria where relevant. **The diagnosis rests on CSF examination after lumbar puncture** — send opening pressure, cell count with differential, protein, glucose with a **paired blood glucose** for the CSF:serum ratio, **Gram stain**, culture with antimicrobial susceptibility testing, and **PCR / multiplex meningitis-encephalitis panel**. Add CSF **CBNAAT and adenosine deaminase** if tuberculosis is suspected, and India ink and cryptococcal antigen if fungal disease is suspected.
7. **When to do CT before lumbar puncture.** Cranial imaging should **not** be performed routinely. Obtain CT first only if there is **immunosuppression, known CNS disease, focal neurological deficit, new-onset seizure, papilloedema or a markedly depressed conscious level**. In those situations, **start empirical antibiotics (with dexamethasone) before scanning**. Where imaging is not available, the lumbar puncture should be deferred until such features resolve — but antibiotics are still given immediately, and the LP performed as soon as it is safe.
8. **Empirical antimicrobial therapy.** For a patient **over 50 years** with suspected community-acquired bacterial meningitis, the recommended empirical regimen is **vancomycin + ampicillin + a third-generation cephalosporin (ceftriaxone or cefotaxime)**. The cephalosporin covers pneumococcus and meningococcus, **ampicillin covers Listeria** (which cephalosporins do **not** cover — a classic examiner trap), and **vancomycin covers penicillin- or cephalosporin-resistant pneumococci**. If the Gram stain shows **Gram-positive diplococci**, treat as pneumococcal with vancomycin plus a third-generation cephalosporin. De-escalate once culture and susceptibility results are available. Adult CNS doses from the textbook are given in the table below.
9. **Adjunctive dexamethasone.** Bacterial lysis by antibiotics triggers a **subarachnoid inflammatory response** that drives morbidity and mortality. In a randomised double-blind trial of 301 adults, adjunctive dexamethasone **reduced unfavourable outcomes and death**, with the greatest benefit in **pneumococcal meningitis** and in **moderate-to-severe disease by admission GCS**. Give **dexamethasone 0.15 mg/kg every 6 hours for 4 days**, **with or just before the first antibiotic dose**. Key qualifications: IDSA advises against starting it once antibiotics have already been given, whereas the **2016 European guideline allows up to 4 hours and the UK guideline up to 12 hours** after the

first dose; it should be **stopped if the organism turns out not to be pneumococcus**, and it is **harmful in Listeria and in cryptococcal meningitis**; benefit is **not seen in resource-poor settings with a high burden of advanced HIV**; and it may reduce CSF penetration of vancomycin and has been linked to **delayed cerebral injury**.

10. **Supportive care, complications, prognosis and prevention.** Nurse in a high-dependency area with neurological observations; manage **raised intracranial pressure** (head-up 30°, mannitol or hypertonic saline as a temporising measure; glycerol is **not** recommended); treat seizures; give maintenance **isotonic** fluids without routine fluid restriction, but allow moderate restriction if **SIADH** develops without hypovolaemia; monitor sodium closely; use an **insulin infusion or basal-bolus regimen targeting roughly 140–180 mg/dL** and stop metformin during acute illness; give VTE prophylaxis and pressure-area care; and apply the **delirium bundle** throughout, since confusion will persist after the infection is controlled. Watch for **hearing loss, seizures, hydrocephalus, cerebral infarction, septic shock and cognitive impairment**. Prevention: all adults **65 years or older** should receive pneumococcal vaccination (both conjugate and polysaccharide vaccines as per schedule), as should those with **asplenia, CSF leak, cochlear implants or immunosuppression**. Give **chemoprophylaxis to close contacts** if meningococcal disease is confirmed.

Table 1. CSF findings — pattern recognition

Parameter	Bacterial	Viral	Tuberculous	Cryptococcal
Opening pressure	**Raised in virtually all**	Normal / mildly raised	Raised	**Markedly raised**
Cells	**> 1000/mm^3 in 66%**, neutrophilic	Lymphocytic, usually < 500	Lymphocytic, 100–500	20–500 lymphocytes; may be normal in AIDS
Protein	**100–500 mg/dL**	Normal / mildly raised	**Very high**	Raised
Glucose	**< 40 mg/dL**; CSF:serum ratio low	Normal	Low	Normal or low
Microbiology	**Gram stain positive in 60–90%**, specificity ~100%	PCR	AFB, **CBNAAT**, ADA	India ink, **cryptococcal antigen**

Table 2. Empirical and definitive therapy (adult CNS doses, normal renal function)

Situation	Drug	Total daily dose & interval
Empirical, age > 50 years	Ceftriaxone *or* Cefotaxime	4 g/day (12–24 h) / 8–12 g/day (4–6 h)
	Ampicillin (for *Listeria*)	12 g/day, 4-hourly
	Vancomycin (resistant pneumococcus)	30–60 mg/kg/day, 8–12 h
S. pneumoniae, penicillin MIC ≥ 2.0	Vancomycin + third-generation cephalosporin	as above (consider adding rifampicin)
Listeria monocytogenes	Ampicillin or penicillin G (add an aminoglycoside)	Ampicillin 12 g/day; alternative co-trimoxazole
N. meningitidis, penicillin MIC < 0.1	Penicillin G or ampicillin	Penicillin G 24 million units/day, 4-hourly
Gram-negative bacilli	Third-generation cephalosporin	alternatives: meropenem, fluoroquinolone
HSV encephalitis suspected	**Aciclovir**	30 mg/kg/day, 8-hourly
Adjunctive steroid	**Dexamethasone**	**0.15 mg/kg 6-hourly × 4 days**, with/just before first antibiotic

Latest Updates — 2 Points

11. WHO guidelines on meningitis diagnosis, treatment and care (2025) — the **first global WHO guideline** on clinical management of acute community-acquired meningitis, developed under the *Defeating meningitis by 2030* road map (WHA73.9) and written specifically to be implementable in low- and middle-income countries. Points of direct examination value:

- **Lumbar puncture as early as possible, preferably before antimicrobials**; CSF Gram stain, cell count, protein, glucose and **CSF:blood glucose ratio** are strongly recommended, with **CSF PCR** strongly recommended in addition (culture with susceptibility testing remains the gold standard).
- **Cranial imaging is strongly recommended against routinely**; CT before LP only for **GCS < 10, focal signs, cranial nerve deficits, papilloedema, new-onset seizures in adults, or severe immunocompromise** — and **treatment must not be delayed** for it.
- **Empirical regimen: IV ceftriaxone or cefotaxime**, with **ampicillin or amoxicillin added whenever a Listeria risk factor is present — explicitly including age over 60 and diabetes mellitus**, exactly as in this patient. Vancomycin is added conditionally where pneumococcal resistance is prevalent (rifampicin is an alternative, but only where the tuberculosis burden is low). Chloramphenicol with ampicillin is the fallback if cephalosporins are unavailable.
- **Corticosteroids are now a strong recommendation** with the first antibiotic dose in non-epidemic settings where LP can be performed, to be **stopped if the CSF is not consistent with bacterial meningitis** or if an organism other than *S. pneumoniae* or *H. influenzae* type b is identified; maximum duration **4 days**. Dexamethasone is the steroid of choice, but hydrocortisone or methylprednisolone may substitute at equivalent dose.
- **Duration:** where no pathogen is identified, empirical therapy may be stopped at **7 days** if the patient has clinically recovered (afebrile, normal vitals, normal mental status for at least 48 hours).
- **Sequelae:** every patient should be **reviewed for sequelae before discharge and again within 4 weeks**, with **formal audiological screening before discharge** and early rehabilitation — a strong recommendation and an easy extra mark.
- **Glycerol is recommended against**; routine fluid restriction is recommended against.

12. Dexamethasone must be stopped once *Listeria* is identified. A prospective nationwide Dutch cohort (eClinicalMedicine 2023) of 162 adults with community-acquired *Listeria monocytogenes* meningitis found a **case fatality of 31%** and an **unfavourable outcome in 56%**, with **age and the standard adjunctive dexamethasone regimen as independent predictors of both unfavourable outcome and death**. This confirms the earlier French MONALISA signal and is now embedded in guidelines: **start dexamethasone empirically, but discontinue it the moment *Listeria* (or *Cryptococcus*) is confirmed.** In an older diabetic patient — who is precisely the Listeria-risk phenotype — this is the single most likely question the examiner will ask on follow-up.

Current Practice Update

Issue	Pathy 6th edition	Current practice (2023–2026)
Guideline anchor	IDSA 2004, ESCMID 2016, UK 2016	**WHO 2025 global meningitis guidelines** — the first WHO clinical guidance, LMIC-oriented
Steroid timing	IDSA: do not start after the first antibiotic dose; Europe up to 4 h; UK up to 12 h	**Strong recommendation** to give with the first antibiotic dose; benefit falls as delay increases; stop if CSF is non-bacterial
Steroid in *Listeria*	Flagged as harmful (French cohort)	**Confirmed harmful** in a second national cohort; guidelines mandate discontinuation
Molecular diagnosis	FilmArray panel described, false positives ~4%	**CSF PCR strongly recommended** alongside — not instead of — culture and susceptibility testing
Cranial imaging	CT before LP in defined groups	Same indications, but now a **strong recommendation against routine imaging**, with GCS < 10 as the explicit threshold
Duration of therapy	Pathogen-directed	**7 days** acceptable for culture-negative disease after clinical recovery
Follow-up	Sequelae described	**Mandatory pre-discharge review + audiological screening + review within 4 weeks + early rehabilitation**

Exam One-Liners — Q33

- Classic triad present in only **41–44%**; but **95% have 2 of 4** cardinal features.
- **Kernig's and Brudzinski's sensitivity is only 5%** — never rely on them.
- Commonest organism over 65 = **S. pneumoniae (~70%)**; then **Listeria**.
- **Diabetes and age > 60 are Listeria risk factors → always add ampicillin**.
- Cephalosporins do **not** cover *Listeria*.
- Empirical regimen > 50 years = **vancomycin + ampicillin + ceftriaxone/cefotaxime**.
- **Dexamethasone 0.15 mg/kg 6-hourly × 4 days**, with or just before the first antibiotic.
- **Stop dexamethasone if the organism is *Listeria* or *Cryptococcus*** — it increases mortality.
- Gram stain positive in **60–90%**, specificity ~100%.
- CSF glucose **< 40 mg/dL**, protein **100–500 mg/dL**, cells **> 1000/mm^3 in 66%**.
- **Antibiotics within 1 hour; never delay for CT or LP.**
- Adverse outcome in **51.9% of elderly vs 7.4% of non-elderly**.
- **Audiological screening before discharge** (WHO 2025).

Recurring Topic — Extra Points to Remember

> Delirium has now appeared four times in this set alone. These are the details that convert a safe answer into a top answer.

1. How to differentiate the four delirium questions

Question	Pivot to use	What NOT to spend words on
Acute confusional state (6 marks)	**Terminology + causes + differential diagnosis**	Detailed pathophysiology, prevention programmes
Delirium (7 marks)	**Full syndrome** — DSM-5, subtypes, SIFH, management, prognosis	Individual scale statistics
Delirium (6 marks)	**Bedside/rapid version** + delirium-vs-dementia table	Trial names and odds ratios
Rating scales (7 marks)	**Classification of tools** + how to choose	Causes and management — not asked
CAM (7 marks)	**One tool in depth** — components, scoring, advantages, limitations	Listing every other scale

2. Numbers to memorise

Item	Value
CAM sensitivity / specificity	94% / 89%
3D-CAM (with dementia / without)	96% & 86% / 93% & 96%
Months of the year backwards (single item)	Sens 83% / Spec 69%
UB-2 two-item screen	Sens 93% / Spec 64%
DSD screens (1 / 2 / 3 items) — sensitivity	84% / 93% / 94%
DSD screens — specificity	41% / 30% / 42%
Delirium in ICU / medical wards / hospice / LTC	30–80% / 18–35% / 26–44% / 16%
Pooled prevalence & incidence, hospitalised elderly (2025)	23.6% & 13.5%
Still delirious at discharge / 1 / 3 / 6 months	45% / 33% / 26% / 21%
Preventable proportion of delirium	30–40%
Meningitis — headache / fever / stiff neck / GCS < 14	84% / 74% / 74% / 71%
Meningitis — classic triad / at least 2 of 4	41–44% / 95%
Meningitis — Kernig's / Brudzinski's / nuchal rigidity sensitivity	5% / 5% / 30%
S. pneumoniae share of meningitis in adults ≥ 65 y	~70%
Listeria meningitis case fatality (2023 cohort)	31%; unfavourable outcome 56%
Dexamethasone regimen	0.15 mg/kg 6-hourly × 4 days

3. Named traps in this set

- **Trap:** writing that CAM *diagnoses* delirium. It **screens**; DSM-5/ICD-10 diagnose.
- **Trap:** writing the CAM algorithm as "any two features". It is **(1 AND 2) + (3 OR 4)**, with features 1 and 2 mandatory.
- **Trap:** equating delirium with agitation. **Hypoactive delirium is commonest.**
- **Trap:** prescribing a benzodiazepine for restlessness — it **causes and prolongs** delirium.
- **Trap:** physical restraint as a safety measure — it is an **independent risk factor**.
- **Trap:** relying on Kernig's and Brudzinski's signs to exclude meningitis (**5% sensitivity**).
- **Trap:** omitting **ampicillin** from the empirical regimen in an older or diabetic patient — cephalosporins miss *Listeria*.
- **Trap:** continuing dexamethasone after *Listeria* is isolated — it **increases mortality**.
- **Trap:** delaying the first antibiotic dose for a CT scan or lumbar puncture.
- **Trap:** forgetting to check **capillary glucose** in a confused diabetic before doing anything else.

4. Indian context lines to add

- **Under-recognition:** Indian referral-based studies detect delirium in under 1% of inpatients, while CAM-ICU screening finds **~30% of elderly ICU patients delirious, ~45% of them hypoactive** — the strongest argument for routine tool-based screening rather than waiting for a psychiatry referral.
- **Tuberculous meningitis** must appear in every Indian differential for fever with confusion and neck stiffness — send **CSF CBNAAT and ADA** alongside routine studies.
- **Rifampicin caution:** WHO 2025 permits rifampicin instead of vancomycin for resistant pneumococcus only in **low tuberculosis-burden** settings — in India, vancomycin is preferred.
- **Alcohol withdrawal** is a very common and under-declared cause of ward delirium in Indian men — always give **parenteral thiamine before glucose**.
- **Family attendants** at the bedside are the norm in Indian wards; formally enlisting them for orientation, hydration, feeding and mobilisation delivers an evidence-based delirium bundle at almost no cost.

- **Programmes to name: NPHCE** geriatric wards and regional geriatric centres; **AB-PMJAY** and the **Ayushman Vay Vandana Card** for those aged 70 and above; adult pneumococcal vaccination is **not** part of the Universal Immunization Programme and remains an out-of-pocket, opportunistic intervention — a legitimate policy-gap comment.

5. Fifteen-second answer skeletons

> **Any delirium question:** Define (acute, fluctuating, inattention, medical cause) → Subtypes → SIFH → Predisposing + Precipitating (DELIRIUM IS VERY PAINFUL) → Differentiate from dementia → Screen (CAM/4AT) then diagnose (DSM-5) → Targeted workup → Treat the cause → Non-pharmacologic bundle + T-A-DA → Drugs only for imminent harm → Prevent (HELP/mHELP/ABCDEF) → Prognosis and follow-up.
>
> **Any acute meningitis question:** Recognise (triad + meningism, but triad in <50%) → Resuscitate + glucose → Blood cultures → Decide on CT (only if GCS < 10, focal signs, papilloedema, seizure, immunocompromise) → **Lumbar puncture** → **Dexamethasone + antibiotics within 1 hour** (never delayed) → Empirical **vancomycin + ampicillin + ceftriaxone** over 50 years → De-escalate on culture; **stop steroid if not pneumococcal** → Supportive care, ICP, sodium, glycaemia, delirium bundle → Complications → **Audiology and sequelae review before discharge** → Vaccination and contact prophylaxis.

*Format used throughout — **7 marks = 6 textbook points + 1 latest update**; **6 marks = 5 textbook points + 1 latest update**; **15 marks = 10 textbook points + 2 latest updates**. Where two questions overlap in subject matter, each answer is written to a stated pivot point so that no answer repeats another. Questions that had appeared at two different mark weightings have been merged into a single entry carrying both versions.*

Section A — Mood Disorders and Depression

The classification of late-life mood disorder, depression in all its aspects, bipolar illness, and the screening instrument you will be asked to describe.

Question 1. Mood disorders in late life [15 marks]

Pivot: the whole mood-disorder spectrum and its classification. Depression-specific management is covered in Questions 2 to 4 and bipolar illness in Question 5.

Textbook Core — 10 Points

1. **Scope and classification. DSM-5 split the former "mood disorders" chapter into two — depressive disorders and bipolar disorders.** Depressive disorders comprise **major depressive disorder, persistent depressive disorder (merging dysthymia and chronic depression, ≥2 years), depressive disorder due to another medical condition, and substance/medication-induced depressive disorder**. Bipolar disorders comprise **bipolar I, bipolar II and cyclothymia**. Additions relevant to late life include the **"with anxious distress" specifier** and the **removal of the bereavement exclusion**.
2. **Burden. Depression is the commonest psychiatric disorder in older people** — major depression in **1–5% of the community**, **clinically relevant depressive symptoms in 8–16%**, rising markedly in **primary care, medical wards and long-term care**. **Bipolar disorder affects only 0.5–1% of over-65s but accounts for 5–10% of geriatric psychiatry outpatients. Clinically significant subthreshold syndromes increase with age** and still carry adverse outcomes.
3. **Why late-life mood disorder is different. Comorbidity is the hallmark of geriatric psychiatry, and this is most pronounced in depression.** Chronic physical illness and its drug treatment produce **overlapping symptoms — fatigue, slowness, loss of initiative and sleep disturbance**. Presentation is **atypical — somatic complaints, hypochondriasis, anxiety, irritability and cognitive complaints rather than expressed sadness**. **Psychomotor symptoms and nihilistic delusions are more frequently reported in older inpatients, sometimes even in the absence of lowered mood.**
4. **Depression subtypes of examination importance. Psychotic depression** — nihilistic and guilt delusions, high suicide risk, requiring antidepressant plus antipsychotic, or ECT. **Melancholic depression with psychomotor change** — predicts response to **TCAs, dopaminergic agents and ECT**. **"Vascular depression", now ischaemic subcortical depression or depression-executive dysfunction syndrome** — late onset, apathy, impaired insight, executive dysfunction and deep white-matter change; its clinical validity is now regarded as limited, with **vascular factors and inflammation mutually reinforcing each other**.
5. **Secondary and organic mood disorders — always exclude. Hypothyroidism and hyperthyroidism**, **vitamin B12 and folate deficiency**, **hyponatraemia (mEq/L)**, **hypercalcaemia (mg/dL)**, **stroke** (post-stroke depression; **right frontal or basotemporal stroke causing secondary mania**), **Parkinson's disease**, **dementia**, occult malignancy (especially pancreatic) and chronic pain. Drugs: **corticosteroids, levodopa and dopamine agonists, beta-blockers, interferon, and 5-alpha reductase inhibitors linked to depression and suicidality**.
6. **Bipolar disorder in late life.** Two groups — **early-onset illness ageing into old age (about two-thirds)** and **late-onset first episode after 50 (about one-third)**. **Late-onset mania is secondary mania until proved otherwise** — cerebrovascular disease, stroke, frontotemporal dementia, hyperthyroidism, steroids, levodopa and antidepressants. Mania is **attenuated — irritability, dysphoria, confusion and paranoia rather than euphoria**; **mixed states and prolonged depressive episodes dominate**. **GERI-BD** found **lithium and divalproex comparably effective** in acute mania in those aged ≥60.
7. **Conditions that mimic mood disorder. Apathy syndrome** — prevalent after stroke and in dementia, characterised by **lack of drive with absence of dysphoria and absence of neurovegetative symptoms**; **SSRIs and antidopaminergic drugs may worsen it**, and low-dose methylphenidate may help in severe cases. Also **delirium**, **dementia (pseudodementia versus true dementia)**, **complicated or prolonged grief**, and **personality disorder with mood lability**.
8. **Assessment.** History with **informant account**; **GDS-15**, or the **Cornell Scale for Depression in Dementia** where cognition is impaired; **MMSE/MoCA**; physical examination with attention to **vascular risk factors, weight, mobility, balance and ADLs**. Investigations: **CBC, sodium and potassium (mEq/L), calcium (mg/dL), glucose (mg/dL), liver function, TSH, vitamin B12 and folate**, plus **ECG before a TCA or lithium**. **Assess suicidal ideation in every case.**
9. **Principles of management across the spectrum. Match intensity to severity** — watchful waiting → psychotherapy → antidepressant → augmentation → ECT. **Antidepressants are as effective in older as in younger adults; psychotherapy is helpful in mild-to-moderate illness; ECT is probably more effective in severe depression in older people than in the young.** For bipolar illness — **a mood stabiliser at lower doses and lower serum levels, with antidepressant monotherapy contraindicated**. Always include **functional recovery, treatment of comorbid physical illness, and multidisciplinary team care**.

10. **Course, prognosis and impact.** Late-life depression has a **more chronic course** than in younger adults, although **over 80% of those without significant medical comorbidity or dementia recover and remain well when optimally treated**. **Worse outcome is predicted by greater severity of depression and more serious physical illness. Mortality is increased — mainly cardiovascular, with suicide risk rising with age, especially in men** — and **both severity and duration of symptoms predict mortality**, with loneliness amplifying the effect. Depression also **worsens the course of physical illness and increases healthcare consumption**.

Latest Updates — 2 Points

11. **Depression as a modifiable dementia risk factor — 2024 Lancet Commission.** The updated **Lancet Commission on dementia prevention, intervention and care (2024)** retains **depression among the modifiable risk factors** contributing to the population burden of dementia. Combined with cohort evidence that **10-year trajectories of depressive symptoms predict incident dementia**, this reframes **active treatment of late-life depression as a dementia-prevention intervention**, and mandates **cognitive assessment and cognitive follow-up in every older patient with depression**.
12. **OPTIMUM trial (*NEJM* 2023) and ISBD lithium targets.** In treatment-resistant late-life depression, **aripiprazole augmentation** outperformed **switching to bupropion** (**remission approximately 28% versus 19%**) with a **lower fall risk**. On the bipolar side, the **ISBD Older-Age Bipolar Disorder Task Force** now supports **age-stratified lithium targets of 0.4–0.8 mEq/L for ages 60–79 and 0.4–0.7 mEq/L for those aged ≥80**, rather than the standard adult range.

Question 2. Describe the prevalence, clinical presentation and management of depression in the elderly. What is the role of ECT in an elderly patient with depression? [15 marks]

Pivot: the full-spectrum essay, with a dedicated ECT section. See also Question 28 for ECT as a stand-alone note.

Textbook Core — 10 Points

1. **Prevalence. Major depression affects 1–5% of community-dwelling elderly**, but **clinically relevant depressive symptoms occur in 8–16%**. Rates rise with setting: **5–10% in primary care**, **10–20% of medical inpatients**, and highest in **long-term care**. In India, **LASI Wave-1 reported major depression in about 8% of those aged 60 and above**. It is the **commonest psychiatric disorder in old age**, yet remains **under-diagnosed and under-treated**.
2. **Risk factors. Female sex**, **widowhood and loneliness**, **physical illness and disability**, **chronic pain**, **cognitive impairment**, previous depression, **family history**, low socioeconomic status, caregiving, and **drug-induced depression** — steroids, beta-blockers, levodopa, and **5-alpha reductase inhibitors (finasteride, dutasteride), which are linked to depression and suicidality**.
3. **DSM-5 classification. Major depressive disorder** = **depressed mood and/or loss of interest for ≥2 weeks** plus a total of **≥5 of 9 symptoms** (worthlessness/guilt, poor concentration, fatigue, psychomotor change, insomnia/hypersomnia, appetite or weight change, recurrent thoughts of death). **Dysthymia is now "persistent depressive disorder" (≥2 years)**; the **"with anxious distress" specifier** was added and the **bereavement exclusion removed** — both especially relevant to older people.
4. **Atypical clinical presentation — the exam favourite.** Older people present with **somatic complaints and hypochondriacal preoccupation rather than sadness**; **"depression without sadness"** is common. Expect **psychomotor retardation or agitation**, **nihilistic delusions**, anxiety, irritability, **weight loss and insomnia**, **non-adherence to medical treatment**, and cognitive complaints.
5. **Important subtypes. Psychotic depression** — nihilistic and guilt delusions, higher suicide risk, needs antidepressant plus antipsychotic, or ECT. **Melancholic depression with psychomotor symptoms** — predicts response to **TCAs, dopaminergic antidepressants and ECT**. **"Vascular depression", now termed ischaemic subcortical depression or depression–executive dysfunction syndrome** — late onset, apathy, impaired insight, **executive dysfunction**, deep white-matter hyperintensities; its clinical validity is now regarded as limited.
6. **Differential diagnosis. Dementia** (depressive pseudodementia versus true dementia), **delirium**, **apathy syndrome** — distinguished by the **absence of dysphoria and absence of neurovegetative symptoms** — **hypothyroidism**, **B12 deficiency**, occult malignancy, Parkinson's disease, and normal grief.
7. **Assessment and workup.** History **plus informant history**; **GDS-15** (or the **Cornell Scale if dementia is present**); MMSE/MoCA; physical examination with attention to **vascular risk factors, weight, mobility, balance and ADLs**. Investigations: **CBC, sodium and potassium (mEq/L), calcium (mg/dL), glucose (mg/dL), liver function, TSH, vitamin B12 and folate**, with an **ECG before a TCA**. **Always ask directly about suicidal ideation — asking does not increase risk and most patients are relieved.**
8. **Non-pharmacological management. Watchful waiting is appropriate for mild depression**, since many improve spontaneously. **Psychotherapy is helpful in mild-to-moderate depression and is as effective in older as in younger adults** — **CBT, problem-solving therapy** (best where executive dysfunction is present), **interpersonal therapy, reminiscence and life review**. **Exercise is effective** in depressive disorder, minor depression and subthreshold symptoms. Add psychoeducation with family and **multidisciplinary outpatient team care**.

9. **Pharmacological management. Antidepressants are just as effective in older people as in younger adults. SSRIs are first-line** (sertraline, escitalopram); SNRIs and mirtazapine are alternatives; **start at half the adult dose and titrate slowly**; allow **6–12 weeks for full response**. On non-response to an SSRI, **switch antidepressant or add lithium**; **after TCA failure, lithium augmentation is probably the best option**. **Continue for at least 1 year after a first recurrence; consider lifelong maintenance after a second or subsequent recurrence.**
10. **Prognosis and impact.** The course is **more chronic than in younger adults**; among those without significant comorbidity or dementia who are optimally treated, **over 80% recover and remain well**. **Mortality is increased** — mainly cardiovascular and, to a lesser extent, suicide — and **both severity and duration of symptoms predict mortality**, especially where loneliness coexists. Depression impairs well-being and daily functioning **more than diabetes, heart disease or lung disease**.

Role of ECT — the Specific Sub-Question

- **Indications: severe depression with somatic complications, severe suicidality, catatonia, refusal of food and fluids, and psychotic depression** — in these, **immediate initiation of ECT is indicated**. It is also the option of choice in **pharmacotherapy-resistant depression**.
- **Positioning:** ECT **should be considered a first-line option in all patients with severe depressive symptoms, especially where psychotic features are present** — not merely a last resort.
- **Age and efficacy: Efficacy does not diminish with advancing age**, although the **seizure threshold rises**; indeed **older age is a predictor of better response to ECT**. **ECT rapidly relieves expressed suicidal intent.**
- **Utilisation: Older adults constitute more than half of all patients receiving ECT for depression**, yet it remains **under-utilised despite its relative safety and high effectiveness**.
- **Adverse effects: remarkably few in older age**, the commonest being **reversible cognitive side effects** — transient confusion, anterograde and retrograde amnesia. Pre-procedure cardiovascular assessment is required. There is **no absolute age limit and no absolute contraindication** (raised intracranial pressure and recent MI are relative).
- **Other geriatric indications: severe, treatment-resistant persistent agitation and aggression in dementia**, and refractory mania.
- **TMS as an alternative:** a non-invasive option for depression resistant to at least one antidepressant trial, with **lower risks than antidepressants**, but carrying some seizure risk after stroke or traumatic brain injury.

Latest Updates — 2 Points

11. **OPTIMUM trial (Lenze et al., *NEJM*, March 2023).** In **adults over 60 with treatment-resistant depression**, **augmentation of the existing antidepressant with aripiprazole** improved psychological well-being more than **switching to bupropion** — **remission approximately 28% for aripiprazole and bupropion augmentation versus 19% for a switch to bupropion** — with a **lower fall risk than the bupropion arm**. Step 2 showed lithium augmentation and a switch to nortriptyline were similarly modest. **Aripiprazole augmentation is therefore now the evidence-based next step** in late-life treatment-resistant depression.
12. **ECT versus ketamine (ELEKT-D, *NEJM* 2023) and modern ECT technique.** In **treatment-resistant depression without psychosis**, **subanaesthetic intravenous ketamine was non-inferior to ECT**, offering an alternative where ECT is refused or unavailable — but **ECT remains superior in psychotic depression, catatonia and acute suicidality**, all of which were excluded from that trial. Current practice favours **right unilateral ultrabrief-pulse ECT**, which gives **comparable efficacy with substantially less cognitive impairment** in older adults.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Treatment-resistant depression	Switch antidepressant, or add lithium	**Aripiprazole augmentation first (OPTIMUM 2023)**; lithium and nortriptyline as later steps	Quote OPTIMUM with the remission figures
ECT positioning	Reserved for severe or resistant illness	**First-line where severe, psychotic, catatonic, suicidal or not eating**; ultrabrief right unilateral technique	Write "ECT is not a last resort" explicitly

Question 3. Depression in the elderly — treatment and management in older adults

[7 marks, with a 6-mark version]

Pivot: treatment framework only — the diagnosis is assumed established. Both the 7-mark and the condensed 6-mark version are given, since this question has appeared at both weightings.

Textbook Core — 6 Points

1. **Principles of treatment.** The indications mirror those in younger adults — **severity, duration, previous failed treatment, and patient preference**. **Watchful waiting for mild depression**; **psychotherapy or medication for mild-to-moderate illness**; **antidepressants and ECT have the most convincing evidence in major depression**. **Functional recovery, not just symptom relief, is always part of the goal.**
2. **The stepped-care model. Step 1** — recognition, psychoeducation, exercise, activity scheduling, watchful waiting. **Step 2** — structured psychotherapy (CBT, problem-solving therapy). **Step 3** — antidepressant, with or without psychotherapy. **Step 4** — switch, augment, or refer to specialist services. **Step 5** — **ECT** for severe, psychotic, catatonic or resistant illness.
3. **Non-pharmacological treatment. Psychotherapy is as effective in older as in younger adults, and many older adults prefer counselling to drugs**; there is currently **excessive reliance on drugs and under-use of psychotherapy**. Use **CBT, problem-solving therapy (best if executive dysfunction is present), interpersonal therapy, and reminiscence/life review**. **Exercise is effective**, including for subthreshold symptoms, and suits a stepped-care programme. Add **psychoeducation involving the family**.
4. **Pharmacological treatment. SSRIs are first-line**; **start low — half the usual adult dose — and go slow**; **assess response at 4 weeks and allow 6–12 weeks for full effect**; **never declare failure before an adequate dose has been given for an adequate duration**. Avoid **TCAs, paroxetine and benzodiazepines** wherever possible.
5. **Resistant depression and duration of treatment.** For non-response to an SSRI — **switch antidepressant (within or between classes) or add lithium**; after TCA failure, **lithium augmentation is probably the best option**; **ECT for pharmacotherapy resistance**. **Continue for ≥1 year after a first recurrence, and consider lifelong maintenance after a second or subsequent recurrence.**
6. **Service delivery and comorbidity.** Depression treatment in the elderly **requires a multidisciplinary approach par excellence** — **multidisciplinary outpatient teams are effective**, with nurses central to rehabilitation. Treat **coexisting physical illness, pain, sensory loss, alcohol misuse and loneliness**, review every drug that could be causing depression, and restore ADL function. Monitor **weight, sodium (mEq/L), falls and suicide risk** throughout.

Latest Update — 1 Point

7. **OPTIMUM trial (*NEJM* 2023).** In adults **over 60 with treatment-resistant depression**, **aripiprazole augmentation** of the existing antidepressant was superior to **switching to bupropion** (**remission approximately 28% versus 19%**) and carried a **lower fall risk than bupropion**, making it the **preferred next step** after SSRI or SNRI failure in late life.

Condensed 6-Mark Version — 5 Textbook Points + 1 Latest Update

Textbook Core — 5 Points

1. **Match treatment to severity. Mild — watchful waiting, exercise, activity scheduling. Mild to moderate — psychotherapy (CBT or problem-solving therapy). Moderate to severe — antidepressant, with or without psychotherapy. Severe, psychotic, catatonic, suicidal or not eating — ECT.**
2. **Prescribing rules in the elderly. SSRI first-line at half the starting dose, titrated slowly**; review at 2 weeks for tolerability and at 4–6 weeks for response; allow **up to 12 weeks** for full benefit. **One drug at a time; an adequate dose for an adequate duration before switching.**
3. **Non-response pathway. Switch antidepressant → augment (lithium, or aripiprazole) → ECT.** Never conclude "treatment resistance" without first confirming **adherence, adequate dose and duration, and the absence of an untreated medical cause**.
4. **Special situations. Depression in dementia** — use the **Cornell Scale**, prioritise psychosocial and behavioural measures; drug benefit is modest (the HTA-SADD trial showed no benefit from sertraline or mirtazapine). **Post-stroke depression** — treat actively, since it impairs rehabilitation. **Apathy** — this is not depression; **SSRIs may worsen it**; manage with activity scheduling, music therapy, outdoor activity, and in severe cases a trial of low-dose methylphenidate.
5. **Maintenance and relapse prevention. Continue for ≥1 year after a first recurrence and consider lifelong maintenance after a second.** Maintain the **same dose that achieved remission**; **taper slowly if stopping**; and continue **exercise, social engagement and structured follow-up** as relapse-prevention measures.

Latest Update — 1 Point

6. **USPSTF 2023 (*JAMA*).** A **Grade B recommendation to screen all adults, including those aged ≥65, for major depressive disorder** wherever systems exist for accurate diagnosis, treatment and follow-up — supporting the **collaborative and stepped-care model (PHQ-2 → PHQ-9 or GDS-15 → structured treatment → follow-up)** now built into India's **NPHCE and Ayushman Arogya Mandirs**, with referral through **Tele-MANAS 14416**.

Question 4. Antidepressant medication in late-life depression [7 marks]

Pivot: pure pharmacology — drug classes, choice, dosing, adverse effects and duration.

Textbook Core — 6 Points

1. **General principle. Antidepressants are just as effective in older people as in younger adults**; tolerability, not efficacy, dictates the choice. **"Start low, go slow — but go all the way"**: the commonest error is an inadequate dose for an inadequate duration. Response begins at **4 weeks and takes 6–12 weeks for full effect**, longer than in younger patients.
2. **SSRIs — first-line. Sertraline** (fewest interactions, safest after myocardial infarction) and **escitalopram** are the drugs of choice. Adverse effects: **hyponatraemia and SIADH (check sodium in mEq/L at baseline and at 2 weeks)**, GI upset, **falls and fracture**, **upper gastrointestinal bleeding, especially with NSAIDs or aspirin**, sexual dysfunction, and **QTc prolongation with citalopram and escitalopram** (maximum citalopram **20 mg/day above 60 years**). **Avoid paroxetine** — anticholinergic, short half-life, marked discontinuation symptoms. **Avoid fluoxetine** — very long half-life and CYP inhibition.
3. **SNRIs — second-line. Venlafaxine** (**dose-dependent hypertension**, prominent discontinuation symptoms) and **duloxetine** (useful when **neuropathic pain or stress incontinence** coexists; avoid in significant hepatic or renal impairment). Venlafaxine was **as effective as nortriptyline** in a randomised trial in elderly depressed inpatients.
4. **Other useful agents. Mirtazapine** — noradrenergic and specific serotonergic; the **drug of choice where insomnia, anorexia and weight loss coexist**; causes **sedation and weight gain**, rarely agranulocytosis. **Bupropion** — activating, no sexual dysfunction, but **lowers the seizure threshold**. **Vortioxetine** — possible pro-cognitive benefit. **Trazodone** — low dose for insomnia; causes **orthostatic hypotension**.
5. **Agents to avoid or use with caution. TCAs** — as effective as SSRIs but with far greater risk: **anticholinergic effects (delirium, urinary retention, constipation, glaucoma), orthostatic hypotension and falls, cardiac conduction delay, and lethality in overdose**. If used, **nortriptyline** is preferred, with a **baseline ECG**. **MAOIs** — tyramine and pressor-amine hypertensive crisis, and **fatal serotonin syndrome if combined with an SSRI or pethidine**. The **Beers Criteria list TCAs and paroxetine as potentially inappropriate in older adults**.
6. **Augmentation, duration and stopping.** For non-response to an SSRI — **switch, or add lithium**; **after TCA failure, lithium augmentation is probably the best option**; **ECT for treatment resistance**. **Continue at the remission dose for ≥1 year after a first recurrence and consider lifelong maintenance after a second or subsequent recurrence. Never stop abruptly** — taper over weeks to avoid a discontinuation syndrome of dizziness, flu-like symptoms, electric-shock sensations and insomnia.

Latest Update — 1 Point

7. **Antidepressant discontinuation (2023–2025).** A **2024 *Lancet Psychiatry* systematic review and meta-analysis** quantified discontinuation symptoms — commonest with **paroxetine and venlafaxine**, least with fluoxetine — and the **Maudsley Deprescribing Guidelines (2024)** established **hyperbolic tapering** (progressively smaller absolute dose reductions, guided by receptor occupancy rather than fixed steps) as the recommended method. This matters especially in older adults, in whom **withdrawal symptoms are easily mistaken for relapse**.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Next step after SSRI failure	Switch, or add lithium	**Aripiprazole augmentation (OPTIMUM 2023)** ahead of lithium or nortriptyline	Name the trial and the drug
Stopping antidepressants	"Taper gradually"	**Hyperbolic taper over months**; distinguish withdrawal from relapse	Add one line on hyperbolic tapering

Question 5. Bipolar affective disorder in late life [15 marks]

Textbook Core — 10 Points

1. **Definition and terminology. Older-age bipolar disorder (OABD)** refers to bipolar disorder in those aged **≥50–60 years**. Two groups exist — **early-onset illness ageing into old age (about two-thirds)** and **late-onset disease with first episode after 50 (about one-third)**.
2. **Epidemiology.** Community prevalence is only **0.5–1%** above 65 years, but bipolar disorder accounts for **5–10% of geriatric psychiatry outpatients** and a large share of psychiatric emergency presentations. It is one of the three conditions classed as **severe mental illness (SMI)**, along with schizophrenia and schizoaffective disorder.
3. **Late-onset mania is "secondary mania" until proved otherwise.** Strong association with **cerebrovascular disease ("vascular mania")**, **right frontal or basotemporal stroke**, head injury, **frontotemporal dementia**, hyperthyroidism, and drugs — **corticosteroids, levodopa, antidepressants**.
4. **Clinical features.** Mania is **attenuated with age** — **irritability, dysphoria, confusion and paranoia** rather than classic euphoria. **Mixed states are common**; **depressive episodes are more frequent and longer**; cognitive impairment is prominent and may mimic dementia (**"pseudo-dementia of mania"**).
5. **Differential diagnosis. Unipolar depression** (the commonest misdiagnosis), **delirium**, **frontotemporal dementia**, agitation of dementia, alcohol/substance misuse, hyperthyroidism, and steroid-induced mood change.
6. **Assessment.** Full physical and neurological examination, complete drug review, **TSH, sodium (mEq/L), calcium (mg/dL), renal and liver function, B12**, ECG, cognitive testing, and **neuroimaging in every first-ever manic episode**. Always assess **suicide risk** — cardiovascular disease is the leading cause of death in SMI, but suicide remains a major contributor.
7. **Acute mania — management. Lithium or valproate** is first-line. The **GERI-BD trial** (the only RCT in those ≥60 years) found lithium and divalproex **comparably effective**, with lithium marginally superior on symptom reduction. Atypical antipsychotics (**quetiapine, aripiprazole, risperidone**) at **one-third to one-half adult dose**. **ECT** for severe, refractory or catatonic mania.
8. **Lithium in the elderly.** Remains the **gold standard for maintenance** and the only agent with a proven **anti-suicidal effect**. Use **30–50% lower doses** and lower target levels. Monitor **creatinine (mg/dL), eGFR, TSH, calcium, ECG**. Toxicity is precipitated by **thiazides, ACE inhibitors/ARBs, NSAIDs, dehydration, diarrhoea and fever**; **neurotoxicity can occur at apparently therapeutic levels**.
9. **Alternative mood stabilisers. Valproate** — monitor LFT, platelets, ammonia (**hyperammonaemic encephalopathy**), parkinsonism, weight gain. **Lamotrigine** — best for bipolar depression maintenance; needs **slow titration** because of rash and Stevens–Johnson syndrome. **Carbamazepine — best avoided** (enzyme induction, hyponatraemia, interactions). **Antidepressant monotherapy is contraindicated** — risk of switch and rapid cycling.
10. **Course, comorbidity and outcome.** High burden of **metabolic syndrome and cardiovascular disease**, greater risk of **cognitive decline and dementia**, poor medication adherence, functional impairment and **excess mortality (CVD death 2–3 times general population)**. Management must include **psychoeducation, adherence support, carer involvement, and aggressive cardiovascular risk factor control**.

Latest Updates — 2 Points

11. **ISBD Older-Age Bipolar Disorder Task Force (2025–26 systematic review, *Bipolar Disorders*).** Supports **age-stratified lithium targets** rather than the adult range of 0.6–1.2 mEq/L: **0.4–0.8 mEq/L for ages 60–79 years** and **0.4–0.7 mEq/L for those ≥80 years**, with more frequent renal monitoring.
12. **AGS Beers Criteria 2023 and current reviews (2024–25).** Beers flags **lithium with loop diuretics or ACE inhibitors** as potentially inappropriate unless levels are closely monitored. Contemporary reviews confirm **quetiapine and aripiprazole** as the preferred antipsychotics in OABD (least EPS and metabolic burden), and note a possible **neuroprotective / dementia-risk-reducing signal for lithium**.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Lithium level	Standard adult therapeutic range quoted	ISBD age-stratified: **0.4–0.8 mEq/L (60–79 y)**, **0.4–0.7 mEq/L (≥80 y)**	Quote the age-stratified figures and attribute to the ISBD OABD Task Force
Cognition	Cognitive change described as secondary	Cognitive impairment recognised as a **core, often persistent feature** of OABD with increased dementia risk	Add cognitive assessment as a standing part of follow-up

Question 6. Geriatric Depression Scale — administration and interpretation [7 marks]

Textbook Core — 6 Points

1. **Purpose.** A **screening — not diagnostic — instrument** for depression in older adults, developed by **Yesavage and Brink (1982)**. Its defining feature is that it **deliberately excludes somatic items** (appetite, sleep, weight, libido, energy) that overlap with physical illness in old age, and instead asks about **mood, satisfaction and outlook**.
2. **Format and administration.** Simple **yes/no answers referring to the past one week**. Versions: the original **GDS-30**, the widely used **GDS-15**, and ultra-brief **GDS-10, GDS-5 and GDS-4**. It may be **self-administered or interviewer-administered** (read aloud for visual impairment or low literacy); **GDS-15 takes about 5 minutes**, GDS-30 about 10.
3. **Scoring. One point for each answer in the depressed direction**; some items are **positively worded and reverse-scored** (a "no" scores the point). **GDS-15: 0–4 normal, 5–8 mild, 9–11 moderate, 12–15 severe** — the usual screen-positive **cut-off is ≥5**. **GDS-30: a score ≥11 suggests depression.**
4. **Interpretation.** A positive score is **not a diagnosis** — it mandates a **full diagnostic interview against DSM-5 / ICD-11 criteria**, plus explicit assessment of **suicidal ideation** (asking about suicide does not increase risk and usually relieves the patient). Serial scores are useful to **monitor treatment response**.
5. **Advantages.** The **yes/no format suits cognitive and sensory impairment**; validated across **community, outpatient, hospital and long-term-care settings**; free of cost, brief, and **translated and validated in multiple Indian languages**; sensitivity and specificity around **80–90%** for GDS-15. The **GDS-3A subset** of three items can also screen for **apathy**.
6. **Limitations. Unreliable in moderate-to-severe dementia (MMSE below about 15)** — the **Cornell Scale for Depression in Dementia (CSDD)**, which uses informant input, should be used instead. Performance is affected by **education, literacy, culture and language**; it is **not valid in delirium**; and it does not assess severity for treatment selection or cover psychotic features.

Latest Update — 1 Point

7. **Screening policy (2023–2025).** The **USPSTF (2023, *JAMA*)** reaffirmed with a **Grade B recommendation that all adults, including older adults, be screened for depression** wherever systems exist for accurate diagnosis, treatment and follow-up. Current evidence supports **PHQ-2/PHQ-9 and GDS-15 as interchangeable first-line tools**, with the **Cornell Scale reserved for those with dementia**. In India, the **NPHCE** and **Ayushman Arogya Mandirs** now include routine depression screening of older adults at the primary-care level, with referral through **Tele-MANAS (14416)**.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Tool of choice	GDS-15/GDS-30 listed as the assessment tool, PHQ-2 as screener	**PHQ-2 → PHQ-9 or GDS-15 are interchangeable**; CSDD if dementia present	Name GDS-15 first, then state when to switch to the Cornell Scale
Who to screen	Screen when clinically suspected	**USPSTF 2023 — screen all adults**, provided follow-up systems exist	Quote "USPSTF 2023, Grade B" for a guaranteed mark

Exam one-liners: *Yesavage & Brink 1982 · yes/no format · past one week · somatic items deliberately excluded · GDS-15 cut-off ≥5 · GDS-30 cut-off ≥11 · GDS-15 takes 5 minutes · invalid if MMSE <15 → use Cornell Scale · screening tool, never diagnostic.*

If asked for 15 marks, add: *the item list of the GDS-15 with reverse-scored items identified; comparison table of GDS vs PHQ-9 vs CSDD vs Hamilton and Montgomery–Åsberg scales; psychometric data (validation studies, Cronbach's alpha, ROC cut-offs by setting); use in special populations (stroke, Parkinson's disease, hospitalised, long-term care); Indian validation studies and LASI data on late-life depression prevalence; and the collaborative-care model of stepped depression management following a positive screen.*

Section B — Suicide, Self-Harm and Clinical Emergencies

Suicide risk in older people, and the two clinical vignettes that test it in practice.

Question 7. Suicide in elders and suicide risk assessment [7 marks]

Textbook Core — 6 Points

1. **Magnitude. Suicide rates are higher in older adults than in most other age groups and have risen over the last decade.** The **WHO estimates rates at age 75 of about 50 per 100,000 in men and 16 per 100,000 in women** — **older men account for considerably more deaths by suicide than women**. In India, **NCRB data show suicides among those aged 60 and above rose from about 11,000 in 2019 to over 15,000 in 2022 — a 40% increase, nearly double the rise in overall suicides**, with **illness the leading recorded cause**.
2. **Why elderly suicide is different — the high-yield contrast.** Older adults **give fewer warnings**, **use more lethal methods**, and have a far lower **attempt-to-completion ratio — about 4:1, compared with 200:1 in adolescents**. Intent is more often **determined and less impulsive**, so **every attempt in an older person must be treated as high risk**.
3. **The missed opportunity. Some 20–50% of older adults who die by suicide have seen their primary care physician within the preceding week**, and most have visited a care facility within the year. **Clinicians are less apt to decide that suicidal thinking in an older adult is a serious condition that may respond to treatment** — this ageist assumption is the central barrier to prevention.
4. **Risk factors. Depression is the strongest risk factor for suicide and for suicidal ideation**, and **non-fatal self-harm is the strongest risk factor for subsequent suicide**. Others include **alcohol and substance misuse, loneliness, recent loss, previous suicide attempt, unrelenting pain, loss of purpose, feelings of being a burden, feelings of being abandoned or rejected by family, and physical disability**, together with male sex, widowhood and living alone. **Protective factors are strong ties to social, family and religious support networks.**
5. **Risk assessment. Ask directly — asking about thoughts of death or suicide is not linked to an increased risk of an attempt; most patients are relieved, and it builds patient-physician trust.** A thorough assessment covers **not only stated suicidal wishes but also behaviours indicating hopelessness and intention to end one's life** — withdrawal, giving away possessions, settling affairs, refusing food or medication. Use **collaborative assessment involving family, nurse and social worker**, and formal instruments (**GDS-15**, Columbia Suicide Severity Rating Scale, Beck Hopelessness Scale). **Every older adult with suicidal ideas or self-harm needs assessment by a psychiatrist, preferably a geriatric psychiatrist.**
6. **Management and prevention. Ensure immediate safety** — admit where there is intent, a plan, psychosis or inadequate supervision; arrange **means restriction with family involvement**. **Prompt and vigorous treatment of depression reduces suicide risk**, and **ECT rapidly relieves expressed suicidal intent** in severe suicidality. At population level, **depression care managers and education of primary care providers reduce suicide risk regardless of depression severity**; **treat loneliness and social isolation**; and **involve the family in understanding the meaning of the suicidal thoughts**, with education and family therapy where appropriate.

Latest Update — 1 Point

7. **India's National Suicide Prevention Strategy, 2022 — the country's first, targeting a 10% reduction in suicide mortality by 2030.** Its pillars are **restricting access to means (including regulation of highly hazardous pesticides), strengthening health services and gatekeeper training, responsible media reporting, and improved suicide surveillance**. It specifically recommends **psychosocial support within the treatment plan for older adults with chronic or terminal illness**, a provision now being routed through **NPHCE**. This sits alongside **Section 115 of the Mental Healthcare Act 2017**, which **decriminalised attempted suicide** by presuming severe stress, and the national helplines **Tele-MANAS (14416)** and **Elder Line (14567)**.

Question 8. A 65-year-old woman presents with loss of appetite, lack of interest in daily work, considerable weight loss and insomnia. She is teary and upset during the consultation, has thoughts of worthlessness and has contemplated killing herself. What would be your approach? What classes of drugs can be given safely in this age group, what is their side-effect profile, and what would be your follow-up? [7 marks]

Textbook Core — 6 Points

1. **Recognise the diagnosis.** She fulfils DSM-5 criteria for **major depressive disorder, severe** — **anhedonia (lack of interest), anorexia, significant weight loss, insomnia, tearfulness, worthlessness and suicidal ideation** for at least two weeks. The presence of **weight loss, insomnia and psychomotor change suggests melancholic features**, which predict a good response to antidepressants and to ECT.

2. **Immediate priority — suicide risk assessment and safety. Ask directly and explicitly** about thoughts of death, intent, plan, timing, means, preparatory acts (settling affairs, giving away possessions), previous attempts and **hopelessness — asking does not increase risk**. Assess protective factors (family, faith, dependants). **Admit** if there is **active intent or a plan, psychotic features, refusal of food and fluids, severe agitation, or no reliable supervision at home**. Arrange **means restriction with the family, remove access to stored medicines, ensure supervision, and provide a written safety plan with crisis numbers — Tele-MANAS 14416 and Elder Line 14567**.
3. **Exclude a physical cause — do not assume the weight loss is psychiatric.** Full history, drug review and examination, then **CBC, ESR, sodium and potassium (mEq/L), calcium (mg/dL), fasting glucose (mg/dL), renal and liver function, TSH, vitamin B12 and folate, urine analysis, chest X-ray and ECG**, with further malignancy screening as indicated. Screen cognition (**MoCA**) and rate severity (**GDS-15** or PHQ-9) as a baseline for monitoring response.
4. **Drug classes that can be given safely, with their side-effect profiles** — see the table below.
5. **Complete the treatment package.** Add **psychotherapy — CBT or problem-solving therapy**, which is as effective in older as in younger adults; **psychoeducation with the family**; **exercise and activity scheduling**; **nutritional support** for the weight loss; and treat pain, sensory impairment and loneliness. **If she becomes psychotic or catatonic, refuses food and fluids, or remains acutely suicidal, ECT is indicated immediately — not as a last resort.**
6. **Follow-up plan. Review within 1 week** (earlier if discharged with suicidal ideation), then **weekly for the first month**, **fortnightly to 3 months**, then **monthly**. At each visit reassess **suicidal ideation, response (GDS/PHQ-9), adherence, weight and adverse effects**. **Check serum sodium (mEq/L) at baseline and 2 weeks after starting an SSRI**, and again after any dose increase. **Expect partial response by 4 weeks and full response by 6–12 weeks**; if there is no response by then, **switch or augment**. **Continue at the remission dose for at least 1 year**, and involve the family in relapse recognition.

Drug Classes and Side-Effect Profile

Class / drug	Why chosen here	Main adverse effects
SSRI — sertraline 25 mg → 50–100 mg (first-line)	Best evidence, safest cardiac profile, fewest interactions	**Hyponatraemia / SIADH**, GI upset, **falls and fracture**, **GI bleeding with NSAIDs**, sexual dysfunction
SSRI — escitalopram 5 mg → 10 mg	Alternative first-line agent	As above, plus **QTc prolongation** — maximum 10 mg in those ≥60 years
Mirtazapine 7.5 mg → 15–30 mg at night	**Best fit for this patient — insomnia, anorexia and weight loss**	Sedation, **weight gain**, dizziness, rarely agranulocytosis
SNRI — venlafaxine / duloxetine	Second-line; duloxetine if pain coexists	**Dose-related hypertension**, nausea, prominent discontinuation symptoms
Avoid — TCAs, paroxetine, benzodiazepines	—	Anticholinergic delirium, orthostatic hypotension, **cardiotoxicity in overdose**; benzodiazepines cause falls, cognitive impairment and dependence

Latest Update — 1 Point

7. **Suicide-risk screening and safety planning (2023–2025).** The **USPSTF 2023** issued an **I-statement — the evidence is insufficient to recommend universal suicide-risk screening in asymptomatic adults**, so the current standard is **targeted assessment in everyone who screens positive for depression**, as this patient does. The interventions with the best trial evidence for reducing subsequent attempts are the **Safety Planning Intervention combined with structured follow-up contact**, together with **means-restriction counselling involving the family**; both are embedded in the **Zero Suicide** care model.

Question 9. A 60-year-old man was found unconscious in the fields with profuse frothing at the mouth. He was well the previous night and had his usual dose of alcohol with his meal. He had incurred heavy debts after marrying off his daughter and had appeared depressed of late. How would you assess, investigate, diagnose and treat him based on evidence in literature? [15 marks]

> **Working diagnosis: Acute organophosphorus (anticholinesterase) compound poisoning, most probably deliberate self-poisoning** — the combination of an agricultural setting, unconsciousness with **profuse frothing (bronchorrhoea and salivation)**, recent **heavy debt**, **low mood** and **alcohol use** is the classic Indian examination presentation. **Differential diagnosis must still be considered:** generalised tonic-clonic seizure with post-ictal state, aluminium phosphide or carbamate or pyrethroid poisoning, snake bite (neurotoxic), heat stroke, hypoglycaemia, stroke, alcohol withdrawal seizure, and acute coronary syndrome with pulmonary oedema.

Textbook Core — 10 Points

1. **Immediate resuscitation comes before diagnosis. Airway, Breathing, Circulation, Disability, Exposure.** Position laterally, **suction copious secretions repeatedly**, give **high-flow oxygen**, and secure the airway by **early intubation** if there is a reduced conscious level, inability to protect the airway, uncontrolled bronchorrhoea or respiratory muscle weakness. Establish **two wide-bore IV lines**, attach a monitor, and check a **capillary blood glucose immediately**. **Wear gloves and an apron and decontaminate the patient** — remove all clothing and wash the skin and hair with soap and water — to protect both the patient and the staff from continuing dermal absorption.
2. **Recognise the toxidrome.** Anticholinesterase poisoning produces a **cholinergic crisis**. **Muscarinic (DUMBBELS)** — **D**iarrhoea, **U**rination, **M**iosis, **B**ronchorrhoea, **B**radycardia, **E**mesis, **L**acrimation, **S**alivation; **bronchorrhoea and bronchospasm are what kill**. **Nicotinic** — fasciculations, muscle weakness, cramps, **respiratory muscle paralysis**, tachycardia, hypertension, mydriasis. **Central** — anxiety, confusion, **seizures, coma and central respiratory depression**. A **garlic-like odour** on the breath or clothes supports the diagnosis.
3. **History and examination.** Obtain a history from **family, neighbours and the people who found him**; ask for the **container, label or a sample of the substance**, the **time of exposure and the approximate amount**, and the route. Document the **psychiatric history — depression, previous attempts, alcohol use, the debt and the recent marriage of his daughter**. Examine for **pupil size, secretions, chest crackles and wheeze, fasciculations, muscle power, reflexes, conscious level (GCS), temperature, and evidence of head injury, snake bite, or aspiration**. Grade severity using the **Peradeniya Organophosphorus Poisoning (POP) scale**.
4. **Investigations. Confirmatory** — **plasma (pseudo)cholinesterase and red cell acetylcholinesterase**; **RBC AChE correlates best with severity and with recovery**, and a **persistently low level is a useful diagnostic marker**. **Baseline and monitoring** — CBC, **sodium and potassium (mEq/L)**, **calcium and magnesium (mg/dL)**, **random blood sugar (mg/dL)**, renal and liver function, **serum amylase and lipase** (pancreatitis is common), **arterial blood gas**, **ECG** (look for **QTc prolongation, bradyarrhythmia and torsades**), **chest X-ray** (aspiration, pulmonary oedema), and **troponin** where indicated. Add a **toxicology screen and blood alcohol**, and **CT head** if the conscious level does not improve as expected.
5. **Atropine — the life-saving antidote, given by rapid dose escalation. Optimise oxygenation before giving atropine** to minimise the risk of dysrhythmia. Give an **initial IV bolus and then double the dose every 5 minutes** (for example 2 → 4 → 8 → 16 mg) until **atropinisation** is achieved. **Far larger doses are needed than for any other indication** — commonly tens of milligrams in the first day. **Endpoints of atropinisation: clear chest on auscultation, dry axillae, heart rate above 80/min, systolic BP above 80 mmHg, and pupils no longer pinpoint**. **Clearing of secretions, not pupil size alone, is the target.** Then maintain with an **infusion titrated to these endpoints**, and watch for **atropine toxicity — hyperthermia, delirium, ileus, urinary retention and tachyarrhythmia**.
6. **Oximes and benzodiazepines. Pralidoxime** reactivates acetylcholinesterase before **"ageing"** of the enzyme occurs, and is therefore most useful **early**; it acts mainly on the **nicotinic features — fasciculations, weakness and respiratory muscle paralysis**. Give as a **loading dose followed by a continuous infusion**. **Its clinical benefit is genuinely controversial** — Indian and international randomised trials have shown **no appreciable benefit of adding pralidoxime to atropine** on mortality, ventilation requirement or length of stay, and high-dose regimens have been associated with more respiratory complications; nonetheless it remains standard therapy in most Indian protocols. **Benzodiazepines (diazepam or midazolam) are indicated for seizures, agitation and fasciculations**, and are neuroprotective.
7. **Decontamination and supportive care. Gastric lavage only if the patient presents within about one hour, with a protected airway**, and it is **never** to be performed in an unprotected unconscious patient; **a single dose of activated charcoal** may be considered early. Otherwise **meticulous supportive care determines the outcome** — mechanical ventilation, **repeated suction**, fluid and electrolyte correction (especially **hypokalaemia and hypomagnesaemia**), glycaemic control, **nutrition**, **DVT and stress-ulcer prophylaxis**, pressure-area care, and prevention and treatment of **aspiration pneumonia** — the commonest cause of late death.

8. **Anticipate the three phases and their complications. (i) Acute cholinergic crisis** — minutes to hours. **(ii) Intermediate syndrome** — **24–96 hours after apparent recovery**, with **proximal limb, neck flexor, cranial nerve and respiratory muscle weakness**, requiring **ventilation**; anticipate it by serial **neck-flexion and single-breath-count testing**, and do not extubate prematurely. **(iii) Organophosphate-induced delayed polyneuropathy (OPIDN)** — **2–3 weeks later**, a distal sensorimotor axonopathy. Also watch for **arrhythmia and torsades, pancreatitis, hyperglycaemia and neuropsychiatric sequelae** — depression, cognitive deficits and recurrent seizures are documented in survivors.
9. **Manage the alcohol dimension.** He drinks regularly, so **anticipate alcohol withdrawal from 6–72 hours after admission**, which may be misread as atropine toxicity or as the intermediate syndrome. Give **parenteral thiamine before any glucose-containing fluid** to prevent Wernicke's encephalopathy, monitor with **CIWA-Ar where the patient is conscious**, use **short-acting benzodiazepines**, and correct **magnesium, potassium and phosphate**. Screen formally with **CAGE or SMAST-G** once he is awake, and treat the alcohol use disorder as part of the discharge plan.
10. **The psychiatric and medico-legal management — where most marks are lost.** Once medically stable, arrange a **formal psychiatric assessment before discharge** for every patient after deliberate self-poisoning. Diagnose and treat the **depressive illness** — the strongest risk factor for suicide — with an **SSRI plus psychotherapy**; **problem-solving therapy is particularly appropriate** given a debt-related, problem-focused crisis. Conduct a **structured suicide risk assessment** — intent, planning, ongoing wish to die, hopelessness, previous attempts — remembering that **an older person's attempt carries far higher lethality and a much lower attempt-to-completion ratio**. Arrange **means restriction and family supervision**, a written **safety plan**, **social work referral** for the debt, and **structured follow-up contact after discharge**. Medico-legally, **Section 115 of the Mental Healthcare Act 2017 presumes severe stress and protects him from prosecution**, and imposes a duty on the state to provide care and rehabilitation; document injuries carefully, preserve samples, and inform the police as required for a medico-legal case while maintaining a non-judgemental therapeutic stance. Signpost **Tele-MANAS 14416** and, given his age, **Elder Line 14567**.

Latest Updates — 2 Points

11. **2023 American Heart Association guidelines for the management of patients with cardiac arrest or life-threatening toxicity due to poisoning.** These recommend **immediate atropine for bronchospasm, bronchorrhoea, seizures or significant bradycardia in severe organophosphate poisoning**, with **rapid dose-doubling escalation** to achieve atropinisation, and note that **early oximes may be considered — particularly where there are fasciculations, weakness or paralysis — but "are not universally effective."** Recent reviews (2024–2025) additionally evaluate **magnesium sulphate, sodium bicarbonate, fresh frozen plasma and haemoperfusion** as adjuncts, all of which remain **investigational and are not standard of care**.
12. **Means restriction as the highest-yield preventive intervention. India's National Suicide Prevention Strategy 2022** — the country's first, targeting a **10% reduction in suicide mortality by 2030** — places **restricting access to highly hazardous pesticides** as its leading pillar, alongside gatekeeper training, responsible media reporting and improved surveillance; India has progressively **banned or restricted several highly hazardous pesticide formulations**, and WHO's **LIVE LIFE** framework cites national pesticide bans as the single most cost-effective population-level suicide-prevention measure. **NCRB data show suicides in those aged 60 and above rose about 40% between 2019 and 2022**, with **illness the leading recorded cause** — making systematic psychiatric follow-up of survivors such as this patient a national priority.

Section C — Anxiety and Related Disorders

The anxiety spectrum, from the general essay through GAD, phobias, OCD and the somatoform disorders.

Question 10. Give an account of anxiety disorders and their management [15 marks]

Textbook Core — 10 Points

1. **Core principle. Disabling anxiety symptoms are not a normal part of ageing. Anxiety disorders are the most prevalent but most under-treated psychiatric disorders in older adults** — under-recognised because symptoms are attributed to physical illness or to ageing itself.
2. **Characteristic themes in late life.** Worries centre on **physical illness and its impact on quality of life — pain, disability and the possibility of death**, and are **exacerbated by feelings of isolation and dependence in hospital or long-term care**. The content is **realistic and health-focused**, unlike the occupational and existential worries of younger adults.
3. **Classification and relative frequency. Agoraphobia and panic disorder are the most common anxiety disorders in older adults**, followed by **phobias** — including the geriatric-specific **fear of falling** — and then **generalised anxiety disorder**. **Half of older adults with GAD have had symptoms for most of their lives; the other half developed GAD within the last five years.** Also relevant are **PTSD**, which may re-emerge in late life, and **obsessive-compulsive disorder**.
4. **The central diagnostic difficulty — comorbidity.** There is **substantial comorbidity of medical and anxiety disorders**, and **physiological symptoms of anxiety may themselves be a manifestation of a medical condition or an adverse effect of a prescribed drug** — this frequently confounds detection. **Incapacitating anxiety symptoms are common in COPD, in patients with pacemakers, and in Parkinson's disease.**
5. **Anxiety as a component of depression. Anxiety symptoms are a common component of depression in older adults, and their presence is associated with an increased likelihood of treatment resistance with antidepressants.** DSM-5 recognises this through the **"with anxious distress" specifier**. **Always screen a newly anxious older patient for depression — and treat the depression.**
6. **Secondary and drug-induced anxiety. Hyperthyroidism**, hypoglycaemia, phaeochromocytoma, arrhythmia, angina, pulmonary embolism, COPD and delirium. Drugs: **over-the-counter sympathomimetics, beta-2 agonists (albuterol/salbutamol), caffeine, nicotine, corticosteroids, dopamine agonists and thyroxine**; and **withdrawal states — alcohol and benzodiazepine withdrawal**. **New onset of panic attacks in an older person requires a thorough evaluation for an underlying general medical condition.**
7. **Assessment.** Detailed history plus informant account; **screen for depression, cognitive impairment, alcohol and drug use**; rate with **GAD-7, the Geriatric Anxiety Inventory, the Geriatric Anxiety Scale or HAM-A**. Investigations directed by the presentation — **TSH, glucose (mg/dL), calcium (mg/dL), ECG, oxygen saturation** — plus a **full drug review including over-the-counter preparations**.
8. **Non-pharmacological management — first-line. Relaxation training, mindfulness-based interventions and cognitive behavioural therapy are safer than and, in the long term, as effective as benzodiazepines.** Add **psychoeducation with family**, **sleep hygiene**, **reduction of caffeine, nicotine and alcohol**, **exercise**, correction of sensory impairment, and **graded exposure** for phobic avoidance. **Many older adults prefer counselling to psychopharmacological intervention.**
9. **Pharmacological management. SSRIs — escitalopram and sertraline — are considered first-line. SNRIs and vortioxetine are second-line. Buspirone** is an option, primarily for **GAD**. **The therapeutic effects of antidepressants and buspirone may take up to six weeks to become noticeable** — warn the patient, or treatment will be abandoned early. **Antipsychotics such as quetiapine should generally not be used for anxiety disorders, as the risks outweigh the benefits.**
10. **Benzodiazepines — the key caution.** They are **often effective in the short run but problematic**, carrying a **high risk of cognitive impairment, falls and fractures**. **Judicious short-term use of a short-acting agent such as lorazepam may be necessary if symptoms are incapacitating, only until other interventions become effective. Chronic use (beyond 120 days) is prevalent, growing, commoner in women, and at higher doses in older adults**; discontinuation is complex, best supervised by a psychiatrist, and **may need several months**. Note that **depression presenting with anxiety features is often inappropriately treated with a benzodiazepine rather than an antidepressant or psychotherapy**.

Latest Updates — 2 Points

11. **USPSTF 2023 (*JAMA*).** For the first time, a **Grade B recommendation to screen for anxiety disorders in adults aged 19–64**, but an explicit **I-statement — the evidence is insufficient to assess the balance of benefits and harms of screening in adults aged 65 and above**, with clinicians advised to use clinical judgement based on risk factors, comorbidity and life events. This is the single most quotable current statement on anxiety in old age and highlights the evidence gap.

12. **Mindfulness as an equal alternative to drug therapy (Hoge et al., *JAMA Psychiatry* 2023).** In a randomised trial in adults with anxiety disorders, an **8-week mindfulness-based stress reduction programme was non-inferior to escitalopram**, with **fewer adverse events** — supporting mindfulness-based intervention as a genuine first-line alternative in older adults, in whom drug adverse effects and interactions are the limiting factor.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Screening	Based on clinical suspicion	**USPSTF 2023 — Grade B for ages 19–64, I-statement for ≥65**	Quote the age split precisely
Non-drug therapy	CBT and relaxation as alternatives to drugs	**Mindfulness non-inferior to escitalopram (2023)** — a first-line option, not merely an adjunct	Name the JAMA Psychiatry trial

Question 11. Anxiety in the elderly; generalised anxiety disorder [7 marks, with a 6-mark version]

Pivot: GAD-specific, so as not to repeat the general anxiety essay in Question 10. Both weightings are given, since this question has appeared as both a 7-mark and a 6-mark note.

Textbook Core — 6 Points

1. **Definition.** GAD is **excessive, difficult-to-control worry about multiple events or activities, present on most days for at least 6 months**, with **at least three of: restlessness, fatigue, poor concentration, irritability, muscle tension and sleep disturbance**, causing distress or functional impairment.
2. **Epidemiology and onset pattern. GAD is the anxiety disorder next in frequency after agoraphobia and panic disorder in older adults.** Crucially, **half of older adults with GAD have had symptoms for most of their lives, whereas the other half report developing GAD within the last five years** — so **both lifelong and genuinely late-onset GAD exist**, and late onset should prompt a search for a medical or drug cause.
3. **Clinical presentation in old age.** Worry is **realistic and health-centred** — about **illness, pain, disability, falls, finances, dependency and death**. Somatic presentation dominates: **palpitations, tremor, dizziness, gastrointestinal symptoms, muscle tension and insomnia**. Older patients typically present to a physician rather than a psychiatrist and **rarely volunteer the word "anxiety"**.
4. **Differential diagnosis. Depression with anxious distress** — the most important, since **anxiety symptoms in depression predict antidepressant treatment resistance**; **medical causes** — hyperthyroidism, arrhythmia, angina, COPD, hypoglycaemia, delirium; **drug-induced anxiety** — sympathomimetics, **beta-2 agonists such as albuterol**, caffeine, nicotine, steroids; and **withdrawal states — alcohol and benzodiazepine**. Also consider early dementia and akathisia.
5. **Assessment.** History plus informant account; **screen for depression first**; rate with **GAD-7, the Geriatric Anxiety Inventory or HAM-A**; conduct a full **drug and over-the-counter review**; targeted tests — **TSH, glucose (mg/dL), calcium (mg/dL), ECG, oxygen saturation**. Assess functional impact — avoidance, restricted mobility and carer burden.
6. **Management. Non-pharmacological first — CBT, relaxation training and mindfulness-based interventions are safe and, in the long term, as effective as benzodiazepines**; add sleep hygiene, reduction of caffeine and alcohol, and exercise. **Drugs: SSRIs (escitalopram, sertraline) first-line; SNRIs and vortioxetine second-line; buspirone is an option primarily for GAD. Warn that the effect may take up to six weeks. Do not use antipsychotics such as quetiapine** — the risks exceed the benefits. **Benzodiazepines only short-term, short-acting, and only where symptoms are incapacitating.**

Latest Update — 1 Point

7. **Mindfulness-based stress reduction is non-inferior to escitalopram (Hoge et al., *JAMA Psychiatry* 2023)** in adults with anxiety disorders including GAD, with **fewer adverse events** — a particularly important finding in older adults, where drug tolerability is the limiting factor. This is reinforced by the **2023 AGS Beers Criteria**, which list **benzodiazepines as potentially inappropriate in all older adults** irrespective of indication or duration of use.

Condensed 6-Mark Version — 5 Textbook Points + 1 Latest Update

Textbook Core — 5 Points

1. **Anxiety is not normal ageing. Anxiety disorders are the most prevalent but most under-treated psychiatric disorders in older adults.** In order of frequency: **agoraphobia and panic disorder → phobias (including fear of falling) → generalised anxiety disorder**.

2. **Always exclude the three mimics before diagnosing. (i) Medical disease** — hyperthyroidism, arrhythmia, angina, hypoglycaemia, COPD, delirium; **(ii) drugs** — sympathomimetics, **beta-2 agonists**, caffeine, nicotine, steroids, dopamine agonists; **(iii) withdrawal** — alcohol and benzodiazepines. **New onset of panic attacks in an older person always requires a thorough medical evaluation.**
3. **Then exclude depression. Anxiety symptoms are a common component of late-life depression**, and their presence **predicts antidepressant treatment resistance**. Treating the depression treats the anxiety; treating the anxiety alone with a benzodiazepine is a recognised prescribing error.
4. **Non-drug treatment is first-line. CBT, relaxation training and mindfulness-based interventions are safer than, and in the long term as effective as, benzodiazepines**, and many older adults prefer them. Add sleep hygiene, exercise, correction of sensory impairment, and reduction of caffeine, nicotine and alcohol.
5. **Drug treatment with the geriatric rules. SSRIs (escitalopram, sertraline) first-line; SNRIs and vortioxetine second-line; buspirone for GAD**; allow **up to six weeks** for effect. **Do not use antipsychotics for anxiety. Benzodiazepines only short-term, short-acting, for incapacitating symptoms** — they cause **cognitive impairment, falls and fractures**, and **chronic use beyond 120 days is common and difficult to reverse**, requiring psychiatrist-supervised withdrawal over months.

Latest Update — 1 Point

6. **USPSTF 2023 (*JAMA*).** A **Grade B recommendation to screen for anxiety disorders in adults aged 19–64**, but an explicit **I-statement for adults aged 65 and above — the evidence is insufficient**, with clinicians advised to screen on the basis of clinical judgement, risk factors, comorbidity and recent life events. Where screening is undertaken, use the **GAD-2/GAD-7 or the Geriatric Anxiety Inventory**.

Question 12. Phobias in old age [7 marks]

Textbook Core — 6 Points

1. **Definition.** A phobia is a **marked, persistent and excessive fear of a specific object, situation or activity**, out of proportion to the actual danger, leading to **avoidance** and functional impairment. Types: **specific phobia**, **social anxiety disorder** and **agoraphobia**.
2. **Epidemiology. Phobias are prevalent, chronic and often persist into old age** — most are long-standing rather than newly acquired. **Agoraphobia is, with panic disorder, the commonest anxiety disorder in older adults**, and in late life it is frequently **secondary** — arising after a fall, a stroke, a myocardial infarction or the onset of incontinence, rather than being primary.
3. **Fear of falling — the geriatric-specific phobia. A typical phobia seen in older adults, especially those with a history of fall and fracture, and rare in younger adults.** It affects **up to half of all fallers and a substantial proportion of non-fallers**. It produces **activity restriction → deconditioning, muscle weakness, gait change and social withdrawal → further falls** — a **self-fulfilling vicious cycle** that is itself an independent risk factor for future falls, disability and nursing-home admission. Measured with the **Falls Efficacy Scale–International (FES-I)** or the Activities-specific Balance Confidence scale.
4. **Other patterns in late life. Social anxiety** worsened by **deafness, tremor, incontinence, disfigurement or dysarthria**; **fear of medical procedures** (dental treatment, MRI, injections) leading to avoidance of necessary care; **fear of crime** and of leaving home, often mislabelled as agoraphobia; and **hypochondriacal phobia of illness**.
5. **Differential diagnosis. Depression with avoidance and apathy**; **realistic avoidance due to genuine physical limitation** (arthritis, orthostatic hypotension, visual loss) — this is **not** phobia; **paranoid disorder**, where the person avoids going out because of persecutory beliefs rather than fear; **early dementia** with loss of confidence; and **secondary avoidance in Parkinson's disease or after stroke**.
6. **Management. Graded exposure with response prevention is the treatment of choice**, delivered as **CBT**, and is effective in older adults. For **fear of falling** specifically, the evidence-based package is **supervised progressive strength and balance training (for example the Otago programme), gait-aid provision and training, home hazard assessment, footwear and vision correction, and CBT to correct catastrophic beliefs**. **Drugs are second-line** — **SSRIs** where comorbid depression or generalised anxiety is present. **Avoid benzodiazepines**, which in this group both worsen falls and reinforce avoidance.

Latest Update — 1 Point

7. **World Guidelines for Falls Prevention and Management (2022–2024, *Age and Ageing*) and subsequent updates** formally require that **"concern about falling" be assessed as a core component of every multifactorial falls assessment**, and recommend **exercise-based intervention combined with cognitive-behavioural strategies** rather than reassurance alone. Recent randomised and meta-analytic evidence (2023–2025) additionally supports **virtual-reality training and treadmill perturbation-based balance training** for reducing fear of falling and improving balance confidence in older adults.

Question 13. Obsessive-compulsive disorder [7 marks]

Textbook Core — 6 Points

1. **Definition. Obsessions** are recurrent, intrusive, unwanted thoughts, images or urges causing marked anxiety and recognised as one's own. **Compulsions** are repetitive behaviours or mental acts performed to reduce that anxiety, according to rigid rules. They are **time-consuming (more than one hour a day)** or cause marked distress or impairment. **DSM-5 moved OCD out of the anxiety disorders into "Obsessive-Compulsive and Related Disorders"**, alongside **body dysmorphic disorder, hoarding disorder, trichotillomania and excoriation disorder**.
2. **Epidemiology in old age.** Prevalence is around **1%** in older adults, and most cases are **long-standing, with onset in adolescence or early adulthood, persisting into old age**. Common themes are **contamination and washing, checking, symmetry, and religious or somatic obsessions**; in late life, **hoarding disorder** is disproportionately common and overlaps with **severe self-neglect (Diogenes syndrome)**.
3. **The critical rule — new-onset OCD in old age is organic until proved otherwise.** True de novo OCD after 60 is rare. Investigate for **frontal lobe and basal ganglia pathology** — **stroke (especially caudate and basal ganglia), frontotemporal dementia, Parkinson's disease, Huntington's disease, tumour and head injury** — and for **drug effects, notably dopamine agonists causing punding and impulse-control behaviours**.
4. **Differential diagnosis. Obsessive-compulsive personality disorder** — ego-syntonic traits without true obsessions or compulsions, and one of the **commonest personality disorders in old age**. Also: **depression with ruminations** (mood-congruent and not resisted), **generalised anxiety** (worries concern real-life problems), **dementia with repetitive or stereotyped behaviour**, **psychosis with delusions** (no insight, not resisted), and **hoarding disorder**.
5. **Assessment.** Direct enquiry, since patients rarely volunteer symptoms because of shame; informant history; rate severity with the **Yale-Brown Obsessive Compulsive Scale (Y-BOCS)**; screen for **depression, present in up to two-thirds, and for suicidality**; assess functional and carer impact. **Neuroimaging and cognitive testing where onset is late or the presentation atypical.**
6. **Management. CBT with exposure and response prevention (ERP) is first-line** and effective in older adults. **Drugs — SSRIs are first-line**, but note that **OCD requires higher doses and longer trials (10–12 weeks) than depression does**; **clomipramine** is effective but its **anticholinergic, orthostatic and cardiac effects make it a poor choice in the elderly**. For resistant cases, **augmentation with a low-dose atypical antipsychotic (risperidone, aripiprazole)**. **Avoid benzodiazepines** — ineffective for OCD and harmful in old age.

Latest Update — 1 Point

7. **Neuromodulation for OCD (2023–2025). Transcranial magnetic stimulation is approved for treating OCD** as well as for antidepressant-resistant depression, and **deep TMS using the H7 coil**, targeting the medial prefrontal and anterior cingulate cortex, now carries the strongest evidence for **treatment-refractory OCD**. Because **TMS carries lower risk than high-dose antidepressants in older adults**, it is an increasingly attractive option — but it **must be used judiciously in those at risk of seizures, such as after stroke or traumatic brain injury**. Deep brain stimulation remains reserved for the most severe refractory cases.

Question 14. Somatoform and conversion disorders in older adults [7 marks]

Textbook Core — 6 Points

1. **Definition.** Physical symptoms **not fully explained by a medical condition**, accompanied by **excessive thoughts, feelings and behaviours** about the symptoms, causing distress and impairment. DSM-5 renamed this group **"Somatic Symptom and Related Disorders"**.
2. **Spectrum. Somatic symptom disorder**, **illness anxiety disorder** (formerly hypochondriasis), **conversion disorder (functional neurological symptom disorder)**, factitious disorder, and psychological factors affecting a medical condition.
3. **The key geriatric rule. New-onset somatoform disorder after 60 years is rare.** A first presentation in old age must trigger a search for **occult organic disease, depression, anxiety, or early dementia**. **Depression is the commonest cause of medically unexplained somatic complaints in the elderly** ("masked depression").
4. **Clinical features. Multiple, shifting complaints** — pain, fatigue, dizziness, gastrointestinal symptoms; repeated consultations and investigations; **doctor-shopping**; poor response to reassurance. Conversion presents with **functional weakness, non-epileptic attacks, gait disorder (astasia–abasia), or aphonia**; **Hoover's sign** is a positive rule-in sign.
5. **Assessment. Proportionate but time-limited investigation**; screen for depression (**GDS-15**), anxiety, and cognition (MoCA); complete medication review; explore **bereavement, loneliness, elder abuse and role loss**. Diagnose functional disorder on **positive clinical signs**, not by exclusion alone.

6. **Management.** One **named coordinating physician**; **regular scheduled (not symptom-triggered) appointments**; **avoid repeat investigations and iatrogenic harm**; validate that the symptoms are real. **CBT is first-line**; treat comorbid depression/anxiety with **SSRIs**; graded **physiotherapy** for functional neurological disorder. **Avoid benzodiazepines and opioids.**

Latest Update — 1 Point

7. **ICD-11 and FND practice (2023–2025).** ICD-11 has replaced the somatoform group with **Bodily Distress Disorder**, graded mild / moderate / severe. **Functional Neurological Disorder is now a rule-in diagnosis** made on positive clinical signs, no longer a diagnosis of exclusion. Current evidence and UK/NICE-aligned FND guidance support **specialist physiotherapy plus CBT** as core treatment, with **clear explanation of the diagnosis itself being therapeutic**.

If asked for 15 marks, add: *detailed DSM-5 versus ICD-11 criteria comparison; epidemiology in Indian primary care; the biopsychosocial model with predisposing / precipitating / perpetuating factors; a table of positive rule-in signs for FND (Hoover's, hip-abductor, tremor entrainment, give-way weakness); prognosis and predictors of poor outcome; and the role of liaison psychiatry services.*

Section D — Psychotic Disorders in Late Life

Three genuinely distinct questions that overlap in content: the broad differential, the schizophrenia-spectrum diagnosis, and delusional disorder. Each answer is written to its own pivot so that the three do not repeat one another.

Question 15. Late-life psychotic disorders [7 marks]

Pivot: the differential diagnosis and classification of psychosis in old age as a whole. Question 16 pivots to late-onset schizophrenia and Question 17 to delusional disorder.

Textbook Core — 6 Points

1. **Definition and burden.** Psychosis is the presence of **delusions and/or hallucinations** with loss of contact with reality. There is an **increased incidence of psychotic symptoms in older adults compared with younger adults**; the lifetime risk of psychosis is about **23%**, and roughly **15% of older adults experience psychotic phenomena**.
2. **The single most important rule. Approximately 60% of new-onset psychosis in late life is secondary** — due to a medical, neurological or drug cause. **Primary psychosis is a diagnosis of exclusion. Older adults presenting with psychotic symptoms for the first time need a thorough evaluation before any psychiatric label is applied.**
3. **Classification — the "six D's" of late-life psychosis. Delirium** · **Disease** (medical/neurological — hypothyroidism, B12 deficiency, hyponatraemia, cancer, temporal lobe lesions, epilepsy) · **Drugs** (levodopa and dopamine agonists, steroids, anticholinergics, alcohol/substance use and withdrawal) · **Dementia** (Alzheimer's, and especially **DLB** and Parkinson's disease dementia) · **Depression** (psychotic depression with nihilistic/guilt delusions) · **Delusional disorder** and late-onset schizophrenia.
4. **Clinical clues that point to the cause. Fluctuating attention and altered consciousness → delirium. Recurrent, well-formed complex visual hallucinations of people, children or animals with parkinsonism, fluctuating cognition and REM sleep behaviour disorder → DLB**, where **misidentification delusions are the commonest type** and **severe neuroleptic sensitivity** may occur. **Nihilistic and guilt delusions with mood disturbance → psychotic depression. Well-systematised non-bizarre persecutory delusions with preserved function → delusional disorder. Purely visual hallucinations with intact insight in visual loss → Charles Bonnet syndrome** (not psychosis, needs no antipsychotic).
5. **Evaluation.** History plus **informant history**; full drug and alcohol review; cognitive testing (**MMSE/MoCA**); **audiometry and vision assessment**. Investigations: **CBC, sodium and potassium (mEq/L), calcium (mg/dL), glucose (mg/dL), renal and liver function, TSH, vitamin B12, VDRL/HIV, urine culture, ECG**, and **CT or MRI brain**. **If the workup is negative, refer to a psychiatrist to diagnose late-onset schizophrenia or delusional disorder.**
6. **Management principles. Treat the cause first** — stop or reduce the offending drug, correct the metabolic abnormality, treat the infection, treat the depression. **Environmental and psychosocial interventions are first-line** — correct sensory deficits with hearing aids and cataract surgery, reduce isolation, simplify the environment, and educate carers. **Antipsychotics are used judiciously, as needed**: **atypical agents at one-quarter to one-third of adult doses**, with **quetiapine or clozapine preferred in DLB and Parkinson's disease**, and **pimavanserin** for Parkinson's disease psychosis. Note the **boxed warning of increased stroke and mortality in dementia-related psychosis**.

Latest Update — 1 Point

7. **Xanomeline-trospium (KarXT), 2024–25.** The first **muscarinic M1/M4 receptor agonist antipsychotic**, FDA-approved in September 2024 for schizophrenia. Because it is **non-dopaminergic** it causes **no extrapyramidal symptoms, no prolactin elevation and no weight gain** — the 2025 *International Psychogeriatrics* overview of late-onset psychoses identifies it as the **most promising emerging therapy for late-life psychosis**, with trials in dementia-related psychosis ongoing.

```
APPROACH TO NEW-ONSET PSYCHOSIS IN AN OLDER ADULT
   New delusions and/or hallucinations after age 60
                |
   Is attention/consciousness fluctuating?  -- YES --> DELIRIUM: find & treat cause
                | NO
   Drug review (levodopa, steroids, anticholinergics, alcohol) -- positive --> withdraw/reduce
                |
   Metabolic + infective screen; B12, TSH, Na, Ca; neuroimaging -- positive --> treat DISEASE
                |
   Cognitive testing + informant history -- impaired --> DEMENTIA (AD / DLB / PDD)
                |
   Mood assessment -- depressed --> PSYCHOTIC DEPRESSION (antidepressant + antipsychotic or ECT)
                |
   Workup negative --> refer psychiatry: DELUSIONAL DISORDER or LATE-ONSET SCHIZOPHRENIA
```

Question 16. Late-onset schizophrenia [7 marks]

Pivot: the schizophrenia spectrum of late life — LOS and VLOSLP — and how it differs from early-onset disease.

Textbook Core — 6 Points

1. **Definitions and terminology (International Late-Onset Schizophrenia Group consensus). Late-onset schizophrenia (LOS)** = onset between **40 and 59 years**. **Very late-onset schizophrenia-like psychosis (VLOSLP)** = onset at **60 years or above**. The older European term for the latter is **late paraphrenia**. Both require the exclusion of dementia, delirium, mood disorder and organic causes.
2. **Epidemiology.** Onset of schizophrenia occurs **after 50 years in about 13% of hospitalised patients with schizophrenia, after 60 in 7%, and after 70 in 3%**. There is a **marked female predominance** in late-onset cases, in contrast to the male predominance of early-onset disease.
3. **Risk factors. Female sex**, **sensory impairment — particularly deafness and visual loss**, **social isolation and living alone**, never-married or childless status, **premorbid paranoid or schizoid personality traits**, migrant status, and a weaker family history of schizophrenia than in early-onset disease.
4. **Clinical features — how it differs from early-onset schizophrenia. Persecutory delusions dominate**, often with **partition delusions** (the belief that people, objects or radiation pass through walls, floors or ceilings) — highly characteristic. **Multimodal hallucinations** (auditory, visual, tactile, olfactory) are common. In contrast, **formal thought disorder, negative symptoms and affective flattening are rare**, and **premorbid function, personality and occupational history are relatively well preserved**. Cognitive impairment is milder and non-progressive.
5. **Differential diagnosis and workup.** Exclude **delirium, dementia (especially DLB and Alzheimer's disease), psychotic depression, mania, delusional disorder, drug-induced psychosis and Charles Bonnet syndrome**. Investigate as for any first-episode late-life psychosis: **CBC, sodium (mEq/L), calcium (mg/dL), glucose (mg/dL), renal and liver function, TSH, vitamin B12, VDRL/HIV, urine culture, ECG, cognitive testing, audiometry, visual assessment and neuroimaging**.
6. **Management. Engagement and trust are the first therapeutic task**, as insight is absent and patients resist the suggestion that they need treatment. **Correct sensory deficits — hearing aids and cataract surgery — and reduce social isolation. Atypical antipsychotics are preferred over conventional agents**, at **much lower doses than in younger patients**. Combine with **psychosocial rehabilitation — social skills training, cognitive remediation, supported accommodation** — plus **assertive community treatment and case management, which greatly increase success**. **Optimally control vascular risk factors** (obesity, hypertension, diabetes, dyslipidaemia), which are highly prevalent. Adherence is poor — consider **long-acting injectables**. Patients typically remain **stable but symptomatic and functionally impaired**, with **higher mortality than earlier-onset schizophrenia**, though **sustained remission can occur even in chronic illness**.

Latest Update — 1 Point

7. **The ATLAS trial remains the only randomised, placebo-controlled evidence in VLOSLP** (*Lancet Psychiatry*) — **amisulpride 100 mg daily was superior to placebo** in reducing psychosis symptoms over **12 and 24 weeks**, with a large effect size and good tolerability despite a modest increase in extrapyramidal symptoms. Reviews through **2025** continue to cite it as the standard, while the **2023 AGS Beers Criteria** permit antipsychotic use where the indication is **schizophrenia or bipolar disorder**, and **xanomeline–trospium (2024)** offers a non-dopaminergic alternative under study.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Drug evidence	Atypicals preferred; no trial data specified	**Amisulpride 100 mg/day (ATLAS)** is the only RCT-supported regimen in VLOSLP	Name ATLAS and the dose — it distinguishes a good answer
First-line step	Drugs plus psychosocial rehabilitation	**Sensory correction and reduction of isolation before drugs**	Lead with hearing aids and cataract surgery

Question 17. Delusional disorder in the elderly [15 marks]

Pivot: delusional disorder as a discrete diagnosis, with its subtypes and its distinction from the wider late-life psychosis differential in Question 15.

Textbook Core — 10 Points

1. **Definition.** Persistent **non-bizarre delusions lasting ≥1 month**, without prominent hallucinations, disorganised speech or negative symptoms. **Personality and functioning are relatively preserved.**

2. **Terminology and burden.** Suspiciousness and paranoia affect **4–6%** of older people. Onset at **≥60 years** with schizophrenia-like features is termed **very late-onset schizophrenia-like psychosis (VLOSLP)**; the older term is **late paraphrenia**.
3. **Risk factors. Female sex**, **social isolation** and living alone, never-married status, **sensory impairment (deafness, poor vision)**, migrant status, premorbid **paranoid or schizoid personality**, and family history.
4. **Subtypes. Persecutory** (commonest), **jealous** (Othello), **somatic** (delusional infestation / Ekbom syndrome), **erotomanic** (de Clérambault), grandiose, and mixed.
5. **Clinical features.** Well-systematised, plausible delusions; **partition delusions** (belief that people or objects pass through walls, floors or ceilings) are characteristic of VLOSLP. Hallucinations, if present, are secondary. **Insight is absent** but daily function is maintained.
6. **Differential diagnosis. Delirium**, **dementia** (especially DLB and Alzheimer's disease), **psychotic depression**, drug-induced psychosis (**levodopa**, steroids, anticholinergics), alcohol/substance use, hypothyroidism, **vitamin B12 deficiency**, and temporal lobe lesions.
7. **Evaluation.** First-episode psychosis in old age **always needs a full workup**: CBC, sodium (mEq/L), calcium (mg/dL), glucose (mg/dL), renal and liver function, TSH, B12, VDRL/HIV, urine culture, complete drug review, cognitive testing (MMSE/MoCA), **audiometry and vision assessment**, and **neuroimaging (CT/MRI brain)**.
8. **Non-pharmacological management (first-line).** Patient engagement and trust-building; **correct sensory deficits — hearing aids, cataract surgery**; reduce isolation through day care and community services; supportive psychotherapy and **CBT for psychosis**; carer education. In India — **NPHCE day-care centres, Elder Line 14567, Tele-MANAS 14416**.
9. **Pharmacological management. Atypical antipsychotics preferred over conventional agents. Start low, go slow** — roughly one-quarter to one-third of adult doses: **risperidone 0.25–1 mg**, **olanzapine 2.5–5 mg**, **quetiapine 12.5–50 mg** (drug of choice if parkinsonism or DLB), **amisulpride 50–100 mg**.
10. **Adverse effects, monitoring, prognosis.** Watch for **EPS, tardive dyskinesia, falls, orthostatic hypotension, QTc prolongation, metabolic syndrome**, and the **boxed warning of increased stroke and mortality in dementia-related psychosis**. Adherence is poor — consider **long-acting injectables**. Course is chronic but function is preserved; VLOSLP carries **higher mortality** than earlier-onset schizophrenia.

Latest Updates — 2 Points

11. **Xanomeline–trospium (KarXT, 2024–25).** The first **muscarinic M1/M4 agonist antipsychotic**, FDA-approved in September 2024 for schizophrenia. Being **non-dopaminergic**, it causes **no EPS, no prolactin rise and no weight gain** — highlighted in the 2025 *International Psychogeriatrics* overview of late-onset psychoses as the most promising emerging option for older adults; trials in dementia-related psychosis are ongoing.
12. **Antipsychotic evidence base reaffirmed.** The **ATLAS trial** (Lancet Psychiatry) remains the only placebo-controlled RCT in VLOSLP — **amisulpride 100 mg/day** was superior to placebo over 12 and 24 weeks and well tolerated. The **2023 AGS Beers Criteria** continue to classify antipsychotics as potentially inappropriate in older adults **unless** the indication is schizophrenia, bipolar disorder, or short-term antiemesis.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Drug class	Atypical antipsychotics preferred over conventional	Same, but with explicit boxed-warning caution; muscarinic agents (KarXT) emerging as non-dopaminergic alternative	Write "atypical, lowest dose, shortest duration" and add KarXT as the newest development
First-line step	Pharmacological + psychosocial rehabilitation	**Sensory correction and reduction of social isolation are first-line**; drugs added if distress or risk persists	Lead with non-pharmacological measures — examiners look for this

Section E — Grief, Personality and Behaviour

Bereavement, the personality questions — normal ageing, disorder and severe self-neglect — and the practical management of agitation.

Question 18. Grief, bereavement and complicated grief [7 marks]

Textbook Core — 6 Points

1. **Definitions. Bereavement** is the objective fact of loss; **grief** is the emotional response; **mourning** is its social and cultural expression. **Anticipatory grief** begins from the moment a life-limiting illness is diagnosed — for an elderly couple this marks the start of a painful parting.
2. **Normal grief.** Waves of **yearning, sadness, disbelief and searching behaviour**, sometimes with **transient hallucinations of the deceased** (culturally normal). Functioning gradually returns over weeks to months. **No active treatment is required.**
3. **Complicated (prolonged) grief.** Characterised by **extreme traumatic distress, numbness, disbelief, bitterness, feeling that part of oneself has died, and assuming the symptoms of the deceased**, with **symptoms enduring beyond 6 months** and causing functional impairment.
4. **Warning signals / risk factors. Sudden or unexpected death**, **traumatic death**, **loss of a child**, and **loss of a partner with an ambivalent relationship** ("can't live with, can't live without"). Also — lack of social support, female sex, older age, previous psychiatric illness, and death in an ICU.
5. **Consequences. Decline in health, increased healthcare utilisation and increased mortality** — highest in the first 6 months. Bereaved elders are at risk of **depression, cardiac events (including takotsubo cardiomyopathy), intercurrent infection, and suicide**. In India, **widowhood also brings loss of income, social status and property rights** — link to the **MWPSC Act 2007** and Elder Line **14567**.
6. **Management.** Normal grief needs **support, not medication** — family, faith and community, support groups, and practical help. Complicated grief responds to **grief-specific psychotherapy (complicated grief therapy), brief dynamic psychotherapy, and crisis intervention**. **Antidepressants are for comorbid major depression, not for grief itself.** Hospice programmes provide bereavement follow-up for about **one year**.

Latest Update — 1 Point

7. **Prolonged Grief Disorder is now a formal diagnosis** — in **DSM-5-TR (2022)** requiring **≥12 months** since the death in adults, and in **ICD-11** requiring **≥6 months**. The **Lancet 2025 Seminar on prolonged grief disorder** and RCTs in *JAMA Psychiatry* (Bryant 2024; Rosner 2025) confirm **grief-specific CBT / Prolonged Grief Therapy as first-line**, superior to interpersonal and present-centred therapy, with **antidepressants adding no benefit over psychotherapy alone**.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Name and duration	"Complicated bereavement", symptoms enduring 6 months	**Prolonged Grief Disorder** — DSM-5-TR ≥12 months, ICD-11 ≥6 months	Write both names and both durations, attributing each correctly
Drug treatment	Antidepressants "may be considered" for complicated bereavement	Psychotherapy is first-line; antidepressants only for comorbid major depression	State psychotherapy first, then the antidepressant caveat

If asked for 15 marks, add: *Kübler-Ross and dual-process models of grief; full DSM-5-TR criteria list; differentiating grief from major depression (self-esteem preserved, waves vs pervasive low mood, suicidal thoughts of joining vs worthlessness); Inventory of Complicated Grief and PG-13-R as screening tools; grief in dementia caregivers; and cultural/Indian mourning practices as protective factors.*

Question 19. Age-associated personality changes [7 marks]

Pivot: normal, non-pathological ageing of personality, trait accentuation, and organic personality change. Personality disorder proper is Question 20.

Textbook Core — 6 Points

1. **Normal ageing of personality.** Personality is **largely stable across the lifespan**; the popular idea that people inevitably become rigid or cantankerous with age is not supported. Longitudinal studies show a **"maturation" pattern** — a modest **rise in agreeableness and conscientiousness and a fall in neuroticism, extraversion and openness to experience**. There is a shift towards **introversion, cautiousness, increased interiority and reminiscence**, with **better emotional regulation and improved positivity of affect**. **These are trends, not pathology.**

2. **Accentuation of traits.** Pre-existing traits are commonly **exaggerated rather than replaced** under the stress of ageing — losses, bereavement, retirement, illness, disability, sensory loss and dependence. A previously thrifty person becomes hoarding; a private person becomes reclusive; an anxious person becomes preoccupied with health. **Personality disorders in old age follow the same pattern — Cluster A becomes more prominent with isolation, Cluster B tends to attenuate, and Cluster C persists or worsens.**
3. **The critical clinical rule. A genuine change in personality beginning in old age is never normal ageing and is never a personality disorder — it is organic until proved otherwise.** A personality disorder by definition has its **onset by adolescence or early adulthood**.
4. **Causes of pathological personality change. Frontotemporal dementia — the prototype**, with **disinhibition, apathy, loss of empathy, perseverative and stereotyped behaviour, and hyperorality**, in a patient with relatively preserved memory. Also **Alzheimer's disease and other dementias**, **frontal lobe stroke, tumour or subdural haematoma**, **traumatic brain injury**, **normal pressure hydrocephalus**, **Parkinson's and Huntington's disease**, **epilepsy**, **hypothyroidism, B12 deficiency, neurosyphilis and HIV**, **alcohol-related brain damage**, and drugs — **steroids, dopamine agonists (impulse-control disorders, punding), benzodiazepines and anticholinergics**.
5. **Assessment.** The diagnosis rests on an **informant history establishing the premorbid personality and the timeline of change** — the patient often has no insight. Add **full neurological examination**, **cognitive testing with emphasis on executive and frontal function (Frontal Assessment Battery, clock drawing, verbal fluency)**, **drug and alcohol review**, screening for depression and mania, and investigations — **CBC, sodium (mEq/L), calcium (mg/dL), glucose (mg/dL), renal and liver function, TSH, vitamin B12, VDRL/HIV**, with **MRI brain** and, where indicated, EEG.
6. **Management. Treat the underlying cause** where reversible. Otherwise the approach is behavioural — a **consistent, coordinated team plan with clear boundaries**, **modification of the environment and of carer approach**, and **carer education and support**, since these behaviours rapidly drain family and staff resources. **Psychotropic medications generally do not reduce aggressive behaviour or mood lability due to personality**; use drugs only for a comorbid disorder or a crisis, and **avoid benzodiazepines**. Address **capacity, financial vulnerability, driving and safeguarding**, and hold **regular team meetings to prevent staff splitting and to manage negative counter-transference**.

Latest Update — 1 Point

7. **ICD-11 dimensional model of personality (in force since 2022, widely adopted 2023–25).** The categorical subtypes have been **abolished** in favour of a **single Personality Disorder diagnosis graded mild, moderate or severe**, described by **five trait domains — negative affectivity, detachment, dissociality, disinhibition and anankastia** — plus a **borderline pattern qualifier**. ICD-11 also retains **"personality change due to another medical condition"** as a separate, organic category. This dimensional framework fits older adults far better than the cluster system, since it captures **degree of severity and trait accentuation** rather than forcing an all-or-none categorical label; DSM-5-TR retains a parallel **Alternative Model in Section III**.

Question 20. Personality disorders in old age [7 marks]

Pivot: the diagnosable personality disorders, their clusters and their ageing course. Normal age-related personality change is Question 19.

Textbook Core — 6 Points

1. **Definition.** An **enduring, pervasive and inflexible pattern** of inner experience and behaviour that deviates markedly from cultural expectation, with **onset by adolescence or early adulthood**, causing distress or impairment.
2. **Prevalence.** About **10% of community-dwelling elderly** and up to **one-third of older psychiatric patients**. It is **under-diagnosed** because diagnostic criteria were validated in younger adults and depend on **work and relationship domains that are irrelevant to a retired, widowed person**.
3. **Clusters and their ageing course. Cluster A** (paranoid, schizoid, schizotypal) — often **becomes more prominent** with isolation and sensory loss. **Cluster B** (antisocial, borderline, histrionic, narcissistic) — impulsive traits tend to **"burn out" or attenuate**. **Cluster C** (obsessive-compulsive, avoidant, dependent) — **persists or worsens**; obsessive-compulsive and avoidant types are the commonest in old age.
4. **Age-specific presentation.** Expressed through **illness behaviour rather than work or sexual life** — **treatment refusal and non-adherence**, **staff splitting in care homes**, repeated crises, hoarding disorder, and **severe self-neglect (Diogenes syndrome)**, querulous or demanding behaviour, and carer burnout.
5. **Differential diagnosis — the critical point.** A **personality change that begins in old age is never a personality disorder**. It is **organic until proved otherwise** — **frontotemporal dementia**, stroke, head injury, tumour, hypothyroidism, alcohol, or medication effect. Also exclude depression, mania and psychosis.
6. **Management.** A **consistent, coordinated team approach** with a single agreed care plan and clear behavioural boundaries. **Psychotherapy (adapted CBT, DBT, schema-focused therapy) has evidence in older adults.** Treat comorbid depression, anxiety and substance misuse. **Medication only for comorbid disorder or crisis**; **avoid benzodiazepines**. Support and supervise family carers and care-home staff.

Latest Update — 1 Point

7. **ICD-11 dimensional model (in force since 2022, widely adopted 2023–25).** The categorical subtypes have been **abolished** and replaced by a **single diagnosis of Personality Disorder graded mild / moderate / severe**, described by **five trait domains — negative affectivity, detachment, dissociality, disinhibition and anankastia** — plus a **borderline pattern qualifier**. This dimensional approach fits older adults far better than the cluster system, and DSM-5-TR retains a parallel **Alternative Model (Section III)**.

If asked for 15 marks, add: *full list of the ten DSM categories with one-line descriptors; theories of trait stability versus change with ageing (maturation vs heterotypic continuity); assessment instruments (SIDP-IV, Gerontological Personality Disorder Scale, informant history); interaction of personality disorder with physical illness outcomes and rehabilitation; medico-legal aspects of self-neglect and capacity; and a worked care-plan example for Diogenes syndrome.*

Question 21. Diogenes syndrome [7 marks]

Textbook Core — 6 Points

1. **Definition.** Diogenes syndrome, also called **senile squalor syndrome** or **severe social breakdown syndrome**, is characterised by the tetrad of **extreme self-neglect, domestic squalor, social withdrawal and refusal of help**, usually accompanied by **hoarding (syllogomania)** and a **striking lack of shame or concern about the situation**. The name is a misnomer — the philosopher Diogenes was an ascetic who rejected possessions, whereas these patients accumulate them.
2. **Epidemiology and typical profile.** Incidence of about **0.5 per 1000 per year in those over 60**. Typically an **older person living alone**, often **widowed or never married**, with **above-average intelligence and a good previous educational and occupational record**, and frequently **not poor** — cases are often discovered to have substantial savings. Both sexes are affected. Presentation is usually precipitated by **a crisis — a fall, a fire, complaints from neighbours, or an emergency admission**.
3. **Classification. Primary (about half)** — no identifiable psychiatric disorder, arising from lifelong personality traits under stress. **Secondary** — associated with an underlying disorder, most often **frontotemporal dementia or other dementia**, **alcohol misuse**, **depression**, **schizophrenia and delusional disorder**, **obsessive-compulsive disorder and hoarding disorder**, and **mania**. Underlying **frontal-executive dysfunction** is the common thread.
4. **Predisposing factors. Premorbid personality** — **paranoid, schizoid, obsessive-compulsive and avoidant traits**, aloofness, suspiciousness, stubbornness and independence; personality disorder is the underlying cause of much provocative and hostile behaviour in older adults. Add **social isolation, bereavement or loss of a supporting relative, sensory impairment, chronic physical illness and poverty of social network**. A **precipitating loss** commonly triggers the decompensation.
5. **Clinical consequences and assessment. Malnutrition, vitamin deficiencies, anaemia, dehydration, hypothermia, infestation and skin infection, pressure ulcers, untreated chronic disease, falls and fire risk.** Assessment requires **a home visit** — the diagnosis cannot be made in clinic. Perform a **comprehensive geriatric assessment** with **cognitive testing including frontal-executive tasks, depression screening (GDS-15), alcohol history, nutritional assessment, and capacity assessment**; investigate with **CBC, albumin, vitamin B12 and folate, TSH, calcium (mg/dL), glucose (mg/dL), renal and liver function, and neuroimaging where cognitive impairment is suspected**.
6. **Management. Slow, patient engagement and trust-building** — **refusal of help is part of the syndrome**, and confrontation or forced clearance triggers withdrawal and a rapid return to squalor. Use a **multi-agency approach** — geriatrician, old age psychiatry, general practitioner, social work, community nursing, public health and environmental services, with **graded cleaning rather than a single mass clearance**. **Treat the treatable** — nutrition, infection, depression, alcohol misuse, psychosis. **Assess decision-making capacity formally**: if capacity is retained, an unwise choice must be respected while support continues; if capacity is absent, act in the person's best interests, using safeguarding and, in India, the framework of the **MWPSC Act 2007**, the **Mental Healthcare Act 2017** and **Elder Line 14567**. **Mortality is high — around 45% at five years** — and **relapse after cleaning is the rule without long-term follow-up**.

Latest Update — 1 Point

7. **Hoarding disorder as an independent diagnosis and current terminology (2023–2025). Hoarding disorder is now a distinct diagnosis in DSM-5 and ICD-11** within the **obsessive-compulsive and related disorders** group, separate from OCD, and defined by **persistent difficulty discarding possessions due to a perceived need to save them, with resulting congestion of living areas**, with an **"with poor or absent insight/delusional beliefs" specifier**. Prevalence rises with age and is around **6% in older adults**. Contemporary literature increasingly favours the neutral terms **"severe domestic squalor"** and **"self-neglect"** over the eponym, and recommends **specialised CBT for hoarding (with motivational interviewing and skills training rather than forced clearance)**, delivered alongside **multi-agency safeguarding**, as the treatment with the best evidence.

Question 22. Non-pharmacological management of the agitated older individual [7 marks]

Textbook Core — 6 Points

1. **Scale and rationale. Agitation and aggressive behaviours will be seen at some point in almost all individuals with dementia**, and behavioural and psychological symptoms of dementia are the **commonest psychiatric problem in nursing homes**. Non-drug management is first-line because **no medication is FDA-approved for treating the neuropsychiatric symptoms of dementia**, and all antipsychotics carry a **boxed warning of increased stroke and mortality** in this population.
2. **Step 1 — search for and treat the medical cause. A medical workup often identifies one or more causes.** Look for **pain** (the single most important and most missed), **infection, especially urinary tract infection**, **dehydration**, **constipation and urinary retention**, hypoxia, hypoglycaemia, electrolyte disturbance, **delirium**, sensory deprivation, and **drug effects — anticholinergic medications**, benzodiazepines, opioids, steroids and dopamine agonists. **Treating pain alone significantly reduces agitation in nursing-home residents (Husebø cluster RCT).**
3. **Step 2 — identify the trigger. Environmental triggers** (excessive noise, poor lighting, clutter, overheating, unfamiliar surroundings, over- or under-stimulation); **psychosocial triggers** (boredom, loneliness, loss of routine); and **interpersonal triggers** (a counter-therapeutic approach by family or professional carers — rushing, confrontation, arguing, task-focused care). **Once these modifiable causes are addressed, the behaviour often improves sufficiently that no further intervention is needed.**
4. **Step 3 — the structured frameworks. DICE — Describe the behaviour, Investigate causes, Create a plan, Evaluate the outcome. ABC analysis — Antecedent, Behaviour, Consequence**, recorded in a behaviour diary over several days to reveal the pattern. **TREA — Treatment Routes for Exploring Agitation**, matching the intervention to the unmet need behind the behaviour. Multiple sources of information may be needed in long-term care, **including video recordings of the behaviour**.
5. **Step 4 — specific evidence-based interventions. Person-centred, individually tailored activity** based on the person's life history and preferences; **music therapy**; **massage and therapeutic touch**; **animal-assisted therapy**; **multisensory stimulation (Snoezelen)**; **bright light therapy and sleep-wake regulation for sundowning**; **exercise and outdoor activity**; **reminiscence therapy**; **doll and simulated-presence therapy**; and **aromatherapy**. Network meta-analytic evidence ranks **massage therapy, animal-assisted intervention and personally tailored intervention** as producing the most substantial reductions in agitation.
6. **Step 5 — communication, environment and staff.** Approach from the front, at eye level, **one carer at a time**; **speak slowly with short simple sentences, one instruction at a time**; **do not argue, correct or confront — validate the emotion and redirect**; **offer choice and allow time**. Modify the environment — **consistent daily routine, familiar objects, adequate lighting, reduced noise, safe wandering space, visible clocks and calendars**. **Education and training of all healthcare providers working in long-term care homes is key**, together with **carer support to prevent burnout**. **Reserve antipsychotics for severe, distressing or dangerous behaviour that persists after these measures, at the lowest dose, with a defined review and withdrawal date.**

Latest Update — 1 Point

7. **International Psychogeriatric Association consensus definition of agitation in cognitive disorders and the 2023–2025 evidence base.** The IPA provisional consensus definition requires **excessive motor activity, verbal aggression or physical aggression causing excess distress or disability, beyond that attributable to another disorder** — giving a standard outcome definition for trials. Recent network meta-analyses and umbrella reviews (through 2025) confirm that **personally tailored activity, massage and touch therapy, animal-assisted intervention, music-based therapy and exercise outperform usual care**, and that **non-pharmacological interventions should be tried first and continued even when a drug is added**. Where a drug is unavoidable, **brexpiprazole (FDA-approved May 2023)** is now the only agent licensed for agitation in Alzheimer's dementia, but it retains the class mortality boxed warning.

```
DICE PATHWAY FOR THE AGITATED OLDER PERSON
 D  DESCRIBE   - what exactly happens, when, where, who is present, how often
 I  INVESTIGATE- pain? infection? constipation/retention? dehydration? drugs?
                 delirium? sensory loss? boredom? carer approach? environment?
 C  CREATE     - treat the cause + tailored activity, music, touch, exercise, light,
                 routine, communication technique, carer training, safe environment
 E  EVALUATE   - re-rate behaviour (Cohen-Mansfield Agitation Inventory), adjust plan
                 -> only if severe/dangerous and persisting: lowest-dose antipsychotic
                    with consent, monitoring, and a fixed review/withdrawal date
```

Section F — Substance Use Disorders

Alcohol, prescribed sedatives, tobacco and the wider substance-misuse question.

Question 23. Alcoholism in the elderly [7 marks]

Textbook Core — 6 Points

1. **Definition and classification.** Alcohol use disorder is a problematic pattern of use causing clinically significant impairment or distress. In older adults it is classified by **onset**: **early-onset ("survivors")**, about two-thirds, with lifelong drinking, more physical damage and more personality and social disruption; and **late-onset ("reactors")**, about one-third, beginning after 60 in response to **bereavement, retirement, loneliness, pain or physical illness**, with better prognosis and better treatment response.
2. **Altered pharmacokinetics — why safe limits are lower. Reduced total body water and lean body mass** raise the blood alcohol concentration for any given intake; **reduced hepatic metabolism and first-pass gastric alcohol dehydrogenase** prolong exposure; and there is **increased CNS sensitivity**. **The same drink produces a substantially higher blood level and greater impairment than in a younger adult**, so recommended limits are lower — no more than about **one standard drink per day and two on any occasion** above 65 years.
3. **Why it is missed.** Older people **present with physical problems rather than with a complaint of drinking**; symptoms are attributed to ageing or dementia — **falls, confusion, incontinence, self-neglect, malnutrition, poor diabetic or hypertensive control, insomnia and depression**. There is **stigma and under-reporting**, an absence of the usual work and legal markers in a retired person, and screening tools validated in the young. Clinicians simply do not ask.
4. **Consequences in old age. Falls, fractures and head injury (including chronic subdural haematoma)**; **cognitive impairment, alcohol-related brain damage and Wernicke–Korsakoff syndrome**; **peripheral neuropathy and cerebellar degeneration**; **liver disease, pancreatitis, gastritis and GI bleeding**; **hypertension, cardiomyopathy and atrial fibrillation ("holiday heart")**; **malnutrition and thiamine, folate and B12 deficiency**; **osteoporosis**; **cancer**; **depression and increased suicide risk**; and **drug interactions** with benzodiazepines, opioids, warfarin, paracetamol, metformin and antihypertensives. **A prior history of alcoholism predisposes to later benzodiazepine misuse.**
5. **Screening and assessment. Ask every older patient** — quantity, frequency, pattern, and the timeline of onset. Tools: the **CAGE questionnaire** and the **Short Michigan Alcohol Screening Test — Geriatric version (SMAST-G)**, which is specifically validated for older adults, plus AUDIT-C. Corroborate with an **informant**. Investigations: **CBC with MCV, liver function including GGT, blood sugar (mg/dL), electrolytes (mEq/L), magnesium, albumin, INR, vitamin B12 and folate**, and **CT head where there has been a fall or confusion**. **Screening for alcohol misuse, depression and delirium is recommended for all elderly people attending the emergency department.**
6. **Management. Detoxification** where dependence exists — **ideally as an inpatient in frail older adults**, using **CIWA-Ar-guided short-acting benzodiazepines such as lorazepam** (safer where liver function is impaired), with **parenteral thiamine before any glucose load** to prevent Wernicke's encephalopathy; **withdrawal is more likely to be complicated by confusion and delirium tremens than in younger adults**. Then **rehabilitation delivered concurrently, not consecutively, across physical, psychological and social domains**. **Age-specific, non-confrontational programmes that promote self-esteem, tolerance and peer relationships achieve roughly twice the abstinence of confrontational programmes**, and improve retention. Add **brief interventions and motivational interviewing**, treat **comorbid depression, pain and insomnia**, rebuild the social network, and consider **relapse-prevention pharmacotherapy — naltrexone or acamprosate**, with **disulfiram generally avoided in older adults**. Outcomes in older patients are **at least as good as in younger patients**.

Latest Update — 1 Point

7. **No safe level of alcohol for cancer risk (2023–2025).** The **WHO statement in *The Lancet Public Health* (2023)** concluded that **no level of alcohol consumption is safe for health**, since alcohol is a **Group 1 carcinogen**, and the **US Surgeon General's Advisory of January 2025** identified alcohol as the **third leading preventable cause of cancer** and called for cancer warning labels. This has removed the older "cardioprotective" framing based on J-shaped curves now attributed to **abstainer bias**. For older adults this reinforces **lower recommended limits, routine screening at every contact, and brief intervention**, and aligns with the **2023 AGS Beers Criteria** caution against combining alcohol with benzodiazepines, opioids or gabapentinoids.

Question 24. Benzodiazepine dependence and withdrawal in the older adult [7 marks]

Textbook Core — 6 Points

1. **Scale of the problem.** Benzodiazepines are among the most prescribed drugs in old age — about **10% of community-dwelling over-65s**, and up to **25% of nursing-home residents**. Roughly **70% of users continue two to four years later**, and **women are twice as likely as men** to be taking one.

2. **Risk factors for dependence. Female sex**, increasing age, **duration of use beyond 4 weeks**, **short-acting high-potency agents (alprazolam, lorazepam)**, insomnia, **comorbid anxiety and depressive disorders**, bereavement, poor physical health, institutionalisation, and **multiple prescribers**.
3. **Harms in the elderly. Falls and hip fracture**, **cognitive impairment and delirium**, daytime sedation, road traffic accidents, **respiratory depression (especially with opioids)**, **paradoxical excitement**, and dependence. Listed as **potentially inappropriate for all older adults in the AGS Beers Criteria**.
4. **Detection.** Watch for **drug-seeking behaviour** — early repeat prescription requests, requests for dose escalation, and obtaining medication from multiple sources. The **Severity of Dependence Scale** (5 items, each scored 0–3) is validated in older adults — a **total score ≥6 indicates problematic use** (sensitivity 97.9%, specificity 94.2%).
5. **Withdrawal syndrome. Rebound insomnia and anxiety**, tremor, sweating, palpitations, **perceptual hypersensitivity**, depersonalisation, and in severe cases **confusion and delirium, psychosis, and seizures**. **Withdrawal in the elderly is far more likely to be complicated by confusion** than in younger adults.
6. **Management. Convert to a long-acting benzodiazepine (diazepam) and taper gradually over months. Avoid rapid detoxification** — it causes breakthrough symptoms and may precipitate convulsions; if unavoidable, conduct it **as an inpatient**. Add **sleep hygiene education, relaxation training and CBT-I**; treat comorbid depression and anxiety. A simple GP letter urging reduction cut total use by **one-third at six months**. **Never stop abruptly.**

Latest Update — 1 Point

7. **ASAM Joint Clinical Practice Guideline on Benzodiazepine Tapering (2025, *J Gen Intern Med*).** Recommends that clinicians **taper benzodiazepines in most older adults unless there is a compelling reason to continue**; use **gradual, symptom-based (hyperbolic) reductions of about 5–10% every 2–4 weeks** with shared decision-making; **forced or abrupt discontinuation is not recommended**; and it formally recognises **Benzodiazepine-Induced Neurological Dysfunction (BIND)** as a protracted withdrawal state.

Current Practice Update

Aspect	Textbook	Current recommendation	Exam approach
Taper rate	"Gradual reduction over months", rate unspecified	**5–10% dose reduction every 2–4 weeks**, symptom-guided, no fixed end-date	Quote the numeric taper rate and credit the ASAM 2025 guideline
Consent	Physician-driven detoxification	**Shared decision-making; no forced taper**; monitor if the patient declines	Add one line on shared decision-making — it is a marked point now

```
TAPER ALGORITHM
Long-term BZD user (>4 weeks) in an older adult
        |
   Assess: SDS score, indication, falls/cognition, opioid co-prescription
        |
   Shared decision-making + psychoeducation  ---> declines ---> monitor, re-offer later
        |
   Convert to equivalent DIAZEPAM dose (long-acting)
        |
   Reduce by 5-10% every 2-4 weeks, symptom-guided
        |
   Add CBT-I / sleep hygiene / relaxation; treat depression & anxiety
        |
   Severe dependence, seizure risk or failure ---> INPATIENT taper
```

If asked for 15 marks, add: *pharmacology of benzodiazepines and altered pharmacokinetics in ageing (increased volume of distribution, prolonged half-life, active metabolites); a diazepam-equivalence table; Z-drugs as an equivalent problem; benzodiazepines and dementia risk evidence; STOPP/START and Beers criteria wording; deprescribing tools (EMPOWER trial, D-PRESCRIBE); and the psychology of deprescribing.*

Question 25. Nicotine dependence and smoking cessation [7 marks]

Textbook Core — 6 Points

1. **It is never too late to quit.** Epidemiological data show that **even among people in their 70s, stopping smoking reduces mortality towards that of non-smokers within a short enough time to justify actively encouraging quitting**. **Benefits for vascular and lung disease are rapid.**
2. **Additional geriatric gains.** Slower decline in **FEV1**, better wound and fracture healing, reduced risk of **stroke, myocardial infarction, cancer, cataract, macular degeneration, osteoporosis and dementia**, and reduced **fire and burn risk** in frail or oxygen-dependent patients.
3. **Assessment of dependence.** Pack-years, the **Fagerström Test for Nicotine Dependence**, and above all the **time to the first cigarette of the day (<30 minutes indicates high dependence)**; exhaled CO; previous quit attempts and reasons for relapse; readiness to change. Screen for **depression, alcohol use and COPD**.

4. **Behavioural framework.** The **5 A's — Ask, Advise, Assess, Assist, Arrange**, with the **5 R's** (Relevance, Risks, Rewards, Roadblocks, Repetition) for the unmotivated. **Brief physician advice alone raises quit rates**; combine with counselling and quitlines. In India — the **National Tobacco Control Programme (NTCP)**, **Tobacco Cessation Centres**, **COTPA 2003**, and the **national quitline 1800-11-2356**.
5. **Pharmacotherapy. Nicotine replacement therapy** — combination of a long-acting patch with a short-acting gum/lozenge is most effective. **Varenicline** — nicotinic partial agonist, the **most effective single agent**; dose-reduce if eGFR <30; causes nausea and vivid dreams. **Bupropion SR** — **lowers the seizure threshold**, contraindicated in seizure and eating disorders, and interacts through **CYP2D6**.
6. **Geriatric precautions.** Nicotine patches need caution in **unstable angina, recent MI and arrhythmia**. Critically, **stopping smoking removes CYP1A2 induction** — plasma levels of **clozapine, olanzapine, theophylline and the effect of warfarin rise**, so doses must be reviewed and reduced. Combine cessation with **pulmonary and cardiac rehabilitation**.

Latest Update — 1 Point

7. **Cytisinicline (cytisine) — the first new cessation drug in two decades.** A plant-derived **nicotinic acetylcholine receptor partial agonist**. The Phase 3 **ORCA-2 and ORCA-3 trials (JAMA 2023; JAMA Internal Medicine 2024)** showed significantly higher biochemically confirmed abstinence versus placebo, sustained to 24 weeks, with **fewer gastrointestinal adverse effects than varenicline**. The **NICE 2025 evidence review** and **ICER 2025** report rate its efficacy as comparable to varenicline; it is already inexpensive and available in several countries, although US approval was delayed in 2026 by a manufacturing-related Complete Response Letter.

Source note: *the uploaded textbooks cover the rationale and epidemiology of cessation in old age but do not detail pharmacotherapy protocols; points 3–6 follow standard tobacco-dependence guidance (NICE NG209 / USPHS 5A framework) integrated with geriatric prescribing principles.*

If asked for 15 marks, add: *neurobiology of nicotine dependence (α4β2 receptor upregulation); a full timeline of health benefits after quitting (20 min → 15 years); detailed NRT dosing by cigarettes/day; e-cigarettes and the current evidence and controversy; smokeless tobacco (khaini, gutkha, zarda) and its dominance in older Indians; COTPA 2003 and the 2019 e-cigarette ban; and relapse prevention.*

Question 26. Substance misuse other than alcohol in older adults [7 marks]

Pivot: prescribed, over-the-counter and illicit substances other than alcohol. Alcohol is Question 23 and benzodiazepines Question 24.

Textbook Core — 6 Points

1. **Three broad categories (textbook classification). (a) Medications** — prescribed (**benzodiazepines, opioids, Z-drugs, anticholinergics**) and non-prescribed / over-the-counter (codeine, antihistamines, laxatives, decongestants); **(b) socially sanctioned psychoactive substances** — tobacco, caffeine; **(c) illicit substances** — cannabis, opioids, cocaine.
2. **Changing epidemiology.** There is a **growing trend of substance misuse in the elderly**, driven by a **generation of lifetime drug users now entering old age**. **Prescribed benzodiazepine and opioid misuse remains far commoner than illicit drug use.** In India, traditional patterns include **opium and doda-post** use in Rajasthan and Punjab, and cannabis (**bhang, ganja**) in older men.
3. **Why it is missed.** Older people **rarely present complaining of substance misuse** — they present with associated physical problems. Symptoms are wrongly attributed to ageing or dementia (**falls, confusion, incontinence, self-neglect, weight loss**). Add **stigma**, screening tools validated in the young, and the absence of work or legal markers in a retired person.
4. **Age-specific vulnerability. Reduced hepatic and renal clearance**, **reduced lean body mass and total body water**, **increased CNS sensitivity**, and **polypharmacy with drug interactions** — so **much smaller quantities produce toxicity and withdrawal** than in younger adults.
5. **Assessment. Sensitive but persistent enquiry** plus an **informant history**, supported by **standardised screening tools**. Review every prescribed and over-the-counter drug, look for **multiple prescribers and early repeat requests**, and **actively treat comorbid depression, pain and insomnia**, which perpetuate the disorder. Examine social factors — housing and a social network of substance users.
6. **Management.** A **multistage, integrated physical + psychological + social package delivered concurrently, not consecutively**, in a form acceptable to older people. **Detoxification** where physical dependence exists. **Age-specific, non-confrontational, supportive group programmes retain older patients better** than mixed-age confrontational programmes — one study found **confrontational programmes achieved half the abstinence** of those promoting self-esteem, tolerance and peer relationships. Follow with rehabilitation, aftercare and relapse prevention.

Latest Update — 1 Point

7. **Cannabis is the fastest-growing substance of misuse in adults aged ≥65 (2023–2025).** Recent national survey data show a sharp rise in past-year use, and current reviews link it in older adults to **falls, orthostatic hypotension, tachyarrhythmia, cognitive impairment and cannabis-induced psychosis**, compounded by drug interactions and unregulated cannabidiol products. In parallel, the **2023 AGS Beers Criteria** strengthened the caution against combining **opioids with benzodiazepines or gabapentinoids** in older adults.

If asked for 15 marks, add: *screening instruments (ASSIST, DAST, Severity of Dependence Scale); detailed opioid misuse and opioid use disorder management with buprenorphine/methadone in the elderly; withdrawal syndromes by substance; Indian data from the NDDTC-AIIMS "Magnitude of Substance Use in India" report and the Nasha Mukt Bharat Abhiyaan; the interface with elder abuse and financial exploitation; and prevention through rational prescribing and deprescribing.*

Section G — Treatments and Therapeutics

The three therapeutic modalities asked as stand-alone notes.

Question 27. Atypical antipsychotics — their uses and side effects in the elderly [7 marks]

Textbook Core — 6 Points

1. **Definition and mechanism.** Second-generation ("atypical") antipsychotics act by **combined dopamine D2 and serotonin 5-HT2A antagonism**, with **looser, more transient D2 binding** than conventional agents. This gives them a **lower risk of extrapyramidal symptoms and tardive dyskinesia**, at the cost of a **higher metabolic burden**. **Atypical antipsychotics are preferred over conventional antipsychotics in older adults.**
2. **Evidence-based indications. Schizophrenia and late-onset schizophrenia / VLOSLP** (amisulpride 100 mg has RCT support); **delusional disorder and late-life psychosis**; **acute mania in bipolar disorder** (quetiapine, aripiprazole, risperidone at one-third to one-half adult dose); **augmentation of antidepressants in treatment-resistant depression**; **psychotic depression** combined with an antidepressant; **Parkinson's disease psychosis** (quetiapine, clozapine, or pimavanserin); and **severe, distressing or dangerous agitation and psychosis in dementia after non-drug measures have failed**.
3. **Choosing the agent. Quetiapine** — the drug of choice where **parkinsonism or DLB** is present; sedating, causes orthostatic hypotension. **Risperidone 0.25–1 mg** — most evidence in dementia-related psychosis, but dose-dependent EPS and hyperprolactinaemia. **Olanzapine 2.5–5 mg** — sedating, most metabolic burden, strongly anticholinergic. **Aripiprazole 2–5 mg** — partial D2 agonist, least metabolic effect, may cause akathisia. **Clozapine** — reserved for treatment-resistant schizophrenia and Parkinson's disease psychosis; requires **mandatory neutrophil monitoring**.
4. **Adverse effects — the geriatric list. Metabolic** — weight gain, hyperglycaemia, dyslipidaemia (worst with olanzapine and clozapine). **Cardiovascular** — **orthostatic hypotension and falls**, **QTc prolongation and torsades**. **Neurological** — EPS, **tardive dyskinesia (risk rises with age)**, **neuroleptic malignant syndrome**, sedation, **worsening of cognition**. **Anticholinergic** — dry mouth, constipation, urinary retention, delirium (olanzapine, clozapine). **Endocrine** — hyperprolactinaemia (risperidone). **Others** — aspiration pneumonia, venous thromboembolism, **agranulocytosis with clozapine**, and **severe neuroleptic sensitivity in DLB** (sedation, worsening parkinsonism, autonomic instability — may be irreversible).
5. **The boxed warning — must be written. All antipsychotics, typical and atypical, carry a boxed warning of increased mortality and cerebrovascular events when used for behavioural symptoms of dementia** (roughly a 1.6–1.7 fold increase in death, mainly cardiac and infective). **No medication is FDA-approved for treating the neuropsychiatric symptoms of dementia.** Use therefore requires **documented failure of non-pharmacological measures, informed consent from the patient or nominated representative, the lowest effective dose, and a defined review and withdrawal date**.
6. **Safe prescribing rules. Start at one-quarter to one-third of the adult dose and titrate slowly.** Baseline and periodic monitoring of **weight and waist circumference, fasting glucose (mg/dL), lipid profile, ECG for QTc, blood pressure lying and standing, prolactin if symptomatic, and an EPS/tardive dyskinesia examination (AIMS)**. **Review for deprescribing every 3 months** — most patients with dementia can be withdrawn without symptom recurrence. Avoid combining with other QT-prolonging or anticholinergic drugs. Note that **antipsychotics such as quetiapine should generally not be used for anxiety disorders, as the risks outweigh the benefits**. The **AGS Beers Criteria list antipsychotics as potentially inappropriate** unless the indication is schizophrenia, bipolar disorder or short-term antiemesis.

Latest Update — 1 Point

7. **Brexpiprazole (FDA-approved May 2023) — the first drug ever approved for agitation associated with dementia due to Alzheimer's disease**, at 2–3 mg daily. It remains subject to the **class boxed warning on mortality in dementia-related psychosis**, effect sizes are modest, and it must still follow rather than replace non-pharmacological management. Alongside this, **xanomeline–trospium (KarXT, 2024)** introduces a **non-dopaminergic muscarinic mechanism** with no EPS, prolactin rise or weight gain — potentially a major advance for older adults, with dementia-related psychosis trials ongoing.

Quick-Reference Comparison

Drug	Geriatric dose	Best used for	Watch for
Quetiapine	12.5–50 mg	Parkinsonism, DLB, Parkinson's disease psychosis	Sedation, orthostatic hypotension, falls
Risperidone	0.25–1 mg	Dementia-related psychosis (most evidence), mania	Dose-dependent EPS, hyperprolactinaemia, stroke risk
Olanzapine	2.5–5 mg	Mania, psychosis where sedation is wanted	Weight gain, hyperglycaemia, anticholinergic delirium
Aripiprazole	2–5 mg	Antidepressant augmentation, mania, OABD	Akathisia, insomnia

Amisulpride	50–100 mg	VLOSLP (ATLAS trial evidence)	EPS, hyperprolactinaemia, renal accumulation
Clozapine	6.25–25 mg	Treatment-resistant schizophrenia, PD psychosis	**Agranulocytosis**, myocarditis, seizures, sialorrhoea

Question 28. Electroconvulsive therapy in older adults [7 marks]

Pivot: ECT as a complete stand-alone answer — technique, consent, adverse effects and continuation treatment. Its role specifically within depression is also covered in Question 2.

Textbook Core — 6 Points

1. **Definition and utilisation.** ECT is the delivery of a **brief electric current to the brain under general anaesthesia and muscle relaxation to produce a generalised cerebral seizure**, given in a course of typically **6–12 treatments, two to three times per week**. **Older adults constitute more than one-half of all patients who receive ECT for depression**, yet it remains **under-utilised despite its relative safety and high effectiveness**.
2. **Indications. Severe depression with somatic complications, severe suicidality, catatonia, and refusal of food and fluids — here immediate initiation of ECT is indicated. Psychotic depression. Pharmacotherapy-resistant depression.** Also **refractory mania**, **severe and treatment-resistant persistent agitation and aggression in dementia**, and neuroleptic malignant syndrome. **ECT should be considered a first-line option in all patients with severe depressive symptoms, especially where psychotic symptoms are present** — it is not a last resort.
3. **Efficacy and the age effect. ECT is probably more effective in more severe depression in older people than in younger adults**, and remission rates in psychotic depression exceed 70–80%. **The efficacy of ECT does not diminish with advancing age, but the seizure threshold increases**, so higher stimulus doses are needed. **Older age is a predictor of better response to ECT. ECT rapidly relieves expressed suicidal intent.**
4. **Pre-ECT assessment.** Confirm the indication and document **informed consent** — from the patient if capacity is present, otherwise from the nominated representative under the **Mental Healthcare Act 2017**, which **prohibits ECT without anaesthesia and muscle relaxants** and bars its use in minors without Mental Health Review Board permission. Assess **cardiovascular and respiratory fitness, cervical spine and dentition, and cognition (baseline MMSE/MoCA)**; obtain **CBC, electrolytes (mEq/L), glucose (mg/dL), renal and liver function, ECG, and chest X-ray**; review drugs — **stop or reduce benzodiazepines and anticonvulsants** (they raise the seizure threshold), continue antihypertensives, and withhold lithium.
5. **Adverse effects. ECT has remarkably few side effects in older age, with reversible cognitive side effects the most common feature** — **post-ictal confusion, anterograde amnesia and retrograde amnesia**, usually resolving within weeks, though patchy autobiographical memory gaps may persist. Others: **transient hypertension, tachycardia and arrhythmia**, headache, myalgia, nausea, prolonged seizure, and anaesthetic risk. **There is no absolute age limit and no absolute contraindication**; raised intracranial pressure, recent myocardial infarction, recent stroke, unstable aneurysm and severe cardiac disease are **relative** contraindications requiring specialist assessment.
6. **Technique, continuation and alternatives. Right unilateral electrode placement** reduces cognitive effects compared with bitemporal, at the cost of needing a higher stimulus dose; **brief and ultrabrief pulse widths** further limit memory impairment. **Relapse is high after a successful course**, so give **continuation pharmacotherapy (antidepressant with or without lithium) or continuation/maintenance ECT**. **Transcranial magnetic stimulation** is a non-invasive alternative for depression resistant to at least one antidepressant, approved also for OCD, and carries **lower risks than antidepressants**, but should be used judiciously where there is seizure risk after stroke or traumatic brain injury.

Latest Update — 1 Point

7. **ELEKT-D trial (*NEJM* 2023).** In **treatment-resistant major depression without psychosis**, **subanaesthetic intravenous ketamine was non-inferior to ECT** with fewer cognitive adverse effects — providing an option where ECT is refused, unavailable or contraindicated. **ECT nevertheless remains superior and first-line in psychotic depression, catatonia and acute suicidality**, all of which were excluded from that trial. Current practice increasingly favours **right unilateral ultrabrief-pulse ECT**, which achieves **comparable efficacy with substantially less cognitive impairment** in older adults.

Exam one-liners: *ECT = brief current under anaesthesia + muscle relaxant → generalised seizure · >50% of ECT recipients for depression are older adults · efficacy undiminished by age but seizure threshold rises · older age predicts better response · commonest adverse effect is reversible cognitive impairment · no absolute contraindication · MHCA 2017 prohibits unmodified ECT · relapse is high — always give continuation treatment.*

Question 29. Cognitive behavioural therapy [7 marks]

Textbook Core — 6 Points

1. **Definition and model.** CBT is an **active, structured, time-limited, goal-directed psychotherapy that aims to change the thinking and behaviour that maintain a disorder**. It rests on the **cognitive model** — a situation triggers an **automatic thought**, which drives **emotion, physiological arousal and behaviour**; these are underpinned by **intermediate beliefs (rules and assumptions)** and **core beliefs (schemas)**. Changing the cognition changes the emotion and the behaviour.
2. **Structure of treatment.** Typically **8–20 weekly sessions of 45–60 minutes**, individual or group, delivered with a **collaborative, agenda-setting style** and **homework between sessions**. Core techniques: **psychoeducation**, **thought records and identification of cognitive distortions** (catastrophising, all-or-nothing thinking, overgeneralisation, mind-reading), **Socratic questioning and cognitive restructuring**, **behavioural activation and activity scheduling**, **graded exposure with response prevention**, **problem-solving**, **relaxation training**, and **relapse prevention**.
3. **Evidence base and indications in older adults. CBT for depression carries Level A evidence and is effective when compared with no treatment. Psychotherapy is as effective in older adults as in younger adults**, and **many older adults prefer counselling to psychopharmacological intervention**. Indications: **depression** (especially mild to moderate), **anxiety disorders and GAD**, **phobias including fear of falling**, **panic disorder**, **OCD (as exposure and response prevention)**, **PTSD**, **insomnia (CBT-I, the first-line treatment for chronic insomnia at any age)**, **chronic non-cancer pain**, **somatic symptom disorder**, **caregiver stress**, and as psychological support during **rational deprescribing**.
4. **Problem-solving therapy — the key geriatric variant. Individual CBT, particularly problem-solving therapy, is the recommended psychological intervention for late-life depression**, and it is **especially effective where executive dysfunction is present** — the group least likely to respond to antidepressants. Its seven steps: define the problem → set a realistic goal → generate solutions → evaluate the options → choose and plan → implement → review the outcome.
5. **Adaptations required in older adults. Psychotherapy may need to be modified to accommodate cognitive and sensory deficits.** Practical adjustments: **slower pace and shorter, more frequent sessions**; **written summaries, large print and audio recordings**; **hearing aids and spectacles in place, quiet well-lit room**; **repetition and memory aids for homework**; **involvement of family or carer**; **home visits or telephone/video delivery** where mobility is limited. Content must be **dynamic and sensitive to the existential issues of loss, dependency and change of status, yet fully aware of opportunities for growth and vigour**, with the **focus best directed at functional outcomes**.
6. **Limitations and related therapies.** CBT requires **some capacity for abstraction, insight and memory**, so it is of limited use in **moderate to severe dementia, delirium, and active psychosis**, and needs motivation and regular attendance. Availability of trained therapists is a real constraint in India. Related and complementary approaches include **interpersonal therapy, reminiscence and life review, behavioural activation, mindfulness-based interventions, dialectical behaviour therapy (personality disorders), and family therapy**. **Psychoeducation should be a routine part of treatment and, whenever feasible, should include family members** — this prevents the unrealistic expectation of rapid, complete recovery that leads to premature termination.

Latest Update — 1 Point

7. **Digital and remotely delivered CBT (2023–2025).** Systematic reviews and randomised trials now show that **internet-delivered and telephone/video CBT are effective in older adults for depression, anxiety and insomnia**, with effect sizes approaching face-to-face therapy when therapist support is included — directly addressing the shortage of trained therapists and the mobility and transport barriers that limit uptake in this age group. Alongside this, **mindfulness-based stress reduction was shown to be non-inferior to escitalopram for anxiety disorders (Hoge et al., *JAMA Psychiatry* 2023)**, and **CBT-I remains the guideline-endorsed first-line treatment for chronic insomnia in older adults**, in preference to any hypnotic.

Section H — Sexuality in Later Life

Question 30. Sexual dysfunction and its psychiatric associations in the elderly [7 marks]

Textbook Core — 6 Points

1. **Normal ageing changes. Men** — slower erection, reduced rigidity, **longer refractory period**, reduced ejaculatory volume. **Women** — vaginal dryness, atrophy, dyspareunia, reduced elasticity (**genitourinary syndrome of menopause, GSM**). **Sexual desire persists into late life** — ageing alone does not abolish sexual interest.
2. **Classification. Desire** disorders (hypoactive sexual desire), **arousal** disorders (**erectile dysfunction**, female arousal disorder), **orgasmic** disorders, and **sexual pain** disorders (dyspareunia, vaginismus).
3. **Organic causes. Diabetes**, cardiovascular and peripheral vascular disease, hypertension, **prostate surgery and pelvic radiotherapy**, neurological disease (**Parkinson's disease**, stroke, neuropathy), **hypogonadism** (testosterone in ng/dL), hyperprolactinaemia, CKD, arthritis, and obesity. **Erectile dysfunction is an early marker of endothelial dysfunction and predicts future cardiovascular events.**
4. **Drug causes. SSRIs and SNRIs** (commonest — delayed orgasm, reduced desire), **antipsychotics** (hyperprolactinaemia), **beta-blockers, thiazides, spironolactone, finasteride**, anticholinergics, opioids, and alcohol.
5. **Psychiatric associations. Depression** — a **bidirectional relationship** (both a cause and a consequence, and its drug treatment worsens it further); **anxiety and performance anxiety**; **dementia** — disinhibition, **inappropriate sexual behaviour**, and difficult **capacity-to-consent** questions in care homes; alcohol misuse; and **bereavement and widowhood — lack of a partner is the commonest reason for sexual inactivity in older women**.
6. **Management.** Use the **PLISSIT model** (Permission → Limited Information → Specific Suggestions → Intensive Therapy). Optimise chronic disease; **review and switch the offending drug** (e.g. SSRI → bupropion or mirtazapine). **PDE-5 inhibitors (sildenafil, tadalafil) are first-line for ED** — **absolutely contraindicated with nitrates**, caution with alpha-blockers. **Low-dose vaginal oestrogen ± lubricants** for GSM. Couple and psychosexual counselling. **Testosterone only in biochemically confirmed hypogonadism.**

Latest Update — 1 Point

7. **2023–2025 guidance.** AUA/EAU reaffirm **PDE-5 inhibitors as first-line for ED at any age**, with cardiovascular risk stratification before resuming sexual activity (**Princeton consensus** low / intermediate / high-risk categories). Menopause society guidance (**NAMS / IMS 2023–24**) endorses **low-dose vaginal oestrogen, prasterone (intravaginal DHEA) and ospemifene** as safe and effective for GSM — including in most breast cancer survivors after discussion with the oncologist — as **systemic absorption is negligible**.

If asked for 15 marks, add: *physiology of the sexual response cycle and its age-related changes; detailed history-taking and examination framework; investigations (fasting glucose, lipids, testosterone ng/dL, prolactin, TSH, PSA ng/mL); management of inappropriate sexual behaviour in dementia (behavioural first, then SSRI, antiandrogen as last resort); capacity and consent in institutional settings; sexuality in LGBT+ elders; and Indian cultural attitudes and the near-absence of sexual history-taking in geriatric practice.*

Section I — Law, Ethics and Capacity

The two statutory and ethical questions that recur in every paper.

Question 31. Mental Healthcare Act 2017 — provisions relevant to geriatric psychiatry [15 marks]

Textbook Core — 10 Points

1. **Background and scope. Act No. 10 of 2017**, assented on **7 April 2017** and in force from **29 May 2018**. It **repeals the Mental Health Act 1987** and was enacted to fulfil India's obligations under the **UN Convention on the Rights of Persons with Disabilities (UNCRPD)**. The shift is from a **custodial to a rights-based model** — mental healthcare is now a **legal right, not a discretionary service**.
2. **Definition of mental illness — Section 2(s).** A **substantial disorder of thinking, mood, perception, orientation or memory** that **grossly impairs judgement, behaviour, capacity to recognise reality, or the ability to meet the ordinary demands of life**; it **includes conditions associated with alcohol and drug abuse** but **excludes mental retardation**. **Dementia and delirium therefore fall within the Act.**
3. **Presumption of capacity — Section 4. Every person is presumed to have the capacity** to make mental healthcare decisions unless proved otherwise. Capacity means the ability to **understand the information, appreciate the reasonably foreseeable consequences, and communicate the decision**. **A diagnosis of dementia alone does not remove capacity**, which is decision-specific.
4. **Advance Directive — Sections 5 to 13.** Any adult with capacity may make a **written advance directive** stating **how they wish to be, and not to be, cared for and treated**, and may register it with the **Mental Health Review Board (MHRB)**. It may be revoked or amended at any time and can be challenged before the MHRB. **Of particular value in early dementia and recurrent bipolar disorder.**
5. **Nominated Representative — Sections 14 to 17.** Every person has the right to **appoint a Nominated Representative (NR)** in writing. If none is appointed, a statutory order of default applies (relative, caregiver, or a person appointed by the MHRB). The NR **receives information, supports the person, and gives consent where capacity is lacking** — a key provision in advanced dementia.
6. **Right to access mental healthcare — Section 18.** A right to **affordable, good-quality, geographically accessible** services run or funded by government — including **outpatient and inpatient care, half-way homes, sheltered accommodation and community-based rehabilitation**, with explicit mention of provision for **older persons**.
7. **Community living and protection from abandonment — Sections 19 to 20.** The right to **live in and be part of the community and not to be segregated**. Crucially, **no person may be kept in a mental health establishment merely because the family is absent or unwilling** — the government must provide **supported accommodation**. This is directly relevant to **abandoned elders**, alongside the **MWPSC Act 2007**.
8. **Other rights — Sections 20 to 28.** Protection from **cruel, inhuman and degrading treatment**; equality and non-discrimination; right to information, **confidentiality**, legal aid, and to make complaints. **Chaining is prohibited**; **seclusion and solitary confinement are prohibited**; **physical restraint only as a last resort** with documentation and NR intimation.
9. **Admission, treatment and ECT. Independent admission (Sec 86)** for those with capacity who consent. **Supported admission (Sec 89 — up to 30 days; Sec 90 — beyond 30 days)** for those lacking capacity who pose a risk of harm to self or others, or are unable to care for themselves — requires **two independent mental health professionals** and MHRB oversight. **ECT is prohibited without muscle relaxants and anaesthesia**, and is **banned for minors without MHRB permission**. **Psychosurgery requires informed consent plus MHRB approval.**
10. **Insurance parity and decriminalisation of suicide. Section 21(4)** — every insurer must provide medical insurance for mental illness **on the same basis as for physical illness**. **Section 115** — a person who attempts suicide is **presumed to be under severe stress, shall not be prosecuted**, and the government must provide care and rehabilitation. This matters greatly given the **high suicide rate in older Indians**. Institutional framework: **Central and State Mental Health Authorities and Mental Health Review Boards**.

Latest Updates — 2 Points

11. **Ayushman Bharat Vay Vandana (from late 2024).** All citizens **aged 70 years and above** are now entitled to **AB-PMJAY cover of ₹5 lakh per family per year irrespective of income**, with **mental health packages included**. This operationalises the Section 18 right of access and the Section 21(4) parity requirement specifically for older adults, and is the single most quotable Indian development in this area.
12. **Implementation gap and delivery route (2024–25 reviews).** Studies in *Indian Journal of Psychological Medicine* and *Lancet Psychiatry* document that **Section 21(4) insurance parity remains poorly implemented**; the current enforcement instrument is the **IRDAI directive requiring all policies to cover mental illness without exclusion**. Service delivery now runs mainly through the **District Mental Health Programme under the NMHP**, **Tele-MANAS (14416)**, and **Ayushman Arogya Mandirs** for community-level screening.

Exam one-liners: *Act No. 10 of 2017 · assented 7 April 2017 · effective 29 May 2018 · repeals MHA 1987 · Sec 2(s) definition · Sec 4 capacity*

· Sec 5 advance directive · Sec 14 nominated representative · Sec 18 right to access · Sec 21(4) insurance parity · Sec 86 independent admission · Sec 89/90 supported admission · Sec 95 prohibited procedures (ECT without anaesthesia, chaining) · Sec 115 decriminalisation of suicide.

Question 32. Capacity assessment and consent in the cognitively impaired patient [15 marks]

Textbook Core — 10 Points

1. **Capacity versus competence. Capacity** is a **clinical judgement** about a person's ability to make a **specific decision at a specific time**. **Competence is a legal term** implying that a person has been declared competent or incompetent **by a court of law**. **Clinicians assess capacity; courts declare competence.**
2. **Ethical basis.** The four principles — **autonomy, beneficence, non-maleficence and justice**, with **fidelity**. **Valid consent requires three things: it must be informed, voluntary, and given by a person with capacity.** Autonomy does not mean "I want, therefore I get" — but it does mean "you may not do things to me without my permission".
3. **The four elements of decisional capacity. (i) Understanding** the disclosed information; **(ii) Appreciation** of its significance for one's own situation; **(iii) Reasoning** — the ability to weigh risks and benefits; **(iv) Communicating a Choice** clearly and consistently.
4. **Core principles. Capacity is presumed until proved otherwise.** It is **decision-specific and time-specific**. **An unwise decision is not evidence of incapacity** — if a patient with capacity refuses treatment, that refusal stands and the duty of care continues without prejudice. **A diagnosis of dementia does not by itself establish incapacity**; deficits are patchy, and a person may decide well with appropriate prompting.
5. **Sliding scale of capacity.** The **standard required rises with the risk of the decision**. A patient may have capacity to consent to a blood test but not to major surgery or a Phase 1 trial. **Match the complexity of the decision to the patient's cognitive capacity** — "stage the ageing as carefully as you stage the disease".
6. **How to assess.** Give information in **simple language, in the patient's own language**, in a **quiet setting**, with **hearing aids and spectacles in place**, at the **patient's best time of day**, with written material in **large type and good contrast**. Ask the patient to **paraphrase the information back**, and **re-check consistency after an interval**.
7. **Cognitive tests and their limits. No cognitive screening test determines decision-making capacity. MMSE and MoCA correlate poorly**; tests of **executive function — the Clock Drawing Test and the Executive Interview — correlate better**. Structured instruments: **MacArthur Competence Assessment Tool for Treatment (MacCAT-T)** is the reference standard, and the **Aid to Capacity Evaluation (ACE)** is the practical bedside tool recommended for hospitalised older adults.
8. **Optimise capacity before declaring it absent.** Treat reversible contributors first — **delirium, infection, pain, hypoxia, hypoglycaemia, constipation, urinary retention, depression, sedatives and anticholinergic drugs, and sensory deprivation**. **Incapacity is common in hospitalised older adults and is under-recognised by physicians.**
9. **When capacity is lacking — the hierarchy.** Follow, in order: **(1) a valid advance directive → (2) the appointed surrogate / nominated representative / power of attorney → (3) a best-interests decision by the lead clinician**, or an application for guardianship where the law requires. **Best interests must weigh the person's past and present wishes, beliefs and values**, not only medical benefit. **Personhood persists even when capacity does not.**
10. **Documentation and common pitfalls.** Record the **specific decision, the information given, the patient's responses under each of the four elements, the conclusion, and who was involved**. Pitfalls to avoid — equating a low MMSE with incapacity; assessing "global" instead of decision-specific capacity; accepting the family's view over the patient's; **infantilising the patient by directing questions to relatives**; and **failing to reassess once delirium has resolved**.

Latest Updates — 2 Points

11. **Indian statutory framework.** The **Mental Healthcare Act 2017, Section 4** creates a **statutory presumption of capacity** with a three-part test (**understand → appreciate consequences → communicate**), and provides for **Advance Directives (Sec 5)** and **Nominated Representatives (Sec 14)**. The **Rights of Persons with Disabilities Act 2016** similarly favours **supported over substituted decision-making**, replacing the older guardianship-based approach.
12. **International direction (2023–2025).** Guidance continues to shift from **substituted to supported decision-making** under **UNCRPD Article 12**. The **2024 Lancet Commission on dementia prevention, intervention and care** reinforces **early advance care planning while capacity is retained**, and current practice recommends **structured instruments (MacCAT-T / ACE) rather than unaided clinical impression** for high-stakes decisions.

```
CAPACITY ASSESSMENT ALGORITHM
Specific decision required
        |
Presume capacity  ->  Optimise: treat delirium/pain/depression, hearing aid, glasses,
        |                          quiet room, simple language, best time of day
Assess the FOUR elements:  Understand -> Appreciate -> Reason -> Communicate a Choice
        |
   ALL PRESENT?
      |        \
     YES        NO
      |          \
  Patient decides  Advance Directive?  --yes--> follow it
  (even if unwise)        | no
                  Nominated Representative / surrogate / POA?  --yes--> they decide
                         | no
                  BEST-INTERESTS decision by lead clinician (+ guardianship if required)
                         |
                  DOCUMENT everything; REASSESS when the reversible cause clears
```

Appendix. Consolidated Night-Before Master Sheet [all 32 questions]

One line of core content and one latest update for every topic in this compilation, merged from all three source sets.

Topic	Must-write core	Must-write latest update
Psychogeriatrics		
Delusional disorder	Non-bizarre delusion ≥1 month, function preserved; partition delusions in VLOSLP; sensory loss + isolation are key risks; atypicals at ¼–⅓ dose	Xanomeline–trospium (KarXT) FDA 2024, first muscarinic antipsychotic; ATLAS — amisulpride 100 mg
Bipolar in late life	Late-onset mania = secondary mania until proved otherwise; irritability not euphoria; GERI-BD — lithium ≈ divalproex	ISBD OABD: lithium 0.4–0.8 mEq/L (60–79 y), 0.4–0.7 (≥80 y)
Somatoform / conversion	New onset after 60 is rare — exclude organic disease and depression; Hoover's sign; CBT first-line; avoid repeat investigations	ICD-11 Bodily Distress Disorder; FND is a rule-in diagnosis
Grief	Complicated grief ≥6 months; risk = sudden/traumatic death, ambivalent relationship; psychotherapy first-line	Prolonged Grief Disorder — DSM-5-TR ≥12 months, ICD-11 ≥6 months
Personality disorders	Cluster A prominent, B burns out, C persists; new-onset change = organic (FTD) until proved otherwise; Diogenes syndrome	ICD-11 — single dimensional diagnosis, severity + 5 trait domains
Sexual dysfunction	Desire persists in old age; ED predicts CVD; SSRIs commonest drug cause; PLISSIT model; PDE-5i first-line	Vaginal oestrogen / prasterone / ospemifene safe for GSM (NAMS-IMS)
Benzodiazepine dependence	10% community, 25% nursing home; SDS score ≥6; convert to diazepam and taper over months; withdrawal → confusion, seizures	ASAM 2025 — taper most older adults, 5–10% every 2–4 weeks, no forced taper; BIND
Nicotine dependence	Quitting benefits even in the 70s; 5 A's; combination NRT / varenicline / bupropion; cessation raises clozapine and olanzapine levels	Cytisinicline — ORCA-2/ORCA-3, efficacy like varenicline, fewer GI effects
Substance misuse	Three categories — medications, sanctioned substances, illicit; prescribed BZD/opioid misuse dominates; non-confrontational age-specific programmes work better	Cannabis fastest-rising in ≥65; Beers 2023 opioid + BZD/gabapentinoid caution
MHCA 2017	Sec 4 capacity, Sec 5 advance directive, Sec 14 NR, Sec 18 access, Sec 21(4) insurance, Sec 89/90 supported admission, Sec 115 suicide	Ayushman Bharat Vay Vandana — ₹5 lakh cover for all aged ≥70, mental health included
Capacity and consent	Capacity is clinical, competence is legal; four elements; decision-specific; unwise ≠ incapable; MacCAT-T / ACE; optimise before declaring absent	Supported over substituted decision-making (UNCRPD Art 12); 2024 Lancet Commission — early ACP
GDS	Yesavage 1982; somatic items excluded; GDS-15 cut-off ≥5; GDS-30 cut-off ≥11; invalid if MMSE <15 → Cornell Scale	USPSTF 2023 Grade B — screen all adults where follow-up exists
Mood, Anxiety & Suicide		
Depression — prevalence	MDD 1–5% community; symptoms 8–16%; higher in primary care, hospital and LTC; LASI ~8% in Indians ≥60	USPSTF 2023 Grade B — screen all adults including ≥65
Depression — presentation	"Depression without sadness"; somatic complaints; psychomotor symptoms; nihilistic delusions; anxious distress specifier; bereavement exclusion removed	Lancet Commission 2024 — depression a modifiable dementia risk factor
Depression — treatment	Stepped care; SSRI first-line at half dose; 6–12 weeks for full effect; ≥1 year after first recurrence, lifelong after second	OPTIMUM 2023 — aripiprazole augmentation, remission 28% vs 19%, fewer falls
Antidepressants	Sertraline/escitalopram first; avoid TCAs and paroxetine; hyponatraemia, falls, GI bleeding, QTc; mirtazapine if	Hyperbolic tapering (Maudsley 2024); withdrawal is not relapse

	anorexia + insomnia	
ECT	First-line if severe, psychotic, catatonic, suicidal or not eating; efficacy undiminished with age; seizure threshold rises; older age predicts better response; reversible cognitive effects only	ELEKT-D 2023 — ketamine non-inferior in non-psychotic TRD; ultrabrief right unilateral ECT
Suicide	WHO at age 75: men 50/100,000, women 16/100,000; attempt-to-completion 4:1 vs 200:1; 20–50% see the PCP within a week; depression strongest risk factor, self-harm strongest predictor	India NSPS 2022 — 10% reduction by 2030; NCRB elderly suicides up 40% from 2019 to 2022
Anxiety (general)	Not normal ageing; most prevalent yet most under-treated; agoraphobia and panic > phobias > GAD; SSRIs first-line, up to 6 weeks; no antipsychotics; benzodiazepines short-term only	USPSTF 2023 — Grade B for 19–64, **I-statement for ≥65**
GAD	Half lifelong, half onset within last 5 years; health-centred worry; buspirone an option; exclude medical, drug and withdrawal causes	MBSR non-inferior to escitalopram (JAMA Psychiatry 2023); Beers 2023
Phobias	Agoraphobia commonest; **fear of falling** is the geriatric-specific phobia, rare in the young; vicious cycle of activity restriction; graded exposure + CBT; avoid benzodiazepines	World Falls Guidelines — assess "concern about falling" in every falls assessment
OCD	DSM-5 own chapter; new onset after 60 is organic (basal ganglia, FTD); Y-BOCS; ERP first-line; SSRIs need higher dose and 10–12 weeks	TMS approved for OCD; deep TMS (H7 coil) for refractory cases
Mood disorders overall	DSM-5 split into depressive and bipolar; persistent depressive disorder ≥2 years; secondary mania; apathy is not depression	ISBD lithium 0.4–0.8 mEq/L (60–79 y), 0.4–0.7 (≥80 y)
Psychosis, Therapeutics, Personality & Alcohol		
Late-life psychosis	~60% of new-onset psychosis in late life is secondary; the **six D's** — delirium, disease, drugs, dementia, depression, delusional disorder; treat the cause, correct sensory loss, then low-dose atypical	Xanomeline–trospium (KarXT), FDA 2024 — first muscarinic antipsychotic
Late-onset schizophrenia	LOS 40–59 y, VLOSLP ≥60 y (late paraphrenia); female predominance; deafness and isolation; **partition delusions**; negative symptoms and thought disorder rare	ATLAS — amisulpride 100 mg/day, the only placebo-controlled RCT in VLOSLP
Atypical antipsychotics	D2 + 5-HT2A; quarter to a third of adult dose; quetiapine in DLB/PD; boxed warning of stroke and death in dementia; monitor weight, glucose, lipids, QTc, EPS; review every 3 months	Brexpiprazole, FDA May 2023 — first drug approved for agitation in Alzheimer's dementia
ECT	>50% of recipients are older adults; first-line if severe, psychotic, catatonic, suicidal or not eating; efficacy undiminished by age but seizure threshold rises; older age predicts better response; reversible cognitive effects; no absolute contraindication	ELEKT-D 2023 — ketamine non-inferior in non-psychotic TRD; ultrabrief right unilateral ECT
CBT	Structured, time-limited, 8–20 sessions; thought records, behavioural activation, graded exposure, homework; **problem-solving therapy** best where executive dysfunction; adapt for sensory and cognitive deficits	Digital and remote CBT effective in older adults; CBT-I first-line for chronic insomnia
Agitation — non-drug	Almost all people with dementia become agitated; look first for **pain, infection, constipation, retention, dehydration, drugs, delirium**; DICE and ABC; tailored activity, music, massage, animal-assisted, light therapy; carer training	IPA consensus definition of agitation; 2023–25 network meta-analyses favour tailored activity, massage, animal-assisted intervention
Personality change	Normal ageing = maturation, not rigidity; traits are accentuated under stress; **new personality change in old age is organic until proved otherwise** — FTD is the prototype; drugs do not help	ICD-11 — single dimensional diagnosis with severity + 5 trait domains; "personality change due to another medical condition" retained separately
Diogenes syndrome	Tetrad — extreme self-neglect, domestic squalor, social withdrawal, refusal of help, with hoarding and no shame; half are primary; premorbid paranoid/schizoid/OC traits; **home visit essential**; ~45% five-year mortality	Hoarding disorder now a distinct DSM-5/ICD-11 diagnosis; specialised CBT, not forced clearance
Alcoholism in the elderly	Early-onset "survivors" two-thirds vs late-onset "reactors" one-third; reduced body water and hepatic metabolism → higher levels; CAGE and **SMAST-G**; inpatient detox with lorazepam and thiamine; non-confrontational programmes double abstinence	WHO 2023 — no safe level; US Surgeon General 2025 — alcohol the third leading preventable cause of cancer
OP poisoning essay	DUMBBELS; decontaminate and protect staff; **atropine by**	AHA 2023 poisoning guidelines; India NSPS 2022 —

	dose doubling to clear chest, dry axillae, HR >80; pralidoxime early (benefit debated); watch intermediate syndrome at 24–96 h and OPIDN at 2–3 weeks; psychiatric assessment before discharge	pesticide restriction as the leading pillar

Cross-Cutting Themes the Examiner Rewards

1. **"Organic until proved otherwise"** — applies to late-onset psychosis, late-onset mania, new personality change, and new somatoform presentation. Write it every time.
2. **"Start low, go slow"** plus explicit numbers — antipsychotics at ¼–⅓ adult dose, mood stabilisers 30–50% lower, lithium 0.4–0.8 mEq/L.
3. **Non-pharmacological measures come first** — sensory correction, reducing isolation, CBT, psychoeducation, carer support.
4. **Deprescribing is treatment** — benzodiazepines, anticholinergics, opioids; cite Beers and STOPP/START.
5. **Indian context in every answer** — MHCA 2017, NPHCE, AB-PMJAY / Vay Vandana, Tele-MANAS 14416, Elder Line 14567, MWPSC Act 2007, NTCP quitline 1800-11-2356, LASI data.

Five Lines That Earn Marks in Every Answer in This Module

1. **"Asking about suicide does not increase risk — most patients are relieved and it strengthens trust."**
2. **"Antidepressants are just as effective in older people as in younger adults"** — tolerability, not efficacy, drives drug choice.
3. **"ECT is not a last resort — it is first-line in severe, psychotic, catatonic or acutely suicidal depression, and older age predicts a better response."**
4. **"Benzodiazepines: short-acting, short-term, and only for incapacitating symptoms"** — cognitive impairment, falls and fractures otherwise.
5. **"New-onset mania, OCD or personality change in old age is organic until proved otherwise."**

Cross-Module Differentiation Grid — How the Overlapping Questions Differ

Question	Pivot point — what the answer must emphasise
Q1 — Depression, full essay	Prevalence figures → atypical presentation → subtypes → management → **ECT as a dedicated section**
Q2 — Treatment and management	**Stepped-care model**, psychotherapy vs drugs, resistant depression pathway, duration of maintenance
Q3 — Antidepressant medication	**Pure pharmacology** — class-by-class, adverse effects, contraindications, augmentation, tapering
Q4 — Clinical vignette	**Safety first** → exclude organic cause of weight loss → drug table with side effects → structured follow-up schedule
Q10 — Mood disorders in late life	**Classification and the whole spectrum** — depressive + bipolar + secondary/organic + apathy and mimics

Six Lines That Earn Marks Across This Whole Module

1. **"About 60% of new-onset psychosis in late life is secondary — primary psychosis is a diagnosis of exclusion."**
2. **"Atypical antipsychotics are preferred over conventional agents — but all carry a boxed warning of increased stroke and death in dementia, and no drug is approved for the neuropsychiatric symptoms of dementia."**
3. **"ECT is not a last resort — older age predicts a better response, and its efficacy does not diminish with age."**
4. **"For agitation, look for pain, infection, constipation and drugs before reaching for any prescription."**
5. **"A personality change that begins in old age is organic until proved otherwise."**
6. **"In organophosphate poisoning, the endpoint of atropinisation is a clear chest and dry axillae — not the pupils."**

MD GERIATRIC MEDICINE — UNIVERSITY EXAMINATION

Compiled Question Bank

Renal · Fluid–Electrolyte · Diabetes · Endocrine · Metabolic Bone
Crystal Arthropathy · Environmental & Systemic Disorders

36 Questions · Mark-wise High-Yield Answers

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition · Kane's Essentials of Clinical Geriatrics
Latest evidence: 2023–present international and Indian guidelines · Indian conventional units throughout

How to Use This Document

ANSWER ARCHITECTURE

Every answer follows the same four-block structure, so you always know where to look:

1. **Textbook Core** — numbered high-yield points drawn from the uploaded textbooks, with the keywords an examiner scans for in bold.
2. **Latest Update (2023–present)** — named trials, guideline changes and regulatory approvals, cited inline.
3. **Current Practice Update** — a comparison table, included *only* where a genuine conflict exists between the textbook position and current evidence, with an explicit exam-approach line.
4. **Recall aids** — exam one-liners, memory anchors, answer skeletons and named examiner traps.

Recurring examination questions carry a red flag in the header and receive additional scaffolding.

POINT-COUNT CONVENTION

Marks	Textbook core points	Latest updates	Total points
20-mark essay	14	3	**17**
15-mark essay	10	2	**12**
7-mark note	6	1	**7**
6-mark note	5	1	**6**

OVERLAPPING QUESTION PAIRS — READ BEFORE YOU REVISE

Several questions in this bank cover neighbouring ground. Each has been given a **distinct pivot** so that the answers do not repeat one another. Learn the pivot, not just the topic.

Pair	First question's pivot	Second question's pivot
Q3 vs Q4 & Q5 Fluid/electrolytes vs hyponatraemia and SIADH	**Q3** — the whole spectrum, grounded in ageing renal physiology	**Q4** — the diagnostic algorithm and correction rules for hyponatraemia of any cause; **Q5** — SIADH itself: criteria, exclusions, therapeutic ladder
Q10 vs Q12 AKI vs starting dialysis	**Q10** — treatment of the acute injury	**Q12** — the decision to start renal replacement therapy
Q12 vs Q13 Starting RRT vs modality	**Q12** — *when* to start (AEIOU, symptom-driven criteria)	**Q13** — *which* modality: PD, HD or conservative management
Q18 vs Q19 Drug selection vs drug class	**Q18** — case-based agent selection by comorbidity profile	**Q19** — pharmacology, outcome trials and geriatric cautions of the two classes
Q25, Q26, Q27 Hypothyroid cluster	**Q25** — when a raised TSH with normal T4 should and should not be treated	**Q26** — practical management in a cardiac patient; **Q27** — the disease itself, its antibodies, associations and complications
Q32 vs Q33 Gout cluster	**Q32** — diagnosis and treatment of the acute attack	**Q33** — the whole disease, weighted to urate-lowering therapy and treat-to-target

A NOTE ON SOURCE COVERAGE

Every answer is grounded in the uploaded textbooks as the primary source. **One topic is an exception:** chronic fatigue syndrome / myalgic encephalomyelitis (Question 36) is **not covered adequately in the uploaded textbooks**. Pathy's addresses *cancer-related fatigue* and refers to *idiopathic chronic fatigue in older adults* being linked to impaired skeletal-muscle mitochondrial content and biogenesis signalling; Kane's addresses fatigue as a non-specific presentation. Those elements are used where they apply, and the diagnostic frameworks are taken from the **IOM/NAM 2015 criteria**, the **Fukuda 1994 CDC criteria** and **NICE NG206 (2021)**, each clearly named in the text.

Contents

Part I — Renal Physiology and Assessment

1. Glomerular filtration rate *(6 marks)* 6

2. Renal biopsy — indications in the older adult *(7 marks)* 8

Part II — Fluid, Electrolyte and Acid–Base Disorders

3. Fluid and electrolyte disturbances in older patients and their management *(20 marks)* 9

4. Hyponatraemia *(7 marks · **recurring**)* 12

5. SIADH — syndrome of inappropriate antidiuretic hormone secretion *(20 marks)* 15

6. Hypokalaemia and hypomagnesaemia *(7 marks)* 18

7. A known diabetic on oral hypoglycaemic agents attends for routine review; serum potassium is 5.7 mEq/L. Investigation and treatment *(7 marks · **recurring**)* 19

8. Hypercalcaemia — causes, evaluation and management, including PTH-independent hypercalcaemia *(7 marks · **recurring**)* 21

9. Metabolic acidosis and its evaluation *(7 marks)* 25

Part III — Kidney Disease

10. Management of acute kidney injury *(7 marks · **recurring**)* 27

11. Chronic kidney disease — etiopathogenesis, diagnosis and management, with conservative management in the elderly *(15 marks · **recurring**)* 28

12. Criteria for initiating renal replacement therapy, with special emphasis on the elderly in our country *(7 marks · **recurring**)* 31

13. Peritoneal dialysis versus haemodialysis in the very old *(7 marks)* 33

14. Acute glomerulonephritis *(7 marks)* 34

15. Nephrotic syndrome and membranous nephropathy in the elderly *(15 marks)* 36

16. Interstitial nephritis *(7 marks)* 37

17. Diabetic nephropathy and its staging *(15 marks)* 39

Part IV — Diabetes Mellitus

18. A 65-year-old newly diagnosed diabetic with HbA1c 10%, hypertension, dyslipidaemia, osteoarthritis and BMI 35 refuses to adhere to diet and exercise. Which antidiabetic to start, and what to add *(7 marks)* 42

19. SGLT2 inhibitors and GLP-1 receptor agonists in the older adult *(15 marks)* 45

20. Alpha-glucosidase inhibitors *(6 marks)* 47

21. Newer insulins — onset, duration and advantages *(7 marks)* 48

22. Hypoglycaemia — evaluation and management *(15 marks)* 50

23. Diabetic ketoacidosis and hyperosmolar hyperglycaemic state *(15 marks)* 52

24. Diabetic foot syndrome *(15 marks)* 55

Part V — Thyroid Disease

25. Subclinical hypothyroidism in the elderly *(7 marks · **recurring**)* 58

26. A 70-year-old on treatment for cardiac failure has TSH 50 µIU/mL with suppressed T3 and T4, constipation, cold intolerance and considerable weight gain. Treatment, follow-up and specific instructions *(7 marks)* 61

27. Hashimoto's thyroiditis *(7 marks)* 63

28. Hyperthyroidism in the elderly — presentation, investigation and treatment *(7 marks)* 65

29. Solitary thyroid nodule and thyroid malignancy *(7 marks)* 67

Part VI — Endocrine and Metabolic Bone Disease

30. Testosterone replacement and andropause *(7 marks)* 69

31. Osteomalacia and vitamin D deficiency *(15 marks)* 71

Part VII — Crystal Arthropathy

32. A 65-year-old man presents with acute onset of severe pain in the right big toe for two days following a binge of alcohol. Most probable diagnosis and management *(7 marks)* 74

33. Management of gout *(7 marks)* 76

34. Pseudogout *(7 marks)* 79

Part VIII — Environmental and Systemic Disorders

35. Heat stroke — clinical features, diagnostic criteria, differential diagnosis and treatment *(7 marks)* 82

36. Chronic fatigue syndrome — diagnostic criteria, clinical manifestations, predisposing factors, course, prognosis and treatment *(15 marks)* 85

Night-Before Master Sheet — All 36 Questions 90

PART I

Renal Physiology and Assessment

Q1 · Q2

QUESTION 1 · RENAL PHYSIOLOGY

Glomerular filtration rate

6-Mark Note — 5 textbook points + 1 latest update = 6 points

TEXTBOOK CORE — 5 POINTS

1. **Definition and the trajectory with age.** GFR is the volume of plasma filtered by the glomeruli per unit time, expressed as **mL/min/1.73 m^2**. It **peaks at approximately 140 mL/min/1.73 m^2 in the third decade** and then **declines at about 8 mL/min/1.73 m^2 per decade**. Effective renal plasma flow falls **proportionally more — about 10% per decade, from 600 mL/min in youth to 300 mL/min by age 80** — so the **filtration fraction (GFR/ERPF) actually increases in the elderly**. Importantly, **in approximately one-third of older adults GFR does not decrease with age at all**.
2. **Why serum creatinine misleads in old age.** The fall in creatinine clearance is **accompanied by a concomitant decrease in creatinine production owing to senile sarcopenia, so serum creatinine does not increase despite the progressive decrease in GFR**. Healthy older people additionally show **net creatinine tubular reabsorption**, so measured creatinine clearance **underestimates** true glomerular filtration. The consequence to quote: **a serum creatinine of 1 mg/dL reflects a GFR of 120 mL/min in a 20-year-old but only 60 mL/min in an 80-year-old.**
3. **The estimating equations. Cockcroft–Gault:** creatinine clearance = **(140 – age) × body weight ÷ (72 × serum creatinine)**, and **15% lower in women**. **MDRD** and **CKD-EPI** are the two other standard formulae. Regarding **cystatin C** as a GFR marker, it has been demonstrated that **in elderly people with glomerular filtration below 60 mL/min it is not superior to that calculated by the Cockcroft–Gault and MDRD formulae**. Keller's simple approximation is **GFR = 130 – age (mL/min)** for people between 25 and 100 years, though this has not been validated against cimetidine creatinine clearance.
4. **Choosing the right equation — a favourite examination point. Cockcroft–Gault underestimates GFR in people over 80**, while **MDRD has the advantage of not requiring the patient's weight**. **CKD-EPI tends to be the most accurate choice at higher levels of GFR and is recommended for estimating creatinine clearance in adults without known chronic kidney disease**, and for risk stratification before percutaneous coronary intervention. **However, when dosing medications based on a patient's GFR, the Cockcroft–Gault equation remains the standard of care and should be used.**
5. **Consequences of senile hypofiltration. (a) Senile hypofiltration and diastolic cardiac failure predispose healthy old people to cardiac failure and to lung congestion after a saline load. (b) The dose of every prescribed drug must be adjusted to the estimated GFR in the elderly. (c) Senile hypofiltration differs**

from chronic kidney disease because the glomerular filtration value is **stable over 6–12 months** and there is **no haematuria and no significant proteinuria (>0.30 g/day)** — a distinction that prevents the over-labelling of healthy older people as having CKD.

Equation	Needs	Strength	Limitation / best use
Cockcroft–Gault	Age, weight, creatinine, sex	Remains the **standard of care for drug dosing**	Underestimates GFR in those over 80; distorted by obesity and oedema
MDRD	Age, creatinine, sex	No weight required	Poor correlation with measured clearance; inaccurate at high GFR
CKD-EPI	Age, creatinine, sex	Most accurate at higher GFR; recommended in adults without known CKD	Still creatinine-dependent, so distorted by sarcopenia
Cystatin C	Cystatin C ± creatinine	Independent of muscle mass	Not superior to CG or MDRD in the elderly below 60 mL/min; cost and availability

LATEST UPDATE (2023–PRESENT) — 1 POINT

6. **KDIGO 2024 CKD guideline — combined creatinine–cystatin C estimation becomes the preferred standard.** The guideline recommends **using a validated GFR estimating equation to derive GFR from serum filtration markers rather than relying on the markers alone**; that **in adults at risk of CKD, creatinine-based eGFR should be used, and if cystatin C is available the GFR category should be estimated from the combination of creatinine and cystatin C (eGFRcr-cys)**; and specifically that **eGFRcr-cys should be used in clinical situations where creatinine-based eGFR is less accurate and GFR affects clinical decision-making** — which describes the **sarcopenic, malnourished, amputee, cirrhotic or very old patient** exactly. The equations are now **race-free**. Two further points of practical relevance: **point-of-care testing for creatinine and urine albumin may be used where laboratory access is limited** — directly applicable to rural India — and **measured GFR using an exogenous filtration marker remains the reference standard** when a more accurate assessment is needed for clinical decision-making.

EXAM ONE-LINERS

- GFR peaks at **140** in the third decade, then falls **8 mL/min/1.73 m² per decade**.
- Filtration fraction **rises** with age, because renal plasma flow falls faster than GFR.
- Creatinine **1 mg/dL** = GFR **120** at 20 years, **60** at 80 years.
- **Cockcroft–Gault for drug dosing; CKD-EPI for staging; eGFRcr-cys when creatinine is unreliable.**
- **One-third of older adults show no age-related decline in GFR** — ageing is not uniform.
- Senile hypofiltration = **stable over 6–12 months, no haematuria, proteinuria <0.30 g/day**.

QUESTION 2 · NEPHROLOGY

Renal biopsy — indications in the older adult

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Age alone is not a contraindication.** The **indications and the incidence of complications of renal biopsy are the same** for older and younger adults. However, **when a complication does occur in an older adult it is generally more serious** — so patient selection and post-procedure monitoring matter more.
2. **Main indications. Nephrotic syndrome** (accounts for **50% of biopsy indications** in the elderly), **unexplained acute kidney injury**, suspected **rapidly progressive glomerulonephritis**, unexplained CKD with **normal-sized kidneys**, non-nephrotic proteinuria with haematuria, and suspected systemic disease — **vasculitis, myeloma, amyloidosis, lupus**.
3. **The yield is high and clinically useful.** Although older adults formed only 23% of the biopsy series, they were **over-represented relative to their share of the population**, and **primary glomerulonephritis was the most frequent biopsy-proven renal disease** in this group — more frequent than in younger adults.
4. **A biopsy finds treatable disease that is easily missed. Crescentic glomerulonephritis peaks at 60–79 years** and presents as rapidly progressive renal failure; **renal vasculitis** is probably the commonest primary cause of renal failure in older adults. Both respond to steroids and cyclophosphamide.
5. **Biopsy also drives the search for a secondary cause.** About **20% of membranous nephropathy in the elderly is secondary** to an underlying malignancy (chiefly lung and colon adenocarcinoma) or to drugs; minimal change disease may be caused by **NSAIDs** or associated with **lymphoma**. The histological diagnosis therefore triggers a malignancy and drug review.
6. **Contraindications and precautions.** Uncontrolled hypertension, bleeding diathesis or continuing anticoagulation/antiplatelet therapy, solitary kidney (relative), **small echogenic kidneys**, active urinary tract infection, large cysts or tumour, and an uncooperative patient. Before biopsy: control BP, stop antiplatelets and anticoagulants, check haemoglobin, platelets and coagulation, and ultrasound for kidney size and number. Afterwards watch for **haematuria, perinephric haematoma and arteriovenous fistula**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **KDIGO Glomerular Diseases guideline — the "biopsy-free" exception, with an important geriatric caveat.** In a patient with **nephrotic syndrome, a positive anti-PLA2R antibody and normal kidney function**, biopsy is **not required** to diagnose membranous nephropathy. But in older adults, membranous nephropathy can **co-exist with renal amyloidosis or diabetic nephropathy** — conditions with entirely different treatment and prognosis — so biopsy should still be performed when the clinical picture is atypical, when renal function is declining, or when a plasma-cell dyscrasia is suspected.

EXAM ONE-LINERS

- Commonest indication for renal biopsy in the elderly = **nephrotic syndrome (50%)**.
- Same indications, same complication rate — but **more serious complications** when they occur.
- Small echogenic kidneys = biopsy will show **only scarring** — do not biopsy.
- Elderly + AKI + haematuria + systemic symptoms = **biopsy for vasculitis, do not delay**.

PART II

Fluid, Electrolyte and Acid–Base Disorders

Q3 · Q4 · Q5 · Q6 · Q7 · Q8 · Q9

QUESTION 3 · FLUID, ELECTROLYTE & ACID–BASE

Fluid and electrolyte disturbances in older patients and their management

20-Mark Essay — 14 textbook points + 3 latest updates = 17 points

TEXTBOOK CORE — 14 POINTS

1. **The ageing kidney is the substrate for every disturbance.** GFR peaks at about **140 mL/min/1.73 m^2 in the third decade** and then falls by roughly **8 mL/min/1.73 m^2 per decade**; effective renal plasma flow falls proportionally more (10% per decade), so the **filtration fraction rises**. Add **aglomerular circulation**, **medullary hypotonicity**, **tubular dysfunction** and **tubular frailty** — the ageing kidney has narrowed margins in every direction.
2. **Body water is reduced, and the loss is intracellular.** Total body water is lower in older people and lower in elderly women than elderly men. Because **the reduction takes place in the intracellular compartment**, **hypovolaemia always represents a pathological state in older adults** — it is never a normal age change.
3. **Thirst is blunted.** When healthy, active older volunteers were water-restricted for 24 hours, their **threshold for thirst was increased and water intake reduced** compared with younger controls. Contributors: dryness of the mouth, decreased taste, altered mental capacity or cortical cerebral dysfunction, **reduced sensitivity of both osmoreceptors and baroreceptors**, and a lower concentration of **angiotensin**, a powerful generator of thirst.
4. **Urinary concentrating ability is impaired.** Maximum urinary concentration remains normal until about the third decade, then falls by about **30 mOsm/kg per decade**. Mechanisms: aglomerular circulation, defective sodium reabsorption in the ascending limb of Henle, reduced distal urea reabsorption, and **decreased responsiveness of the collecting tubule epithelium to antidiuretic hormone** — which is why **plasma vasopressin levels are higher in older adults**.
5. **Urinary diluting ability is also impaired.** Minimum urine concentration is only **92 mOsm/kg in the elderly versus 52 mOsm/kg in the young**, and **maximum free water clearance falls from 16.2 to 5.9 mL/min**. **Clinical consequence:** older people develop **dehydration and hypernatraemia under water restriction**, and **volume overload and hyponatraemia under a water load**.
6. **Sodium is wasted and conserved slowly.** The **24-hour urinary sodium output and fractional excretion of sodium are significantly greater** in old and very old people. Clinically this produces **slow adaptation to salt restriction or salt loss**, orthostatic hypotension, and a tendency to hypovolaemia during illness, fasting or bowel preparation.

7. **Potassium — depleted stores but a tendency to retain. Total body potassium is lower** (reduced muscle mass, poor intake), yet **renal potassium excretion is significantly lower in the aged** because of **reduced serum aldosterone and reduced tubular response to aldosterone**, plus increased **H^+/K^+-ATPase activity in the intercalated cells** of the aged collecting duct. Result: serum potassium is usually normal, but older people develop **hypokalaemia more rapidly on diuretics** and are **predisposed to hyperkalaemia on NSAIDs, ACE inhibitors, beta blockers and potassium-sparing diuretics**.
8. **Urea and creatinine handling changes.** The **fractional excretion of urea is increased — 65% in the old versus 50% in the young** — contributing to **osmotic diuresis and nocturia**, medullary hypotonicity, and a **characteristically low serum urea in the healthy older person**. Healthy older people also show **net creatinine tubular reabsorption**, so creatinine clearance **underestimates** true glomerular filtration.
9. **Calcium, phosphate and magnesium.** Serum levels and fractional excretion are **similar in the healthy young, old and very old**. However, low dietary vitamin D, reduced sunlight exposure, decreased renal hydroxylation of vitamin D and low sex hormone levels, combined with **poor intestinal calcium absorption**, lead to **senile secondary hyperparathyroidism**. On volume overload, **renal magnesium excretion increases enough to significantly lower serum magnesium**.
10. **Acid–base.** The ageing kidney **handles an acute acid load poorly** — acidification is slower and recovery is slower — so metabolic acidosis is both commoner and more prolonged. **Type 4 renal tubular acidosis** (hyporeninaemic hypoaldosteronism) is common in the older diabetic and presents as a **normal anion gap acidosis with hyperkalaemia**.
11. **Dehydration is the commonest disturbance.** Causes: **reduced intake** — dementia, delirium, immobility, dysphagia, depression, fear of incontinence, restricted access to fluid, restraint; and **increased losses** — fever, diarrhoea, vomiting, diuretics, uncontrolled hyperglycaemia, hot weather. **Physical signs are unreliable in the elderly**: skin turgor and mucous membranes mislead. Use instead **serial daily weight, postural blood pressure, urine output, urea:creatinine ratio and serum osmolality**.
12. **Hyponatraemia — a serious and often overlooked problem of the older patient.** Three general causes: **(a)** decreased renal blood flow with a decreased ability to excrete a water load; **(b) diuretic administration leading to water intoxication** — a condition rapidly corrected by discontinuing the diuretic; and **(c)** excess vasopressin secretion. Older adults seem **more prone to develop SIADH**, and certain drugs such as **chlorpropamide and barbiturates** cause it more frequently in older individuals. **Elderly patients may manifest cognitive impairment with even mild hyponatraemia.**
13. **Hypernatraemia — the mirror image, with higher mortality.** Almost always due to **water deficit rather than salt excess**: the febrile, immobile, tube-fed or institutionalised patient who cannot access water. Correct the free water deficit **slowly (≤10–12 mEq/L per 24 hours)** to avoid cerebral oedema, preferably by the enteral route.
14. **Principles of management common to all these disturbances. (i)** Identify and treat the underlying cause. **(ii) Medication review is the single highest-yield intervention** — diuretics, SSRIs, carbamazepine, NSAIDs, ACE inhibitors, PPIs, laxatives. **(iii)** Correct **slowly**: rapid correction of serum sodium **should not exceed a 20 mEq/L rise during the first 48 hours (1 mEq/L/h)**, to avoid neurological damage and **central pontine myelinolysis**. **(iv)** Give fluid cautiously — **senile hypofiltration and diastolic cardiac failure predispose healthy old people to cardiac failure and lung congestion after a saline load**. **(v)** Prefer the oral route; use **subcutaneous hypodermoclysis** where venous access is difficult in the frail. **(vi)** Monitor daily weight, input–output and electrolytes; **adjust every drug dose to the estimated GFR**.

Age change	Physiological consequence	Clinical disturbance	Practical guard
↓ Thirst threshold, ↓ osmoreceptor sensitivity	Inadequate water intake for a given osmolality	Dehydration, hypernatraemia	Scheduled fluid rounds; do not rely on the patient asking
↓ Concentrating ability (−30 mOsm/kg per decade)	Obligatory water loss continues despite deficit	Hypernatraemia, nocturia	Daily weights; early enteral water
↓ Diluting ability (free water clearance 5.9 mL/min)	Cannot excrete a water load	Hyponatraemia	Avoid hypotonic IV fluids; review thiazides and SSRIs
↑ FENa, ↑ FEurea	Salt and urea wasting	Hypovolaemia, postural hypotension, low serum urea	Do not over-interpret a "normal" urea or a high FENa
↓ Aldosterone and tubular response	Impaired potassium excretion	Hyperkalaemia on RAS blockers and NSAIDs	Check K^+ 1–2 weeks after any RASi change
↓ Muscle mass, net creatinine reabsorption	Serum creatinine stays "normal"	Occult renal impairment, drug toxicity	Dose by estimated GFR, never by creatinine alone

LATEST UPDATES (2023–PRESENT) — 3 POINTS

15. **Correction limits have tightened, and re-lowering is now standard practice.** Current guidance caps sodium correction at **≤8–10 mEq/L in the first 24 hours and ≤18 mEq/L over 48 hours**, and at **≤6–8 mEq/L per 24 hours in those at high risk of osmotic demyelination** — malnutrition, alcohol use, hypokalaemia, liver disease and initial sodium below 105 mEq/L, all common in frail older patients. If the limit is breached, **active re-lowering with 5% dextrose ± desmopressin (the "DDAVP clamp")** is recommended, and proactive desmopressin co-administration from the outset is increasingly used to make correction predictable.
16. **SGLT2 inhibitors have entered electrolyte medicine.** In a randomised, double-blind, placebo-controlled crossover trial in outpatients with chronic SIAD (*JASN* 2023), four weeks of **empagliflozin 25 mg** added to fluid restriction raised median serum sodium by **4.1 mEq/L** versus placebo, with no hypoglycaemia, hypotension, overcorrection or AKI, and a small improvement in neurocognitive function. Separately, SGLT2 inhibitors **raise serum magnesium** — a useful incidental effect in the older patient on a diuretic or a proton-pump inhibitor.
17. **Potassium binders have changed the hyperkalaemia doctrine.** The **KDIGO 2024 CKD guideline** states that potassium binders **may facilitate essential use of RAS inhibitors and mineralocorticoid receptor antagonists**, that **binders should be considered before reducing the RAS inhibitor**, and that **RASi discontinuation should be the last resort**. **Sodium zirconium cyclosilicate** and **patiromer** are the modern agents; **sodium polystyrene sulphonate has been removed from acute guidance** because of weak evidence and the risk of colonic necrosis.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Sodium correction rate	Up to 20 mEq/L in 48 h (1 mEq/L/h)	≤8–10 mEq/L in 24 h; ≤6–8 mEq/L in high-risk patients; re-lower if exceeded
Hyperkalaemia on a RAS blocker	Reduce or stop the ACE inhibitor	Add a potassium binder and keep the RAS blocker; stopping is the last resort
Cation-exchange resin	Calcium/sodium polystyrene sulphonate	Replaced by SZC or patiromer; resin withdrawn from acute algorithms

Exam approach: Quote the textbook 20 mEq/48 h figure as the classical teaching, then state the modern 8–10 mEq/24 h cap. Writing both, and naming osmotic demyelination, is what separates a pass from a distinction here.

MEMORY ANCHORS & ESSAY SKELETON

Skeleton (20 marks, 4 paragraphs): (1) Ageing renal physiology — thirst, concentrating, diluting, sodium, potassium, urea, calcium, acid–base. (2) The specific disturbances — dehydration, hyponatraemia, hypernatraemia, hypo/hyperkalaemia, hypo/hypercalcaemia, acidosis. (3) Assessment — why signs mislead; what to measure. (4) Management principles — cause, drug review, slow correction, cautious volume, monitoring. Close with the three updates.

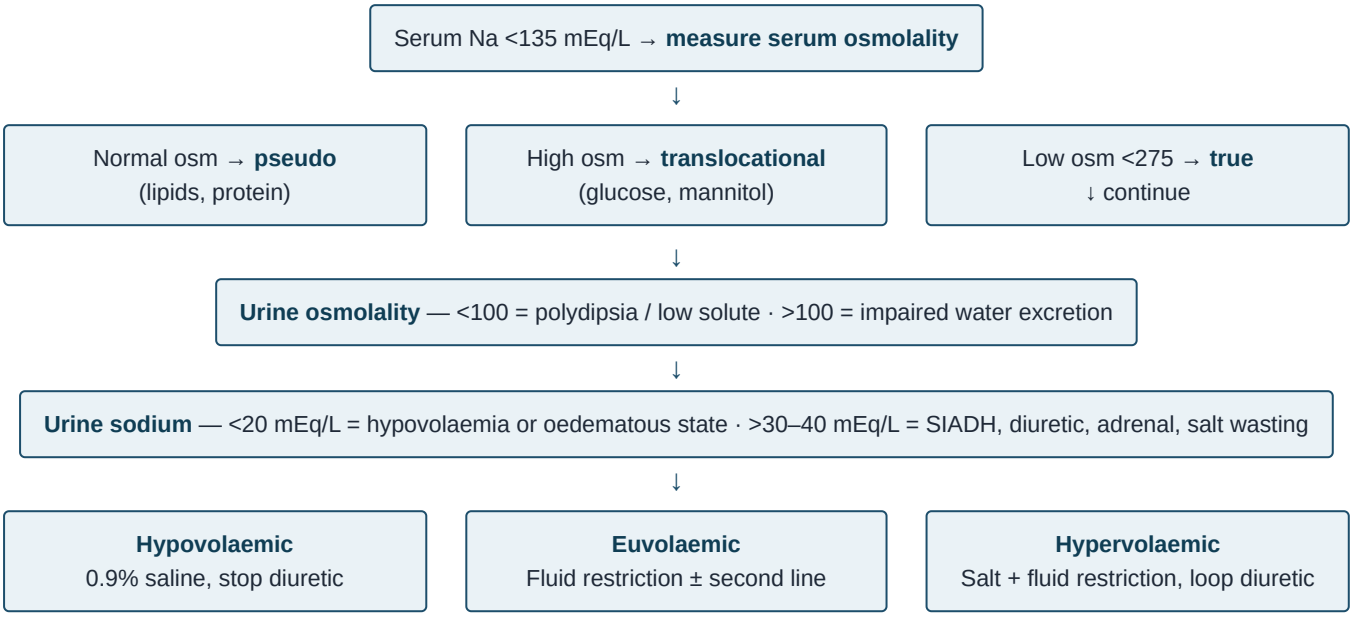
Numbers to memorise: GFR peak 140, −8 per decade · concentrating −30 mOsm/kg per decade · min urine osm 92 vs 52 · free water clearance 5.9 vs 16.2 mL/min · FEurea 65% vs 50% · creatinine 1 mg/dL = GFR 120 at 20 years, 60 at 80 years · Na correction ≤8–10 mEq/24 h.

EXAMINER TRAPS

- Listing electrolyte abnormalities without first explaining the **ageing physiology that causes them** — this is what the 20-mark format is testing.
- Assessing dehydration by **skin turgor** in an 85-year-old.
- Reassuring yourself with a **normal serum urea** — it is characteristically low in the healthy old because of urea wasting.
- Aggressive saline resuscitation without noting that **senile hypofiltration plus diastolic failure causes pulmonary congestion after a saline load**.
- Forgetting that **hypovolaemia in an older adult is always pathological**, never a normal age change.

QUESTION 4 · SODIUM & WATER

Hyponatraemia



7-Mark Note — 6 textbook points + 1 latest update = 7 points

Recurring question — asked ×3. Extra scaffolding provided below.

TEXTBOOK CORE — 6 POINTS

1. **Definition, severity and significance.** Serum sodium **<135 mEq/L**; mild 130–134, moderate 125–129, **severe or profound <125 mEq/L**. It is the commonest electrolyte abnormality in hospitalised older adults and is described as **"a serious and often overlooked problem of the older patient"**. Critically, **elderly patients are more susceptible and may manifest cognitive impairment with even mild hyponatraemia**.

2. **Why older people are predisposed. Impaired water excretion** — minimum urine osmolality is only **92 mOsm/kg versus 52 in the young**, and maximum free water clearance falls from **16.2 to 5.9 mL/min**. In addition, infusion of hypertonic saline produces a **greater rise in plasma vasopressin in older than in younger persons**, and older adults are heavily exposed to the precipitating drugs.
3. **The three general causes. (a)** Decreased renal blood flow with a **decreased ability to excrete a water load**; **(b) diuretic administration leading to water intoxication** — a condition **rapidly corrected by discontinuing the diuretic**; and **(c) excess vasopressin secretion (SIADH)**, to which older adults are more prone. The drugs to interrogate: **thiazides** (the classic), **SSRIs and other antidepressants** (risk increases with age, female sex, low body weight and renal failure), **carbamazepine**, **chlorpropamide and barbiturates** (more frequent in older individuals), NSAIDs, PPIs, opioids and desmopressin.
4. **Step 1 of evaluation — is it true hypotonic hyponatraemia?** Measure **serum osmolality**. **Normal osmolality** = **pseudohyponatraemia** (severe hyperlipidaemia, hyperproteinaemia, paraproteinaemia). **High osmolality** = **translocational** hyponatraemia (hyperglycaemia, mannitol infusion). **Low osmolality (<275 mOsm/kg)** = true hypotonic hyponatraemia — proceed.
5. **Step 2 — urine osmolality, then urine sodium, then volume status. Urine osmolality <100 mOsm/kg** = appropriately dilute urine → **primary polydipsia** or **low solute intake** ("tea-and-toast" diet, beer potomania) — both common in the socially isolated older person. **Urine osmolality >100** = impaired water excretion → check **urine sodium**: **<20 mEq/L** suggests **hypovolaemia or an oedematous state** (heart failure, cirrhosis, nephrotic syndrome); **>30–40 mEq/L** suggests **SIADH, diuretic use, adrenal insufficiency or salt wasting**. Always also check **TSH and a 9 a.m. cortisol**.
6. **Step 3 — treat by volume status, and correct slowly. Hypovolaemic** → 0.9% saline and stop the diuretic. **Euvolaemic (SIADH)** → fluid restriction. **Hypervolaemic** → salt and fluid restriction with a loop diuretic; treat the heart or liver disease. **Water restriction and hypertonic saline are indicated when the patient is symptomatic or the sodium level is below 120 mEq/L**; in an emergency give **3% saline 100–150 mL over 10–20 minutes**, repeated up to three times until symptoms abate or sodium rises 4–6 mEq/L. **This rapid correction should not exceed a 20 mEq/L rise during the first 48 hours (1 mEq/L/h), to avoid neurological damage and central pontine myelinolysis.**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Correction limits have tightened, and deliberate re-lowering is now standard.** Current practice caps correction at **≤8–10 mEq/L in the first 24 hours and ≤18 mEq/L over 48 hours**, and at **≤6–8 mEq/L per 24 hours in patients at high risk of osmotic demyelination syndrome — malnutrition, alcohol use, hypokalaemia, liver disease, and initial sodium below 105 mEq/L**, a risk profile that describes a large share of frail older inpatients. If the cap is breached, **active re-lowering with 5% dextrose with or without desmopressin (the "DDAVP clamp")** is recommended, and **proactive desmopressin co-administration** from the outset is increasingly used to make the rise predictable. Note also the danger of **autocorrection**: once a hypovolaemic stimulus or a thiazide is removed, vasopressin switches off and the sodium can rise dangerously fast on its own — so recheck sodium **every 4–6 hours** in the first day.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Maximum correction	20 mEq/L over 48 h (1 mEq/L/h)	≤8–10 mEq/L in 24 h; ≤6–8 in high-risk patients
Overcorrection	Avoid it	Actively re-lower with 5% dextrose ± desmopressin
Emergency therapy	Hypertonic saline infusion	3% saline as 100–150 mL boluses, targeting a 4–6 mEq/L rise

Exam approach: Write the textbook 20 mEq/48 h rule *and* the modern 8–10 mEq/24 h cap, and name **osmotic demyelination syndrome** (the current term for central pontine myelinolysis). Both together is the full-mark answer.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Define and grade → why the old are vulnerable (diluting defect + vasopressin + drugs) → three general causes → **serum osmolality** → **urine osmolality** → **urine sodium** → **volume status** → treat by volume compartment → correction rate and osmotic demyelination.

Numbers: 135 / 130 / 125 / 120 · urine osm cut-off **100** · urine Na cut-offs **20 and 30–40** · serum osm **275** · 3% saline **100–150 mL** boluses · target rise **4–6** · cap **8–10 per 24 h** · min urine osm **92 vs 52**.

EXAMINER TRAPS

- Diagnosing SIADH **without excluding hypothyroidism, adrenal insufficiency and diuretic use** — the commonest error in the whole topic.
- Skipping **serum osmolality** and treating a pseudohyponatraemia.
- Giving **0.9% saline to a patient with SIADH** — the urine is more concentrated than the infusate, so free water is retained and the sodium *falls further*.
- Forgetting the risk of **autocorrection** after the thiazide is stopped or volume is restored.
- Treating the number rather than asking **"is this patient symptomatic, and is it acute or chronic?"** — that question dictates everything.

QUESTION 5 · SODIUM & WATER

SIADH — syndrome of inappropriate antidiuretic hormone secretion

20-Mark Essay — 14 textbook points + 3 latest updates = 17 points

TEXTBOOK CORE — 14 POINTS

1. **Definition.** A **euvolaemic, hypotonic hyponatraemia** caused by **non-osmotic, non-physiological release of antidiuretic hormone (arginine vasopressin)**, with continued renal water reabsorption despite plasma hypo-osmolality. It is now often called **SIAD (syndrome of inappropriate antidiuresis)**, because a minority of cases are due to a **gain-of-function V2 receptor mutation** with undetectable circulating ADH.
2. **The four textbook diagnostic features. (i) Inappropriately high urine osmolality for the concomitant plasma hypo-osmolality**; **(ii) continued renal excretion of sodium**; **(iii) clinical normovolaemia**; and **(iv) normal renal, adrenal and thyroid function**. All four must be satisfied.
3. **Full Bartter–Schwartz criteria — essential.** Hypotonic hyponatraemia (Na <135 mEq/L, effective osmolality <275 mOsm/kg); **urine osmolality >100 mOsm/kg**; clinical euvolaemia with no oedema and no signs of volume depletion; **urine sodium >30–40 mEq/L** on normal salt and water intake; normal thyroid and adrenal function; and **no recent diuretic use**.
4. **Supplemental criteria that strengthen the diagnosis. Low serum uric acid (<4 mg/dL)** and **low blood urea** — both reflect dilution and increased fractional excretion; **fractional excretion of urate >12%**; fractional excretion of sodium >0.5%; **failure to correct with 0.9% saline**; and correction with fluid restriction. A **normal or high uric acid should make you doubt the diagnosis**.
5. **Pathophysiology.** Excess ADH drives **aquaporin-2 insertion into the collecting duct** → water retention → mild volume expansion → **suppression of aldosterone and release of natriuretic peptides** → **secondary natriuresis**. The patient therefore remains **clinically euvolaemic while the sodium falls**, and continues to excrete sodium in the urine. **Vasopressin escape** limits further water retention and prevents gross oedema — which is why SIADH does not cause oedema.
6. **Ageing itself is a predisposing factor.** Infusion of hypertonic saline leads to a **greater increase in plasma vasopressin in older compared with younger persons**, possibly through impaired baroreceptor input to the supraoptic nucleus. Combined with the reduced diluting capacity of the ageing kidney, this means **older adults seem more prone to develop SIADH** from any given trigger.
7. **Causes — central nervous system. Stroke, meningitis, subdural haematoma, tumour, intracranial metastases, haemorrhage, head injury and encephalitis.** Any acute intracranial event in an older adult should prompt a sodium check.
8. **Causes — pulmonary. Pneumonia** (a very common trigger in the elderly), **tuberculosis** (highly relevant in India), lung abscess, pulmonary metastases and infection, and positive-pressure ventilation.
9. **Causes — malignancy.** SIADH is a **paraneoplastic condition classically associated with small-cell carcinoma of the lung**; also head and neck cancers, thymoma, and others. In an older smoker with unexplained SIADH, **image the chest**.
10. **Causes — drugs, which are the commonest in geriatric practice. SSRIs and other antidepressants** — the risk of antidepressant-induced hyponatraemia **increases with age** and is associated with **female sex, low body weight, renal failure** and concurrent drugs that cause hyponatraemia. Also **carbamazepine and oxcarbazepine**, **chlorpropamide**, **barbiturates** (both of which **cause this syndrome more frequently in older individuals**), thiazides, antipsychotics, NSAIDs, opioids, PPIs, desmopressin, and the chemotherapeutic agents **vincristine, vinblastine, ifosfamide and cyclophosphamide**.

11. **Other causes. Pain, nausea, surgery and general anaesthesia** (all potent non-osmotic ADH stimuli — a frequent cause of postoperative hyponatraemia in the elderly), HIV infection, and **idiopathic SIAD of the elderly**, a recognised entity in which no cause is found and the hyponatraemia is chronic and recurring.
12. **Clinical features. Symptoms depend on the depth and the rate of development**, but **elderly patients are more susceptible and may manifest cognitive impairment with mild hyponatraemia**. **Acute** (<48 hours) — headache, nausea, vomiting, confusion, seizures, coma and respiratory arrest from cerebral oedema. **Chronic** — apparently "asymptomatic", but in reality associated with **gait instability, attention and memory deficits, falls, osteoporosis and fracture** (chronic hyponatraemia mobilises sodium from bone). **In an older adult, chronic hyponatraemia is almost never truly asymptomatic.**
13. **Differential diagnosis to exclude before you accept the label. Hypovolaemia**; **diuretic use, especially thiazides**; **hypothyroidism**; **adrenal insufficiency** — a 9 a.m. cortisol is mandatory, because glucocorticoid deficiency mimics SIADH exactly; **cerebral salt wasting** — which is **hypovolaemic with a high urine output and negative salt balance, and is treated with salt and fluid, the opposite of SIADH**; and low-solute states such as beer potomania and the tea-and-toast diet.
14. **Treatment. Treat the underlying disease — successful therapy for paraneoplastic SIADH requires treatment of the underlying disease by chemotherapy and/or radiotherapy**. **Acute measures are indicated in symptomatic patients with severe hyponatraemia (plasma sodium <125 mEq/L)**: the textbook protocol is to **initiate and maintain rapid diuresis with intravenous furosemide while restricting free water intake to 500–1000 mL per day, and to replace the sodium and potassium lost in the urine with 0.9% saline infusions with added potassium**; current emergency practice is **3% hypertonic saline 100–150 mL over 10–20 minutes, repeated up to three times, targeting a rise of 4–6 mEq/L** to abort seizures. **This rapid correction should not exceed a 20 mEq/L rise in serum sodium during the first 48 hours (1 mEq/L/h) to avoid neurological damage and central pontine myelinolysis.** For **chronic SIADH**: **fluid restriction to 500–1000 mL/day is first line**; then increased solute intake (salt and protein, or **oral urea 15–30 g/day**); a loop diuretic with salt tablets; **demeclocycline (demethylchlortetracycline) may be needed in resistant patients — it induces a partial nephrogenic diabetes insipidus and thus corrects the hyponatraemia, and serum creatinine and blood urea must be closely monitored**; and **vaptans (tolvaptan)** with strict inpatient sodium monitoring.

Feature	SIADH	Cerebral salt wasting	Adrenal insufficiency
Volume status	**Euvolaemic**	**Hypovolaemic**	Hypovolaemic
Urine sodium	>30–40 mEq/L	Very high	High
Urine output	Low / normal	**High (polyuria)**	Variable
Serum uric acid	**Low**	Low	Normal / high
Serum potassium	Normal	Normal / low	**High**
Response to 0.9% saline	**Worsens or no change**	**Improves**	Improves
Treatment	Fluid restriction	**Salt and fluid replacement**	Hydrocortisone

LATEST UPDATES (2023–PRESENT) — 3 POINTS

15. **Empagliflozin is emerging as a practical new option for chronic SIAD.** In a **randomised, double-blind, placebo-controlled crossover trial in outpatients with chronic SIAD (*JASN* 2023)**, four weeks of **empagliflozin 25 mg** added to fluid restriction of about 1500 mL/day **raised median serum sodium by 4.1 mEq/L versus placebo**, an effect achieved by the end of the first week and sustained thereafter. It was **well tolerated with no hypoglycaemia, hypotension, overcorrection or acute kidney injury**, and produced a small improvement in neurocognitive function, particularly when normonatraemia was restored. This followed an earlier inpatient randomised trial in 88 hospitalised patients (*JASN* 2020). The mechanism is **glucosuria-induced osmotic diuresis with increased electrolyte-free water excretion**. Its appeal in older adults is that it is **oral, inexpensive, and does not require the intensive monitoring or carry the overcorrection risk of vaptans**.
16. **Fluid restriction fails more often than is taught — predict failure and escalate early.** The recognised predictors of failure are **urine osmolality >500 mOsm/kg**, a **urine (Na + K) to serum Na ratio ≥1 (the Furst ratio)**, and a **24-hour urine volume <1500 mL**. Current practice is to identify these at the outset and **move to second-line therapy rather than persist with an ineffective restriction** — which in a frail older person also causes thirst, distress, constipation and delirium. Among second-line agents, **oral urea is increasingly favoured over vaptans** on grounds of cost, safety and the absence of overcorrection risk; palatability is the limiting factor.
17. **In geriatric practice, deprescribing is the definitive treatment.** The commonest reversible cause of SIADH in an older patient is **a drug — the SSRI, thiazide, carbamazepine or PPI**. A structured medication review using **STOPP/START and the AGS Beers criteria**, followed by stopping or substituting the culprit, corrects more cases than any pharmacological manoeuvre. The corresponding preventive standard is to **recheck serum sodium at 2 and 4 weeks after starting or changing any of these drugs in a person over 65** — a simple intervention that prevents a substantial proportion of hyponatraemic admissions.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Correction rate	Up to 20 mEq/L over 48 h (1 mEq/L/h)	≤8–10 mEq/L in 24 h; ≤6–8 in high-risk; re-lower if exceeded
Resistant SIADH	Demeclocycline	Oral urea, tolvaptan, or empagliflozin; demeclocycline now rarely used (nephrotoxicity, photosensitivity)
Emergency treatment	IV furosemide + fluid restriction + saline with potassium	3% saline 100–150 mL boluses targeting a 4–6 mEq/L rise
Terminology	SIADH / central pontine myelinolysis	SIAD / osmotic demyelination syndrome

Exam approach: Give the textbook protocol first — it is what the paper is set from — then add the modern correction cap and the second-line ladder. Naming **osmotic demyelination syndrome** and **empagliflozin** in the same answer signals current reading.

MEMORY ANCHORS & ESSAY SKELETON

Skeleton (20 marks, five blocks): (1) Define and give the four textbook features + Bartter–Schwartz criteria + supplemental criteria. (2) Pathophysiology — ADH → aquaporin-2 → volume expansion → secondary natriuresis → euvolaemic hyponatraemia, with vasopressin escape. (3) Causes in four groups — CNS, pulmonary, malignancy, drugs — plus pain/surgery and idiopathic SIAD of the elderly. (4) Clinical features acute versus chronic, and the differential (hypovolaemia, thyroid, adrenal, cerebral salt wasting). (5) Treatment ladder and correction rate. Close with the three updates.

Mnemonic for causes — "CNS · Chest · Cancer · Chemicals": the four Cs, then add pain/surgery and idiopathic.

Numbers: urine osm **>100** · urine Na **>30–40** · serum osm **<275** · uric acid **<4 mg/dL** · FEurate **>12%** · acute measures below Na **125** · fluid restriction **500–1000 mL** · urea **15–30 g/day** · empagliflozin **25 mg**, +**4.1 mEq/L** · cap **8–10 per 24 h**.

EXAMINER TRAPS

- Diagnosing SIADH **without documenting euvolaemia and without excluding hypothyroidism, adrenal insufficiency and diuretics**. State the exclusions explicitly — they carry marks.
- Giving **0.9% saline in SIADH**: when the urine osmolality exceeds that of the infusate, the salt is excreted and the free water is retained, so **the sodium falls further**.
- Confusing SIADH with **cerebral salt wasting** after a stroke — the entire treatment reverses. Volume status and urine output separate them.
- Forgetting **oedema is absent** in SIADH because of vasopressin escape.
- Omitting **drug causes** — in geriatric practice they are the majority, and the SSRI is the single commonest.

QUESTION 6 · FLUID, ELECTROLYTE & ACID–BASE

Hypokalaemia and hypomagnesaemia

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definitions and the ageing background. Hypokalaemia = serum K^+ <3.5 mEq/L** (severe <2.5); **hypomagnesaemia = serum Mg^{2+} <1.7 mg/dL. Total body potassium is lower in healthy older people**, and the potassium-controlling ATPases of the collecting tubule are impaired by ageing — so a given loss produces greater depletion and slower repletion than in the young.
2. **Causes of hypokalaemia in the elderly. Diuretics (loop and thiazide) are by far the commonest**; also GI losses (diarrhoea, vomiting, **laxative abuse**), poor dietary intake and malnutrition, primary or secondary hyperaldosteronism, and drugs — corticosteroids, insulin, **β_2-agonists**, amphotericin B. **Magnesium depletion** is an under-recognised cause.
3. **Causes of hypomagnesaemia in the elderly. Chronic proton-pump inhibitor use** (the classic geriatric cause), diuretics, alcohol excess, chronic diarrhoea and malabsorption, **aminoglycosides, cisplatin, amphotericin, calcineurin inhibitors**, and poorly controlled diabetes with osmotic diuresis.
4. **Clinical features.** Hypokalaemia — muscle weakness, cramps, **constipation and ileus**, polyuria (nephrogenic DI), rhabdomyolysis, and ECG changes: **flattened T waves, ST depression, prominent U waves, prolonged QU, ventricular ectopy**. Hypomagnesaemia — tremor, **tetany with positive Trousseau and Chvostek signs**, seizures, and **torsades de pointes**. In older adults, both frequently present **atypically as falls, generalised weakness or delirium**.

5. **The critical link — correct magnesium first.** Magnesium depletion causes **refractory hypokalaemia and refractory hypocalcaemia**: low intracellular magnesium **releases the inhibition of the ROMK channel** in the distal nephron, so potassium is wasted in the urine and **cannot be corrected until magnesium is replaced**. Hypomagnesaemia also impairs PTH secretion and end-organ response.
6. **Management.** Replace **magnesium first** — oral magnesium salts if mild; **IV magnesium sulphate 1–2 g** for symptomatic disease or torsades. Then potassium: **oral KCl is preferred** whenever the patient can take it; **IV KCl only for severe or symptomatic hypokalaemia**, at a maximum of **10 mEq/h peripherally (up to 20 mEq/h centrally with cardiac monitoring)**, and **never in dextrose** — dextrose stimulates insulin and drives potassium intracellularly, worsening the deficit. Finally, **review and deprescribe the culprit diuretic, laxative or PPI**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Deprescribing, not escalating replacement, is the modern answer to drug-induced hypomagnesaemia.** Chronic PPI use is now firmly established as a cause of **hypomagnesaemia and of acute interstitial nephritis**, and PPIs have accordingly become a **major target of deprescribing strategies in older adults**. Current guidance in unexplained or recurrent hypomagnesaemia is to **stop the PPI** rather than keep increasing magnesium supplements. Note also that **SGLT2 inhibitors consistently raise serum magnesium**, an incidental benefit in the diabetic older patient on a diuretic.

EXAM ONE-LINERS

- **You cannot correct potassium until you correct magnesium** — the single highest-yield line in this answer.
- U waves = hypokalaemia; torsades = hypomagnesaemia.
- Never give IV potassium in dextrose; never exceed 10 mEq/h peripherally.
- Elderly + unexplained hypomagnesaemia = **look at the PPI**.
- Falls and delirium may be the **only** presenting features of severe electrolyte disturbance in the very old.

QUESTION 7 · POTASSIUM

A known diabetic on oral hypoglycaemic agents attends for routine review; serum potassium is 5.7 mEq/L. Investigation and treatment

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **First — confirm the value and assess urgency simultaneously.** Exclude **pseudohyperkalaemia** by repeating with a properly taken sample: causes are a **tight or prolonged tourniquet, fist clenching, haemolysis, difficult venepuncture, delayed transport or prolonged storage**, and marked **thrombocytosis or leucocytosis**. At the same time perform a **12-lead ECG** — the presence of ECG change converts this from an outpatient problem into an emergency, and its absence permits an unhurried outpatient approach.
2. **Understand why this particular patient is at risk — the geriatric-diabetic substrate. Renal excretion of potassium is significantly lower in the aged**: there is **reduced serum aldosterone and a reduced tubular response to aldosterone**, together with **increased H^+/K^+-ATPase activity (potassium reabsorption) in the intercalated cells of the aged collecting duct**. Consequently **elderly people are predisposed to hyperkalaemia, particularly when treated with NSAIDs, ACE inhibitors, beta blockers and/or potassium-sparing diuretics**. In a diabetic, add **type 4 renal tubular acidosis (hyporeninaemic hypoaldosteronism)**, **diabetic nephropathy**, and **insulin deficiency**, since insulin drives potassium into cells.

3. **Take a targeted drug and diet history — the highest-yield step.** Drugs: **ACE inhibitors, ARBs, spironolactone or eplerenone, amiloride, beta blockers, NSAIDs, co-trimoxazole (trimethoprim acts like amiloride), heparin, digoxin, calcineurin inhibitors**. Diet and over-the-counter items: **"low-sodium" salt substitutes, which are potassium chloride** — a very common and frequently missed cause in Indian practice — plus **tender coconut water, banana, citrus, tomato, potato and dry fruits**. Also ask about **constipation** (the colon is an important route of potassium excretion in CKD) and about traditional or ayurvedic preparations.
4. **Investigate systematically.** Repeat serum potassium on a clean sample; **ECG**; **urea, creatinine and eGFR**; sodium; **serum bicarbonate** — a normal anion gap acidosis with hyperkalaemia points to **type 4 RTA**; blood glucose and HbA1c; **urine albumin–creatinine ratio**; calcium and magnesium; full blood count and platelet count (for pseudohyperkalaemia); creatine kinase if rhabdomyolysis is possible; and **9 a.m. cortisol with a short Synacthen test** if adrenal insufficiency is plausible. Where the cause remains unclear, a **urine potassium or transtubular potassium gradient** distinguishes impaired renal excretion from a transcellular shift.
5. **Know the ECG sequence and its limitations.** In order: **tall peaked T waves → flattening and loss of P waves → PR prolongation → widening of the QRS → sine wave → ventricular fibrillation or asystole**. Critically, **ECG changes correlate poorly with the potassium level in chronic hyperkalaemia** and may be entirely absent even at 6.5 mEq/L — so a normal ECG does not exclude danger, and a changing ECG demands action irrespective of the number.
6. **Treat this level — 5.7 mEq/L, asymptomatic, no ECG change — as moderate chronic hyperkalaemia, not an emergency.** This does **not** require calcium, insulin-dextrose or salbutamol. Do the following: **(a)** stop or reduce the culprit — **NSAIDs first, then reassess the potassium-sparing diuretic**, and **eliminate salt substitutes**; **(b)** dietary potassium restriction with dietitian input; **(c)** correct **metabolic acidosis with oral sodium bicarbonate if bicarbonate is below 22 mEq/L**; **(d)** improve glycaemic control; **(e)** add or increase a **loop or thiazide diuretic** if the patient is volume-replete; **(f)** treat constipation; **(g) recheck potassium in 3–7 days**. Reserve **emergency treatment for K^+ ≥6.5 mEq/L or any ECG change**: **10% calcium gluconate 10 mL IV** for membrane stabilisation (repeat as needed; it does not lower potassium), **10 units soluble insulin with 25% dextrose 50–100 mL**, **nebulised salbutamol 10–20 mg**, sodium bicarbonate if acidotic, and **dialysis if refractory or if renal failure is advanced**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Potassium binders now allow prognostically important RAS blockade to be continued — a change of doctrine directly relevant to this patient.** The **KDIGO 2024 CKD guideline** states that in hyperkalaemia, **potassium binders may help facilitate essential use of RAS inhibitors and mineralocorticoid receptor antagonists**, that **potassium binders should be considered before reducing the RAS inhibitor**, and that **RASi discontinuation should be the last resort**. The modern agents are **sodium zirconium cyclosilicate (SZC)** and **patiromer**, both licensed for adults and both effective for chronic control and prevention of recurrence; the **UK Kidney Association 2023 guideline** broadened their use to **moderate as well as severe hyperkalaemia** and **removed calcium resonium (sodium polystyrene sulphonate) from the acute algorithm** because of weak evidence and the risk of colonic necrosis. For this diabetic patient, whose ACE inhibitor or ARB is renoprotective, the correct modern reasoning is therefore to **remove the avoidable contributors first (NSAID, salt substitute, dietary potassium), then add a binder — and only then, if all else fails, reduce the RAS blocker**.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Response to hyperkalaemia on a RASi	Reduce or stop the ACE inhibitor	Consider a potassium binder first; discontinuation is the last resort
Cation-exchange resin	Calcium / sodium polystyrene sulphonate	Replaced by SZC or patiromer; resin removed from acute guidance
Threshold for binder use	Severe hyperkalaemia only	Moderate as well as severe, when RASi preservation matters

Exam approach: This is a clinical-scenario question, so **structure the answer as confirm → why this patient → history and drugs → investigations → ECG → graded treatment**. Say explicitly that 5.7 mEq/L with a normal ECG is *not* an emergency — candidates who reflexively write "calcium gluconate, insulin-dextrose" lose marks for misjudging severity.

MEMORY ANCHORS

Causes mnemonic — "MACHINE": Medications (ACEi/ARB, spironolactone, NSAIDs, trimethoprim, beta blockers) · **A**cidosis · **C**ellular destruction (rhabdomyolysis, haemolysis, tumour lysis) · **H**ypoaldosteronism (type 4 RTA, Addison's) · **I**ntake (salt substitutes, diet) · **N**ephrons (renal failure) · **E**xcretion impaired.

Numbers: mild 5.5–5.9 · moderate 6.0–6.4 · **severe ≥6.5** or any ECG change · calcium gluconate 10% 10 mL · insulin 10 units + 25% dextrose 50–100 mL · salbutamol 10–20 mg nebulised · bicarbonate target ≥22 mEq/L · recheck in **3–7 days**.

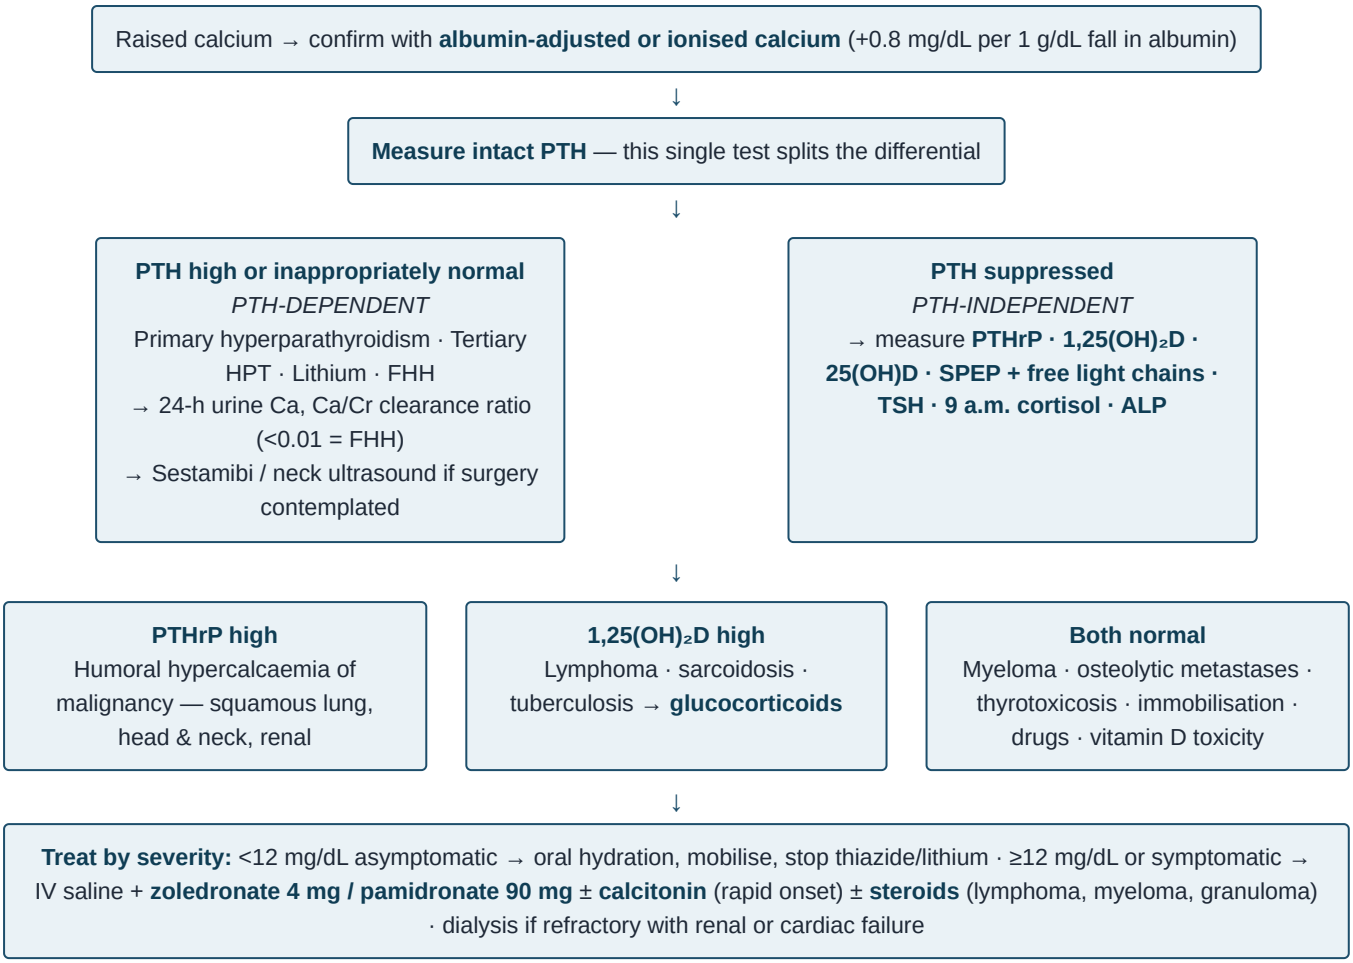
EXAMINER TRAPS

- Treating 5.7 mEq/L as a crash call. **Judge severity by symptoms and ECG, not by the number alone.**
- Forgetting to **repeat the sample** — pseudohyperkalaemia is the commonest cause of a spuriously abnormal outpatient potassium.
- Missing the **salt substitute** — ask about it by name; patients do not consider it a medicine.
- Thinking **calcium gluconate lowers potassium**. It stabilises the myocardium and buys 30–60 minutes; nothing more.
- Stopping the ACE inhibitor reflexively and losing its renal and cardiac protection.
- Overlooking **type 4 RTA** — check the bicarbonate in every diabetic with hyperkalaemia.

QUESTION 8 · CALCIUM

Hypercalcaemia — causes, evaluation and management, including PTH-independent hypercalcaemia

7-Mark Note — 6 textbook points + 1 latest update = 7 points



Recurring question — asked ×4. Extra scaffolding and full evaluation flow chart provided below.

TEXTBOOK CORE — 6 POINTS

1. **Definition and thresholds. Hypercalcaemia is defined by an elevation of calcium above 10.6 mg/dL, and values above 11.0 mg/dL should be considered an indication to initiate treatment.** This threshold applies **only when the albumin level is normal**. If there is any doubt about the validity of the total serum calcium,

measuring ionised calcium or calculating the albumin-adjusted calcium is essential. Correction: **add 0.8 mg/dL to the measured calcium for every 1 g/dL fall in albumin below 4 g/dL** — vital in the malnourished older patient, in whom true hypercalcaemia is otherwise missed.

2. **Two causes account for 90%. Primary hyperparathyroidism** — the commonest cause in **outpatients**, typically detected incidentally on routine biochemistry, and **PTH-dependent**. **Malignancy** — the commonest cause in **hospital inpatients**, usually with the cancer already overt, and **PTH-independent**. Other PTH-dependent causes: **tertiary hyperparathyroidism** in long-standing CKD, **lithium**, and **familial hypocalciuric hypercalcaemia**.
3. **PTH-independent causes — the part of the question most often under-answered. (a) Malignancy** by three mechanisms: **humoral hypercalcaemia via PTHrP** (squamous carcinoma of lung and head and neck, renal, bladder, ovarian), **osteolytic metastases and local cytokines** (breast cancer, **multiple myeloma**), and **excess 1,25-dihydroxyvitamin D production by lymphoma**. **(b) Granulomatous disease** with extrarenal 1α-hydroxylase activity — **sarcoidosis and tuberculosis** (the latter of major importance in India), plus fungal infection. **(c) Drugs** — **thiazides, lithium, vitamin D or vitamin A toxicity, calcium-alkali (milk–alkali) syndrome from over-the-counter antacids and supplements, teriparatide, and tamoxifen flare**. **(d) Endocrine** — **thyrotoxicosis**, adrenal insufficiency, phaeochromocytoma, acromegaly. **(e) Immobilisation** in a patient with high bone turnover — Paget's disease, myeloma, recent fracture — **highly relevant in the bed-bound older patient**. **(f)** Recovery phase of rhabdomyolysis-associated AKI, and parenteral nutrition.
4. **Clinical features and the geriatric presentation.** The classical formulation is **"bones, stones, abdominal groans and psychic moans"** — **bone** pain and fracture; **renal** stones, nephrocalcinosis and **nephrogenic diabetes insipidus with polyuria, dehydration and prerenal AKI**; **gastrointestinal** anorexia, nausea, vomiting, **constipation**, peptic ulceration and pancreatitis; **neuropsychiatric** fatigue, depression, confusion, stupor and coma. **In the older adult the presentation is typically delirium, constipation, dehydration and falls**, and it is routinely misattributed to dementia, infection or drugs. The **ECG shows a short QT interval**. **Serum calcium belongs in the confusion screen of every older patient.**
5. **Evaluation — one measurement decides the whole pathway.** Confirm with an **albumin-adjusted or ionised calcium**, then measure **intact PTH**. If PTH is **high or inappropriately normal**, the hypercalcaemia is **PTH-dependent** — primary or tertiary hyperparathyroidism, lithium, or familial hypocalciuric hypercalcaemia, which is distinguished by a **24-hour urinary calcium and a calcium/creatinine clearance ratio below 0.01**. If PTH is **suppressed**, the hypercalcaemia is **PTH-independent** — measure **PTHrP, 25(OH)D and $1,25(OH)_2D$, serum protein electrophoresis and free light chains, TSH, 9 a.m. cortisol, alkaline phosphatase**, and image for malignancy or granulomatous disease. Always also review every drug and supplement.
6. **Management by severity. Asymptomatic patients with minimally elevated calcium (below about 12 mg/dL) may be treated as outpatients**, with encouragement to adopt **oral hydration, mobilisation, and elimination of drugs contributing to hypercalcaemia — thiazides and lithium**. **Patients who are symptomatic, or whose calcium exceeds about 12 mg/dL, should be considered for inpatient management** using **volume expansion with saline infusion, corticosteroids and bisphosphonates**: **(i) Rehydration** generally has **mild and transient effects on calcium levels**; the volume of saline depends on the extent of hypovolaemia, with **particular care for the patient's cardiac and renal function**. **(ii) Bisphosphonates have supplanted all other drugs except calcitonin**, which remains useful in severe refractory hypercalcaemia because of its **rapid onset — 2 to 4 hours, versus 72 hours for bisphosphonates**. Recommended doses: **pamidronate 90 mg IV over 2–4 hours** or **zoledronate 4 mg IV over 15 minutes**; in patients with pre-existing renal disease **no change in dosage, infusion time or interval is required**. **(iii) Glucocorticoids** are helpful in hypercalcaemia caused by **lymphoma, myeloma and breast cancer**, and may be of some value in other malignancies, at **10–100 mg per day of prednisone equivalent**. Also: stop calcium and vitamin D supplements, mobilise the patient, **avoid loop diuretics unless the patient is volume-overloaded**, and consider **haemodialysis** in severe hypercalcaemia with renal or cardiac failure.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Endocrine Society Clinical Practice Guideline on the Treatment of Hypercalcaemia of Malignancy in Adults — the first evidence-based guideline in this area, co-sponsored by ASBMR and the European Society of Endocrinology.** Its key positions: **all adults with hypercalcaemia of malignancy should be treated with denosumab or an intravenous bisphosphonate** rather than left untreated; **denosumab is suggested in preference to an intravenous bisphosphonate as first-line therapy**; and **denosumab is specifically suggested for recurrent or refractory hypercalcaemia in patients previously treated with an intravenous bisphosphonate**. In **severe or symptomatic** disease, **calcitonin should be combined with the bisphosphonate or denosumab rather than the antiresorptive used alone**. For hypercalcaemia from tumours producing **high calcitriol, such as lymphoma**, in patients already on glucocorticoids but still severely hypercalcaemic, **add an IV bisphosphonate or denosumab**. In **parathyroid carcinoma**, use either a **calcimimetic (cinacalcet)** or an IV bisphosphonate/denosumab. **Two geriatric practice points:** denosumab requires **no renal dose adjustment and can be used at low eGFR** where zoledronate is problematic — a real advantage in the older patient with CKD — but it carries a genuine risk of **prolonged, severe hypocalcaemia in advanced CKD**, so calcium and vitamin D must be monitored, and its effect **cannot be reversed** once given.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
First-line antiresorptive in malignancy	Bisphosphonates have supplanted all other drugs	Denosumab suggested *in preference to* IV bisphosphonate as first line
Refractory / recurrent disease	Calcitonin for rapid onset	Denosumab after prior IV bisphosphonate; calcitonin *combined* with the antiresorptive in severe disease
Renal impairment	No dose change needed for bisphosphonate	Denosumab preferred at low eGFR — but watch for prolonged hypocalcaemia

Exam approach: Reproduce the textbook doses (pamidronate 90 mg, zoledronate 4 mg, calcitonin onset 2–4 h versus 72 h) — they are frequently asked verbatim — then add the denosumab-first recommendation in a single sentence.

MEMORY ANCHORS & 15-SECOND SKELETON

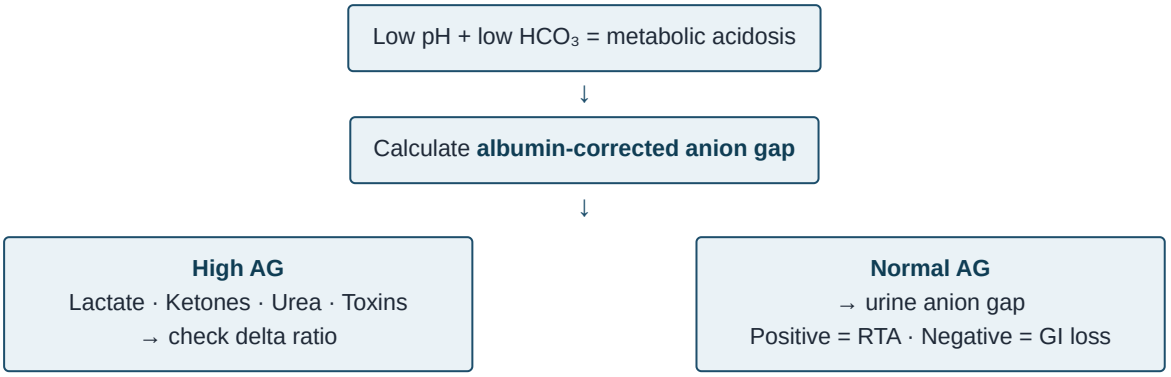
Skeleton: Define with the albumin caveat → 90% = hyperparathyroidism (outpatient) or malignancy (inpatient) → list PTH-independent causes in six groups → bones/stones/groans/moans, but *delirium and falls in the elderly* → **correct for albumin, then measure PTH** → branch → treat by severity with saline, bisphosphonate, calcitonin, steroids.

PTH-independent mnemonic — "GRAND MIT": Granulomatous (sarcoid, TB) · **R**habdomyolysis recovery · **A**drenal insufficiency · **N**eoplasia (PTHrP, osteolytic, calcitriol) · **D**rugs (thiazide, lithium, vitamins A and D, milk–alkali) · **M**yeloma · **I**mmobilisation · **T**hyrotoxicosis.

Numbers: 10.6 mg/dL defines it · **11.0** mg/dL is the treatment threshold · **12** mg/dL separates outpatient from inpatient · albumin correction **+0.8 per 1 g/dL** · pamidronate **90 mg over 2–4 h** · zoledronate **4 mg over 15 min** · calcitonin onset **2–4 h** versus bisphosphonate **72 h** · prednisone **10–100 mg/day** · FHH Ca/Cr clearance ratio **<0.01**.

EXAMINER TRAPS

- Not **correcting for albumin** — in a hypoalbuminaemic older patient a "normal" total calcium can conceal significant hypercalcaemia.
- Ordering a scan before measuring **PTH**. PTH is the branch point of the entire flow chart, and the examiner is looking for it.
- Giving a **loop diuretic** to "promote calciuresis" in a dehydrated patient — this worsens hypovolaemia and hypercalcaemia. Rehydrate first; furosemide only for fluid overload.
- Forgetting that **rehydration alone has only mild and transient effects** — the definitive agent is the antiresorptive.
- Omitting **tuberculosis** from the granulomatous causes in an Indian examination.
- Missing **immobilisation hypercalcaemia** in a bed-bound patient with Paget's disease or myeloma.



QUESTION 9 · FLUID, ELECTROLYTE & ACID–BASE

Metabolic acidosis and its evaluation

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition and the ageing kidney.** Metabolic acidosis is a **primary fall in serum bicarbonate (<22 mEq/L)** with a low arterial pH (<7.35). The **ageing kidney handles an acute acid load poorly** — older people acidify the urine more slowly and take longer to recover, so acidosis is both commoner and more prolonged in old age.
2. **First step — the anion gap. AG = Na^+ – (Cl^- + HCO_3^-)**, normal **8–12 mEq/L**. Always **correct for albumin**: add 2.5 mEq/L to the measured gap for every 1 g/dL fall in serum albumin below 4 g/dL — otherwise a high-gap acidosis is missed in the malnourished older patient.
3. **High anion gap causes (GOLD MARK): G**lycols (ethylene glycol, propylene glycol), **O**xoproline (chronic paracetamol), **L**-lactate (sepsis, shock, **metformin**), **D**-lactate, **M**ethanol, **A**spirin, **R**enal failure (uraemia), **K**etoacidosis (diabetic, alcoholic, starvation).
4. **Normal anion gap (hyperchloraemic) causes: diarrhoea, renal tubular acidosis** — of which **type 4 (hyporeninaemic hypoaldosteronism) is the classic one in the older diabetic with CKD** — ureteric diversion, excessive saline, and drugs (**acetazolamide, spironolactone, trimethoprim, amiloride**).
5. **Stepwise evaluation.** ABG/VBG with simultaneous electrolytes → confirm the acidosis → calculate **albumin-corrected anion gap** → if high, calculate the **delta ratio** ($\Delta AG/\Delta HCO_3$) to detect a mixed disorder → if normal, calculate the **urine anion gap** ($U_{Na} + U_K - U_{Cl}$): a **positive** gap means **RTA**, a **negative** gap means **GI bicarbonate loss** → finally check respiratory compensation with **Winter's formula** (expected $pCO_2 = 1.5 \times HCO_3 + 8 \pm 2$).
6. **Management.** Treat the underlying cause — fluids and antibiotics for sepsis, insulin and fluids for ketoacidosis, dialysis for severe uraemia or toxic alcohols. **Sodium bicarbonate** is reserved for severe acidaemia (pH <7.1) or chronic CKD acidosis. In older adults, remember that bicarbonate carries a **sodium load that can precipitate volume overload and heart failure**, and rapid correction can cause hypokalaemia and hypocalcaemia.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Treating chronic metabolic acidosis of CKD is now standard renoprotective care.** Current KDIGO-aligned practice is to give **oral sodium bicarbonate to maintain serum bicarbonate ≥22 mEq/L** in CKD, because chronic acidosis accelerates GFR decline and drives **muscle protein catabolism, sarcopenia and bone demineralisation** — all of which are especially damaging in the frail older patient. The hydrochloric-acid–binding polymer **veverimer**, developed as a sodium-free alternative, **did not meet its primary endpoint in the VALOR-CKD trial**, so **sodium bicarbonate remains the treatment of choice**, with careful attention to volume status and blood pressure in older adults.

MEMORY ANCHORS

GOLD MARK for high-gap · **USED CARP** for normal-gap (Ureteric diversion, Saline, Endocrine/Addison, Diarrhoea, Carbonic anhydrase inhibitors, Ammonium chloride, RTA, Pancreatic fistula) · **Winter's = 1.5 × HCO_3 + 8 ± 2** · albumin correction **2.5 per 1 g/dL**.

EXAMINER TRAPS

- Forgetting to **correct the anion gap for albumin** in a malnourished 80-year-old — the commonest reason a high-gap acidosis is called "normal gap".
- Calling type 4 RTA rare — it is **common** in older diabetics on ACE inhibitors, spironolactone or trimethoprim, and presents as **hyperkalaemia with a normal-gap acidosis**.
- Giving bicarbonate for lactic acidosis of sepsis — treat the sepsis, not the number.

PART III

Kidney Disease

Q10 · Q11 · Q12 · Q13 · Q14 · Q15 · Q16 · Q17

QUESTION 10 · KIDNEY DISEASE

Management of acute kidney injury

7-Mark Note — 6 textbook points + 1 latest update = 7 points

Recurring question — asked ×2. Extra scaffolding provided below.

TEXTBOOK CORE — 6 POINTS

1. **Recognise and stage first.** AKI is defined by a rise in serum creatinine of **≥0.3 mg/dL within 48 hours**, or **≥1.5 times baseline within 7 days**, or urine output **<0.5 mL/kg/h for 6 hours**. In older adults the incidence is higher because of systemic illness, polypharmacy and the renal ageing process itself, and it is **frequently multifactorial**.
2. **Classify the cause, because two of the three categories are reversible. Prerenal — dehydration is the main cause in the elderly**, plus haemorrhage and cardiogenic or septic shock. **Renal** — acute tubular necrosis from persistence of prerenal causes and/or **nephrotoxins such as aminoglycosides**, rapidly progressive glomerular damage, and acute interstitial nephritis. **Postrenal** — stones, tumour, stricture and **prostatic hypertrophy**. **Prerenal and postrenal causes are of particular importance because their early identification and treatment may prevent or reverse the injury.**
3. **Immediate bedside assessment.** Assess volume status; **catheterise or bladder-scan to exclude retention**; send urinalysis and microscopy for casts and cells; arrange **renal ultrasound within 24 hours if obstruction is possible**; and **review every single drug**, prescribed and over-the-counter.
4. **The five therapeutic priorities. (i) Restore renal perfusion** with judicious fluid, guided by clinical reassessment — but give it cautiously, because **senile hypofiltration and diastolic cardiac failure predispose older people to cardiac failure and lung congestion after a saline load**. **(ii) Relieve obstruction** promptly. **(iii) Stop nephrotoxins** — NSAIDs, ACE inhibitors and ARBs, diuretics, aminoglycosides, contrast, PPIs. **(iv) Treat sepsis** with appropriately dosed antibiotics. **(v) Correct the consequences** — hyperkalaemia, acidosis, fluid overload — and **re-dose every drug to the current GFR**.
5. **Interpret the urinary indices with geriatric caution.** The urinary indices used for diagnosing AKI — **urinary sodium, fractional excretion of sodium and fractional excretion of urea — may be slightly different in older adults from those accepted for younger people**, because the aged kidney wastes sodium and urea at baseline. A higher-than-expected value therefore **does not exclude prerenal AKI**. Importantly, **age per se is not an important determinant of survival in AKI**.
6. **Dialysis, recovery and prevention. Temporary or permanent dialysis may sometimes be needed.** Although AKI is treated similarly in older and younger patients, older patients are **more vulnerable to dialysis-related complications** — haemodynamic instability, bleeding and disequilibrium syndrome. **If the kidney does not**

recover after approximately three months, the condition remains as chronic kidney disease. Because treatment options are limited, **prevention is paramount**: maintain adequate extracellular volume, avoid nephrotoxins, and **tailor drug dosage to the GFR**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **There is still no drug that treats AKI — but three practice points have changed. (a) Fluid choice: balanced crystalloids are preferred to 0.9% saline**, which causes hyperchloraemic acidosis; and there is **no role for low-dose dopamine, mannitol, or loop diuretics to "convert" oliguric to non-oliguric AKI** — diuretics are for volume overload only. **(b) Timing of dialysis:** the **STARRT-AKI trial** showed that **accelerated initiation of renal replacement therapy gave no mortality benefit and left more patients dialysis-dependent at 90 days**, supporting a watchful, **indication-driven** rather than number-driven strategy. **(c) Systems of care:** electronic **AKI alerts**, **nephrotoxin stewardship**, and **structured post-AKI follow-up** — because survivors of AKI carry a markedly elevated risk of subsequent CKD, recurrent AKI and cardiovascular death, and older survivors are the group least likely to be followed up.

MEMORY ANCHORS

Management mnemonic — "STOP AKI": Sepsis treated · **T**oxins stopped · **O**ptimise perfusion and blood pressure · **P**revent and relieve obstruction · then **A**ssess for **K**idney replacement **I**ndications.

Numbers: creatinine +0.3 mg/dL in 48 h · 1.5× baseline in 7 days · urine output <0.5 mL/kg/h × 6 h · ultrasound within 24 h · no recovery by **3 months** = CKD.

EXAMINER TRAPS

- Forgetting the **bladder**. In an older man, palpate and scan before you do anything clever.
- Using **FENa mechanically** in an 85-year-old — the ageing kidney wastes sodium at baseline.
- Giving furosemide to "improve urine output" — it improves the chart, not the kidney.
- Fluid-loading a frail patient with diastolic dysfunction into pulmonary oedema.
- Discharging without a **post-AKI follow-up plan** or restarting the ACE inhibitor without a repeat creatinine and potassium.

QUESTION 11 · KIDNEY DISEASE

Chronic kidney disease — etiopathogenesis, diagnosis and management, with conservative management in the elderly

15-Mark Essay — 10 textbook points + 2 latest updates = 12 points

Recurring question — asked ×2. Extra scaffolding provided below.

TEXTBOOK CORE — 10 POINTS

1. **Definition and burden.** CKD is a syndrome characterised by **progressive and generally irreversible deterioration of renal function due to a reduction in nephron mass**, present for more than three months with health implications. It is **predominantly a disease of older adults** — its incidence rises steadily with age and it is **at least ten times more common at 75 years and above than between 15 and 45 years**.
2. **Causes in old age.** The leading causes are **hypertension and nephrosclerosis, diabetes mellitus, and obstructive uropathy**. Two causes deserve special emphasis because they are potentially reversible: **vascular disease of the main renal arteries** and **prostatic hypertrophy**. In as many as **one-third of older patients no**

specific cause can be identified. Also consider amyloidosis, myeloma and chronic interstitial nephritis from long-term NSAID use.

3. **Etiopathogenesis — the mechanisms of progression. (a) Glomerular hyperfiltration** in surviving nephrons — initially compensatory but ultimately **accelerating glomerular sclerosis**. **(b) Retention of uraemic toxins** — polyamines, guanidines, middle molecules and hormonal peptides. **(c)** A **high parathyroid hormone level is itself a significant uraemic toxin**. **(d) Deficiency of erythropoietin and 1,25-dihydroxycholecalciferol** → anaemia and hypocalcaemia. **(e) Phosphate retention** → secondary hyperparathyroidism and **renal osteodystrophy**. **(f) Derangement of the renin–angiotensin–aldosterone system** → hypertension, which in turn accelerates nephron loss.
4. **Distinguish CKD from senile hypofiltration — a uniquely geriatric step.** In older adults, **senile hypofiltration differs from CKD** because the glomerular filtration value is **stable over 6–12 months**, and there is **no haematuria and no significant proteinuria (>0.30 g/day)**. Labelling every low eGFR in an 85-year-old as "CKD" causes unnecessary alarm, referral and treatment.
5. **Clinical features.** When creatinine clearance falls to about **25 mL/min** the full picture of uraemia appears: a **yellow-brown pallor**, pruritus, asthenia, anorexia and vomiting; cardiovascular — hypertension, heart failure, pulmonary oedema, coronary disease, arrhythmias and pericarditis; neurological — **polyneuropathy, clonus, asterixis and uraemic coma**; endocrine — **secondary hyperparathyroidism and hyperprolactinaemia**; plus **impaired cellular immunity** and **clotting abnormalities** from platelet dysfunction.
6. **Diagnosis and staging.** Stage with **eGFR (G1–G5) and albuminuria (A1–A3)**. Investigations: urinalysis and sediment, **urine albumin–creatinine ratio**, serum creatinine and electrolytes, bicarbonate, calcium, phosphate, **intact PTH**, haemoglobin and iron studies, and **renal ultrasound** for kidney size, symmetry and obstruction. Always **exclude reversible contributors first** — obstruction, volume depletion, infection, hypercalcaemia and nephrotoxic drugs.
7. **Management — slowing progression. Blood pressure control**, **RAS blockade with a single agent** for proteinuric disease (accept a creatinine rise of up to 30%; monitor potassium), **glycaemic control** individualised to frailty, **statin therapy**, smoking cessation, moderate protein intake with adequate calories to prevent sarcopenia, and **avoidance of nephrotoxins** — NSAIDs, aminoglycosides, iodinated contrast, and high-dose PPIs.
8. **Management — treating the complications. Anaemia** — iron repletion then an erythropoiesis-stimulating agent, targeting haemoglobin 10–11.5 g/dL, not normal. **CKD–mineral and bone disorder** — dietary phosphate restriction, phosphate binders, active vitamin D analogues, control of PTH. **Metabolic acidosis** — oral sodium bicarbonate to keep serum bicarbonate **≥22 mEq/L**, which also protects muscle mass. **Hyperkalaemia**, volume overload, vaccination, and **dose adjustment of every drug to the estimated GFR**.
9. **When to consider renal replacement.** Textbook threshold: when **GFR falls below 10 mL/min** it becomes necessary to start replacement therapy — dialysis or transplantation. **Age itself does not constitute a contraindication** to either. In practice the decision is **symptom-driven**, and access should be planned well in advance (see Question 12).
10. **Conservative kidney management (CKM) in the elderly — the second half of this question.** CKM is an **active, planned, non-dialytic pathway — not "no treatment"**. Its components are: **(i) symptom control** — pruritus, nausea, restless legs, breathlessness, fatigue and pain; **(ii) medical management** of anaemia, acidosis, fluid balance and blood pressure; **(iii) dietary modification** without inducing malnutrition; **(iv) advance care planning** and documentation of ceilings of care; **(v) psychosocial, spiritual and carer support**; and **(vi) integration with palliative care**. It is most appropriate where the predictors of poor dialysis outcome are present — **poor nutritional status, dementia, gait disorders, impaired ADLs and IADLs, and late referral**. The supporting figures: median survival on haemodialysis is **15.6 months at 80–84 years and 11.6 months at 85–89 years**, and **elective withdrawal accounts for 38% of deaths** in the oldest dialysis patients — evidence that for the frail, dependent, multimorbid very old, dialysis may add little survival while costing function and time at home.

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **KDIGO 2024 CKD guideline — the shift from an eGFR-based to a risk-based approach.** Key changes: stage CKD preferably with the **race-free eGFRcr-cys equation** (creatinine plus cystatin C) where cystatin C is available, and use eGFRcr-cys whenever creatinine-based eGFR is likely to be inaccurate; in **CKD G3–G5, use an externally validated risk equation such as the Kidney Failure Risk Equation** to estimate absolute risk of kidney failure and guide referral; **SGLT2 inhibitors for adults with CKD regardless of diabetes** — eGFR ≥20 with ACR ≥200 mg/g, or heart failure irrespective of albuminuria (Level 1A), and suggested for eGFR 20–45 with ACR <200 mg/g; **non-steroidal MRA (finerenone)** for type 2 diabetes with eGFR >25, normal potassium and persistent albuminuria on maximally tolerated RASi; **statins for all adults over 50 with CKD G1–G5** not on dialysis; **urate-lowering therapy only if symptomatic**; and **point-of-care creatinine and albumin testing** where laboratory access is limited.
12. **Indian context.** India carries a heavy and partly distinct CKD burden, including **CKD of unknown aetiology (CKDu)** in agricultural belts of Andhra Pradesh, Odisha and Tamil Nadu, linked to heat stress, dehydration and agrochemical exposure. The **Pradhan Mantri National Dialysis Programme** under the National Health Mission provides free haemodialysis at district hospitals in public–private partnership mode, with an explicit policy push to expand **peritoneal dialysis**; **AB-PMJAY** and the **Ayushman Vay Vandana Card** (all citizens aged 70 and above) cover dialysis packages. Early detection depends on opportunistic screening for diabetes and hypertension through **NPCDCS** at health and wellness centres.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Staging tool	Creatinine-based eGFR	Race-free eGFRcr-cys preferred; KFRE for risk in G3–G5
Disease-modifying therapy	RAS blockade, BP and glycaemic control	Add SGLT2i for all CKD regardless of diabetes; finerenone in diabetic CKD
Non-dialytic pathway	Implicit / not named	Conservative kidney management is a named, structured, guideline-endorsed option

Exam approach: Give the textbook mechanisms of progression in full — that is the "etiopathogenesis" the question asks for — then compress diagnosis, and reserve real space for **conservative management**, which is the half of the question candidates routinely under-answer.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Define → causes in the old (HTN, DM, obstruction; ⅓ unknown; renal artery disease and prostate are reversible) → six mechanisms of progression → *distinguish senile hypofiltration* → uraemia at CrCl 25 → stage by G and A → slow progression + treat complications → RRT below GFR 10 → **conservative kidney management in six components** with the survival figures.

Mnemonic for the six mechanisms — "HUP–PEP": **H**yperfiltration · **U**raemic toxins · **P**TH as a toxin · **P**hosphate retention · **E**PO and vitamin D deficiency · **P**ressure (RAAS/hypertension).

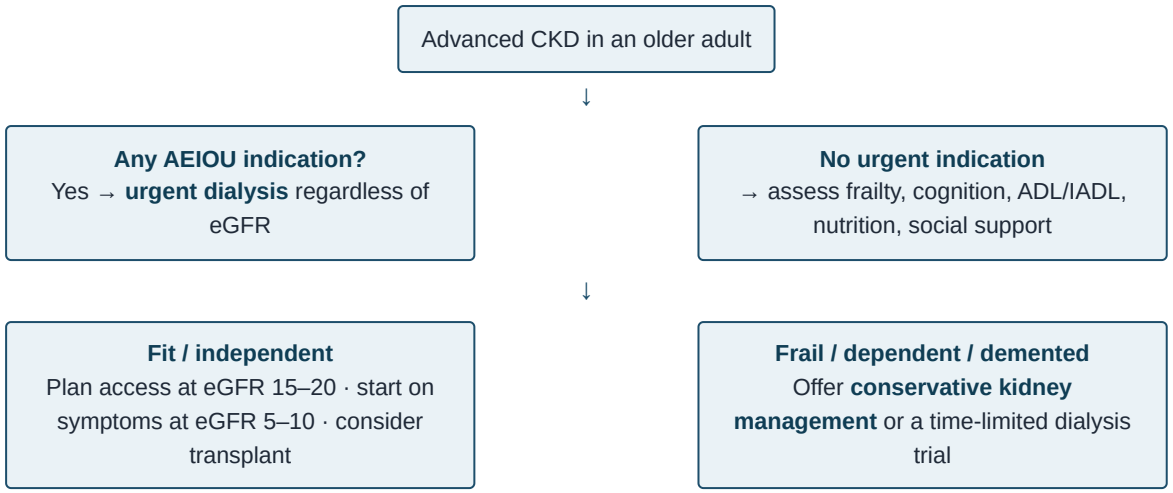
Numbers: 10× commoner at ≥75 · one-third no cause found · uraemia at CrCl 25 mL/min · RRT below GFR 10 · HCO_3 ≥22 mEq/L · Hb target 10–11.5 g/dL · HD median survival 15.6 and 11.6 months · withdrawal 38%.

EXAMINER TRAPS

- Writing a generic adult CKD answer with no **geriatric content** — the marks are in senile hypofiltration, reversible causes, and conservative management.
- Presenting CKM as "withdrawing care". State explicitly that it is an **active, planned pathway** with six named components.
- Missing **prostatic obstruction and renal artery disease** — the two potentially reversible causes the textbook singles out in the elderly.
- Targeting a **normal haemoglobin** with an ESA.

QUESTION 12 · KIDNEY DISEASE

Criteria for initiating renal replacement therapy, with special emphasis on the elderly in our country



7-Mark Note — 6 textbook points + 1 latest update = 7 points

Recurring question — asked ×2. Extra scaffolding provided below.

TEXTBOOK CORE — 6 POINTS

1. **The textbook threshold.** As CKD progresses and creatinine clearance falls to about **25 mL/min** the full picture of uraemia appears; when the **GFR falls below 10 mL/min it is necessary to start replacement therapy** — dialysis or transplantation. **Age itself does not constitute a contraindication to dialysis and/or transplantation.**
2. **Absolute and urgent indications — mnemonic "AEIOU".** **A**cidosis, severe and refractory to bicarbonate. **E**lectrolytes — **refractory hyperkalaemia**. **I**ntoxications that are dialysable — lithium, salicylate, methanol, ethylene glycol, metformin. **O**verload — **refractory pulmonary oedema** unresponsive to diuretics. **U**raemic complications — **pericarditis, encephalopathy, neuropathy, intractable nausea and vomiting, and bleeding diathesis**. Any one of these mandates dialysis regardless of the eGFR number.
3. **Elective, planned initiation is symptom-driven, not number-driven.** The trigger is a cluster of **anorexia, nausea, weight loss, fatigue, declining functional status, uncontrolled fluid or blood pressure and progressive malnutrition**, typically at an eGFR of **5–10 mL/min/1.73 m^2**. Vascular access should be created well ahead — plan the **arteriovenous fistula at an eGFR of about 15–20**, as it needs weeks to mature and is harder to create in the elderly.
4. **Geriatric modifiers of the decision.** Predictors of a poor outcome on dialysis are **poor nutritional status, dementia, gait disorders, impaired ADLs and IADLs, and late nephrology referral**. Median survival on haemodialysis is **15.6 months at 80–84 years and 11.6 months at 85–89 years**; the leading causes of death are **elective withdrawal (38%)**, cardiovascular events (24%) and infection (22%). The survival gain must therefore be weighed against dialysis burden, travel, hospital time and loss of independence.
5. **Transplantation remains on the table.** Age alone does not exclude it: in the elderly, **one-year patient survival is about 85% and one-year graft survival about 75%**, with **five-year functional graft survival of 55–60% in those over 60**. Comorbidity, not the birth date, decides.
6. **Three pathways, chosen by shared decision-making.** Present **haemodialysis**, **peritoneal dialysis** (including assisted or automated forms for the more vulnerable, such as nursing-home residents) and **conservative kidney management** as genuine alternatives. Discuss prognosis honestly, undertake **advance care planning**, and where

uncertainty remains, offer a **time-limited trial of dialysis** with an agreed review point. Genuine barriers in the very old are advanced dementia with inability to cooperate, terminal malignancy, unmanageable haemodynamic instability, absence of a carer for peritoneal dialysis, and the patient's own refusal — **none of which is age**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **The Indian picture — access has improved, but the decision framework has changed more.** The **Pradhan Mantri National Dialysis Programme** under the National Health Mission provides **free haemodialysis at district hospitals in public–private partnership mode**, with an explicit policy push to expand **peritoneal dialysis** because it is home-based, needs no thrice-weekly transport and is haemodynamically gentler — all decisive advantages for the very old. **AB-PMJAY** covers dialysis packages, and the **Ayushman Vay Vandana Card** extends cover to **all citizens aged 70 and above irrespective of income**. Practical Indian barriers persist: distance and transport for thrice-weekly haemodialysis, caregiver availability for peritoneal dialysis, out-of-pocket cost of erythropoietin and drugs, and very low rates of transplantation in the elderly. Contemporary international practice — now reflected in Indian nephrology and geriatrics guidance — is to **start on symptoms rather than on an eGFR number**, and to present **conservative kidney management as an explicit third option**, supported where available by state palliative networks such as **Kerala's community palliative care programme**.

MEMORY ANCHORS

AEIOU for urgent dialysis · access at eGFR **15–20**, start at **5–10**, textbook threshold **<10** · uraemia appears at CrCl **25** · survival **15.6 / 11.6 months** · withdrawal **38%** · transplant **85% / 75%** at one year, **55–60%** graft survival at five years.

EXAMINER TRAPS

- Giving only a number. The examiner wants **AEIOU plus the symptom-driven elective criteria plus the geriatric modifiers**.
- Saying dialysis is contraindicated in the very old — say instead that **age is not a contraindication, but frailty and dependency predict poor outcome**.
- Omitting the **Indian delivery context** when the question explicitly asks about "our country".
- Forgetting to mention **timely access creation** — late referral is itself a predictor of poor outcome.

QUESTION 13 · NEPHROLOGY

Peritoneal dialysis versus haemodialysis in the very old

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Age itself is not a contraindication to dialysis or transplantation.** Older patients can be treated effectively with **either haemodialysis (HD) or peritoneal dialysis (PD)**, and **most studies confirm that survival on PD and HD is similar** in the elderly. Replacement therapy is started when **GFR falls below 10 mL/min**.
2. **Practical problems with HD in the very old:** difficulty **creating an arteriovenous fistula**, permanent catheter or graft **infection**, gastrointestinal bleeding, **intradialytic hypotension**, headache, vomiting, cramps, angina, arrhythmias and **cardiovascular instability**.
3. **Practical problems with PD in the very old: dialysate leakage**, formation of **hernias**, backache, **difficulty in learning** the technique, **social isolation**, **family burn-out**, and worsening of **peripheral vascular disease or malnutrition**.
4. **When PD is the better choice.** PD is preferable in patients with **residual diuresis**, **severe hypotension**, **complicated or short-lived vascular access**, **intradialytic arrhythmias**, **angina**, or **cardiovascular instability**. Automated forms — **CCPD and nightly PD** — are alternatives for the more vulnerable elderly, including nursing-home residents.
5. **Nutrition and bone.** Malnutrition is frequent: provide **>1 g/kg/day protein on HD and >1.2 g/kg/day on PD**. Older dialysis patients develop **more severe bone disease** than the young because of osteopenia, unbalanced diet, reduced physical activity and lack of sun exposure.
6. **Prognosis and predictors of poor outcome.** Poor nutritional status, **dementia**, gait disorders, impaired **ADLs and IADLs**, and **late referral to nephrology**. Median survival on HD is **15.6 months at 80–84 years** and **11.6 months at 85–89 years**. Leading causes of death in the oldest dialysis patients: **elective withdrawal 38%**, cardiovascular events 24%, infection 22%.

Domain	Haemodialysis	Peritoneal dialysis
Haemodynamics	Intradialytic hypotension, arrhythmia, angina	Gentle, continuous — better in cardiac instability
Access	AV fistula often difficult; catheter infection	Peritoneal catheter; leaks, hernias
Residual renal function	Lost faster	Better preserved — favours PD
Burden	Thrice-weekly travel to centre	Home-based; needs learning ability and a carer
Typical failure mode	Vascular access failure	Peritonitis, technique failure, carer burn-out
Survival in the elderly	**Similar in most studies**	

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Shared decision-making with conservative kidney management as a genuine third option.** Current international practice frames the choice not as "HD versus PD" but as **HD versus PD versus conservative kidney management (CKM)**, with modality decided by **frailty, cognition, functional status and what matters to the patient** rather than by age or eGFR alone — CKM may deliver comparable survival with better quality of life in the frail, dependent very old. In India, **assisted / home-based PD is being expanded under the national dialysis programme and AB-PMJAY**, because it avoids thrice-weekly travel, is haemodynamically gentler, and suits an older population living with family caregivers.

EXAM ONE-LINERS

- Survival on HD and PD in the elderly = **similar**. Choose by comorbidity and social situation, not by age.
- PD for the **cardiovascularly unstable**; HD for the **cognitively impaired without a carer**.
- Commonest cause of death in the oldest dialysis patients = **elective withdrawal (38%)**.
- Protein: **>1 g/kg HD, >1.2 g/kg PD**.
- Five-year graft survival after transplant in those >60 years = **55–60%**.

QUESTION 14 · KIDNEY DISEASE

Acute glomerulonephritis

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition — the acute nephritic syndrome.** Abrupt onset of **haematuria with dysmorphic red cells and red cell casts**, **proteinuria** (usually sub-nephrotic), **hypertension**, **oedema** and **oliguria**, with a rising creatinine. When crescents involve more than 50% of glomeruli and function is lost over days to weeks, it is termed **rapidly progressive glomerulonephritis (RPGN)**.
2. **Age-specific epidemiology — this is a disease of the old. Crescentic glomerulonephritis reaches its greatest incidence between 60 and 79 years** and presents as rapidly progressive acute renal failure. **Renal vasculitis is probably the most common primary cause of renal failure in older adults. Post-streptococcal and other post-infectious glomerulonephritis are more frequent in older than in younger patients** — in the elderly typically **staphylococcal-associated or endocarditis-related** rather than streptococcal.
3. **Classification by immunofluorescence — the framework the examiner wants. (a) Pauci-immune** — ANCA-associated vasculitis (granulomatosis with polyangiitis, microscopic polyangiitis); **commonest pattern in the elderly**. **(b) Immune-complex (granular)** — post-infectious, IgA nephropathy and Henoch–Schönlein purpura, lupus nephritis, cryoglobulinaemia (hepatitis C), membranoproliferative GN. **(c) Linear** — **anti-glomerular basement membrane disease**, which has a second incidence peak in older adults.
4. **Presentation in old age is non-specific and easily missed.** Malaise, weight loss, low-grade fever, arthralgia, anorexia, **normocytic anaemia**, cough or haemoptysis (**pulmonary–renal syndrome**), purpuric rash, mononeuritis multiplex, or scleritis. The renal failure is often **discovered incidentally on routine bloods** and is at real risk of being dismissed as "ageing", dehydration or prerenal AKI — losing treatable time in a condition where **days matter**.

5. **Investigations. Urine microscopy for dysmorphic red cells and red cell casts** is the single most useful bedside test. Then urine protein–creatinine ratio, creatinine, **ANCA (MPO and PR3)**, **anti-GBM**, ANA and anti-dsDNA, **C3 and C4**, ASO titre, blood cultures and echocardiography if endocarditis is possible, hepatitis B and C serology, cryoglobulins, and chest imaging. **Renal biopsy is the definitive investigation** — its complications are **no more frequent** in older adults, though they are more serious when they occur.
6. **Management.** Treat the underlying cause. For crescentic and vasculitic disease, **steroids and other immunosuppressive drugs such as cyclophosphamide can be used in older as in younger adults, although with special attention to their side effects**; **careful monitoring of therapy can minimise adverse effects in this population**. Add **plasma exchange** for anti-GBM disease and for severe pulmonary haemorrhage. Supportive care: blood pressure control, salt and fluid restriction, loop diuretics, correction of hyperkalaemia, and dialysis where required. **Post-infectious glomerulonephritis needs antibiotics and supportive care only**, not immunosuppression.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **KDIGO ANCA-Associated Vasculitis guidance — rituximab and steroid sparing, both particularly valuable in the elderly.** For new-onset organ-threatening disease, induction is with **glucocorticoids plus either rituximab or cyclophosphamide**, with **rituximab preferred in older adults** and in anyone at risk of cyclophosphamide toxicity — infection, marrow suppression, malignancy and infertility. **Rituximab is also preferred for maintenance of remission**. Two further changes matter for geriatric practice: a **reduced-dose glucocorticoid taper (PEXIVAS-style)** achieves the same remission rates with significantly fewer serious infections; and the oral **C5a receptor antagonist avacopan** permits substantial steroid sparing — directly relevant in an older patient at risk of steroid-induced diabetes, osteoporosis, infection, delirium and myopathy. Prophylaxis against *Pneumocystis jirovecii* with co-trimoxazole is standard during induction.

EXAM ONE-LINERS

- Crescentic GN peaks at **60–79 years** — this is a geriatric disease, not a paediatric one.
- **Renal vasculitis is probably the commonest primary cause of renal failure in older adults.**
- Red cell casts = glomerular. Their presence changes the whole diagnostic pathway.
- Post-infectious GN in the elderly is usually **staphylococcal or endocarditis-related**, not streptococcal.
- **Low C3** = post-infectious, lupus, MPGN, cryoglobulinaemia. **Normal C3** = ANCA vasculitis, anti-GBM, IgA.
- Immunosuppression works just as well in the old — the difference is in **monitoring, not withholding**.

EXAMINER TRAP

Writing the classical **paediatric post-streptococcal** answer. In a geriatrics examination the expected emphasis is **ANCA-associated crescentic glomerulonephritis presenting as RPGN**, its non-specific systemic prodrome, and the fact that **it is treatable if biopsied early**. Lead with that.

QUESTION 15 · NEPHROLOGY

Nephrotic syndrome and membranous nephropathy in the elderly

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definition.** Nephrotic syndrome is **proteinuria >3.5 g/24 h** with **hypoalbuminaemia (<3 g/dL)**, **oedema** and **hyperlipidaemia**. It accounts for about **50% of all renal biopsy indications** in older adults.
2. **Commonest causes in old age. Membranous nephropathy**, **minimal change disease**, **diabetic nephropathy** and **amyloidosis**. Among older patients biopsied for glomerulonephritis, 59% had primary and 20% secondary glomerulonephritis.
3. **Age-related shift in histology. Membranous nephropathy, membranoproliferative GN, minimal change disease, crescentic GN** and post-streptococcal GN are all **more frequent** in older than younger patients. Only **FSGS and IgA / non-IgA mesangioproliferative nephritis are less frequent**.
4. **Membranous nephropathy is often secondary in the elderly.** In about **20%** it is related to an **underlying malignancy** — mainly **lung or colon adenocarcinoma** — or to **drug ingestion**. A malignancy screen is mandatory before labelling it primary.
5. **Minimal change disease behaves atypically.** Senile structural renal changes make histology difficult; presentation is usually atypical with **hypertension, microhaematuria and/or renal failure**, and it may be drug-related (**NSAIDs**) or associated with **lymphoma**.
6. **Crescentic GN must not be missed.** Its incidence peaks between **60–79 years** and it presents as **rapidly progressive acute renal failure**. Renal vasculitis (granulomatosis with polyangiitis, microscopic polyangiitis) is probably the commonest primary cause of renal failure in older adults.
7. **Other secondary glomerulopathies frequent in the elderly:** diabetic nephropathy, **nephroangiosclerosis** from essential hypertension, glomerular vasculitis, and diseases with **abnormal plasma-cell proteins** — light chain, fibrillary and immunotactoid nephropathy.
8. **Investigations.** Urine protein-creatinine ratio, serum albumin, lipid profile, creatinine (mg/dL), **anti-PLA2R antibody**, blood glucose, **serum protein electrophoresis and free light chains**, ANA/ANCA, hepatitis B and C serology, and an age-appropriate malignancy screen.
9. **Supportive management.** Salt restriction, loop diuretics, **RAS blockade** for antiproteinuric effect, statin, and anticoagulation when albumin is very low — **membranous nephropathy carries the highest thromboembolic risk of the primary glomerular diseases**. Watch closely for AKI and hyperkalaemia.
10. **Immunosuppression. Steroids and cyclophosphamide can be used in older as in younger adults**, but with special attention to their side effects — infection, bone marrow suppression, hyperglycaemia, osteoporosis and delirium.

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **KDIGO Glomerular Diseases guideline — biopsy-free diagnosis and rituximab first-line.** In nephrotic syndrome with a **positive anti-PLA2R antibody and preserved kidney function**, kidney biopsy is **not required** to diagnose membranous nephropathy. **Rituximab is first-line** for moderate- and high-risk disease (1 g × 2 doses two weeks apart, or 375 mg/m^2 weekly), while **cyclophosphamide + steroid remains preferred in the very-high-risk category**.
12. **Antibody-guided therapy and the elderly caveat.** Serial **anti-PLA2R titres at 3–6 months predict remission**; immunosuppression can be stopped once the antibody is undetectable at 6 months. Recent 2025 series support **low-dose / personalised rituximab** in frail older patients. Important caveat: in the elderly, membranous nephropathy may **co-exist with renal amyloidosis or diabetic nephropathy**, so anti-PLA2R positivity alone should not stop you from biopsying an atypical case.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Diagnosis of MN	Renal biopsy in all cases	Biopsy may be omitted if anti-PLA2R positive with normal kidney function
First-line immunosuppression	Steroids ± cyclophosphamide	Rituximab first-line in moderate/high risk; cyclophosphamide reserved for very high risk
Treatment decision	Uniform, after 6 months of supportive care	Risk-stratified (proteinuria, eGFR trend, anti-PLA2R titre, epitope spreading)

Exam approach: Write the textbook histology and the malignancy association first, then add KDIGO risk stratification and rituximab as the "current practice" paragraph — this earns the highest marks.

EXAM ONE-LINERS

- Commonest cause of nephrotic syndrome in an older adult = **membranous nephropathy**.
- **1 in 5** elderly membranous nephropathy = **malignancy-associated** (lung, colon).
- Target antigen in ~70% of primary MN = **PLA2R1**; antibody is **IgG4** subclass.
- Highest thrombosis risk among primary glomerular diseases = **membranous nephropathy**.
- Nephrotic syndrome + rapidly rising creatinine in a 70-year-old = think **crescentic GN / vasculitis** — biopsy urgently.

QUESTION 16 · KIDNEY DISEASE

Interstitial nephritis

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition.** Inflammation of the **renal tubulointerstitium with relative sparing of glomeruli and vessels**. It presents either as **acute interstitial nephritis (AIN)** causing acute kidney injury, or as **chronic interstitial nephritis** causing slowly progressive CKD with tubular dysfunction.
2. **Mechanism and the classical drug causes.** Interstitial nephritis **results mainly from a delayed hypersensitivity response to drugs** — it is idiosyncratic, not dose-dependent. **Acute interstitial nephritis may develop following the use of nearly all NSAIDs or diuretics**, and although the number of reported cases is

small, **most of these patients are elderly**. Other established causes: beta-lactams, sulphonamides and co-trimoxazole, rifampicin, ciprofloxacin, allopurinol, mesalamine and phenytoin.

3. **Proton-pump inhibitors — the classic geriatric cause.** PPIs such as **omeprazole, esomeprazole and pantoprazole are increasingly recognised as a cause of acute interstitial nephritis**, and **the diagnosis requires a high index of suspicion**. It is partly for this reason that **PPIs have become a target of deprescribing strategies in older adults**. The latency is long — **weeks to months** — which is exactly why the connection is missed.
4. **Clinical features — usually silent, rarely classical.** The textbook triad of **fever, rash and eosinophilia is present in fewer than 10%** and is **even less common in the elderly**. Expect instead **non-oliguric AKI** with a bland or mildly abnormal urine: **sterile pyuria, white cell casts, mild sub-nephrotic proteinuria**, and **eosinophiluria** (poor sensitivity and specificity — do not rely on it). Tubular dysfunction may dominate: **Fanconi syndrome, renal tubular acidosis, hypokalaemia and hypomagnesaemia**.
5. **Chronic interstitial nephritis in older adults.** Patients taking **NSAIDs for months or years** may develop **papillary necrosis, chronic interstitial nephritis or even end-stage renal disease**. Other causes: **lithium**, analgesic nephropathy, chronic obstruction, reflux, sarcoidosis, Sjögren's syndrome and myeloma cast nephropathy. In India also consider **aristolochic acid in traditional herbal preparations** and **CKD of unknown aetiology / heat-stress nephropathy** in agricultural workers.
6. **Diagnosis and management. Renal biopsy confirms the diagnosis and demonstrates eosinophilic infiltration**; the usual pattern is **interstitial oedema with a lymphocyte, monocyte and eosinophil infiltrate and tubulitis**. The **cornerstone of treatment is prompt withdrawal of the offending drug**. **Usually the associated renal abnormalities improve after the drug is discontinued, with or without steroid therapy**, but possible complications include **chronic kidney disease or even end-stage renal disease**. **Renal biopsy followed by prompt steroid therapy results in improvement of renal function** — typically **prednisolone 0.5–1 mg/kg/day for 2–4 weeks with a taper over 4–6 weeks**. Add supportive care, avoid all other nephrotoxins, and correct the electrolyte disturbances.

Drug class	Typical latency	Geriatric relevance
NSAIDs	Weeks to months	Often self-medicated for osteoarthritis; may cause nephrotic-range proteinuria with AIN and papillary necrosis
Proton-pump inhibitors	Weeks to months	Frequently continued for years without indication; prime deprescribing target
Beta-lactams / sulphonamides	Days to 2 weeks	Most likely to show the classical triad
Diuretics (thiazide, furosemide)	Variable	Textbook-named cause; confounded by concurrent volume depletion
Allopurinol, rifampicin, mesalamine	Weeks	Allopurinol AIN may accompany DRESS with hepatitis
Immune checkpoint inhibitors	Weeks to months	Increasingly common as older adults receive immunotherapy

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Immune checkpoint inhibitor–associated AIN is now a leading cause of drug-induced interstitial nephritis, and older adults receive an increasing share of immunotherapy.** It differs from classical drug AIN: the latency is **longer (weeks to months after initiation)**, **eosinophilia is usually absent**, and a concurrent PPI or NSAID often acts as a co-trigger. Management is to **hold the checkpoint inhibitor and give corticosteroids**, with successful rechallenge possible in a substantial proportion after recovery. The wider practice point, reinforced across recent series, is that **delay of more than about two weeks before starting steroids predicts incomplete renal recovery** — so in an older patient with unexplained non-oliguric AKI and a bland sediment, review not only antibiotics and NSAIDs but also the **PPI and any immunotherapy**, and consider **early biopsy rather than watchful waiting**.

EXAM ONE-LINERS

- Fever + rash + eosinophilia occurs in **<10%**, and less often still in the elderly — its absence proves nothing.
- **Sterile pyuria with white cell casts and non-oliguric AKI** = interstitial nephritis until proven otherwise.
- **Stopping the drug is the treatment.** Steroids are the adjunct, and they work best **early**.
- Unexplained AKI in an older person: think **NSAID, PPI, antibiotic** — in that order of frequency.
- Long-term NSAIDs → **papillary necrosis, chronic interstitial nephritis, ESRD**.

QUESTION 17 · NEPHROLOGY

Diabetic nephropathy and its staging

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definition.** Diabetic nephropathy is **persistent albuminuria with progressive decline in GFR** in a person with diabetes, usually accompanied by **retinopathy and hypertension**, in the absence of another renal disease. It is one of the **frequent secondary glomerulopathies in the elderly**.
2. **Mogensen staging (classical, five stages). Stage I** — hyperfiltration and renal hypertrophy. **Stage II** — silent stage, GBM thickening and mesangial expansion with normoalbuminuria. **Stage III** — incipient nephropathy, **microalbuminuria 30–300 mg/day**. **Stage IV** — overt nephropathy, **macroalbuminuria >300 mg/day**, hypertension, falling GFR. **Stage V** — end-stage renal disease.
3. **Current KDIGO "CGA" staging** is now used in practice: **C**ause + **G**1–G5 by eGFR (≥90, 60–89, 45–59, 30–44, 15–29, <15) + **A**1–A3 by albuminuria (UACR <30, 30–300, >300 mg/g). Risk of progression is graded green–yellow–orange–red on this grid.
4. **Histopathology.** GBM thickening, **mesangial expansion**, **Kimmelstiel–Wilson nodular glomerulosclerosis**, hyaline arteriolosclerosis of both afferent and efferent arterioles. RPS classification: **Class I–IV** with separate interstitial and vascular scores.
5. **Risk factors.** Duration of diabetes, poor glycaemic control, **hypertension**, smoking, dyslipidaemia, obesity, genetic susceptibility, and pre-existing age-related nephrosclerosis.
6. **Geriatric-specific caveats.** A **normoalbuminuric CKD phenotype** is common; **sarcopenia lowers serum creatinine** so eGFR **overestimates** true renal function; ageing itself brings glomerulosclerosis and aglomerular circulation, so a fall in eGFR is often multifactorial.

7. **Screening.** Annual **UACR plus eGFR from the time of diagnosis** in type 2 diabetes. Confirm an abnormal UACR on **2 of 3 samples over 3–6 months**; exclude fever, infection, exercise, heart failure and menstruation as transient causes.
8. **When to suspect non-diabetic renal disease and biopsy: absence of retinopathy**, active urinary sediment (RBC casts), short duration of diabetes, abrupt onset of heavy proteinuria, rapid unexplained fall in GFR, or features of a systemic disease such as myeloma or vasculitis.
9. **Management pillars.** Individualised glycaemic control (see targets below), **blood pressure control**, **RAS blockade with a single agent** — ACE inhibitor or ARB, never both — statin therapy, smoking cessation, protein moderation and avoidance of nephrotoxins (NSAIDs, aminoglycosides, contrast). Accept a creatinine rise of **up to 30%** after starting a RAS blocker; monitor potassium.
10. **Complications and prognosis.** Progression to ESRD, **very high cardiovascular mortality**, hyperkalaemia, anaemia of CKD, CKD–mineral and bone disorder, and increased drug toxicity. In the very old, the **competing risk of death exceeds the risk of reaching dialysis** — this must shape how aggressively you treat.

Patient group	HbA1c target	Blood pressure	Lipids
Functionally independent / non-frail	7.0–7.5%	<140/90 mmHg	Statin unless contraindicated; intensity by CVD risk
Functionally dependent	7.0–8.0%	<140/90 mmHg	
Frail / highly comorbid / poor health	<8.0–8.5%	<150/90 mmHg	

Consolidated from EDWPOP, IDF and ADA targets as tabulated in Pathy's. Avoid HbA1c <6% — a J/U-shaped relationship exists, with optimal HbA1c around 7.5–8%.

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **FLOW trial (NEJM 2024) — the fourth pillar.** In 3,533 adults with type 2 diabetes and CKD (**mean age 66.6 years**), **semaglutide 1 mg weekly reduced major kidney disease events by 24%**, MACE by 18% and **all-cause death by 20%**, and slowed eGFR decline by **1.16 mL/min/1.73 m^2/year**. Benefit was consistent across all strata of CKD severity. Current therapy of diabetic kidney disease is therefore **four-pillar: RAS blocker + SGLT2 inhibitor + finerenone + GLP-1 receptor agonist**.
12. **ADA Standards of Care 2026 (Section 13, endorsed by the American Geriatrics Society). A tighter blood pressure goal for those at high cardiovascular or kidney risk and a more relaxed goal for most other older adults.** Also: in kidney failure, recent blood loss or erythropoietin therapy, **HbA1c is unreliable** — use blood glucose monitoring and/or **CGM** for goal setting instead; CGM is now recommended for older adults with type 2 diabetes on insulin.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Staging	Mogensen stages I–V	KDIGO CGA grid (G1–G5 + A1–A3); Mogensen retained for teaching
Renoprotection	RAS blockade + glycaemic and BP control	Four pillars: RASi + SGLT2i + finerenone + GLP-1 RA
Monitoring in advanced CKD	HbA1c	CGM / glucose profiles, as HbA1c is falsely low

Exam approach: Give Mogensen stages as the "staging" answer — that is what the question asks — then add the KDIGO grid in one line to show currency.

MEMORY ANCHORS

Mogensen mnemonic — "HS-MOE": **H**yperfiltration → **S**ilent → **M**icroalbuminuria → **O**vert → **E**SRD.

Numerical anchors: UACR 30 and 300 mg/g · creatinine rise ≤30% acceptable after RASi · SGLT2i can be started down to eGFR 20 · HbA1c 7–8% in most older adults · FLOW = 24 / 18 / 20 (kidney / MACE / death).

PART IV

Diabetes Mellitus

Q18 · Q19 · Q20 · Q21 · Q22 · Q23 · Q24

QUESTION 18 · DIABETES — CLINICAL SCENARIO

A 65-year-old newly diagnosed diabetic with HbA1c 10%, hypertension, dyslipidaemia, osteoarthritis and BMI 35 refuses to adhere to diet and exercise. Which antidiabetic to start, and what to add

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Frame the problem before naming a drug.** This man has **obesity-driven type 2 diabetes with a very high HbA1c (10%), hypertension, dyslipidaemia and osteoarthritis** — a cluster that is essentially the **metabolic syndrome with a mechanical complication**. Two consequences follow. First, **at 65 with a long life expectancy he is not in the "frail, relax the target" category**; aim for an HbA1c around **7.0–7.5%**. Second, his refusal of diet and exercise is not a reason to abandon lifestyle counselling but a reason to **choose drugs that deliver weight loss and cardiovascular and renal protection independently of adherence** — the pharmacological choice must do the work that lifestyle is not doing.
2. **First-line: metformin, and start it at diagnosis. Metformin is first-line therapy in overweight diabetic patients.** It is **weight-neutral to weight-reducing, does not cause hypoglycaemia, and is inexpensive** — decisive in Indian practice. Start **500 mg once daily with food and titrate slowly** to limit gastrointestinal intolerance; use the extended-release preparation if needed. Check **eGFR before starting and periodically**: **do not use metformin in renal insufficiency or heart failure**, reduce the dose below an eGFR of 45 and stop below 30, and monitor **vitamin B12** on long-term therapy.
3. **An HbA1c of 10% will not be controlled by metformin alone — start combination therapy immediately.** Metformin lowers HbA1c by about **1–1.5%**, which leaves him well short of target. Current practice is that when HbA1c is **more than 1.5–2% above target, dual therapy should be initiated from the outset** rather than sequentially. If he were **markedly symptomatic with polyuria, polydipsia and weight loss, or had glucose above 300 mg/dL or ketosis**, the correct answer would be **initial basal insulin** to relieve glucotoxicity, with subsequent de-escalation to oral agents once glucose falls — but the question describes weight gain, not catabolism, so combination oral and injectable non-insulin therapy is appropriate.
4. **Second agent: a GLP-1 receptor agonist — the best fit for this specific patient.** Its advantages align exactly with his problem list: **the largest HbA1c reduction of the non-insulin classes (about 1.0–1.5%)**, **substantial weight loss (3–6 kg, more with semaglutide or tirzepatide)**, **no intrinsic hypoglycaemia** because insulin release is glucose-dependent, **proven benefit in established atherosclerotic cardiovascular disease**, and —

critically here — **weight loss is the single most effective disease-modifying intervention for knee osteoarthritis**, so one drug addresses the diabetes, the obesity and the joint. Counsel about **nausea, vomiting and anorexia**, titrate slowly, and monitor for excessive weight loss and sarcopenia. Cost is the practical barrier in India.

5. **Third agent, or an alternative second agent: an SGLT2 inhibitor.** Add **empagliflozin or dapagliflozin** for the **hypertension** (a modest natriuretic blood-pressure reduction), for **cardiovascular and renal protection irrespective of HbA1c**, and for **2–3 kg of weight loss without hypoglycaemia**. Generic empagliflozin and dapagliflozin are **widely available and inexpensive in India**, which makes this the pragmatic partner for metformin where a GLP-1 receptor agonist is unaffordable. Counsel on **genital mycotic infection, perineal hygiene, volume depletion, and sick-day rules**, and warn about **euglycaemic ketoacidosis**.
6. **What to avoid, and the non-drug obligations you must still discharge. Avoid sulphonylureas** — they cause **hypoglycaemia and weight gain**, both wrong for this man; **avoid thiazolidinediones — do not use in heart failure**, and they cause **weight gain, fluid retention and fracture**; use **DPP-4 inhibitors only as a weight-neutral, well-tolerated fallback**, remembering that they showed **no cardiovascular benefit**. Alongside the diabetes: treat the **hypertension — the antihypertensive regimen of a diabetic should include an ACE inhibitor or ARB** — prescribe a **statin**, since **therapy of these risk factors may be of greater benefit than tight glucose control in older diabetics**, and manage the osteoarthritis with **paracetamol, topical NSAIDs, physiotherapy and quadriceps strengthening rather than systemic NSAIDs**, which threaten his kidneys and blood pressure. Finally, **his refusal is a communication problem, not a closed door**: use **motivational interviewing**, negotiate one small, specific, achievable change, involve the family, and revisit it at every visit.

Agent	HbA1c effect	Weight	Why it fits — or does not	Watch for
Metformin	↓1.0–1.5%	Neutral / ↓	**First-line in the overweight;** cheap, no hypoglycaemia	GI upset, B12 deficiency; avoid if eGFR <30 or heart failure
GLP-1 RA	↓1.0–1.5%	↓↓ 3–6 kg	**Best fit — diabetes + obesity + knee OA + ASCVD risk**	Nausea, anorexia, sarcopenia, gallstones, cost
SGLT2 inhibitor	↓0.5–0.8%	↓ 2–3 kg	BP lowering, cardiorenal protection, **cheap generics in India**	Genital infection, volume depletion, euglycaemic DKA
DPP-4 inhibitor	↓0.5–0.8%	Neutral	Fallback only — well tolerated but **no CV benefit**	Rare pancreatitis; do not combine with GLP-1 RA
Sulphonylurea	↓1.0–1.5%	↑	**Avoid** — hypoglycaemia and weight gain	Glibenclamide is a Beers-criteria drug
Pioglitazone	↓0.8–1.2%	↑↑	**Avoid** — oedema, heart failure, fracture	Bladder cancer signal; worsens immobility
Basal insulin	Unlimited	↑	Only if catabolic, glucose >300 mg/dL or ketosis	Hypoglycaemia; de-escalate once glucotoxicity resolves

65 years · HbA1c 10% · BMI 35 · HTN · dyslipidaemia · knee OA · refuses lifestyle change

↓

Symptomatic, catabolic, glucose >300 mg/dL or ketosis? → **Yes = start basal insulin first**, de-escalate later

↓ No

Start dual therapy from the outset: Metformin + **GLP-1 receptor agonist** (weight, ASCVD, knee OA)

↓ if cost prohibits GLP-1 RA

Metformin + **SGLT2 inhibitor** (BP, cardiorenal, cheap generic in India)

↓ if HbA1c still above target at 3 months

Triple therapy: **Metformin + GLP-1 RA + SGLT2 inhibitor** · then basal insulin if needed

↓ In parallel, always

ACE inhibitor or ARB · statin · paracetamol and topical NSAID with quadriceps strengthening for the knee · motivational interviewing at every visit

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **ADA Standards of Care 2026 — treat the comorbidity, not just the glucose, and treat the obesity as a disease.** Glucose-lowering therapies are now recommended explicitly **for heart, kidney and liver protection independent of HbA1c**, and there is new guidance on **individualised dosing of obesity medications in people with diabetes**. For this patient with a BMI of 35, that reframes the question: obesity is a treatment target in its own right, and **tirzepatide**, a dual GIP/GLP-1 receptor agonist, delivers the greatest combined HbA1c and weight reduction of any non-insulin agent. Two further points make this directly examinable: the **SELECT trial** showed cardiovascular benefit from semaglutide in **overweight and obese patients without diabetes**, confirming that the benefit is not purely glycaemic; and ADA Section 12 highlights a **GLP-1-associated reduction in amputation risk**. The geriatric caveat to state alongside this: these agents cause **loss of lean mass as well as fat**, so in anyone over 65 you must **ensure adequate protein intake and resistance exercise, and monitor for sarcopenia** — which, incidentally, is the argument that finally persuades many patients to accept the exercise they had refused.

EXAMINER TRAPS

- Answering "metformin" and stopping there. At an **HbA1c of 10%** the expected answer is **dual therapy from the outset**.
- Reaching for a **sulphonylurea** because it is cheap and lowers HbA1c briskly — it is exactly wrong in an obese patient at risk of hypoglycaemia.
- Prescribing **pioglitazone** in a patient who is obese and immobile.
- Treating the refusal as the end of the conversation. State that you would use **motivational interviewing and negotiate one small change** — examiners reward this explicitly.
- Forgetting the **ACE inhibitor or ARB and the statin**. The textbook is explicit that treating these risk factors may benefit an older diabetic more than tight glucose control.
- Prescribing **systemic NSAIDs** for his knee — hypertension, renal risk and gastrointestinal bleeding.

QUESTION 19 · DIABETES MELLITUS

SGLT2 inhibitors and GLP-1 receptor agonists in the older adult

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **SGLT2 inhibitors — mechanism.** They block the **sodium–glucose cotransporter 2 in the proximal tubule**, producing **glycosuria and natriuresis**. The natriuresis restores **tubuloglomerular feedback**, causing afferent arteriolar constriction and a fall in **intraglomerular pressure** — this, not the glucose lowering, explains the renoprotection. Drugs: **empagliflozin, dapagliflozin, canagliflozin**.
2. **GLP-1 receptor agonists — mechanism.** They produce **glucose-dependent insulin secretion**, **suppress glucagon**, **delay gastric emptying** and act centrally to **reduce appetite**. Drugs: **liraglutide, semaglutide, dulaglutide, exenatide**; **tirzepatide** is a dual GIP/GLP-1 receptor agonist.
3. **The key geriatric advantage — negligible intrinsic hypoglycaemia risk.** Because the insulin effect of GLP-1 receptor agonists is **glucose-dependent** and SGLT2 inhibitors act independently of insulin, neither causes hypoglycaemia on its own. **Risk appears only when they are combined with a sulphonylurea or insulin** — so reduce the dose of those agents when adding either class. Both also cause **weight loss**.
4. **Cardiovascular outcome trial data.** Overall **cardiovascular safety was demonstrated across all classes** using the **three-point MACE** endpoint (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke). **DPP-4 inhibitors showed no cardiovascular benefit**, whereas **empagliflozin and canagliflozin significantly reduced cardiovascular and renal events**, with **empagliflozin also reducing hospitalisation for heart failure and worsening nephropathy**.
5. **GLP-1 receptor agonists in older participants.** Among the GLP-1 receptor agonist trials, **exenatide showed cardiovascular benefit in participants aged 65 and over** — but with a **43% treatment discontinuation rate**, which is itself an important geriatric lesson about tolerability and adherence in this age group.
6. **Indications now extend well beyond glycaemia. SGLT2 inhibitors** are indicated in **heart failure with both reduced and preserved ejection fraction** and in **chronic kidney disease, with or without diabetes**. **GLP-1 receptor agonists** are indicated in **established atherosclerotic cardiovascular disease** and in **obesity**. Prescribe them for the organ, not only for the HbA1c.
7. **Adverse effects of SGLT2 inhibitors. Genital mycotic infection** and urinary tract infection, **volume depletion with postural hypotension**, **euglycaemic diabetic ketoacidosis**, an **initial reversible "eGFR dip"** of up to 30% which is haemodynamic and expected, rare **Fournier's gangrene**, and the **amputation and fracture signal seen with canagliflozin**.
8. **Adverse effects of GLP-1 receptor agonists. Nausea, vomiting and diarrhoea** (dose-limiting, and the reason for the high discontinuation rate), **anorexia with unintended weight loss**, gallstones and cholecystitis, pancreatitis, and injection-site reactions. **Contraindicated with a personal or family history of medullary thyroid carcinoma or MEN2**.
9. **Geriatric prescribing cautions — the marks are here. Avoid or use SGLT2 inhibitors very cautiously** in recurrent urinary tract infection, urinary incontinence, poor perineal hygiene, recurrent genital candidiasis, or in a patient on a loop diuretic with orthostatic hypotension and falls. **Avoid GLP-1 receptor agonists** in frailty with unintentional weight loss, **sarcopenia**, gastroparesis, poor oral intake or significant anorexia — the weight loss that is a benefit in the obese 55-year-old is a **hazard in the sarcopenic 85-year-old**. Screen for sarcopenia and monitor weight before and during therapy.

10. **Practical use.** Start an SGLT2 inhibitor down to an **eGFR of 20 mL/min/1.73 m²** and continue until dialysis. Apply **sick-day rules** — suspend during acute illness, dehydration, fasting or before surgery. Reduce sulphonylurea or insulin doses when adding either agent. In India, **generic empagliflozin and dapagliflozin are widely available and inexpensive**, whereas **GLP-1 receptor agonists remain costly and are a major barrier to access** — a point worth stating in an Indian examination.

Domain	SGLT2 inhibitor	GLP-1 receptor agonist
Route	Oral, once daily	Injection (daily or weekly); oral semaglutide available
HbA1c reduction	~0.5–0.8%	~1.0–1.5%
Weight	↓ 2–3 kg	↓ 3–6 kg (more with semaglutide/tirzepatide)
Heart failure	**Strong benefit (HFrEF and HFpEF)**	Neutral
Kidney	**Strong benefit**	**Benefit (FLOW)**
Atherosclerotic CVD	Benefit	**Strong benefit**
Main geriatric hazard	Volume depletion, genital/urinary infection, euglycaemic DKA	Anorexia, sarcopenia, GI intolerance, discontinuation
Best older candidate	Heart failure or CKD, well hydrated, continent	Obese, ASCVD, preserved appetite and muscle mass

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **FLOW trial (NEJM 2024) — GLP-1 receptor agonists become a kidney drug.** In 3,533 adults with type 2 diabetes and CKD, **mean age 66.6 years** and median follow-up 3.4 years, **semaglutide 1 mg weekly reduced major kidney disease events by 24%** (HR 0.76), **major cardiovascular events by 18%** and **all-cause death by 20%**, and slowed the annual eGFR decline by **1.16 mL/min/1.73 m²**. The trial was **stopped early for efficacy**, and benefit held **across every stratum of baseline eGFR and albuminuria, including advanced CKD**. This established the **four-pillar** approach: RAS blocker + SGLT2 inhibitor + finerenone + GLP-1 receptor agonist.
12. **ADA Standards of Care 2026.** Glucose-lowering therapies are now recommended explicitly **for heart, kidney and liver protection independent of HbA1c**; there is new guidance on **individualised dosing of obesity medications** in people with diabetes; Section 12 highlights **GLP-1-associated reduction in amputation risk** in diabetic foot disease; and Section 13 adds guidance on **protein intake and on assessing geriatric syndromes** in older adults — relevant because both classes cause weight loss in a population already at risk of sarcopenia.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Choice of agent	Driven by HbA1c reduction	Driven by comorbidity — heart failure, CKD, ASCVD, obesity
GLP-1 RA and the kidney	Renal benefit uncertain	Proven renoprotection (FLOW)
SGLT2i eGFR floor	Restricted at moderate CKD	Initiate down to eGFR 20; continue until dialysis

Exam approach: The examiner wants to see that you weigh proven organ protection against **sarcopenia, volume depletion, continence and cost** — that balance is the geriatric answer.

MEMORY ANCHORS

"Flozins for the Failing heart and Filtering kidney; -glutides for Fat and arteries." · SGLT2i harms = **4 Fs**: Fungal (genital), Fluid depletion, Fournier's, Fractures (canagliflozin) · GLP-1 RA harms = **4 As**: Anorexia, Appetite loss/sarcopenia, Abdominal upset, Acute pancreatitis · FLOW numbers = **24 / 18 / 20**.

QUESTION 20 · DIABETES

Alpha-glucosidase inhibitors

6-Mark Note — 5 textbook points + 1 latest update = 6 points

TEXTBOOK CORE — 5 POINTS

1. **Mechanism.** Alpha-glucosidase inhibitors are **competitive, reversible inhibitors of the α-glucosidase enzymes of the intestinal brush border** — glucoamylase, sucrase, maltase and isomaltase — and **acarbose additionally inhibits pancreatic α-amylase**. They **delay the breakdown of complex carbohydrates and disaccharides into absorbable monosaccharides**, so glucose absorption is **slowed and shifted distally along the small intestine**. The result is a **blunted postprandial glucose peak**. They do **not** stimulate insulin secretion and do **not** cause hypoglycaemia when used alone.
2. **Drugs and dosing. Acarbose 25–100 mg three times daily**, **miglitol 25–100 mg three times daily**, and **voglibose 0.2–0.3 mg three times daily** — voglibose being widely used in India. Each must be taken **with the first mouthful of each main meal**; a dose taken without food has no effect. **Start low (acarbose 25 mg once daily) and titrate over weeks** to limit flatulence, which is the main reason for discontinuation.
3. **Indications and place in therapy.** Type 2 diabetes with predominantly **postprandial hyperglycaemia**, as monotherapy or as add-on to metformin, sulphonylureas or insulin. The expected HbA1c reduction is modest — about **0.5–0.8%** — so they are **second- or third-line agents**. They are **particularly relevant in India**, where high-carbohydrate diets of rice, wheat and millets produce a large postprandial excursion, and where the drugs are cheap. They are also **weight-neutral or mildly weight-reducing**, and they were shown to **reduce progression from impaired glucose tolerance to diabetes**.
4. **Advantages in the older patient. No intrinsic hypoglycaemia** — the single most valuable property in geriatric practice; **no weight gain**; **no systemic absorption** to speak of (acarbose is minimally absorbed), so few systemic drug interactions; and a **lowering of postprandial glucose**, which is the component that contributes relatively more to total hyperglycaemia in older people than basal glucose does.

5. **Adverse effects, precautions and one critical rule. Adverse effects** are almost entirely gastrointestinal and arise from colonic bacterial fermentation of unabsorbed carbohydrate: **flatulence, abdominal distension, borborygmi, cramps and diarrhoea** — poorly tolerated and often socially unacceptable in older adults. **Raised transaminases** occur with higher acarbose doses, so **monitor liver function**. **Contraindications: inflammatory bowel disease, colonic ulceration, partial intestinal obstruction or predisposition to it, chronic intestinal disease with malabsorption, large hernias, cirrhosis, and severe renal impairment (avoid acarbose if eGFR is below 25–30)**. **The critical rule:** if hypoglycaemia occurs because the patient is *also* on a sulphonylurea or insulin, it **must be treated with oral glucose (dextrose) or intravenous dextrose — NOT with sucrose, table sugar, sweets or fruit juice**, because the drug blocks the very enzyme that would split sucrose into absorbable glucose.

LATEST UPDATE (2023–PRESENT) — 1 POINT

6. **Alpha-glucosidase inhibitors have been displaced from international algorithms but retain a defined niche in Indian practice.** Current international guidance — **ADA Standards of Care 2026** and the ADA/EASD consensus — organises second-line therapy around **cardiovascular, renal and weight benefit**, and on those criteria the alpha-glucosidase inhibitors have **no demonstrated cardiovascular or renal protection** and so rank below SGLT2 inhibitors and GLP-1 receptor agonists; the **ACE (Acarbose Cardiovascular Evaluation) trial** found that acarbose **did not reduce major adverse cardiovascular events** in patients with impaired glucose tolerance and coronary disease, although it **did reduce progression to diabetes**. However, **RSSDI and Indian national guidance continue to recognise a role** for them where postprandial hyperglycaemia predominates on a high-carbohydrate diet, where cost is decisive, and — importantly for geriatrics — where **hypoglycaemia must be avoided at all costs**, such as in the frail patient living alone. The examinable summary: **a safe, cheap, hypoglycaemia-free but weakly effective and poorly tolerated agent, now a third-line option internationally and a legitimate second-line adjunct in the Indian setting**.

MEMORY ANCHORS

Skeleton (drug question format): Mechanism → drugs and dose → indications → benefits → adverse effects → precautions. Six headings, one or two lines each.

Numbers: HbA1c reduction **0.5–0.8%** · acarbose and miglitol **25–100 mg TDS** · voglibose **0.2–0.3 mg TDS** · take with the **first mouthful** · avoid acarbose if eGFR **<25–30**.

EXAMINER TRAP — THE QUESTION THAT IS ALWAYS ASKED

"How would you treat hypoglycaemia in a patient taking acarbose?" The answer is **oral glucose or dextrose, or intravenous dextrose — never sucrose, table sugar, sweets, honey or fruit juice**, because the drug prevents disaccharide hydrolysis so sucrose cannot be absorbed as glucose. Volunteering this before you are asked marks the answer out.

QUESTION 21 · DIABETES MELLITUS

Newer insulins — onset, duration and advantages

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Classification by pharmacokinetics. Rapid-acting analogues** (lispro, aspart, glulisine) — onset 10–20 min, peak 1–2 h, duration 3–5 h. **Ultra-rapid** (faster aspart, lispro-aabc) — onset ~5 min. **Short-acting regular human insulin** — onset 30–60 min, peak 2–4 h, duration 6–8 h. **Intermediate NPH** — onset 1–2 h, peak 4–8 h,

duration 12–18 h. **Long-acting analogues** — glargine U100 and detemir, ~24 h and 12–20 h. **Ultra-long-acting** — **glargine U300 and degludec**, flat and peakless, lasting **24–42 h**.

2. **The core textbook point on basal insulins.** The availability of **various basal insulins with a shelf life of 24 hours or longer — including glargine, degludec, glargine U300 and detemir — has provided much-needed options to lower baseline glucose with a single daily injection**, in addition to non-insulin agents. This simplification is the main gain for older patients.
3. **Insulin carries a higher hypoglycaemia risk than most oral agents in older adults.** The stated principle is to **decrease that risk by carefully choosing an insulin preparation that matches the timing of hyperglycaemia, and by matching the complexity of the regimen to the patient's coping ability** — not to the ideal physiological profile.
4. **The pattern of hyperglycaemia differs with age.** In older people, the **relative contribution of basal hyperglycaemia is lower and that of postprandial hyperglycaemia higher** than in younger patients. This argues for rapid-acting analogues at meals when a full regimen is feasible — but a **basal-only regimen remains simpler and safer** for most frail patients.
5. **Advantages of analogues over human insulin in the elderly. Fewer nocturnal and severe hypoglycaemic episodes** — degludec and glargine U300 have the flattest, most reproducible profiles and the lowest nocturnal hypoglycaemia; **no need for exact 30-minute pre-meal timing** with rapid analogues, which suits erratic eating and carer-dependent meals; and **true once-daily dosing**. For those unable or unwilling to manage a basal-bolus regimen, consider a **twice-daily premixed analogue** (analogues preferentially, to reduce hypoglycaemia).
6. **Delivery devices.** There appear to be **no benefits on glycaemic control from using a pen, pump or vial-and-syringe in older populations**. However, **visual impairment and low dexterity due to arthritis may make vial and syringe impractical in the frail older adult**. **Pre-filled insulin pens are safe and effective for older adults**, and in institutional care various patient, staff and cost factors make pen injectors the preferred mode of delivery.

Insulin	Onset	Peak	Duration	Geriatric note
Lispro / aspart / glulisine	10–20 min	1–2 h	3–5 h	Can be given *after* the meal if intake is unpredictable
Regular human	30–60 min	2–4 h	6–8 h	Needs strict pre-meal timing — poor fit for frailty
NPH	1–2 h	4–8 h	12–18 h	Distinct peak → nocturnal hypoglycaemia
Detemir	1–2 h	Minimal	12–20 h	May need twice daily
Glargine U100	2–4 h	Peakless	~24 h	Reliable once daily
Glargine U300 / degludec	2–6 h	Peakless	**24–42 h**	**Lowest nocturnal hypoglycaemia; flexible timing**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Once-weekly basal insulin icodec (approved 2024 in the EU, Canada and Switzerland).** In the **ONWARDS 1–5** phase 3 programme in type 2 diabetes, icodec was **non-inferior and in several trials superior to once-daily basal insulin for HbA1c reduction**, while cutting basal injections from **seven to one per week**; a pooled analysis showed **efficacy and hypoglycaemia profiles consistent across age subgroups**. It was **not recommended for type 1 diabetes** because **ONWARDS 6** showed higher rates of level 2 and level 3 hypoglycaemia versus degludec. **Relevance to geriatrics:** a once-weekly basal insulin is potentially transformative for the older adult with type 2 diabetes who depends on a family caregiver, a visiting nurse or a nursing home for injections — but note that **steady state is not reached until 3–4 injections**, a loading dose is used, and any hypoglycaemia is correspondingly **prolonged and not rapidly reversible**.

EXAM ONE-LINERS

- Flattest basal profile, lowest nocturnal hypoglycaemia = **degludec and glargine U300**.
- In the elderly, **postprandial** hyperglycaemia contributes relatively more than basal.
- No glycaemic advantage of pen over syringe — but **pens win on vision and dexterity**.
- Match the regimen to the patient's **coping ability**, not to physiology.
- Icodec: approved for T2DM, **not** for T1DM.

EXAMINER TRAP

Do not recommend a basal-bolus regimen for a frail, cognitively impaired 88-year-old simply because it is "physiological". The correct geriatric answer is **the simplest regimen that avoids symptomatic hyperglycaemia and hypoglycaemia** — often basal insulin once daily, or a twice-daily premixed analogue given by a carer.

QUESTION 22 · DIABETES MELLITUS

Hypoglycaemia — evaluation and management

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definition and grading. Level 1 (alert value)** — glucose **<70 mg/dL**; **Level 2 (clinically significant)** — **<54 mg/dL**; **Level 3 (severe)** — any level associated with **cognitive impairment requiring external assistance**, with no glucose threshold. **Hypoglycaemia is the critical limiting factor in achieving glycaemic targets in older adults with diabetes.**
2. **Why older people are especially vulnerable.** Higher levels of **polypharmacy**, presence of **frailty**, and a **high comorbid burden**. Additional risk factors: **cognitive impairment**, **renal disease**, exposure to **sulphonylureas — particularly long-acting agents**, insulin exposure — particularly **twice-daily mixed and basal-bolus regimens** — a **low glycated haemoglobin**, and **low body mass**.
3. **Symptom classification. Autonomic** — palpitations, tremor, sweating, hunger, anxiety. **Neuroglycopaenic** — behavioural change, confusion, incoordination, seizure, coma. Autonomic symptoms are the warning system; neuroglycopaenic symptoms are the damage.
4. **The geriatric problem — blunted warning.** Hypoglycaemic symptoms **become less intense with advancing age, especially the autonomic ones**, and the **symptom profile is modified**. This reduction in autonomic symptoms is perceived by older people as **hypoglycaemia unawareness**. Their **symptom threshold may differ**

from the conventional cut-off of 70 mg/dL — so a "normal-sounding" glucose may still be symptomatic.

5. **Atypical presentation in old age.** With increasing age and disease progression, presentations become atypical: **falls**, **delirium**, **focal neurological deficit mimicking stroke**, angina or arrhythmia, nocturnal sweating and nightmares, or simply behavioural disturbance. These are routinely **misattributed to dementia, ageing or transient ischaemic attack**.
6. **Consequences.** Hypoglycaemia causes **hospital admission**, injurious falls and fracture, myocardial ischaemia and arrhythmia (the "dead-in-bed" mechanism), **accelerated cognitive decline** — with a bidirectional relationship between hypoglycaemia and dementia — loss of confidence, driving cessation and treatment non-adherence.
7. **Evaluation in a diabetic patient.** Document the episode and its timing; review **every drug**, especially sulphonylurea type and dose and insulin regimen; assess **renal and hepatic function**, nutritional intake and meal pattern, alcohol, recent weight loss, cognition and the patient's **ability to self-administer treatment**; look for a precipitating acute illness; and check whether the HbA1c is inappropriately low.
8. **Evaluation in a non-diabetic older adult.** Establish **Whipple's triad** — symptoms, a documented low plasma glucose, and relief on raising the glucose. Then, **during a spontaneous episode or a supervised 72-hour fast**, measure **insulin, C-peptide, proinsulin, β-hydroxybutyrate and a sulphonylurea screen**. Causes to consider: **drugs (sulphonylurea, quinolones, quinine), alcohol, sepsis, hepatic or renal failure, adrenal insufficiency, hypopituitarism, non-islet-cell tumour hypoglycaemia (IGF-2), insulinoma** and severe malnutrition.
9. **Acute treatment. Conscious and able to swallow** — the **"15/15 rule"**: 15–20 g of fast-acting carbohydrate (glucose tablets, 3–4 teaspoons of sugar, 150 mL fruit juice), recheck at 15 minutes, repeat if still <70 mg/dL, then give a complex carbohydrate snack. **Unconscious or unable to swallow** — **25% dextrose 50–100 mL IV** followed by a 10% dextrose infusion, or **glucagon 1 mg IM/SC** if no venous access. Glucagon is **ineffective in hepatic glycogen depletion** — malnutrition, alcohol, prolonged fasting.
10. **Prevention — the highest-scoring section.** Key recommendations to minimise hypoglycaemia and its admissions are to **assess hypoglycaemia risk and adjust glucose targets for frailty, functional status and life expectancy**, and to **regularly review diabetes medicines** — sulphonylureas, insulin and its regimens — including **the patient's capacity to self-administer treatment**. Practically: relax HbA1c (7.0–7.5% if non-frail, up to 8.5% if frail), **avoid HbA1c <6%**, **de-intensify** therapy, prefer agents with low hypoglycaemia risk (metformin, DPP-4 inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists), avoid **glibenclamide** (long-acting, renally cleared active metabolites — a Beers criteria drug), and educate the patient and carer.

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **ADA Standards of Care 2026, Section 13 "Older Adults" (endorsed by the American Geriatrics Society). Continuous glucose monitoring is now recommended for older adults with type 1 diabetes and, newly in 2026, for those with type 2 diabetes on insulin** — explicitly "to improve glycaemic outcomes, **reduce hypoglycaemia** and reduce treatment burden". Alongside this, **Recommendation 13.2 requires at least annual screening for geriatric syndromes (cognitive impairment, depression, incontinence, falls, persistent pain, frailty), for hypoglycaemia and for polypharmacy** in every older adult with diabetes. There is also new guidance on assessing geriatric syndromes with validated screening questions, and on protein intake.
12. **Sulphonylurea-induced hypoglycaemia is a prolonged, relapsing admission — not a treat-and-discharge event.** Current practice is to **admit and observe for at least 24–48 hours** with a continuous dextrose infusion, because recurrence after apparent recovery is the rule — especially with renal impairment. **Octreotide 50–100 µg subcutaneously** is used for refractory or recurrent sulphonylurea hypoglycaemia because it suppresses further insulin release; it is more effective than escalating dextrose alone. Deprescribing the sulphonylurea, not merely reducing it, is the discharge action.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Monitoring	Self-monitored capillary glucose	CGM for older adults with T1DM and T2DM on insulin
HbA1c in CKD/anaemia	Used as the target measure	Unreliable — use CGM / glucose profiles
Screening	Opportunistic enquiry	Structured annual screening for hypoglycaemia, geriatric syndromes and polypharmacy
Goal of care	Intensification to reach target	**De-intensification** is an explicit quality-of-care goal

Exam approach: Emphasise that in geriatrics *avoiding hypoglycaemia outranks achieving a glycaemic target*. State it as a principle at the start of the management section.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Three levels (70 / 54 / any-with-assistance) → why the old are vulnerable → blunted autonomic warning & unawareness → atypical presentation (falls, delirium, pseudo-stroke) → consequences → evaluate drugs and renal function → Whipple's triad if non-diabetic → 15/15 rule and IV dextrose/glucagon → prevention by relaxing targets and de-intensifying → CGM.

Numbers: 70 / 54 · 15 g and 15 minutes · 25% dextrose 50–100 mL · glucagon 1 mg · observe sulphonylurea overdose 24–48 h · HbA1c 7.0–7.5 / 8.0 / 8.5% by frailty tier.

EXAMINER TRAPS

- Quoting a single glucose threshold — the examiner wants **three levels**, with Level 3 defined by **function, not a number**.
- Discharging a sulphonylurea hypoglycaemia after one correction.
- Giving glucagon in an alcoholic or malnourished patient — **no hepatic glycogen, so it will not work**.
- Treating a low HbA1c as a success in a frail 85-year-old — it is a **red flag for hypoglycaemia**.

QUESTION 23 · DIABETES MELLITUS

Diabetic ketoacidosis and hyperosmolar hyperglycaemic state

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definitions. DKA** = hyperglycaemia + **ketonaemia** + **metabolic acidosis** (classically glucose >250 mg/dL, pH <7.30, HCO_3 <18 mEq/L, ketones positive). **HHS** = **marked hyperglycaemia (usually >600 mg/dL)** with **raised effective osmolality** and **profound dehydration**, but **no significant ketosis or acidosis**. Both are the **metabolic comas** of diabetes.
2. **Which one occurs in whom. HHS is the characteristic emergency of the older person with type 2 diabetes**; DKA is classically type 1 but occurs in older type 2 patients under severe physiological stress. **Overlap syndromes are common in the elderly** — up to a third have mixed features.

3. **Precipitants. Infection is the commonest** — urinary tract infection and pneumonia — followed by **myocardial infarction, stroke, sepsis**, non-adherence or omission of insulin, newly diagnosed diabetes, and drugs: **corticosteroids, thiazides, atypical antipsychotics** and **SGLT2 inhibitors** (euglycaemic DKA).
4. **Why older adults do worse.** A **blunted thirst mechanism**, raised osmotic threshold for thirst, **impaired urinary concentrating ability**, reduced free water clearance and dependence on carers for fluids mean that dehydration is **deeper and better tolerated symptomatically** before presentation. **Mortality in HHS is several-fold higher than in DKA** and is driven largely by the precipitating illness.
5. **Clinical features.** Common to both — polyuria, polydipsia, weight loss, dehydration, tachycardia, hypotension. **DKA**: **Kussmaul respiration**, acetone breath, abdominal pain, vomiting, developing over hours. **HHS**: insidious over days to weeks, with **altered sensorium, focal neurological deficits mimicking stroke, seizures and coma**. **In the older adult, delirium or a fall may be the only presentation.**
6. **Investigations.** Capillary and laboratory glucose, **blood β-hydroxybutyrate** (preferred to urine ketones), venous or arterial blood gas, urea, creatinine and electrolytes, **corrected sodium** (add 1.6 mEq/L per 100 mg/dL glucose above 100), **effective osmolality = 2 × Na^+ + glucose/18**, anion gap, full blood count, CRP, blood and urine cultures, chest radiograph and **ECG** (silent myocardial infarction).
7. **Fluids are the first priority.** Start **0.9% sodium chloride**. In older adults with cardiac or renal disease, use **slower, more cautious rates with close monitoring of jugular venous pressure, chest and urine output**. HHS requires a **larger total fluid deficit to be replaced but more slowly**, aiming to lower osmolality by no more than **3–8 mOsm/kg/h** to avoid cerebral oedema.
8. **Insulin.** DKA — **fixed-rate intravenous insulin infusion at 0.1 units/kg/h**. HHS — insulin is started at a **lower rate (0.05 units/kg/h)** and **only after fluids alone have stopped lowering the glucose**, since fluid alone corrects much of the hyperglycaemia. Target a fall of **50–70 mg/dL/h**; add **5–10% dextrose** when glucose reaches ~250 mg/dL in DKA or ~300 mg/dL in HHS, continuing insulin to clear ketones.
9. **Potassium and other electrolytes.** Total body potassium is always depleted despite a normal or high initial level. **Withhold insulin if K^+ <3.3 mEq/L** until potassium is replaced; **add potassium once K^+ <5.3 mEq/L** with adequate urine output. **Bicarbonate only if pH <6.9.** Phosphate only for severe depletion (<1 mg/dL) with cardiac or respiratory muscle weakness.
10. **Complications and resolution.** Iatrogenic **hypokalaemia, hypoglycaemia, fluid overload and pulmonary oedema** (especially in the elderly), hyperchloraemic acidosis, **venous thromboembolism** — give prophylactic low-molecular-weight heparin, particularly in HHS — aspiration, AKI, and rarely cerebral oedema. **DKA has resolved** when ketones have cleared with pH ≥7.3 or HCO_3 ≥18 mEq/L; **HHS has resolved** when osmolality is normal, urine output adequate and mental status has returned to baseline.

Feature	DKA	HHS
Typical patient	Type 1; younger, or stressed type 2	**Older type 2 diabetic**
Onset	Hours	Days to weeks
Glucose	>250 mg/dL (may be euglycaemic)	Usually >600 mg/dL
Ketones (β-OHB)	≥3.0 mmol/L	<3.0 mmol/L
pH / HCO_3	<7.3 / <18 mEq/L	≥7.3 / ≥15 mEq/L
Effective osmolality	Variable	**>300–320 mOsm/kg**
Fluid deficit	~100 mL/kg	**~100–200 mL/kg (greater)**
Insulin rate	0.1 units/kg/h	0.05 units/kg/h, after fluids
Neurological signs	Uncommon	**Common — coma, seizures, focal deficit**
Mortality	Lower	**Substantially higher**

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **ADA/EASD/JBDS/AACE/DTS 2024 Consensus Report on Hyperglycaemic Crises — new diagnostic criteria.** **DKA** now requires the "**DKA triad**": **D** — glucose **≥200 mg/dL** (lowered from 250) **or any prior history of diabetes irrespective of glucose**; **K** — **β-hydroxybutyrate ≥3.0 mmol/L** or urine ketones ≥2+; **A** — **pH <7.3 and/or HCO_3 <18 mmol/L**. The **anion gap has been removed** from both the diagnostic and the resolution criteria (it is distorted by hyperchloraemia from saline). **HHS** now requires glucose ≥600 mg/dL, **effective osmolality >300 mOsm/kg (or total >320)**, β-OHB <3.0 mmol/L and pH ≥7.3 with HCO_3 ≥15. **Direct measurement of β-hydroxybutyrate is strongly recommended** over urine ketones. Severe DKA = β-OHB >6 mmol/L, pH <7.0, HCO_3 <10, or stupor/coma — these plus all HHS need **ICU care**.
12. **SGLT2 inhibitors and euglycaemic DKA.** SGLT2 inhibitors now account for the majority of euglycaemic DKA cases. Practical consequences: **check ketones whenever an unwell patient on an SGLT2 inhibitor presents, whatever the glucose**; apply **sick-day rules** — withhold the drug during acute illness, dehydration, fasting or reduced oral intake, and **stop it 3–4 days before elective surgery**. The 2024 consensus also recommends that **CGM be offered at discharge to all patients admitted with DKA**, and gives specific guidance for frail older adults.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Glucose criterion for DKA	>250 mg/dL	≥200 mg/dL, or any prior diabetes regardless of glucose
Ketone assessment	Urine nitroprusside	Blood β-hydroxybutyrate ≥3.0 mmol/L (point-of-care)
Anion gap	Part of diagnosis and resolution	Removed from both criteria
Mild–moderate uncomplicated DKA	IV insulin infusion for all	Subcutaneous rapid-acting analogue protocols acceptable outside ICU

Exam approach: Give the classical criteria, then state the 2024 DKA "D–K–A" triad in one sentence. Examiners reward the euglycaemic DKA point.

MEMORY ANCHORS & 15-SECOND SKELETON

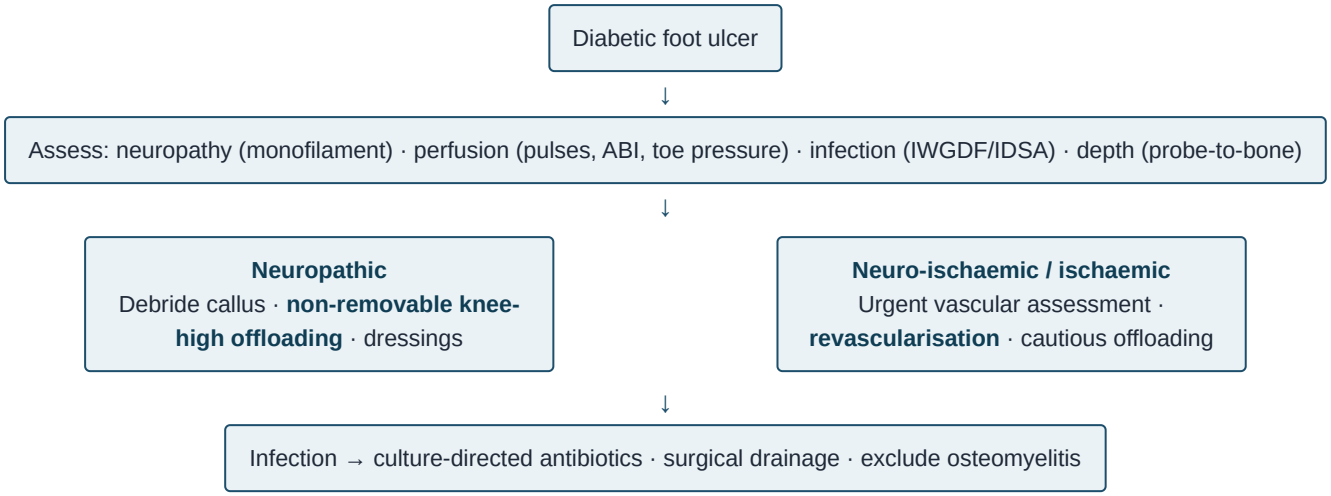
Skeleton: Define both → who gets which → precipitants (infection commonest) → why the old do worse (thirst + concentrating defect) → clinical picture → investigations including corrected Na and osmolality → **Fluids, Insulin, Potassium (FIP)** in that order → complications → resolution criteria → 2024 criteria + SGLT2i.

Numbers to memorise: 200 / 3.0 / 7.3 / 18 (DKA) · 600 / 300 / 320 (HHS) · insulin 0.1 vs 0.05 units/kg/h · K^+ 3.3 and 5.3 · bicarbonate only if pH <6.9 · fall in glucose 50–70 mg/dL/h.

EXAMINER TRAPS

- Starting insulin before fluids, or before checking potassium — both are marked down heavily.
- Forgetting that **a normal or high initial potassium hides total body depletion**.
- Aggressive fluid resuscitation in an 85-year-old with heart failure — say "cautious, monitored" explicitly.
- Missing **euglycaemic DKA** on an SGLT2 inhibitor because the glucose "looked fine".
- Forgetting **thromboprophylaxis in HHS**.

QUESTION 24 · DIABETES MELLITUS



Diabetic foot syndrome

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definition.** Diabetic foot syndrome is **ulceration, infection and/or destruction of deep tissues of the foot** in a person with diabetes, arising from the interaction of **peripheral neuropathy, peripheral arterial disease and repetitive mechanical stress**. **The majority of the elderly diabetic population is at increased risk of developing foot ulcers.**
2. **Principal antecedents. Peripheral vascular disease**, **sensorimotor and autonomic neuropathy**, **limited joint mobility — which impairs the ability of older people to inspect their own feet** — and **high foot pressures**. **Coexisting visual loss exacerbates the consequences** of this situation, and visual acuity is impaired in about 40% of older diabetics.
3. **Peripheral sensorimotor neuropathy is the dominant mechanism** — the primary cause or a contributory factor in the **vast majority of cases**. It causes numbness, **lancinating and burning pain, "pins and needles" and hyperaesthesia typically worse at night**, and produces high foot pressures leading to **gait disturbance, falls and other foot injuries**. Autonomic neuropathy causes dry, fissured skin and arteriovenous shunting.
4. **Ulcer characteristics.** Diabetic ulcers most commonly form in **weight-bearing areas — the metatarsal heads and heel**. They are usually **deep, with undermined edges, surrounded by hyperkeratosis (callus)**, and are **often painless because of the peripheral neuropathy** — which is why they present late.
5. **Distinguish from the other foot ulcers of old age. Arterial** — painful, with coldness, atrophy and hairlessness of surrounding skin. **Venous** — between the ankle and calf, shallow, irregular borders, substantial exudate, with oedematous and hyperpigmented surrounding tissue. **Decubitus (pressure)** — posterior heel or malleoli in those confined to bed or using wheelchairs.
6. **Clinical classification.** Describe the ulcer as **neuropathic** (loss of protective sensation, no PAD), **neuro-ischaemic** (both) or **ischaemic** (PAD without loss of protective sensation). Severity is graded by the **Wagner** grades, or by the **SINBAD** and **WIfI** systems; infection severity by the **IWGDF/IDSA** scheme.

7. **Assessment. 10 g Semmes–Weinstein monofilament** and 128 Hz tuning fork for loss of protective sensation; palpation of pedal pulses and **ankle–brachial index**, with **toe pressures or $TcPO_2$ when vessels are calcified and the ABI is falsely high**; **probe-to-bone test**; plain radiograph and MRI for **osteomyelitis**; deep tissue culture rather than superficial swab; plus glycaemic, renal, nutritional and **vision and gait** assessment.
8. **Management principles.** Managing foot ulceration in older people involves **addressing the underlying aetiology** — **surgical revascularisation for arterial ulcers** and **optimum management of blood sugar levels for diabetic foot ulcers** — **in addition to debridement, management of infection, and application of appropriate topical medications, wound dressings and offloading techniques**.
9. **Prognosis and burden.** The **three-year survival following lower extremity amputation is about 50%**, and in about **70% of cases amputation is precipitated by foot ulceration**. **Increasing age and a higher level of amputation** are important factors increasing both length of hospitalisation and cost. A **history of foot ulceration is independently associated with visual loss and with increased mortality** at ten years.
10. **Prevention — five key elements. Identify the at-risk foot**; **inspect and examine the at-risk foot regularly**; **educate the patient, family and healthcare providers**; **ensure routine wearing of appropriate footwear**; and **treat pre-ulcerative signs** — callus, haemorrhage under callus, blister, fissure, ingrowing nail. A **multidisciplinary foot-care team approach decreases the incidence of major amputation**.

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **IWGDF 2023 classification guideline. SINBAD (Site, Ischaemia, Bacterial infection, Area, Depth) is the recommended first-choice system** for communication between healthcare professionals — **stating the presence or absence of each composing variable rather than only a total score** — and the **full SINBAD score is recommended for regional, national and international audit**. Use the **IWGDF/IDSA (2015) system to classify infection severity** and consider **WIfI** to stratify healing likelihood and amputation risk in peripheral arterial disease. Crucially, **no currently available classification should be used to give an individual patient an outcome prognosis**.
12. **IWGDF 2023 offloading guideline — offloading is the single most important healing intervention.** The **preferred treatment for a neuropathic plantar forefoot or midfoot ulcer is a non-removable knee-high offloading device** — either a **total contact cast** or a **removable walker rendered irremovable by the provider fitting it**. If a non-removable device is contraindicated or not tolerated, use a **removable knee-high or ankle-high device** with explicit education on adherence; if no other biomechanical relief is available, use **felted foam only in combination with appropriate footwear**. For ulcers on **digits 2–5 secondary to a flexible toe deformity, perform digital flexor tenotomy**. Be **more cautious with offloading when infection or ischaemia is present**.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Classification	Wagner grading	SINBAD first choice for communication and audit; IWGDF/IDSA for infection; WIfI for PAD
Offloading	Listed among treatment measures	Non-removable knee-high device (TCC) is first choice and the key determinant of healing
Prognostication	Grades used to predict outcome	No classification should be used for individual prognosis

Exam approach: Wagner is still acceptable to quote, but naming **SINBAD** and the **total contact cast** marks the answer out as current.

INDIAN CONTEXT

- **Barefoot walking and religious barefoot practice** are major, modifiable ulcer risks — address footwear explicitly in counselling.
- Presentation is **late and more often infected**; Charcot neuro-osteoarthropathy is **under-diagnosed** and misread as cellulitis or gout.
- **NPCDCS** provides opportunistic diabetes and foot screening at HWC/CHC level; therapeutic footwear can be accessed through **ADIP–ALIMCO** for eligible older persons.
- Multidisciplinary foot clinics, where available, reduce major amputation — cite this as the service-level recommendation.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Define the triad → antecedents (neuropathy, PAD, limited joint mobility, high pressure, poor vision) → why painless and late → ulcer site and appearance → differentiate arterial/venous/pressure → classify (neuropathic / neuro-ischaemic / ischaemic; SINBAD) → assess (monofilament, ABI, probe-to-bone) → manage (revascularise, debride, treat infection, **offload**, control glucose) → prognosis (50% three-year survival post-amputation) → prevent (five elements + MDT).

Numbers: 70% of amputations preceded by ulcer · **50%** three-year survival after amputation · **10 g** monofilament · **SINBAD** = Site, Ischaemia, Neuropathy/Bacterial infection, Area, Depth.

PART V

Thyroid Disease

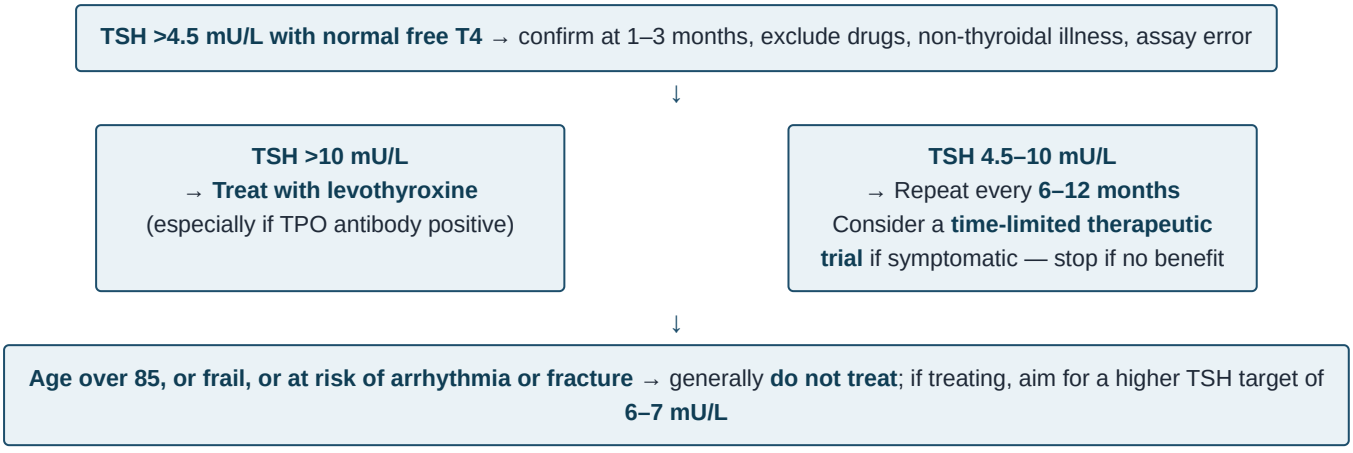
Q25 · Q26 · Q27 · Q28 · Q29

QUESTION 25 · THYROID

Subclinical hypothyroidism in the elderly

7-Mark Note — 6 textbook points + 1 latest update = 7 points

Recurring question — asked ×2. Extra scaffolding provided below.



TEXTBOOK CORE — 6 POINTS

1. **Definition and prevalence.** Subclinical hypothyroidism is **an elevated serum TSH level in the face of normal or normal-low free thyroid hormone values**. Overall prevalence is **4–10% in the general population and up to 20% in women older than 60**. Subclinical disorders are **more prevalent than overt disease in older populations** — a consequence of sensitive TSH assays and more frequent testing.
2. **Confirm before you act.** A TSH measurement **over 4.5 mU/L should be confirmed within 1–3 months**, and then **repeated every 6–12 months in asymptomatic patients**. If confirmed, consider **past radioiodine administration, previous thyroid surgery, thyroid enlargement, and a family history of thyroid dysfunction**, explore **subtle clinical signs of hypothyroidism**, and check the **lipid profile**. Also exclude non-thyroidal illness recovery, drugs and assay interference.
3. **Natural history. Progression to overt hypothyroidism varies from 3 to 20% but is generally around 5% per year**; the risk is **greater in patients with goitre or thyroid antibodies, or both**. **Antithyroid antibodies are useful for improving the prognosis of progression to overt hypothyroidism, but they may not change the management of the patient**. Hence patients should be **followed and eventually treated** rather than treated immediately.
4. **The treatment threshold. If, during follow-up, TSH increases to over 10 mU/L, the patient should be treated with levothyroxine. When TSH is between 4.5 and 10 mU/L, an *ex adiuvantibus* (therapeutic trial) administration of levothyroxine may be considered on an individual basis** to help improve subtle clinical symptoms — with a clear plan to stop if no benefit accrues.
5. **The paradox of advanced age — mild thyroid failure may be protective. In the oldest old (over 85 years), thyroid hormone substitution in subclinical hypothyroidism is not likely to be beneficial and may even be harmful.** In the Leiden 85-plus study, **none of the patients with subclinical hypothyroidism had progressed to overt disease when retested at age 88**, there was **no association between TSH and cognition, depression or ADL disability**, and **increased TSH at baseline was associated with a slower decline in instrumental ADL ability and with lower all-cause and cardiovascular mortality** despite higher cholesterol. The explanation offered is that **subclinical hypothyroidism seems detrimental in young to middle-aged people, whereas it may be harmless or possibly beneficial at an advanced age**.

6. **Individualise, and use a higher TSH target in the old. The decision to treat should be individualised — not based on TSH cut-offs alone, but also considering chronic comorbidities and frailty — and restricted to high-risk patients**, to avoid the adverse effects of unnecessary replacement in vulnerable older people. **A higher target serum TSH of 6 or 7 mU/L has been suggested in people over 70–80, particularly if they are at risk of cardiac arrhythmias or fragility fractures.** Remember too that **many older patients started levothyroxine when younger for inappropriate reasons or for transient hypothyroidism and continue it without review** — in one nursing-home study **thyroid hormone therapy was successfully withdrawn from half the residents studied**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **The TRUST trial settled the symptomatic question, and subsequent practice has consolidated around not treating.** TRUST was a double-blind, randomised, placebo-controlled trial of **737 adults aged 65 and over (mean age 74.4) with persistent subclinical hypothyroidism**, randomised to **levothyroxine 50 µg/day — or 25 µg/day if body weight was under 50 kg or coronary heart disease was present** — titrated to TSH, versus placebo with simulated dose adjustment. Mean baseline TSH was **6.40 mU/L**; at one year it fell to **3.63 mU/L on levothyroxine versus 5.48 on placebo**, yet there was **no difference in the Hypothyroid Symptoms score or the Tiredness score**, and **no benefit on executive cognitive function, blood pressure, weight, waist circumference, Barthel index or instrumental ADL scores**. Current guidance and the consolidated position is therefore that **treatment of minor TSH abnormalities meeting the criteria for subclinical hypothyroidism in the elderly is not recommended**. Two honest caveats to state in the exam: the trial was **underpowered for cardiovascular outcomes**, and **patients with higher TSH concentrations, high symptom burden, positive TPO antibodies, and the oldest patients over 80 were under-represented or not assessed**, so no definitive conclusion can be drawn for those subgroups.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Symptomatic benefit of levothyroxine	Trial of therapy may be considered at TSH 4.5–10	TRUST: no symptomatic, cognitive or functional benefit in those over 65 — do not treat routinely
TSH target when treating an older patient	Normalise TSH	Accept a higher target of 6–7 mU/L over age 70–80, especially with arrhythmia or fracture risk
Existing long-term levothyroxine	Continued indefinitely	Actively review for deprescribing — successfully withdrawn in half of nursing-home residents studied

Exam approach: The single sentence that earns the mark is that **subclinical hypothyroidism appears detrimental in the middle-aged but harmless or possibly protective in the oldest old**. Say it explicitly, then give the TSH 10 threshold.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Define (high TSH, normal free T4) → prevalence 4–10%, up to 20% in women over 60 → confirm at 1–3 months, repeat 6–12 monthly → progression ~5%/year, higher with antibodies or goitre → **treat if TSH >10**, individualise 4.5–10 → in the oldest old do not treat, possibly protective → higher TSH target 6–7 → review existing prescriptions → TRUST.

Numbers: TSH **4.5** to confirm · **10** to treat · **6–7** target over age 70–80 · prevalence **4–10%**, **20%** in women over 60 · progression **~5%/year** · TRUST **737** patients, mean age **74.4**, levothyroxine **50 µg** (25 µg if under 50 kg or CHD), baseline TSH **6.40** → **3.63** versus **5.48**.

EXAMINER TRAPS

- Treating on a **single TSH value** — always confirm at 1–3 months.
- Forgetting that **TSH rises physiologically with age**, so an age-specific reference range matters; a TSH of 6 in an 85-year-old may be normal for them.
- Missing the **non-thyroidal illness** explanation — a recovering acute illness transiently raises TSH.
- Quoting TRUST as proving levothyroxine is useless in *everyone* — it was underpowered for cardiovascular outcomes and under-represented those over 80 and those with high TSH or positive antibodies.
- Overlooking **iatrogenic thyrotoxicosis**: over-replacement in an older person causes atrial fibrillation, bone loss and fracture.

QUESTION 26 · THYROID — CLINICAL SCENARIO

A 70-year-old on treatment for cardiac failure has TSH 50 µIU/mL with suppressed T3 and T4, constipation, cold intolerance and considerable weight gain. Treatment, follow-up and specific instructions

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Establish the diagnosis and its cause before prescribing.** This is **overt primary hypothyroidism** — a markedly elevated TSH with low free T4. **The most frequent cause of hypothyroidism in old age is autoimmune thyroiditis, followed by earlier thyroid surgery or radiation therapy for previous thyrotoxicosis.** Confirm with **free T4 and antithyroid (anti-TPO) antibodies**. In this patient specifically, ask about **amiodarone** — a common drug in heart failure and a classic cause of hypothyroidism — and about lithium, and check the **lipid profile, creatine kinase (often raised), haemoglobin** (normocytic anaemia responds to replacement), sodium and an **ECG**.
2. **Recognise that his "heart failure" may itself be the hypothyroidism.** The symptoms of hypothyroidism in old age are atypical and include **memory loss, lethargy, constipation, cold intolerance, fatigue, congestive heart failure, depression and weight gain — all of them often attributed to old age or other causes rather than to decreased thyroid function**. Hypothyroidism causes **bradycardia, reduced cardiac output, diastolic hypertension, pericardial effusion and non-pitting myxoedematous oedema** that mimics cardiac failure. Reassess the cardiac diagnosis after he becomes euthyroid — his diuretic dose may need reduction.
3. **Treatment — start low and go slow, because he has cardiac disease. Therapy should be started at 0.025 to 0.05 mg (25–50 µg) of levothyroxine per day and increased by the same increment at 1- to 3-week intervals. Given established cardiac disease, start at 12.5–25 µg daily.** The rationale is that thyroid hormone increases myocardial oxygen demand and can precipitate **angina, atrial fibrillation, acute coronary syndrome or worsening failure**. **The decreased metabolic clearance rate of thyroid hormone in ageing may lead to a lower maintenance dose of T4**, and **the replacement dose in older people is usually lower than in younger people**.
4. **Titration and monitoring. Increase the dose slowly, every six to eight weeks**, guided by TSH — a shorter interval simply measures a level that has not yet equilibrated. Monitor **heart rate, symptoms of angina, weight, bowel habit and mental state** at each visit, and **the TSH level in the laboratory**. **When indicated for symptomatic cardiovascular disease, a beta blocker may be added to the levothyroxine regimen.** Aim for a TSH in the reference range but at the **higher end — around 4–6 mU/L is acceptable in a 70-year-old with heart disease**; avoid a suppressed TSH, which risks atrial fibrillation and bone loss.
5. **Follow-up schedule.** Review **clinically and with TSH every 6–8 weeks during titration**; once stable, check TSH at **6 months and then annually**. Recheck earlier if there is a change in weight, a new drug that alters absorption or metabolism, an intercurrent illness, or new symptoms. At every review, reassess the **heart failure medication**, since diuretic and rate-control requirements often fall as he becomes euthyroid, and screen for **over-replacement — palpitations, tremor, weight loss, insomnia, angina, atrial fibrillation**.
6. **Specific instructions to give this patient. (i)** Take levothyroxine **once daily on an empty stomach, 30–60 minutes before breakfast, with water** — or at bedtime, at least two hours after food, if that is easier to remember. **(ii) Separate it by at least four hours** from **calcium, iron, antacids, proton-pump inhibitors, sucralfate and soya products**, which impair absorption — an important point in an older patient on multiple drugs. **(iii) Do not stop or alter the dose yourself, and do not double up a missed dose**; take it the next day. **(iv) Treatment is lifelong. (v) Report immediately** chest pain, palpitations, breathlessness or an irregular pulse. **(vi)** Expect **gradual improvement over weeks to months, not days** — constipation and cold intolerance

settle first, weight last. **(vii)** Tell every doctor and pharmacist that you take levothyroxine, and **stay on the same brand** where possible. **(viii)** Continue a high-fibre diet, fluids and activity for the constipation while replacement takes effect.

Stage	Action	Rationale in this patient
Confirm	Free T4, anti-TPO antibodies, review amiodarone, CK, lipids, haemoglobin, ECG	Autoimmune is commonest; amiodarone is a heart-failure drug and a classic cause
Initiate	**Levothyroxine 12.5–25 µg once daily**	Cardiac disease — avoid precipitating angina, arrhythmia or worsening failure
Titrate	Increase by 12.5–25 µg every **6–8 weeks** guided by TSH	TSH takes 6 weeks to equilibrate; ageing lowers clearance so the final dose is small
Target	TSH in range, upper half (**~4–6 mU/L** acceptable)	Avoid iatrogenic thyrotoxicosis, atrial fibrillation and fracture
Maintain	TSH at 6 months, then annually	Stable requirement; recheck on any drug or weight change
Reassess	Re-evaluate the heart failure diagnosis and drug doses	Myxoedema mimics failure; diuretic need often falls

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Current practice has moved further towards individualised, age-adjusted TSH targets and away from combination therapy.** Three points are worth stating. **(a)** An **age-specific upper TSH reference limit** is now widely accepted, since TSH rises physiologically with age; targeting the young adult range in a 70-year-old with heart disease produces **over-treatment**, and registry data link a suppressed TSH on levothyroxine to **atrial fibrillation, osteoporotic fracture and increased mortality in older adults** — so the target here is the **upper half of the reference range**. **(b) Liothyronine (T3) and combination T4/T3 therapy are not recommended** for routine use, and are specifically inadvisable in older patients with cardiac disease because of the sharp, non-physiological T3 peaks. **(c)** If he is on **amiodarone**, the guidance is that amiodarone-induced hypothyroidism **does not usually require stopping the amiodarone** — treat with levothyroxine and continue the antiarrhythmic if it is needed, monitoring thyroid function **every 6 months** for as long as he takes it and for a year afterwards.

EXAMINER TRAPS

- Starting a **full weight-based replacement dose (1.6 µg/kg)** in a 70-year-old with cardiac failure. This is the single commonest error in this scenario — the marks are in "start low, go slow".
- Rechecking TSH at **two weeks**. It has not equilibrated; wait 6–8 weeks.
- Aiming for a low-normal or suppressed TSH.
- Omitting the **drug-absorption instructions** — the question explicitly asks what you would "specifically instruct him", so calcium, iron, PPIs and the empty-stomach rule carry marks.
- Failing to consider that the **heart failure may be the hypothyroidism**, and failing to plan a reassessment.
- Not asking about **amiodarone** in a patient on heart-failure treatment.

IF ASKED TO EXTEND — MYXOEDEMA COMA

If the examiner escalates the scenario to **hypothermia, hypoventilation, hyponatraemia, bradycardia and reduced consciousness**, that is **myxoedema coma**: an intensive-care emergency in which you give **intravenous levothyroxine (a loading dose, then daily), intravenous hydrocortisone before thyroid hormone until adrenal insufficiency is excluded**, passive rewarming, ventilatory and haemodynamic support, cautious fluid and sodium correction, and treatment of the precipitant — usually **infection, cold exposure, a sedative drug, or omission of levothyroxine**. Mortality remains high.

QUESTION 27 · THYROID

Hashimoto's thyroiditis

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition and importance in old age.** Hashimoto's thyroiditis is **chronic autoimmune (lymphocytic) thyroiditis** — the classic organ-specific autoimmune disease, in which lymphocytic infiltration and antibody-mediated destruction of thyroid follicular cells produce progressive gland failure. **The most frequent cause of hypothyroidism in old age is autoimmune thyroiditis**, followed by earlier thyroid surgery or radiation therapy for previous thyrotoxicosis.
2. **Why it is commoner with ageing — the immunological basis. With ageing there is a decrease in T-suppressor lymphocytes and an increase in autoantibodies.** Since many endocrine disorders are autoimmune, **these changes amplify the possibility of an older person developing hypoendocrine disease in old age**, and there is **an increased likelihood of developing autoimmune polyglandular failure syndromes**. A caution the textbook adds: **ageing is frequently associated with an increased prevalence of thyroid autoantibodies, which may be an expression of age-associated diseases rather than a consequence of the ageing process itself** — so a positive antibody in an 80-year-old is not automatically clinically significant.
3. **Pathology.** Diffuse **lymphocytic and plasma cell infiltration with germinal centre formation**, **Hürthle (Askanazy) cell change** of follicular epithelium, follicular atrophy and **fibrosis**. Two clinical forms: the **goitrous** variant with a firm, bosselated, painless gland, and the **atrophic** variant — commoner in the elderly — with a small, impalpable gland. Antibodies are directed against **thyroid peroxidase (anti-TPO, the most sensitive)** and **thyroglobulin**; blocking TSH-receptor antibodies contribute to the atrophic form.
4. **Clinical spectrum.** May be **euthyroid with goitre or antibodies alone**, **subclinically hypothyroid**, or **overtly hypothyroid**. An early transient thyrotoxic phase — **"Hashitoxicosis"** — occurs from destructive hormone release. In older people the presentation is atypical and insidious: **memory loss, lethargy, constipation, cold intolerance, fatigue, congestive heart failure, depression and weight gain, all often attributed to old age or other causes**. **Lack of these symptoms does not rule out hypothyroidism, so a high index of suspicion is needed.** Associated laboratory findings include a **raised creatine phosphokinase** and a **normocytic normochromic anaemia which responds to thyroid hormone replacement**; there is an **increased incidence of pernicious anaemia**, though **iron deficiency remains the most common anaemia associated with hypothyroidism**.
5. **Diagnosis and prognostic value of antibodies. An elevated serum TSH level should be confirmed and supplemented with measurements of serum thyroxine (T4) and with thyroid antibodies.** Ultrasound shows a **hypoechoic, heterogeneous gland with increased vascularity** — useful but not required. In

subclinical disease, **antithyroid antibodies are useful for improving the prognosis of progression to overt hypothyroidism, but they may not change the management of the patient**: progression is **generally around 5% per year and greater in those with goitre or thyroid antibodies, or both**.

6. **Associations, complications and treatment. Associations:** other autoimmune disease — **pernicious anaemia, vitiligo, Addison's disease, type 1 diabetes, coeliac disease, rheumatoid arthritis, Sjögren's syndrome** — as part of **autoimmune polyglandular failure**. **Complications:** overt hypothyroidism and, rarely, **myxoedema coma**; compressive symptoms from a large goitre; **encephalopathy associated with autoimmune thyroiditis (Hashimoto's encephalopathy)**, a steroid-responsive cause of subacute confusion, seizures and myoclonus that is a genuinely reversible dementia mimic in the elderly; and the important association with **primary thyroid lymphoma** — **lymphoma of the thyroid and undifferentiated cancers occur with increasing frequency in the elderly**, so a rapidly enlarging gland in known Hashimoto's demands urgent biopsy. **Treatment:** levothyroxine for overt disease, **started at 25–50 µg daily and increased slowly every six to eight weeks**, at a **lower maintenance dose than in younger people**; no immunosuppression is indicated; euthyroid antibody-positive patients need **surveillance only, with annual TSH**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Two current themes are worth a sentence each. (a) Immune checkpoint inhibitor–induced thyroiditis** is now a common iatrogenic cause of autoimmune thyroid destruction, and older adults receive an increasing share of immunotherapy: it typically produces a **transient thyrotoxic phase within the first weeks followed by permanent hypothyroidism**, is managed with **levothyroxine without stopping the immunotherapy**, and requires **thyroid function monitoring before each cycle** — it is the modern differential for new autoimmune hypothyroidism in an older cancer patient. **(b) Selenium supplementation**, long promoted to lower anti-TPO titres, has **not been shown to alter progression to overt hypothyroidism or improve quality of life** and is **not recommended**. The wider position — reinforced by the TRUST trial and current guidance — is that **antibody positivity in an older adult justifies surveillance, not treatment**: it refines the prognosis without changing management until TSH crosses the treatment threshold.

EXAM ONE-LINERS

- **Commonest cause of hypothyroidism in old age = autoimmune (Hashimoto's) thyroiditis.**
- Ageing → **fewer T-suppressor cells, more autoantibodies** → more autoimmune endocrine failure.
- **Anti-TPO** is the most sensitive antibody; it predicts progression but does not change management.
- Progression to overt disease **~5% per year**, higher with goitre or antibodies.
- Rapidly enlarging gland in known Hashimoto's = **primary thyroid lymphoma until proven otherwise**.
- **Hashimoto's encephalopathy** — a steroid-responsive, reversible cause of confusion in the elderly.
- Raised **CPK** plus normocytic anaemia in a tired older patient — check the TSH.

EXAMINER TRAP

Treating **antibody positivity itself**. A euthyroid older adult with positive anti-TPO needs an **annual TSH**, not levothyroxine. Equally, do not dismiss the antibodies as meaningless — they identify the patient who *will* need treatment, and they raise the index of suspicion for **other autoimmune disease and for thyroid lymphoma**.

QUESTION 28 · THYROID

Hyperthyroidism in the elderly — presentation, investigation and treatment

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition and causes.** Overt hyperthyroidism is characterised by **high levels of thyroid hormones with a low TSH**. The most common causes in old age are **Graves' disease in iodine-sufficient areas** and **nodular goitre (Plummer's disease or multinodular toxic goitre) and functioning follicular adenoma in iodine-deficient areas**. **Toxic multinodular goitre is more frequent in older persons than in the young. Transient thyrotoxicosis** occurs in **subacute thyroiditis** and during treatment with **amiodarone** (particularly in iodine-deficient areas), which may represent a major therapeutic challenge; thyrotoxicosis during levothyroxine or interferon treatment is self-limited and remits on drug withdrawal.
2. **Presentation is paucisymptomatic and atypical — the highest-yield point.** Whereas younger patients have multiple emblematic symptoms, **the older patient may have few symptoms and they are frequently atypical**. Patients **lack the hyperdynamic symptomatology — tremor, heat intolerance, ocular signs, nervousness or tachycardia — and instead have a more sedated, apathetic presentation**. However, **the frequency of atrial fibrillation is higher**. **Weight loss and cardiac symptoms frequently predominate, and goitre is frequently absent, making the diagnosis less obvious. Approximately one-third have no goitre. Depression and mania can be manifestations of hyperthyroidism in older adults.**
3. **Apathetic thyrotoxicosis and the masked presentation. Apathetic thyrotoxicosis is due in part to the decreased post-receptor responsiveness of β-adrenergic receptors that occurs with ageing.** Its classical features are **depression, weight loss, atrial fibrillation, heart failure, blepharoptosis and proximal myopathy**, and it occurs in **about 7% of older people with hyperthyroidism**. **Severe non-thyroidal disease may disguise thyrotoxicosis; congestive heart failure, stroke and infection are common disorders associated with masked hyperthyroidism.** Suspect it in **unexplained heart failure or tachyarrhythmia, recent-onset psychiatric disorder, or profound myopathy**. The triad of **weight loss, anorexia and constipation — which may raise the possibility of neoplastic disease — occurs in 15% of older thyrotoxic patients**.
4. **Investigation. Ultrasensitive TSH assays can differentiate hyperthyroidism from normal, and in the absence of acute non-thyroidal disease this test alone may confirm the clinical diagnosis. In the presence of acute illness, concomitant determination of TSH and free T4 is more appropriate.** Then free T3 (for T3 toxicosis), **TRAb** for Graves' disease, and a **radioisotope uptake scan** to separate Graves' (diffuse uptake), toxic nodular goitre (patchy or focal) and thyroiditis or exogenous hormone (low uptake). Also ECG for atrial fibrillation, liver function and full blood count before antithyroid drugs, and bone densitometry where relevant. **A T3 suppression test should not be done in older adults because of the risk of angina or myocardial infarction.**
5. **Treatment — radioiodine is the treatment of choice. Treatment of older patients with hyperthyroidism includes antithyroid drugs and radioactive iodine. ^{131}I is the treatment of choice, especially when concomitant cardiovascular diseases are present**, while **surgery may be considered if obstructive symptoms caused by large goitres are present, even though it is rarely indicated owing to the high operative risk in older patients with comorbidity** — though **radioiodine may also be successfully used in large compressive goitres**. **Antithyroid drugs (methimazole/carbimazole or propylthiouracil) may be the treatment of choice for controlling hyperfunction before definitive treatment with ^{131}I.** A crucial closing line: **treatment of an underactive thyroid after definitive treatment with ^{131}I may be simpler than a recurrence of hyperthyroidism in an older patient** — that is, accept hypothyroidism as a planned outcome.

6. **Adjunctive treatment and the special situations. Beta-adrenergic blockers (propranolol, metoprolol) may be used with prudence, and when needed the dosage should be the lowest possible; treatment with beta blockers may prevent symptoms of thyrotoxicosis following ^{131}I treatment. In general, atrial fibrillation reverts to sinus rhythm within a few months after the restoration of euthyroidism** — so do not rush to cardiovert, but do anticoagulate according to stroke risk. For **severe thyrotoxicosis or thyroid storm**: antithyroid drugs, **preferably propylthiouracil because it blocks peripheral conversion of T4 to T3**, plus **iodides to block thyroid hormone secretion** (given after the thionamide) and beta blockers. Where beta blockers are contraindicated or the patient is allergic to antithyroid drugs, **calcium ipodate 3 g every 3 days** inhibits peripheral T4-to-T3 conversion, and **dexamethasone 2 mg every 6 hours** does the same and may be added to any of these regimens.

Feature	Young patient	Older patient
Adrenergic symptoms	Tremor, heat intolerance, nervousness, tachycardia	**Often absent — apathetic, sedated presentation**
Goitre	Usually present	**Absent in about one-third**
Eye signs	Common in Graves'	Uncommon; **blepharoptosis** rather than lid retraction
Atrial fibrillation	Less common	**Markedly more frequent**
Dominant complaint	Weight loss with increased appetite	**Weight loss, anorexia, constipation — mimics malignancy (15%)**
Psychiatric	Anxiety, agitation	**Depression, mania, apathy**
Muscle	Mild weakness	**Profound proximal myopathy**
First-line definitive treatment	Antithyroid drugs, then choice	**Radioactive iodine (^{131}I)**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Long-term low-dose antithyroid drug therapy has become an accepted alternative to definitive treatment, and a large network meta-analysis has now compared the three modalities head to head.** Revised American Thyroid Association guidance reflects **less of a push towards definitive therapy**: whereas antithyroid drug duration was previously limited on safety grounds, **it is now accepted to remain on antithyroid drugs long term**, with methimazole at **2.5–10 mg/day continued for many years shown to be safe and effective**, and prolonged low-dose therapy producing **better outcomes and fewer side effects than radioiodine** in relapsed Graves' disease. A **2025 systematic review and network meta-analysis in *Thyroid* examined the long-term mortality risks of antithyroid drugs, radioiodine and surgery**. Practical relevance for geriatrics: in a frail older patient with toxic multinodular goitre, radioiodine remains preferable because the disease does not remit; but in Graves' disease, **continuing low-dose carbimazole with six-monthly thyroid function tests is a legitimate, low-burden option** that avoids radiation precautions, the risk of transient post-radioiodine thyrotoxic exacerbation, and the near-certain need for lifelong levothyroxine. Always warn about **agranulocytosis** — stop the drug and check a full blood count urgently for fever or sore throat — and about hepatotoxicity.

MEMORY ANCHORS & 15-SECOND SKELETON

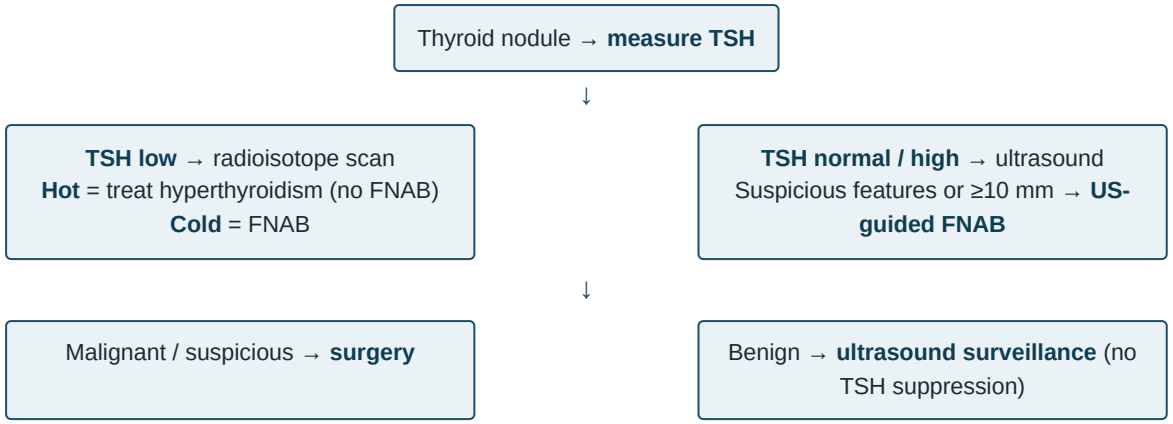
Skeleton: High T4/T3 with low TSH → Graves' or toxic nodular goitre (commoner in the old) → **apathetic, paucisymptomatic presentation, AF, weight loss, no goitre in one-third** → TSH first, then free T4/T3, TRAb, uptake scan; no T3 suppression test → **^{131}I is the treatment of choice**, antithyroid drugs to prepare, surgery rarely → beta blocker at lowest dose, AF usually reverts, accept hypothyroidism.

Numbers: apathetic thyrotoxicosis **7%** · no goitre in **one-third** · weight loss/anorexia/constipation triad **15%** · calcium ipodate **3 g every 3 days** · dexamethasone **2 mg every 6 hours** · long-term methimazole **2.5–10 mg/day**.

EXAMINER TRAPS

- Describing the **young patient's presentation**. The examiner is testing whether you know that in old age it is **apathetic, cardiac and paucisymptomatic**.
- Excluding hyperthyroidism because there is **no goitre and no eye signs**.
- Ordering a **T3 suppression test** — contraindicated in older adults.
- Missing **amiodarone-induced thyrotoxicosis**, which is a genuine therapeutic challenge and needs distinction between type 1 (iodine-induced excess synthesis — thionamide) and type 2 (destructive thyroiditis — glucocorticoid).
- Interpreting a low TSH in an acutely ill older patient as thyrotoxicosis — **non-thyroidal illness, fasting and glucocorticoids must be excluded first**.

QUESTION 29 · ENDOCRINOLOGY



Solitary thyroid nodule and thyroid malignancy

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Prevalence and baseline risk.** Thyroid nodules **occur with increasing frequency in older people** and about **95% are benign**. Palpable nodules are found in **3–7%** of the population, but prevalence rises to about **50% on ultrasound or at autopsy**. Crucially, **the risk of malignancy is the same for a solitary nodule as for a multinodular goitre** — so a multinodular gland does not reassure.
2. **Red flags requiring urgent referral.** A nodule that is **growing rapidly over a few weeks**, or is associated with **stridor, hoarseness or cervical lymphadenopathy**. Otherwise, routine evaluation is appropriate.
3. **Start with TSH, and let it direct the pathway.** If **TSH is low or suppressed**, perform a **radioisotope scan**: a **"hot" (autonomous) nodule** is treated as hyperthyroidism and **does not require FNAB**, whereas a **"cold" nodule requires FNAB**. If **TSH is normal**, proceed directly to **ultrasound and FNAB**. If TSH is raised with positive antithyroid antibodies and low free T4, treat with levothyroxine.
4. **FNAB is the cornerstone. Fine-needle aspiration biopsy is the most accurate method of evaluating a thyroid nodule** and determines who is referred for surgery; its **accuracy is improved by high-resolution ultrasound guidance**. FNAB is recommended for nodules **≥10 mm** with any of: **irregular margins, chaotic intranodular vascular spots, a shape more tall than wide, or microcalcifications**. For nodules **<10 mm**, FNAB only if clinical information or ultrasound features are suspicious.
5. **Limitations and risk stratification.** A significant limitation of FNAB is an **inadequate or indeterminate result in 10–25%** of cases, after which surgery is usually recommended for diagnosis — though the majority prove benign. **No ultrasound finding is diagnostic on its own.** EU-TIRADS malignancy risk: **category 2 benign ≈ 0%, 3 low risk 2–4%, 4 intermediate 6–17%, 5 high risk 26–87%**.

6. **Malignancy in old age, and what not to do.** Thyroid cancer in old age is **generally well differentiated, but its course is frequently less predictable than in younger patients**; **lymphoma of the thyroid and undifferentiated (anaplastic) cancers occur with increasing frequency in the elderly**. Malignant or suspicious nodules are treated **surgically**; radioiodine is first choice for thyroid autonomy and hyperthyroidism; surgery is advised for large non-toxic goitres with compressive symptoms. **Routine TSH-suppressive levothyroxine for benign nodules is NOT recommended** — the potential harm outweighs benefit, and in multinodular goitre it may produce **exogenous hyperthyroidism with cardiac and bone adverse effects**.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Natural-history data have shifted practice towards active surveillance rather than intervention in the older adult.** In a prospective multicentre study of 992 patients with cytologically and sonographically benign nodules, **only 11.1% grew over five years, thyroid cancer was diagnosed in just 0.3%, and age ≥60 was associated with a LOWER risk of nodule growth than in younger participants**. Current practice is therefore **ultrasound at 12 months, then at progressively longer intervals of 2–5 years**, with **repeat FNA only for substantial growth (>50% change in volume or ≥20% increase in at least two dimensions), new suspicious ultrasound features, or new symptoms**. In parallel, **active surveillance of low-risk papillary microcarcinoma** is now an accepted alternative to immediate surgery in older adults, where the competing risk of death and the operative risk often outweigh the risk from the tumour.

EXAM ONE-LINERS

- **~95% benign**; malignancy risk is **the same** for solitary nodule and multinodular goitre.
- **First test = TSH**, not ultrasound and not FNAB.
- **Hot nodule = no FNAB.** Cold nodule = FNAB.
- FNAB = cornerstone; indeterminate in **10–25%**.
- Anaplastic carcinoma and **primary thyroid lymphoma** are diseases of the elderly — a rapidly enlarging, hard goitre with compressive symptoms.
- **Never** give suppressive levothyroxine for a benign nodule in an older person.

EXAMINER TRAP

A calcified large goitre in an older woman can be **misdiagnosed as cancer metastatic to lymph nodes** — FNAB is recommended to determine the nature of calcified lesions. Also remember that **hyperkyphosis and postural change from osteoporosis complicate the physical examination**: if you can palpate the thyroid in an older woman, it is probably enlarged.

PART VI

Endocrine and Metabolic Bone Disease

Q30 · Q31

QUESTION 30 · ENDOCRINOLOGY

Testosterone replacement and andropause

7-Mark Answer — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **"Andropause" does not exist.** Circulating testosterone declines with age, but **unlike menopause, men do not suffer a rapid, inevitable loss of gonadal function**. After age 30 free testosterone falls at about **1% per year**; in the European Male Ageing Study, between ages 40 and 79 **total testosterone fell 0.4% per year and free testosterone 1.3% per year**. The steeper fall in free testosterone is due to the **age-related rise in SHBG**. The preferred term is **late-onset hypogonadism**, whose prevalence is only about **2–3%**.
2. **Definition and classification.** Hypogonadism is a **combination of subnormal serum testosterone AND one or more symptoms attributable to it** — a biochemical value alone is not a diagnosis. It may be **primary** (testicular) or **secondary** (pituitary or hypothalamic). It is common, **underdiagnosed and often untreated**: only 5–35% of hypogonadal men receive treatment.
3. **Mechanism of the age-related fall.** Older men show a **decrease in episodic and stimulated gonadotropin secretion**, together with a **reduced ability of the testicular Leydig cell to respond to luteinising hormone** with increased testosterone production. Comorbidity contributes strongly — **obesity, type 2 diabetes and chronic illness** all lower testosterone.
4. **Diagnosis — look for a correctable cause first. When faced with a symptomatic decrease in circulating testosterone, one should look first for a correctable cause before attributing the decrease to age alone.** Take **two morning fasting total testosterone measurements**; measure **free testosterone** when SHBG is altered (obesity, ageing, thyroid disease, liver disease). Then measure LH and FSH to separate primary from secondary, and image the pituitary if secondary.
5. **Benefits of replacement.** Testosterone replacement at relatively high doses in older hypogonadal men **increases muscle mass, strength, functional status and bone mineral density**, and improves **erythropoiesis**. It **increases libido in both sexes**, and in men increases **erectile strength, volume of ejaculation and visuospatial cognition**. In the **"T-Trials"** (790 symptomatic men over 65, testosterone gel versus placebo for one year), raising testosterone from low to moderate levels gave a **moderate benefit in sexual function and some benefit in mood and depressive symptoms, but NO benefit in vitality or walking distance**.
6. **Risks, contraindications and monitoring.** The **major side effect is an excessive increase in haematocrit**; also **gynaecomastia, water retention and at least temporary worsening of sleep apnoea**. The **major contraindication is prostate carcinoma**; effects on benign prostatic hypertrophy and prostate cancer are

unclear, and **long-term safety data are lacking**. **Control of prostate size, PSA and haematocrit is mandatory.** Do **not** replace testosterone in **asymptomatic older men with an age-related decline alone**; offer it on an **individualised basis** after explicit discussion. **Target a lower concentration in older men — 300–400 ng/dL rather than 500–600 ng/dL.** If symptoms and signs do not improve, **discontinue** and investigate other causes.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **TRAVERSE trial (NEJM 2023) — the definitive cardiovascular safety study.** In **5,246 men aged 45–80** with hypogonadism and pre-existing or high risk of cardiovascular disease, randomised to transdermal testosterone gel or placebo for a mean of 27 months, **testosterone was non-inferior to placebo for the primary MACE endpoint** (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke), and there was **no increase in prostate cancer or prostate-related events**. However, the testosterone arm had **more atrial fibrillation and other non-fatal arrhythmias requiring intervention, more acute kidney injury, more pulmonary embolism, and — unexpectedly — MORE fractures** despite the known gain in bone mineral density. **Interpretation for the examination:** TRAVERSE resolves the cardiovascular controversy that prompted the FDA's 2015 caution, but it is **not a licence to treat age-related testosterone decline** — the indication remains **symptomatic, biochemically confirmed hypogonadism**, and **fracture protection cannot be claimed**.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Cardiovascular risk	Possible increase in events in men ≥65, especially in the first year (FDA caution)	TRAVERSE: non-inferior to placebo for MACE; new signals for atrial fibrillation, VTE and AKI
Bone	Increases bone mineral density; fracture data unavailable	TRAVERSE: fracture rate **higher** on testosterone — do not treat to prevent fracture
Prostate	Effects unclear; PSA monitoring mandatory	No increase in prostate cancer or prostate events; PSA monitoring still advised

Exam approach: State the textbook FDA caution, then TRAVERSE, then the conclusion — **cardiovascular reassurance without expansion of the indication**.

EXAM ONE-LINERS

- **"Andropause does not exist"** — open the answer with this sentence.
- Free T falls faster than total T because **SHBG rises with age**.
- Diagnosis needs **low testosterone PLUS symptoms** — never a number alone.
- Commonest adverse effect = **rising haematocrit**; absolute contraindication = **prostate carcinoma**.
- Target **300–400 ng/dL** in older men, not the young adult range.
- T-Trials: **sex and mood yes; vitality and walking distance no.**

QUESTION 31 · METABOLIC BONE DISEASE

Osteomalacia and vitamin D deficiency

15-Mark Answer — 10 textbook points + 2 latest updates = 12 points

TEXTBOOK CORE — 10 POINTS

1. **Definition and distinction.** Osteomalacia is **defective mineralisation of newly formed osteoid in the mature skeleton**, most often due to vitamin D deficiency; the childhood equivalent is **rickets**. Contrast with **osteoporosis**, in which mineralisation is normal but bone **quantity** is reduced. The two commonly **coexist** in older adults.
2. **Vitamin D falls with ageing.** Longitudinal data show vitamin D **declines with age**, and deficiency is **associated with increased mortality**. **Old skin exposed to ultraviolet light is less effective than young skin at manufacturing cholecalciferol**, so sun exposure alone corrects deficiency less reliably in the elderly.
3. **Causes in older adults. Reduced sun exposure** — housebound, institutionalised, fully covered clothing, urban living, skin pigmentation (all highly relevant in India); **poor dietary intake**; **malabsorption** — coeliac disease, post-gastrectomy, bariatric surgery, pancreatic insufficiency; **chronic kidney disease** with reduced 1α-hydroxylation; liver disease; and **drugs** — anticonvulsants, rifampicin, glucocorticoids. Non-vitamin-D causes include **hypophosphataemia, renal tubular acidosis** and **tumour-induced osteomalacia**.
4. **Clinical features. Diffuse bone pain and bony tenderness** — pelvis, ribs, spine; **proximal myopathy** with a **waddling gait and difficulty rising from a chair**; **falls**; and **fragility fractures**. In older people this is routinely misdiagnosed as "just ageing", fibromyalgia, polymyalgia rheumatica or metastatic bone disease.
5. **The key biochemical clue. Vitamin D deficiency should be suspected in any older person with a borderline low calcium level and an elevated alkaline phosphatase.** The full biochemical picture is: **calcium low or low-normal (<8.5 mg/dL), phosphate low, alkaline phosphatase raised, PTH raised (secondary hyperparathyroidism), and 25(OH)D low**.
6. **Thresholds. Deficiency <20 ng/mL, insufficiency 20–30 ng/mL, sufficiency ≥30 ng/mL.** The textbook position is that **ideally vitamin D levels should be 30 ng/mL or greater**, matching the International Osteoporosis Foundation target, whereas the Institute of Medicine suggests **20 ng/mL**; the threshold concentration associated with clinically relevant disease events is **near 20 ng/mL**.
7. **Radiology.** Generalised osteopenia with blurred, indistinct trabeculae; **Looser's zones (pseudofractures)** — radiolucent bands perpendicular to the cortex at the **medial femoral neck, pubic rami, scapula and ribs**; "codfish" biconcave vertebrae; and, in severe disease, a triradiate pelvis. **Bone biopsy with tetracycline double labelling is the gold standard** but is rarely needed in practice.
8. **Why vitamin D matters beyond bone. In bone, vitamin D stimulates bone turnover while protecting osteoblasts from apoptosis; in muscle it maintains the function of type II fibres, preserving strength and preventing falls.** In the Cardiovascular Health Study, vitamin D deficiency was associated with **poorer physical performance, lower muscle strength and prevalent mobility and ADL disability**. Both osteoporosis and sarcopenia have been linked to the development of **frailty**.
9. **Treatment.** Replete with **cholecalciferol**: a loading phase — the common Indian regimen is **60,000 IU weekly for 6–8 weeks** — followed by maintenance of **800–2000 IU daily**, together with **elemental calcium 1000–1200 mg/day** and adequate dietary protein. Recheck **calcium, phosphate, alkaline phosphatase and 25(OH)D at about 3 months**; alkaline phosphatase falls last, as healing completes. **Always correct vitamin D deficiency BEFORE starting a bisphosphonate or denosumab**, or severe hypocalcaemia may follow.
10. **Evidence for benefit and dosing.** There is **clear evidence that vitamin D 800 IU together with calcium decreases the rate of hip fracture in older people**, and this is associated with a **decline in mortality**. **Vitamin D replacement in people who have clear vitamin D deficiency improves muscle strength and decreases**

falls. Older people should get **regular skin exposure of 15–30 minutes per day without sunblock, or take 800–1000 IU of vitamin D per day** — this is especially true for **residents of long-term care facilities**, who require at least **800 IU per day**, double the usual recommended daily requirement.

Parameter	Osteomalacia	Osteoporosis	Primary hyperparathyroidism
Serum calcium	Low or low-normal	Normal	**High**
Serum phosphate	Low	Normal	Low
Alkaline phosphatase	**Raised**	Normal	Raised
PTH	Raised (secondary)	Normal	**Raised (primary)**
25(OH)D	**Low**	Variable	Normal or low
Pain	Diffuse bone pain, tenderness	Painless until fracture	Bones, stones, groans
Muscle	**Proximal myopathy**	Normal	Weakness, fatigue
Radiology	**Looser's zones**	Low BMD, wedge fractures	Subperiosteal resorption, brown tumours

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **Endocrine Society 2024 guideline "Vitamin D for the Prevention of Disease" — a major change in the testing paradigm.** The panel suggests **empiric daily vitamin D supplementation for everyone aged 75 years and older**, because of its **potential to lower mortality**, and suggests **AGAINST empiric supplementation above the dietary reference intake in healthy adults younger than 75**. It also suggests **against routine 25(OH)D testing in all the populations considered**, because no clinical trial evidence supports screening and no optimal target level could be defined — a clear departure from the 2011 guideline's 30 ng/mL target. For non-pregnant people over 50 in whom vitamin D is indicated, **daily low-dose administration is preferred to intermittent high doses**. **Critical distinction for the exam:** this guideline addresses **disease prevention in generally healthy people** — it does **not** apply to the diagnosis or treatment of **established osteomalacia, CKD, malabsorption or hypocalcaemia**, where measuring 25(OH)D remains essential.
12. **VITAL trial and the Indian public-health position.** In **VITAL** (25,871 participants, cholecalciferol 2000 IU/day), **supplementation did not lower the incidence of invasive cancer or cardiovascular events compared with placebo** — but **only 12.7% of participants had a 25(OH)D below 20 ng/mL**, so the results **cannot be applied to genuinely deficient people**. This is the key to reconciling "vitamin D does nothing" trial headlines with the real benefit seen in deficiency. In India, where vitamin D deficiency is **highly prevalent across all age groups**, the pragmatic approach endorsed by **ICMR-NIN** is **food fortification plus routine supplementation of at-risk groups — the housebound, institutionalised and older adults — rather than population-wide testing**, which is expensive and does not change management.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current Recommendation
Testing 25(OH)D	Measure; target ≥30 ng/mL	Endocrine Society 2024 advises against routine testing in healthy people; no target level defined. Testing retained for suspected osteomalacia, CKD, malabsorption, hypocalcaemia
Who to supplement	All older adults, 800–1000 IU/day	Empiric supplementation for **all aged ≥75**; against routine supplementation above DRI in healthy adults <75
Dosing schedule	Daily or intermittent high dose	**Daily low dose preferred** over intermittent high dose in those >50

Exam approach: Present the textbook thresholds for **diagnosis of osteomalacia**, then state the 2024 shift for **prevention in the healthy**. Making that distinction explicitly is what earns the top mark here.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Define (defective mineralisation of osteoid) → contrast with osteoporosis → causes (sun, diet, malabsorption, CKD, drugs) → bone pain + proximal myopathy + falls → **low Ca, low PO_4, high ALP, high PTH, low 25(OH)D** → Looser's zones → treat with cholecalciferol loading then maintenance + calcium → recheck at 3 months → prevention 800 IU/day → Endocrine Society 2024 and VITAL.

Numbers: 20 / 30 ng/mL · 800 IU (fracture reduction) · 60,000 IU weekly × 6–8 weeks (Indian loading) · calcium 1000–1200 mg/day · sun 15–30 min/day · age **75** (Endocrine Society empiric supplementation cut-off).

EXAMINER TRAPS

- Calling a raised alkaline phosphatase "hepatic" without checking calcium, phosphate and 25(OH)D — this is **the** missed diagnosis of osteomalacia.
- Starting a bisphosphonate or denosumab before repleting vitamin D → **severe hypocalcaemia**.
- Quoting VITAL as proof that vitamin D "does not work" without noting that **only 12.7% of participants were deficient**.
- Confusing the **prevention** guideline (no testing) with the **diagnosis** of osteomalacia (test).

PART VII

Crystal Arthropathy

Q32 · Q33 · Q34

QUESTION 32 · CRYSTAL ARTHROPATHY — CLINICAL SCENARIO

A 65-year-old man presents with acute onset of severe pain in the right big toe for two days following a binge of alcohol. Most probable diagnosis and management

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **The diagnosis is acute gout — podagra of the first metatarsophalangeal joint. Gout is characterised by intra-articular monosodium urate crystals** and **generally presents as acute, affecting the first metatarsophalangeal joint, mid foot or ankle**, although the knee, elbow or wrist can also be involved. The features that make it near-certain here are the **abrupt onset reaching maximum severity within 6–24 hours**, the **site**, the **male sex and age**, and the **alcohol binge**. Beer and spirits raise urate by **increasing purine load and by lactate-mediated inhibition of renal urate excretion**; dehydration after a binge concentrates urate further.
2. **Examine and exclude the one diagnosis that would kill him.** The joint will be **exquisitely tender, hot, red and swollen with overlying desquamation**, and even bedclothes may be intolerable. Look for **tophi — subcutaneous urate deposits on extensor surfaces**, which **can develop in later phases and are sometimes confused with rheumatoid arthritis and its nodules**. **The critical differential is septic arthritis**, which can be indistinguishable and may coexist; also consider **pseudogout, cellulitis, trauma or fracture, reactive arthritis and acute osteoarthritic flare**. Fever, rigors, a portal of entry, immunosuppression, diabetes or a prosthetic joint mandate urgent aspiration.
3. **Investigations. The definitive diagnosis of gout is established by observing the presence of needle-shaped crystals in the involved joint** — **negatively birefringent under polarised light, and intracellular within neutrophils during an attack**. Send the same aspirate for **Gram stain, culture and cell count**. **Some patients will have elevated uric acid levels** — note the wording: **serum urate is often normal or low during an acute attack and does not confirm or exclude the diagnosis**; repeat it two weeks after the flare settles. **Radiographs may reveal well-defined gouty erosions in or around joints** — punched-out, with overhanging sclerotic margins and preserved joint space — but these are features of chronic disease. Also check **renal function, glucose, lipids, full blood count and liver function**, both to find comorbidity and to choose the safest drug.
4. **Treat the acute attack — the choice is dictated by comorbidity, not by efficacy. The goal of treatment is to terminate the acute attack and then to prevent future attacks by considering underlying causes. The acute phase should be managed using short-term NSAIDs, colchicine, corticotrophin or corticosteroids, and treatment choices should be based on patient comorbidities such as renal function and gastrointestinal disease.** All three first-line options are of **similar efficacy**, so choose on safety: **NSAIDs** —

effective but hazardous in the older adult with renal impairment, heart failure, hypertension, anticoagulation or peptic ulcer; **colchicine — low-dose regimens (1.2 mg then 0.6 mg one hour later, then 0.5–0.6 mg once or twice daily)** are as effective as and far better tolerated than the old high-dose regimen, but **reduce the dose in renal impairment and avoid with clarithromycin, ciclosporin, verapamil, diltiazem and statins** because of myopathy and marrow suppression; **corticosteroids — intra-articular injection is ideal for a single joint**, or oral prednisolone 30–35 mg daily for 5 days, and this is often the **safest choice in an older patient with chronic kidney disease**. Add rest, elevation and ice.

5. **Do not start urate-lowering therapy during the attack — but do plan it. Treatment to decrease uric acid levels should not be initiated during the acute phase, because drugs such as allopurinol or probenecid may exacerbate the acute attack** by mobilising crystals. **If the patient is already established on allopurinol, continue it** — never stop it during a flare. Plan to start urate-lowering therapy **2–4 weeks after the flare has fully settled**, under anti-inflammatory cover.
6. **Address the cause and the man, not just the toe.** Review **alcohol** — advise reduction and screen for alcohol-use disorder, since a "binge" in a 65-year-old may signal a wider problem. Review **drugs that raise urate**: **thiazide and loop diuretics, low-dose aspirin, ciclosporin, tacrolimus, pyrazinamide and ethambutol** — substituting a diuretic is often curative. Advise reduction of **red meat, organ meat, shellfish and fructose-sweetened drinks**, **adequate hydration**, and **weight loss**. Screen for the associated conditions that make gout a cardiovascular marker: **hypertension, chronic kidney disease, obesity, diabetes, dyslipidaemia and ischaemic heart disease**.

Feature	Acute gout	Septic arthritis	Pseudogout
Typical joint	**First MTP, midfoot, ankle**	Knee, hip; any joint	**Knee, wrist**
Onset	Peak in 6–24 hours	Hours to days, progressive	Subacute, over days
Systemic upset	Mild fever possible	**Fever, rigors, unwell**	Mild
Crystals	**Needle-shaped, negatively birefringent**	None	**Rhomboid, positively birefringent**
Synovial white cells	2,000–50,000/mm^3	**>50,000/mm^3, >90% neutrophils**	2,000–50,000/mm^3
Gram stain / culture	Negative	**Positive**	Negative
Radiograph	Punched-out erosions with overhanging edge	Early normal, later destruction	**Chondrocalcinosis**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **Current guidance has reversed the old rule that urate-lowering therapy must never be started during or soon after a flare.** The **ACR gout guideline** and subsequent practice hold that **starting urate-lowering therapy during a flare does not increase or prolong symptoms as long as anti-inflammatory treatment is given concurrently**, and the ACR explicitly notes that **patients are most motivated for treatment during an exacerbation** — so the pragmatic modern approach in a patient likely to be lost to follow-up is to **start allopurinol at a low dose under colchicine or NSAID cover rather than wait**. Two further current points: **anti-inflammatory prophylaxis should be continued for 3–6 months rather than less than 3 months** after starting urate-lowering therapy, with ongoing evaluation; and **HLA-B*5801 testing should be offered before starting allopurinol in people of Southeast Asian or African descent**, in whom the allele — carried by about **7% of those of Southeast Asian descent** — predicts severe allopurinol hypersensitivity. The examination-safe formulation is to **state the textbook rule first, then note that current guidance permits concurrent initiation under anti-inflammatory cover**.

EXAMINER TRAPS

- Diagnosing gout on a **raised serum urate**. Urate is frequently **normal or low during an acute attack**; the diagnosis rests on crystals.
- Not **aspirating the joint**, or not sending it for culture. Septic arthritis and gout can coexist, and a missed septic joint destroys it within days.
- Prescribing an **NSAID reflexively** in a 65-year-old with unknown renal function.
- Using the **old high-dose colchicine regimen** until diarrhoea occurs — obsolete and dangerous.
- **Stopping allopurinol** in a patient already established on it.
- Treating the toe and ignoring the **alcohol, the diuretic and the cardiovascular risk profile**.

QUESTION 33 · CRYSTAL ARTHROPATHY

Management of gout

7-Mark Note — 6 textbook points + 1 latest update = 7 points

PIVOT FOR THIS ANSWER

Question 32 covers the **acute attack**. This answer is weighted towards the **whole disease** — the four phases, urate-lowering therapy, treat-to-target, and the special problems of gout in the older adult. Give acute management in a single point and spend the rest on long-term control.

TEXTBOOK CORE — 6 POINTS

1. **The two goals, and the four phases they map onto. The goal of treatment is to terminate the acute attack and then prevent future attacks by considering underlying causes — for example, considering hypouricaemic therapy.** Gout progresses through **asymptomatic hyperuricaemia → acute intermittent gout → the intercritical period → chronic tophaceous gout**, in which **tophi, which are subcutaneous urate deposits on extensor surfaces, develop in the later phases and are sometimes confused with rheumatoid arthritis and its nodules**. Management differs at each phase, and the fundamental principle is that **the acute attack is treated with anti-inflammatories and the disease is cured only by lowering urate**.

2. **Acute attack — summarised. The acute phase should be managed using short-term NSAIDs, colchicine, corticotrophin or corticosteroids, with the choice based on patient comorbidities such as renal function and gastrointestinal disease.** In older adults, **low-dose colchicine or corticosteroids (intra-articular for a single joint, oral for polyarticular disease) are usually safer than NSAIDs**. **Colchicine can be used for acute management as well as for prophylaxis.** Never stop existing urate-lowering therapy during a flare.
3. **Who needs urate-lowering therapy, and which drug.** Indications: **two or more flares per year, any tophus, radiographic erosion, chronic kidney disease stage 3 or worse, urolithiasis, or a very high serum urate**. **Allopurinol is the first-line urate-lowering therapy**, and **due to the renal changes associated with ageing, allopurinol is recommended over probenecid in older individuals** — probenecid is a uricosuric and loses efficacy as GFR falls, besides risking stones. **Febuxostat**, the other xanthine oxidase inhibitor, is the alternative in allopurinol intolerance, but **is limited by the increased cardiovascular and all-cause mortality seen in studies** (the CARES trial), so it is second-line. **An xanthine oxidase inhibitor is recommended over probenecid in CKD stage 3 or worse.**
4. **How to prescribe it — start low, titrate to target, cover with prophylaxis. Start at a low dose with subsequent titration to target rather than starting high** — allopurinol **under 100 mg/day, and lower still in CKD (50 mg)**; febuxostat **under 40 mg/day**. **Adjust the dose upward every 2–5 weeks according to the uric acid level**. **ACR guidance advises that the allopurinol dose can be raised above 300 mg/day even in patients with renal impairment, provided there is adequate monitoring** — the older practice of capping the dose by creatinine clearance left most patients under-treated. **Initiate concomitant anti-inflammatory prophylaxis — colchicine, an NSAID, or low-dose prednisolone — over no prophylaxis**, and **continue it for 3–6 months rather than less than 3 months**, since urate-lowering drugs precipitate attacks by mobilising crystal deposits.
5. **Treat-to-target, and when to stop prophylaxis. Titrate to a serum urate below 6 mg/dL** — this **decreases flares and increases treatment adherence** — and to **below 5 mg/dL in tophaceous gout**, because tophi dissolve only below the saturation point. **Once the target has been achieved and maintained for 6 months, discontinue colchicine prophylaxis, unless the patient has one or more tophi on clinical examination. Urate-lowering therapy itself is continued indefinitely** — continuing it is preferred over stopping even in patients who are flare-free and tophus-free. **Asymptomatic hyperuricaemia should not, as a general rule, be treated.**
6. **Non-pharmacological management and the geriatric considerations.** Address **alcohol (especially beer and spirits), red and organ meat, shellfish, and fructose-sweetened drinks**; encourage **weight loss, hydration, low-fat dairy and vitamin C**. **Adjust contributing medications such as diuretics** — substituting a thiazide, or switching to **losartan** (mildly uricosuric) or a calcium-channel blocker for hypertension, is one of the most effective single interventions in an older patient. Geriatric-specific issues: **gout in older adults is more often polyarticular, involves the upper limbs and small hand joints, is more frequent in women after the menopause, is strongly diuretic-associated, and presents with tophi earlier** — sometimes on osteoarthritic Heberden's and Bouchard's nodes, where it is easily mistaken for nodal osteoarthritis or rheumatoid arthritis. Monitor renal function, review the whole drug list, and remember that **carpal tunnel syndrome is common in older adults and can be confused with gout, rheumatoid arthritis or pseudogout**.

Drug	Class / mechanism	Dose in the older adult	Cautions
Allopurinol	Xanthine oxidase inhibitor	Start 50–100 mg daily; titrate every 2–5 weeks; may exceed 300 mg	**HLA-B*5801** hypersensitivity (test in Southeast Asian and African descent); rash, DRESS; interacts with azathioprine
Febuxostat	Xanthine oxidase inhibitor	Start <40 mg daily	**Second-line — cardiovascular and all-cause mortality signal (CARES)**; hepatotoxicity
Probenecid	Uricosuric	500 mg once or twice daily, titrated	**Avoid in the elderly and in CKD stage >3**; urolithiasis
Colchicine	Anti-inflammatory (tubulin)	Acute: 1.2 mg then 0.6 mg at 1 h. Prophylaxis: 0.5–0.6 mg once or twice daily	Reduce in renal and hepatic impairment; **myopathy and marrow suppression with statins, clarithromycin, verapamil, diltiazem, ciclosporin**
Corticosteroid	Anti-inflammatory	Intra-articular, or prednisolone 30–35 mg for 5 days	Hyperglycaemia, delirium, fluid retention, infection risk
Pegloticase	Recombinant uricase	Specialist use, IV	Refractory tophaceous gout only; infusion reactions, anaphylaxis; **contraindicated in G6PD deficiency**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **The two current shifts are treat-to-target with early initiation, and the head-to-head vindication of allopurinol.** The **ACR guideline's central change was the emphasis on a "treat-to-target" strategy — treating as aggressively as needed to keep serum urate below 6 mg/dL**, supported by trials published since the 2012 guideline. Alongside this, **urate-lowering therapy may now be started during a flare under anti-inflammatory cover**, capitalising on the moment the patient is most motivated. On drug choice, the **STOP-Gout trial (NEJM Evidence 2022)** found **allopurinol non-inferior to febuxostat** when both were properly dose-escalated to target, including in patients with chronic kidney disease — confirming that most "allopurinol failure" is in fact **under-dosing rather than drug failure**. The **FAST trial (Lancet 2020)** did not replicate the CARES cardiovascular mortality signal for febuxostat, so the position is now that **febuxostat is a reasonable alternative but allopurinol, correctly titrated, remains first choice**. Finally, gout is increasingly framed as a **cardiovascular risk marker**, with guideline-concordant therapy improving endothelial function and reducing intercritical inflammation — a useful closing line in a geriatrics answer.

MEMORY ANCHORS & 15-SECOND SKELETON

Skeleton: Two goals and four phases → acute attack (NSAID / colchicine / steroid, chosen by comorbidity) → who needs ULT → **allopurinol first-line, preferred over probenecid in the elderly** → start low, titrate every 2–5 weeks, cover with prophylaxis 3–6 months → **target urate <6 mg/dL (<5 with tophi)** → stop prophylaxis after 6 months at target unless tophi → diet, alcohol, diuretics, weight → geriatric pattern: polyarticular, upper limb, women, diuretic-associated, early tophi.

Numbers: target urate **<6 mg/dL**, tophaceous **<5** · allopurinol start **<100 mg** (50 in CKD), titrate every **2–5 weeks** · febuxostat start **<40 mg** · prophylaxis **3–6 months** · stop prophylaxis after **6 months** at target · ULT indicated at **≥2 flares/year** · HLA-B*5801 in **7%** of Southeast Asians.

EXAMINER TRAPS

- **Treating asymptomatic hyperuricaemia.** As a general rule, do not.
- Starting allopurinol at **300 mg** and never titrating — the commonest real-world error, and the reason most patients never reach target.
- Capping the allopurinol dose by creatinine clearance and accepting failure. **The dose may be raised above 300 mg even in renal impairment, with monitoring.**
- Omitting **anti-inflammatory prophylaxis** when starting urate-lowering therapy, then blaming the drug when a flare follows.
- Choosing **probenecid in an older patient** — allopurinol is recommended over it because of age-related renal change.
- Missing the **diuretic**. In a hypertensive older patient with gout, changing the antihypertensive may achieve more than any urate-lowering drug.

QUESTION 34 · CRYSTAL ARTHROPATHY

Pseudogout

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition and nomenclature.** Pseudogout is **acute inflammatory arthritis caused by deposition of calcium pyrophosphate dihydrate (CPPD) crystals** in articular cartilage and fibrocartilage. The current terminology is **"acute CPP crystal arthritis"**, with **chondrocalcinosis** denoting the radiographic calcification and **CPPD disease** the umbrella term. **It is predominantly a disease of the elderly** — prevalence rises steeply after 65 and chondrocalcinosis is present in a substantial minority of those over 80.
2. **Causes and associations.** Most cases are **idiopathic and age-related**, but a secondary cause must be sought in anyone presenting young or with florid disease. The classic associations — mnemonic **"5 Hs"** — are **Hyperparathyroidism, Haemochromatosis, Hypophosphatasia, Hypomagnesaemia and Hypothyroidism**; add **Wilson's disease, gout, osteoarthritis, and previous joint trauma or meniscectomy**. Attacks are precipitated by **acute illness, surgery (especially parathyroidectomy), trauma, dehydration, myocardial infarction, stroke and intra-articular hyaluronate injection** — which is why pseudogout so often appears in an already unwell hospitalised older patient.
3. **Clinical presentations — it has more than one face. (a) Acute pseudogout** — a hot, swollen, painful joint, most often the **knee, then the wrist**, developing over days rather than hours, frequently with **fever and a raised white cell count and CRP**, so it convincingly mimics sepsis. **(b) Chronic CPP crystal inflammatory arthritis** — a symmetrical polyarthritis mimicking **rheumatoid arthritis** ("pseudo-rheumatoid"). **(c) Osteoarthritis with CPPD** — affecting unusual joints for osteoarthritis such as the **metacarpophalangeal joints, wrist, elbow and shoulder**. **(d) Asymptomatic chondrocalcinosis** — an incidental radiographic finding. **(e) Crowned dens syndrome** — CPPD around the odontoid peg presenting as acute neck pain, stiffness and fever, mimicking meningitis, polymyalgia rheumatica or giant cell arteritis in an older patient. In the elderly it also presents non-specifically as **immobility, delirium, a fall or "off legs"**.
4. **Diagnosis. Joint aspiration is essential**, both to identify crystals and to exclude infection. CPP crystals are **rhomboid or rod-shaped, weakly positively birefringent under polarised light** — the mirror image of the **needle-shaped, strongly negatively birefringent** urate crystals of gout. Synovial fluid is inflammatory with **2,000–50,000 white cells/mm^3**; always send **Gram stain and culture**. Radiographs show **chondrocalcinosis** — linear or punctate calcification of the **knee menisci and hyaline cartilage, the triangular fibrocartilage of the**

wrist, and the symphysis pubis — though its presence does not prove that CPPD is causing this attack. **Ultrasound** shows hyperechoic bands within hyaline cartilage. Screen for secondary causes: **calcium, phosphate, magnesium, alkaline phosphatase, PTH, ferritin and transferrin saturation, and TSH**.

5. **The critical differential remains septic arthritis, and it may coexist.** Pseudogout in an older adult reproduces every feature of sepsis — **fever, a hot swollen joint, leucocytosis and a high CRP** — and crystals in the fluid **do not exclude infection**. **Aspirate, culture, and if there is any doubt treat empirically for sepsis while awaiting results.** Other differentials: gout, acute osteoarthritic flare, haemarthrosis in an anticoagulated patient, cellulitis, reactive arthritis and, for the polyarticular form, rheumatoid arthritis and polymyalgia rheumatica. **Carpal tunnel syndrome is common in older adults and can be confused with gout, rheumatoid arthritis or pseudogout.**
6. **Management. There is no therapy that removes CPP crystals** — this is the essential contrast with gout, where urate-lowering therapy is curative. Treatment is therefore **anti-inflammatory and supportive**. **Acute attack: joint aspiration alone is often therapeutic**; then **intra-articular corticosteroid** for a single joint, which is the **preferred first choice in the older adult**; or **short-course NSAIDs with gastroprotection** if renal function, blood pressure and gastrointestinal history permit; or **low-dose colchicine**; or **oral prednisolone 30–35 mg for 5 days** for polyarticular disease. Add rest, ice and analgesia. **Prophylaxis** for recurrent attacks (three or more a year): **low-dose colchicine 0.5 mg once or twice daily**, dose-reduced for renal function. **Treat any identified secondary cause** — correcting **hypomagnesaemia** and treating **hyperparathyroidism, haemochromatosis or hypothyroidism**. Refractory chronic inflammatory disease may need **hydroxychloroquine, methotrexate or an IL-1 inhibitor** under specialist care. Physiotherapy and joint protection preserve function.

Feature	Gout	Pseudogout
Crystal	Monosodium urate	**Calcium pyrophosphate dihydrate**
Shape	**Needle-shaped**	**Rhomboid / rod-shaped**
Birefringence	**Strongly negative** (yellow parallel to the compensator)	**Weakly positive** (blue parallel to the compensator)
Typical joint	First MTP, midfoot, ankle	**Knee, wrist**
Speed of onset	Peak in 6–24 hours	Over several days
Sex and age	Middle-aged men; older women on diuretics	**Elderly, both sexes equally**
Radiograph	Punched-out erosions with overhanging edge	**Chondrocalcinosis**
Provoking factors	Alcohol, purine load, diuretics, dehydration	Acute illness, surgery, trauma, **parathyroidectomy**
Crystal-lowering therapy	**Yes — allopurinol, treat-to-target**	**None available**

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **CPPD disease now has formal ACR/EULAR classification criteria (2023) and a defined role for imaging and IL-1 blockade.** The **2023 ACR/EULAR classification criteria for calcium pyrophosphate deposition disease** were the first for this condition: entry requires at least one episode of joint swelling, tenderness and pain in a peripheral joint, the **presence of CPP crystals in synovial fluid is a sufficient criterion**, and in their absence a weighted score combines **clinical features, age, associated metabolic disease and — importantly — imaging evidence of chondrocalcinosis on radiograph, ultrasound or dual-energy CT**. The practical consequences are three. First, **ultrasound has become a validated, bedside, radiation-free way to demonstrate crystal deposition** — useful in a frail patient in whom aspiration is difficult. Second, the criteria formally recognise **crowned dens syndrome**, which matters because it is a treatable mimic of meningitis and of giant cell arteritis in older adults. Third, **IL-1 inhibition (anakinra)** is increasingly used for acute attacks in patients in whom NSAIDs, colchicine and steroids are all contraindicated — a situation that is common in multimorbid older patients with chronic kidney disease and heart failure. The unchanged core message remains: **there is still no crystal-dissolving therapy, so management is anti-inflammatory plus treatment of the underlying metabolic cause**.

MEMORY ANCHORS

The 5 Hs of secondary CPPD: Hyperparathyroidism · **H**aemochromatosis · **H**ypophosphatasia · **H**ypomagnesaemia · **H**ypothyroidism.

Birefringence mnemonic: "Pseudogout is **P**ositive and **P**arallelogram-shaped" · gout is **N**eedle-shaped and **N**egative.

EXAMINER TRAPS

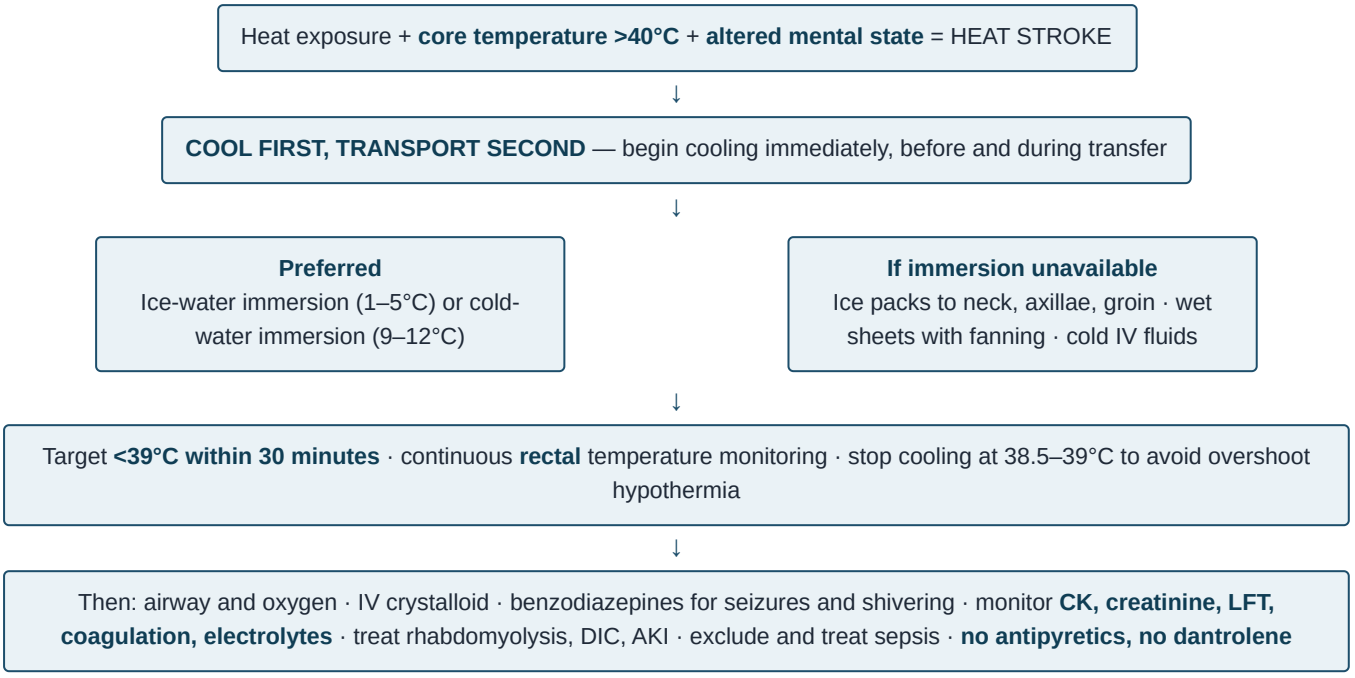
- Assuming that **finding crystals excludes infection**. It does not; the two coexist, particularly in the elderly.
- Diagnosing pseudogout from **chondrocalcinosis on the radiograph alone** — it is common and asymptomatic in the very old.
- Forgetting to screen for the **5 Hs**, especially **hyperparathyroidism and haemochromatosis**, in anyone with florid or early-onset disease.
- Offering "urate-lowering therapy" for pseudogout — **no crystal-lowering therapy exists**.
- Missing **crowned dens syndrome** in an older patient with acute neck pain, fever and a raised CRP, and treating it as meningitis or giant cell arteritis.
- Overlooking a **recent parathyroidectomy** as the precipitant.

PART VIII

Environmental and Systemic Disorders

Q35 · Q36

QUESTION 35 · ENVIRONMENTAL



Heat stroke — clinical features, diagnostic criteria, differential diagnosis and treatment

7-Mark Note — 6 textbook points + 1 latest update = 7 points

TEXTBOOK CORE — 6 POINTS

1. **Definition and diagnostic criteria — the classic triad. Heat stroke is defined as a failure to maintain body temperature and is characterised by a core temperature above 40.6°C (105°F), severe central nervous system dysfunction — psychosis, delirium, coma — and anhidrosis with hot, dry skin. The two groups primarily affected are older adults who are chronically ill, and the young undergoing strenuous exercise** — that is, **classic (non-exertional)** and **exertional** heat stroke. **Mortality is as high as 80% once this syndrome is manifest.**
2. **Predisposing factors in older adults. There are multiple predisposing factors for heat stroke in older adults, but most often there is a prolonged heat wave.** Add the age-related and iatrogenic contributors: **reduced thirst and impaired water conservation, reduced sweating capacity, impaired cardiovascular compensation, immobility and dependence on carers, social isolation, dementia, absence of air conditioning**, and **drugs** — **anticholinergics and antihistamines (impair sweating), antipsychotics and antidepressants (impair thermoregulation), diuretics (volume depletion), beta blockers (blunt the cardiac response), and alcohol**. Chronic cardiac, respiratory, renal and neurological disease all raise the risk.
3. **Clinical features — early and late. The diagnosis requires a high level of suspicion. Early manifestations of heat exhaustion are non-specific: dizziness, weakness, a sensation of warmth, anorexia, nausea, vomiting, headache and dyspnoea. Later, severe central nervous system dysfunction and anhidrosis develop — psychosis, delirium, coma, and hot, dry skin.** In older adults the presentation is frequently just **confusion, a fall or collapse**, and the history of heat exposure must be sought actively.
4. **Differential diagnosis.** The differential is essentially **every cause of hyperthermia with altered mental state**: **sepsis and meningoencephalitis** (the commonest and most important alternative — and heat stroke may be complicated by infection); **neuroleptic malignant syndrome** (antipsychotics, lead-pipe rigidity, raised CK); **serotonin syndrome** (serotonergic drugs, clonus, hyperreflexia); **malignant hyperthermia** (anaesthetic exposure); **anticholinergic toxicity** (hot, dry skin, dilated pupils, urinary retention); **thyroid storm**; **drug withdrawal states**; **status epilepticus**; **cerebrovascular event affecting the hypothalamus**; and **stimulant or cocaine toxicity**. The distinguishing features are the **environmental history, the drug history and the muscle findings**.

5. **Complications — the multi-organ failure that determines outcome. Myocardial damage, congestive heart failure and arrhythmias; renal failure in 20–25%; cerebral oedema and seizures with diffuse and focal findings; hepatocellular necrosis, jaundice and liver failure; rhabdomyolysis with myoglobinuria; bleeding diathesis and disseminated intravascular coagulation; electrolyte disturbances; metabolic acidosis with respiratory alkalosis; infection including aspiration pneumonia and sepsis; and dehydration with shock. Once the full syndrome has developed for any length of time the prognosis is very poor.**
6. **Treatment — cool first, and cool fast. Management at this stage requires intense multisystem care, but the key is rapid specific therapy consisting of cooling to 38.9°C (102°F) within the first hour. Ice packs and ice-water immersion are superior to convection cooling with alcohol sponge baths or electric fans.** Alongside cooling: secure the airway, give **oxygen**, obtain a **rectal core temperature**, resuscitate with **intravenous crystalloid guided by cardiac status**, treat **seizures with benzodiazepines**, give **generous fluids and monitor CK and urine output for rhabdomyolysis**, correct electrolytes and coagulopathy, and treat infection. **Antipyretics — paracetamol and NSAIDs — are useless because the hypothalamic set point is normal, and are potentially harmful given hepatic and renal injury; dantrolene has no role. In view of the poor survival, efforts must be directed towards prevention: older patients should be cautioned about the dangers of hot weather, and for those at particularly high risk, temporary relocation to more protected environments should be considered. Prevention appears to be the most appropriate approach to management of temperature dysregulation in older adults** — through education about susceptibility, appropriate behaviour in extreme temperatures, and close monitoring of the most vulnerable.

LATEST UPDATE (2023–PRESENT) — 1 POINT

7. **The Society of Critical Care Medicine published the first formal Guideline for the Treatment of Heat Stroke (Crit Care Med 2025), and India's NCDC issued a national emergency cooling protocol (March 2024).** The SCCM guideline makes **active cooling recommended over passive cooling**, with **cold- or ice-water immersion achieving the fastest cooling rate and to be prioritised where available — ice-water immersion at 1–5°C or cold-water immersion at 9–12°C**. Its good-practice statements are precise and highly quotable: **clinicians may use similar strategies for either classic or exertional heat stroke**; **cooling methods should reach the target temperature within 30 minutes of recognition**; and **modalities achieving a cooling rate of at least 0.155°C per minute should be prioritised**. It also states that **there is no evidence to support pharmacological interventions affecting temperature control, so they should be avoided**. In India, the **NCDC/NPCCHH "Emergency Cooling for Severe Heat-Related Illnesses" (March 2024)** operationalises this for Indian emergency departments, including **improvised cold-water immersion using a body bag or tarpaulin** where a tub is unavailable, and the **NDMA Heat Action Plans** — with the **Ahmedabad Heat Action Plan** as the model, credited with a substantial reduction in heat mortality — provide the preventive framework: early-warning alerts, cool shelters, rescheduled outdoor work, and **active check-in on isolated older people during heatwaves and power cuts**, which is the single highest-yield preventive measure for this population.

CURRENT PRACTICE UPDATE

Aspect	Textbook	Current recommendation
Temperature threshold	>40.6°C (105°F) with anhidrosis	**>40°C with CNS dysfunction; anhidrosis is NOT required** — many patients are still sweating
Cooling target	38.9°C within the first hour	**<39°C within 30 minutes**, cooling rate ≥0.155°C/min
Method	Ice packs and ice-water immersion superior to fans	Confirmed — **cold/ice-water immersion is first choice for classic and exertional alike**
Drugs	Not addressed	**Avoid all pharmacological temperature control** — no antipyretics, no dantrolene

Exam approach: Quote the textbook triad, then state that **anhidrosis is no longer required for the diagnosis** — waiting for dry skin delays cooling and costs lives. This single correction is the highest-value line in the answer.

MEMORY ANCHORS

Skeleton: Define with the triad → two populations (classic elderly, exertional young) → predisposing factors and drugs → early non-specific then late CNS features → differential (sepsis, NMS, serotonin syndrome, anticholinergic, thyroid storm) → complications by organ system → **cool first, transport second**; immersion; target <39°C in 30 minutes → supportive care → prevention.

Numbers: core temperature **>40°C** (textbook 40.6°C / 105°F) · mortality up to **80%** · renal failure **20–25%** · cooling target **<39°C in 30 minutes** · cooling rate **≥0.155°C/min** · immersion water **1–5°C or 9–12°C**.

EXAMINER TRAPS

- Requiring **anhidrosis** before making the diagnosis. Many patients with classic heat stroke are still sweating — do not wait.
- Measuring an **oral, axillary or tympanic** temperature. Only a **rectal core temperature** is reliable.
- Giving **paracetamol**. The hypothalamic set point is normal, so it does not work, and it adds hepatotoxicity to a liver already injured.
- Investigating before cooling. **Cooling precedes CT, cooling precedes transfer.**
- Cooling past the target and producing **overshoot hypothermia** — stop at 38.5–39°C.
- Forgetting **rhabdomyolysis and DIC**, and forgetting that **sepsis may coexist**.
- Omitting **prevention**, which the textbook states is the most appropriate approach in older adults.

QUESTION 36 · SYSTEMIC

Chronic fatigue syndrome — diagnostic criteria, clinical manifestations, predisposing factors, course, prognosis and treatment

15-Mark Essay — 10 textbook points + 2 latest updates = 12 points

SOURCE NOTE

Chronic fatigue syndrome / myalgic encephalomyelitis is not covered adequately in the uploaded textbooks. Pathy's addresses *cancer-related fatigue* in detail and refers to *idiopathic chronic fatigue in older adults* being linked to impaired skeletal-muscle mitochondrial content and biogenesis signalling; Kane's addresses fatigue as a non-specific presentation. Those elements are used where they apply, and the diagnostic frameworks are taken from the **IOM/NAM 2015 criteria**, the **Fukuda 1994 CDC criteria** and **NICE NG206 (2021)**, each clearly named.

CORE ANSWER — 10 POINTS

1. **Definition.** Chronic fatigue syndrome, also called **myalgic encephalomyelitis (ME/CFS)** and, in the IOM formulation, **systemic exertion intolerance disease**, is a **chronic, disabling, multisystem illness** characterised by **profound fatigue that is not explained by ongoing exertion, is not relieved by rest, and causes a substantial reduction in previous levels of occupational, social and personal activity**, together with **post-exertional malaise** and **unrefreshing sleep**, persisting for **at least six months** (or, under NICE, three months for diagnosis) and not attributable to another disorder.
2. **Diagnostic criteria — IOM / National Academy of Medicine 2015.** Diagnosis requires **all three** of: **(i)** a **substantial reduction or impairment in the ability to engage in pre-illness levels of activity**, persisting more than six months, accompanied by fatigue that is **often profound, of new or definite onset, not the result of ongoing excessive exertion, and not substantially alleviated by rest**; **(ii) post-exertional malaise**; and **(iii) unrefreshing sleep**. **Plus at least one** of: **cognitive impairment** or **orthostatic intolerance**. Symptoms should be present for at least half the time and of at least moderate intensity.
3. **Diagnostic criteria — Fukuda (CDC) 1994, still widely quoted in examinations. Clinically evaluated, unexplained, persistent or relapsing fatigue for six months or more**, of new onset, not the result of ongoing exertion, not substantially alleviated by rest, and resulting in substantial reduction in previous activity levels — **plus four or more** of the following eight, concurrently present for six months: **impaired short-term memory or concentration; sore throat; tender cervical or axillary lymph nodes; muscle pain; multi-joint pain without swelling or redness; headaches of a new type, pattern or severity; unrefreshing sleep; and post-exertional malaise lasting more than 24 hours**.

4. **Post-exertional malaise is the cardinal feature — and the examinable one.** PEM is a **disproportionate worsening of symptoms after physical, cognitive, emotional or social exertion that was previously tolerated**, characteristically **delayed in onset by hours to days** and **disproportionately prolonged, taking days, weeks or longer to recover**. It is **not** ordinary post-exertional fatigue, and this distinction determines the entire management approach. **NICE NG206 makes post-exertional malaise mandatory for the diagnosis.**
5. **Clinical manifestations. Constitutional** — profound fatigue, PEM, unrefreshing sleep, sleep-phase disturbance. **Neurocognitive** — "brain fog", impaired concentration, word-finding and short-term memory difficulty, slowed information processing, sensory hypersensitivity to light and noise. **Autonomic** — **orthostatic intolerance, postural orthostatic tachycardia, palpitations, dizziness, nausea, temperature dysregulation**. **Musculoskeletal** — widespread myalgia, arthralgia without swelling, muscle weakness. **Immune-like** — recurrent sore throat, tender lymph nodes, flu-like malaise. **Gastrointestinal** — irritable bowel symptoms. Severity spans from those who continue reduced work to the **severely affected, who are housebound or bedbound and require assistance with all activities of daily living** — a group of about 25%.
6. **Predisposing, precipitating and perpetuating factors. Predisposing** — female sex (2–4:1), genetic susceptibility, pre-existing anxiety or depression, childhood adversity, and a personality pattern of high achievement and persistence. **Precipitating** — most characteristically an **infection**: Epstein–Barr virus, Q fever, Ross River virus, enterovirus, influenza, and now **SARS-CoV-2**; also major physical trauma, surgery, or severe psychological stress. **Perpetuating** — the **boom-and-bust cycle of over-activity followed by collapse**, deconditioning, disturbed sleep, chronic pain, comorbid mood disorder, and iatrogenic harm from inappropriate exercise prescription. Proposed mechanisms — none diagnostic — include **immune dysregulation with altered cytokine profiles, hypothalamic–pituitary–adrenal axis hypofunction, autonomic dysfunction, and impaired cellular energy metabolism**. This last is directly supported in the geriatric literature: **idiopathic chronic fatigue in older adults has been linked to impaired mitochondrial content and biogenesis signalling in skeletal muscle**.
7. **Diagnosis is clinical — investigations are to exclude, not to confirm. There is no diagnostic test.** A baseline screen excludes the treatable mimics: **full blood count, ESR and CRP, urea and electrolytes, creatinine, liver function, calcium, glucose and HbA1c, TSH, creatine kinase, ferritin, vitamin B12 and folate, vitamin D, coeliac serology, urinalysis**, and, where indicated, HIV, hepatitis serology, chest radiograph, ANA and cortisol. **NICE recommends baseline investigation to exclude alternative diagnoses and regular follow-up investigation to capture new or missed diagnoses.** The **differential in an older adult is wide and matters more than in the young**: **anaemia, hypothyroidism, diabetes, occult malignancy, heart failure, chronic kidney disease, COPD, obstructive sleep apnoea, polymyalgia rheumatica, depression, sarcopenia and frailty, undernutrition, and — above all — drug adverse effects** from beta blockers, opioids, antihistamines, benzodiazepines, antidepressants, statins and antihypertensives.
8. **The particular problem in older adults. ME/CFS characteristically begins between 20 and 50 and a new diagnosis after 65 should be made only with great caution**, because in that age group fatigue is far more likely to be the presenting feature of **occult disease, polypharmacy, depression or frailty**. In geriatric practice fatigue is therefore treated as a **syndrome requiring evaluation, not a diagnosis**. Where CFS/ME *is* genuinely present in an older person, it is usually **long-standing disease carried into later life**, in which case the clinical task is managing the **interaction of ME/CFS with accumulating comorbidity, deconditioning, sarcopenia and falls risk**. In the related and better-studied model of **cancer-related fatigue**, the textbook approach is instructive: it is a **multicomponent disturbance of neuroendocrine regulation and cytokine signalling**, and management begins with **a review of associated symptoms — pain, insomnia, depression — and a complete evaluation of possible medication side effects**, since fatigue-inducing drugs are so often the cause.
9. **Course and prognosis.** The course is **fluctuating, with relapses and remissions**, typically punctuated by PEM-driven "crashes". Onset may be **abrupt and post-infectious** or **insidious**. Prognosis is **generally poor for full recovery in adults**: **full recovery occurs in roughly 5–10%**, some degree of improvement in about **40%**, and the

remainder run a **chronic, fluctuating course**; children and adolescents do considerably better. **Favourable prognostic factors**: shorter duration before diagnosis, milder illness, absence of comorbid psychiatric disorder, a clear infective trigger, younger age, and good social and family support. **Adverse factors**: long duration, severe or bedbound disease, older age, comorbid depression or anxiety, chronic pain, ongoing pursuit of a purely psychological explanation, and — importantly — **iatrogenic deterioration from enforced exercise**. Mortality is not directly increased, but there is **excess suicide risk** in the severely affected, and profound impairment of quality of life.

10. **Treatment — there is no cure; management is supportive, individualised and multidisciplinary. (a) Energy management ("pacing")** is the cornerstone: the patient **establishes an individual "energy envelope" and stays within it, planning and prioritising activity and building in rest, rather than pushing through symptoms**. **(b) Sleep management** — sleep hygiene, treatment of a reversed sleep-wake cycle, and screening for obstructive sleep apnoea, without hypnotics where possible. **(c) Symptom-directed treatment** — analgesia for pain following the analgesic ladder with attention to constipation and delirium risk in the old; **low-dose amitriptyline or duloxetine** for pain and sleep; **increased fluid and salt, compression garments, and slow positional change** for orthostatic intolerance, with fludrocortisone or midodrine reserved for specialist use; management of irritable bowel symptoms; and treatment of coexisting depression or anxiety, which is a comorbidity to be treated in its own right and **not an explanation of the illness**. **(d) Psychological support** — **cognitive behavioural therapy may be offered as an adjunct to support coping and reduce the distress of chronic illness, but it is not a cure and must not be offered as one**. **(e) Rehabilitation and social care** — physiotherapy aimed at **maintaining, not increasing, function**; occupational therapy, aids, adaptations, home care, disability certification and carer support. **(f) Ruthless deprescribing** of fatigue-inducing drugs, and correction of anaemia, thyroid disease and nutritional deficiency. In the specific setting of **cancer-related fatigue**, where a pharmacological trial is contemplated, **methylphenidate is the best-studied agent and the usual first choice, with close monitoring**, although trials show a marked placebo response and benefit largely confined to those with severe fatigue.

Criterion set	Duration	Core requirements
Fukuda / CDC 1994	6 months	Unexplained persistent fatigue causing substantial reduction in activity, **plus 4 of 8** minor criteria
IOM / NAM 2015	6 months	**All 3**: activity reduction with profound fatigue · **post-exertional malaise** · unrefreshing sleep — **plus 1 of**: cognitive impairment *or* orthostatic intolerance
NICE NG206 (2021)	**3 months**	**All 4**: debilitating fatigue worsened by activity · **post-exertional malaise (mandatory)** · unrefreshing sleep or sleep disturbance · **cognitive difficulties**

LATEST UPDATES (2023–PRESENT) — 2 POINTS

11. **NICE NG206 reversed the previous standard of care, and the reversal has held.** The changes are the most examinable content in this topic. **Post-exertional malaise is now recognised as a core symptom and must be present for the diagnosis. ME/CFS can be confirmed after 3 months of symptoms rather than 4–6**, balanced by **baseline investigations to exclude alternative diagnoses and regular follow-up investigation to capture new or missed diagnoses. Graded exercise therapy is no longer recommended and should not be offered as a treatment for ME/CFS; people with ME/CFS should aim to remain within their energy limit and should not push through symptoms to complete tasks. Cognitive behavioural therapy is no longer considered a treatment for ME/CFS itself and should be used only as an adjunct** — the guideline states explicitly that CBT **"is not a cure for ME/CFS and should not be offered as such"**, but aims to improve wellbeing and quality of life and to reduce the distress of living with a chronic illness. **Individualised care should be provided by a multidisciplinary team.** The evidence base for graded exercise has continued to be criticised through 2025 for reliance on subjective self-report, poor recording of adverse effects, and biological data showing distinct immune and metabolic abnormalities in patients with PEM, which suggest that exercise may worsen symptoms.
12. **Long COVID has transformed the epidemiology and the research landscape.** A substantial proportion of people with long COVID meet ME/CFS criteria, so **prevalence has risen sharply** and the two conditions now share diagnostic and management pathways — **pacing and energy management have been adopted in long-COVID rehabilitation precisely because of the ME/CFS experience with graded exercise**. Two caveats to state for balance. First, **NICE itself notes that NG206 should not be assumed to apply to post-COVID-19 syndrome**, since its evidence was reviewed before the pandemic. Second, the relationship is not identical: in a comparative study, **self-reported PEM was common in long COVID (67% of one questionnaire cohort), but objectively observed PEM after standardised cardiopulmonary exercise testing was infrequent, and when present was less severe and less prolonged than in ME/CFS**. The practical geriatric implication is that **older adults with post-COVID fatigue should be assessed for PEM specifically**, since its presence dictates a pacing-based rather than a reconditioning-based rehabilitation plan — and getting this wrong causes harm.

CURRENT PRACTICE UPDATE

Aspect	Older teaching	Current recommendation (NICE NG206)
Graded exercise therapy	First-line evidence-based treatment	**Should not be offered** — risk of harm through PEM
Cognitive behavioural therapy	Curative treatment addressing illness beliefs	**Adjunct only**; explicitly "not a cure"
Duration for diagnosis	6 months (Fukuda)	**3 months**, with investigation to exclude mimics
Post-exertional malaise	One of eight minor criteria	**Mandatory core symptom**
Activity advice	Push through, increase gradually	**Stay within the energy envelope; do not push through**

Exam approach: Give Fukuda and IOM criteria for completeness, then state the NICE 2021 reversal explicitly. An answer that still recommends graded exercise therapy as first-line treatment reads as a decade out of date.

MEMORY ANCHORS & ESSAY SKELETON

Skeleton (15 marks, six blocks): (1) Define, name the three synonyms. (2) Criteria — Fukuda, IOM, NICE, in a table. (3) Clinical manifestations by system, and the severity spectrum. (4) Predisposing / precipitating / perpetuating factors, plus proposed mechanisms. (5) Diagnosis of exclusion — investigations and the wide geriatric differential; the caution about diagnosing it de novo after 65. (6) Course, prognosis with numbers, and treatment centred on pacing. Close with NICE NG206 and long COVID.

Mnemonic for the IOM criteria — "FUME + 1": Fatigue with activity reduction · **U**nrefreshing sleep · **M**alaise post-exertional · **E**verything for 6 months — **plus one** of cognitive impairment or orthostatic intolerance.

Numbers: 6 months (Fukuda, IOM) versus **3** months (NICE) · **4 of 8** Fukuda minor criteria · PEM lasting **>24 hours** · female:male **2–4:1** · onset typically **20–50 years** · **25%** severely affected · full recovery **5–10%**, improvement **~40%** · self-reported PEM in long COVID **67%**.

EXAMINER TRAPS

- Diagnosing chronic fatigue syndrome **de novo in a 75-year-old**. In geriatrics, new fatigue is **occult disease, drugs, depression or frailty until proven otherwise**. Say this explicitly — it is the geriatric marking point.
- Recommending **graded exercise therapy** as first-line treatment. This is now specifically advised against.
- Presenting CBT as **curative**, or implying the illness is psychological. Both lose marks and, in practice, lose the patient.
- Confusing **post-exertional malaise** with ordinary tiredness after exertion. The delay, the disproportion and the prolonged recovery define it.
- Ordering an exhaustive, expensive battery of tests. **Investigations exclude mimics; there is no confirmatory test.**
- Omitting the **medication review** — the single most productive intervention in an older patient with fatigue.

Night-Before Master Sheet — All 36 Questions

One row per question. Left column = the line that must appear in your answer. Right column = the current-evidence line that lifts it above a pass.

PART I — RENAL PHYSIOLOGY AND ASSESSMENT

Question	Must-write core	Update to quote
1 GFR	Peak **140** in the third decade, **−8 mL/min/1.73 m² per decade**; creatinine 1 mg/dL = GFR 120 at age 20 but **60 at age 80**; **Cockcroft–Gault for drug dosing**; one-third of older adults show no decline	**KDIGO 2024**: race-free **eGFRcr-cys** preferred, especially where creatinine is unreliable; point-of-care testing where labs are scarce
2 Renal biopsy	Same indications as the young, but **complications more serious**; nephrotic syndrome = **50% of biopsies**; crescentic GN peaks at 60–79	Biopsy-free membranous diagnosis if anti-PLA2R positive with normal function — but biopsy the atypical elderly, since amyloid coexists

PART II — FLUID, ELECTROLYTE AND ACID–BASE DISORDERS

Question	Must-write core	Update to quote
3 Fluid & electrolytes	Lead with ageing physiology: blunted thirst, concentrating **−30 mOsm/kg per decade**, free water clearance **5.9 vs 16.2 mL/min**, salt and urea wasting, hypoaldosteronism. **Hypovolaemia is always pathological in the old**	Correction cap **8–10 mEq/24 h** with DDAVP re-lowering; empagliflozin for SIAD; potassium binders before stopping RASi
4 Hyponatraemia	Serum osm → urine osm (**100**) → urine Na (**20 / 30–40**) → volume status. **Cognitive impairment even with mild hyponatraemia**	Cap **8–10 mEq/24 h** (6–8 if high risk); active re-lowering; beware **autocorrection** once the thiazide stops
5 SIADH	Four features: high urine osm, continued natriuresis, **euvolaemia**, normal renal/adrenal/thyroid. **Low uric acid**. Exclude **cerebral salt wasting**	**Empagliflozin 25 mg** raised Na by **4.1 mEq/L** in chronic SIAD; urea preferred over vaptans; deprescribing the SSRI is definitive
6 K^+ and Mg^{2+}	**Correct magnesium before potassium** (ROMK unblocking); never IV potassium in dextrose; U waves vs torsades	Deprescribe the **PPI** rather than escalate magnesium; SGLT2i incidentally raise serum magnesium
7 Potassium 5.7	**Not an emergency without ECG change.** Repeat the sample, ECG, drug review, **salt substitute**, bicarbonate for **type 4 RTA**	**KDIGO 2024**: binder *before* reducing RASi; SZC/patiromer; resonium removed from acute algorithms
8 Hypercalcaemia	Correct for albumin (**+0.8 per 1 g/dL**) → **measure PTH** → branch. Saline + **zoledronate 4 mg / pamidronate 90 mg**; calcitonin for speed (2–4 h vs 72 h)	**Endocrine Society**: **denosumab preferred to IV bisphosphonate** first-line in malignancy; combine with calcitonin if severe
9 Metabolic acidosis	**Albumin-corrected anion gap** → GOLD MARK vs urine anion gap; **type 4 RTA** in the older diabetic; Winter's formula	Keep serum bicarbonate **≥22 mEq/L** in CKD; veverimer failed VALOR-CKD, so bicarbonate remains standard

PART III — KIDNEY DISEASE

Question	Must-write core	Update to quote
10 AKI	Prerenal and postrenal are **reversible** — dehydration and the prostate. **FENa unreliable in the old.** No recovery by **3 months** = CKD	Balanced crystalloid; **STARRT-AKI** — no benefit from early dialysis; AKI alerts, nephrotoxin stewardship, post-AKI follow-up
11 CKD	Six mechanisms of progression (**HUP–PEP**); distinguish **senile hypofiltration**; conservative kidney management is an **active six-component pathway**	**KDIGO 2024**: eGFRcr-cys, KFRE risk equation, **SGLT2i regardless of diabetes**, statin for all over 50
12 Starting RRT	**AEIOU** for urgent dialysis; symptom-driven at eGFR 5–10; access at 15–20; **frailty and dependency, not age**, predict outcome	**PMNDP + AB-PMJAY + Ayushman Vay Vandana Card**; conservative kidney management as an explicit third option
13 PD vs HD	Survival **similar**; PD for cardiovascular instability and residual diuresis; median HD survival **15.6 and 11.6 months**; withdrawal **38%** of deaths	Shared decision-making across three pathways; assisted/home PD expanding in India under the national dialysis programme
14 Acute GN	Crescentic GN peaks at **60–79**; **renal vasculitis is the commonest primary cause of renal failure in the old**; **red cell casts**	**KDIGO AAV**: rituximab preferred in older adults; reduced-dose steroid taper; **avacopan** for steroid sparing
15 Nephrotic / membranous	Membranous is commonest; **20% secondary to malignancy** (lung, colon); highest thrombosis risk of the primary glomerular diseases	KDIGO: anti-PLA2R positive + normal function = no biopsy; **rituximab first-line** in moderate/high risk
16 Interstitial nephritis	Delayed hypersensitivity to **NSAIDs, diuretics, PPIs**; triad in **<10%**; **stopping the drug is the treatment**; steroids early	**Checkpoint-inhibitor AIN** — longer latency, no eosinophilia; steroid delay beyond 2 weeks predicts incomplete recovery
17 Diabetic nephropathy	**Mogensen I–V**; suspect non-diabetic disease if **no retinopathy**; RASi with creatinine rise **≤30%** acceptable	**FLOW 2024**: semaglutide ↓ kidney events **24%**; four-pillar therapy — RASi + SGLT2i + finerenone + GLP-1 RA

PART IV — DIABETES MELLITUS

Question	Must-write core	Update to quote
18 New diabetic, HbA1c 10%	**Dual therapy from the outset**: metformin + **GLP-1 RA** (weight, ASCVD, knee OA) or SGLT2i; **avoid sulphonylurea and pioglitazone**; ACEi/ARB + statin	**ADA 2026**: organ protection independent of HbA1c; obesity as a treatment target; tirzepatide; watch lean mass
19 SGLT2i / GLP-1 RA	No intrinsic hypoglycaemia; watch **volume depletion, genital infection, sarcopenia**; SGLT2i down to eGFR 20	**FLOW**: **24 / 18 / 20** (kidney / MACE / death); ADA 2026 — treat the organ, not the HbA1c
20 Alpha-glucosidase inhibitors	Block brush-border α-glucosidase → ↓ postprandial glucose; **treat hypoglycaemia with GLUCOSE, never sucrose**	Displaced internationally (no CV benefit, ACE trial) but retain an **Indian niche** for postprandial control and cost
21 Newer insulins	**Degludec and glargine U300** = flattest, least nocturnal hypoglycaemia; match the regimen to **coping ability**, not physiology	**Insulin icodec** once weekly — approved for type 2, **not** type 1 (ONWARDS 6 hypoglycaemia)

Question	Must-write core	Update to quote
22 Hypoglycaemia	Levels **70 / 54 / assistance**; **blunted autonomic warning**; presents as **falls and delirium**; sulphonylurea overdose needs 24–48 h observation	**ADA 2026**: CGM for older adults on insulin; annual screening for geriatric syndromes, hypoglycaemia and polypharmacy
23 DKA / HHS	**Fluids → Insulin → Potassium**; HHS = older type 2, higher mortality, slower correction; insulin 0.1 vs 0.05 units/kg/h	**ADA/EASD 2024**: glucose **≥200**, β-OHB **≥3.0**, pH <7.3; **anion gap removed**; euglycaemic DKA on SGLT2i
24 Diabetic foot	Neuropathy + PAD + pressure + limited joint mobility; **70%** of amputations follow an ulcer; **50%** three-year survival after amputation	**IWGDF 2023**: SINBAD for communication and audit; **non-removable knee-high offloading (total contact cast)** first choice

PART V — THYROID DISEASE

Question	Must-write core	Update to quote
25 Subclinical hypothyroidism	Treat if **TSH >10**; individualise 4.5–10; **in the oldest old it is harmless or possibly protective**; higher TSH target **6–7**	**TRUST**: 737 patients over 65 — TSH fell, but **no symptomatic, cognitive or functional benefit**
26 TSH 50 + heart failure	**Start 12.5–25 µg, titrate every 6–8 weeks**; empty stomach, 4 h from calcium/iron/PPI; lifelong; report chest pain. **The "heart failure" may be the myxoedema**	Age-adjusted TSH target (upper half of range); **no T3 or combination therapy**; amiodarone need not be stopped
27 Hashimoto's	**Commonest cause of hypothyroidism in old age**; ageing → fewer T-suppressor cells, more autoantibodies; **rapidly enlarging gland = lymphoma**	**Checkpoint-inhibitor thyroiditis**; selenium not recommended; antibodies justify surveillance, not treatment
28 Hyperthyroidism	**Apathetic, paucisymptomatic, atrial fibrillation, no goitre in one-third**; **^{131}I is the treatment of choice**; accept hypothyroidism as the planned outcome	ATA: **long-term low-dose antithyroid drugs now accepted**; 2025 network meta-analysis of the three modalities
29 Thyroid nodule	**95% benign**; risk equal for solitary and multinodular; **first test = TSH**; hot = no FNAB; **never suppress with levothyroxine**	Benign nodules rarely grow — ultrasound at 12 months then 2–5 yearly; active surveillance of low-risk microcarcinoma

PART VI — ENDOCRINE AND METABOLIC BONE DISEASE

Question	Must-write core	Update to quote
30 Testosterone	**Andropause does not exist**; treat only symptomatic, biochemically confirmed low T; target **300–400 ng/dL**; monitor haematocrit and PSA	**TRAVERSE 2023**: MACE non-inferior, but more atrial fibrillation, VTE, AKI and **fractures**
31 Osteomalacia	Low Ca + low PO_4 + **high ALP** + high PTH; bone pain with **proximal myopathy**; **Looser's zones**; replete before any bisphosphonate	**Endocrine Society 2024**: empiric vitamin D for all aged **≥75**; against routine 25(OH)D testing in the healthy; VITAL caveat

PART VII — CRYSTAL ARTHROPATHY

Question	Must-write core	Update to quote
32 Acute podagra	**Aspirate — needle-shaped, negatively birefringent; exclude sepsis.** Urate is often normal in the attack. Choose the drug by comorbidity. **Don't start ULT — but don't stop it either**	ACR: **ULT may be started during a flare under anti-inflammatory cover**; HLA-B*5801 testing in those of Southeast Asian descent
33 Management of gout	**Allopurinol first-line, preferred over probenecid in the elderly**; start low, titrate every 2–5 weeks; **target urate <6 mg/dL**; prophylaxis 3–6 months	**Treat-to-target** is the central shift; **STOP-Gout** — allopurinol non-inferior to febuxostat when properly titrated
34 Pseudogout	**Rhomboid, weakly positively birefringent**; knee and wrist; the **5 Hs**; **no crystal-lowering therapy exists**; aspiration alone is often therapeutic	**ACR/EULAR 2023 classification criteria**; ultrasound validated; anakinra when NSAIDs, colchicine and steroids are all contraindicated

PART VIII — ENVIRONMENTAL AND SYSTEMIC DISORDERS

Question	Must-write core	Update to quote
35 Heat stroke	Core **>40°C + CNS dysfunction**; mortality up to **80%**; **cool first, transport second**; immersion beats fanning; **no antipyretics, no dantrolene**	**SCCM 2025**: target **<39°C in 30 minutes**, rate ≥0.155°C/min; **NCDC India March 2024** cooling protocol; NDMA Heat Action Plans
36 Chronic fatigue syndrome	**Post-exertional malaise is the cardinal feature**; a diagnosis of exclusion; **pacing within the energy envelope**; full recovery only 5–10%	**NICE NG206**: PEM mandatory, 3-month diagnosis, **graded exercise therapy NOT recommended**, CBT adjunct only

Cross-Cutting Principles and Indian Context

SIX THREADS THAT RUN THROUGH EVERY ANSWER IN THIS BANK

1. **The ageing kidney and the ageing endocrine system explain most of this syllabus.** Blunted thirst, impaired urinary concentration and dilution, salt and urea wasting, hypoaldosteronism, poor acid handling, reduced receptor and post-receptor responsiveness. Open almost any answer with one line of that physiology and the clinical features follow logically.
2. **Atypical presentation is the geriatric signature.** Hypoglycaemia, HHS, hyponatraemia, hypercalcaemia, hypokalaemia, osteomalacia, pseudogout, thyrotoxicosis and heat stroke all present as **falls, delirium, immobility or "just ageing"** rather than as textbook syndromes. Say this once in every answer.
3. **Creatinine lies, and so does HbA1c.** Sarcopenia plus net tubular reabsorption means a normal creatinine can conceal a halved GFR; anaemia, CKD and transfusion make HbA1c falsely low. Dose every drug to the estimated GFR, and use glucose profiles or CGM where HbA1c is unreliable.
4. **Deprescribing is treatment, not the absence of it.** The thiazide in hyponatraemia and gout, the NSAID or PPI in interstitial nephritis and hypomagnesaemia, the SSRI in SIADH, the salt substitute in hyperkalaemia, the sulphonylurea in hypoglycaemia, the unnecessary levothyroxine — successfully withdrawn from half of the nursing-home residents studied.
5. **Start low, go slow, and accept an imperfect target.** Levothyroxine 12.5–25 µg, allopurinol under 100 mg, acarbose 25 mg, HbA1c 7–8%, TSH 6–7, sodium correction ≤8–10 mEq per 24 hours. The old are harmed by aggressive normalisation, and correction speed punishes more often than the number itself.
6. **Function and frailty, not chronological age, drive every decision** — renal biopsy, immunosuppression, dialysis modality, transplantation, thyroid surgery, testosterone therapy and glycaemic targets alike. Age is never, on its own, a contraindication.

INDIAN CONTEXT — READY-TO-USE LINES FOR ANY ANSWER

Programme / framework	What to write
NPHCE	National Programme for the Health Care of the Elderly — geriatric clinics, Regional Geriatric Centres, district geriatric units
NPCDCS	Opportunistic screening for diabetes and hypertension at health and wellness centres; the entry point for early CKD and diabetic foot detection
PMNDP	Pradhan Mantri National Dialysis Programme — free district-level haemodialysis in PPP mode, with policy expansion of peritoneal dialysis
AB-PMJAY / Ayushman Vay Vandana Card	Dialysis and hospital packages; the Vay Vandana Card covers **all citizens aged 70 and above irrespective of income**
NDMA Heat Action Plans · NCDC/NPCCHH	Ahmedabad HAP as the national model; NCDC "Emergency Cooling for Severe Heat-Related Illnesses" (March 2024), including improvised immersion using a body bag or tarpaulin; ambulance **108**
ICMR-NIN	Dietary reference values, calcium and vitamin D intake, and food-fortification policy — the pragmatic alternative to population-wide 25(OH)D testing
ADIP–ALIMCO · Rashtriya Vayoshri Yojana	Assistive devices including therapeutic footwear for the diabetic foot
Disease-specific Indian points	**CKD of unknown aetiology (CKDu)** in the agricultural belts of Andhra Pradesh, Odisha and Tamil Nadu · **tuberculosis** as a granulomatous cause of hypercalcaemia and a pulmonary cause of SIADH · **iodine-deficient regions** making toxic nodular goitre relatively commoner than Graves' disease · **potassium-containing "low-sodium salt"** and **aristolochic acid** in herbal preparations · **barefoot walking** as a diabetic-foot risk · **high-carbohydrate diets** justifying voglibose and acarbose · cheap **generic empagliflozin and dapagliflozin** against costly GLP-1 receptor agonists · **HLA-B*5801** in about 7% of those of Southeast Asian descent · **Kerala's community palliative care network** as the model for conservative kidney management

MD GERIATRIC MEDICINE

Consolidated Examination Answer Bank

Cardiovascular System · Respiratory Medicine & Sleep

54 Questions | 15-Mark Essays, 7-Mark and 6-Mark Notes

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (2022); Essentials of Clinical Geriatrics, 7th edition.

Answer architecture. 15-mark = **10 textbook points + 2 latest updates** (12 total). 7-mark = **6 textbook points + 1 latest update** (7 total). 6-mark = **5 textbook points + 1 latest update** (6 total). No point count is exceeded anywhere.

Structure of each answer. High-yield numbered points with bolded keywords → **Latest Updates** panel (2023–present, inline citation only) → **Current Practice Update** table wherever the textbook has been meaningfully superseded. Textbook content and current evidence are kept clearly separated throughout.

Latest evidence. 2025 AHA/ACC hypertension guideline; 2024 ESC atrial fibrillation and hypertension guidelines; 2023 ESC ACS, endocarditis, cardiomyopathy and heart failure updates; 2023 HRS physiologic pacing; 2024 ACC/AHA PAD; GOLD 2025–26; GINA 2025; BTS 2023; ATS/ERS/JRS/ALAT 2022; ACIP 2024; AASM and AGS Beers 2023; WHO EML 2023; and NEJM, Lancet, JAMA and Circulation trials to 2026.

Compilation note. This volume consolidates three separately compiled sets (Topics 25–36, 61–85 and 86–102) into a single continuously numbered document, reorganised by organ system and clinical theme. All source questions were distinct on review; no answer content has been abridged.

Table of Contents

PART I — CARDIOVASCULAR SYSTEM

A. Heart Failure and the Cardiorenal Axis

1. Chronic and congestive cardiac failure — aetiology, clinical features and management, including in an 85-year-old lady 5
2. Management of refractory heart failure 6
3. Role of beta blockers in heart failure 7
4. Diastolic dysfunction — clinical presentation, diagnosis and treatment options 8
5. Case — 70-year-old man in cardiac failure with hypotension and tachypnoea: pathophysiology, differentials, investigations, and management in the ED, ward and after discharge 10
6. Cardiorenal syndrome 12

B. Ischaemic Heart Disease and Atherosclerosis

7. Unstable angina — clinical features, evaluation and management 13
8. Uses and limitations of the electrocardiogram in acute coronary syndromes 15
9. Case — advice to a 65-year-old man with diabetes, hypertension, dyslipidaemia and BMI 35, seen in clinic after two coronary stents 16
10. Drug-eluting stents and in-stent restenosis 17
11. Statins in the very old — primary and secondary prevention 18
12. Atherosclerosis and the biomarkers associated with it 19

C. Hypertension and Blood Pressure Disorders

13. Management of hypertension in a 65-year-old with dyslipidaemia and coronary artery disease 20
14. Stages of hypertension according to JNC 8, and the JNC 8 target blood pressure in people over 60 22
15. Accelerated hypertension 23
16. Isolated systolic hypertension — cut-off value, treatment and prognosis 24
17. Postural hypotension in the elderly — evaluation and management 25

D. Valvular and Myocardial Disease

18. Aortic stenosis — clinical presentation, diagnosis and management 27
19. Aortic sclerosis 28
20. Mitral regurgitation in the elderly 29
21. Infective endocarditis in the elderly 30
22. Cardiomyopathies — classification and management 31

E. Arrhythmias and Cardiac Pacing

23. Complete heart block and pacemaker indications 32
24. Sick sinus syndrome 33
25. Atrial fibrillation 34
26. CHA2DS2-VASc and HAS-BLED scores in atrial fibrillation 35
27. Tachyarrhythmias 36

F. Syncope, Falls and Autonomic Disorders

28. Head-up tilt test — indication, procedure and interpretation 37
29. Syncope — aetiology, pathogenesis, differential diagnosis and management 39
30. Drop attacks 41

G. Vascular Disease, Thrombosis and Prevention

31. Ankle brachial index and toe pressures — indications, assessment and interpretation 42
32. Direct oral anticoagulants — choice, dosing and reversal 44
33. Deep vein thrombosis — prophylaxis and treatment 44
34. Polypill 45

PART II — RESPIRATORY MEDICINE AND SLEEP

H. Respiratory Infection

35. What is community-acquired pneumonia? Etiopathogenesis, diagnosis and management 47
36. Pneumonia in the elderly 48
37. Hospital-acquired pneumonia 49
38. Case — 67-year-old man with cough, purulent expectoration, fever, tachypnoea, tachycardia and hypotension 50

I. Obstructive Airway Disease and Inhaled Therapy

39. Management of chronic obstructive airway disease 51
40. Asthma management based on GINA guidelines 52

41. Senile emphysema 53
42. Metered dose inhalers and inhaler technique in the older adult 54

J. Parenchymal and Pleural Disease

43. Diffuse parenchymal lung disease in older adults 55
44. Pleural effusion in a 70-year-old — etiopathogenesis, features, differential diagnosis, approach and management 57

K. Respiratory Failure and Critical Care

45. Respiratory failure, including acute type 2 respiratory failure 59
46. Management of ARDS 60
47. Long-term oxygen therapy and home non-invasive ventilation 61

L. Pulmonary Vascular Disease

48. Pulmonary embolism 62
49. Chronic pulmonary thromboembolism (CTEPD / CTEPH) 63

M. Thoracic Oncology

50. Bronchogenic carcinoma — types and management 64
51. Case — solitary pulmonary nodule on chest X-ray in a 30 pack-year smoker with cough 65

N. Sleep Medicine

52. Obstructive sleep apnoea — features, comorbidities, tests, management and prognosis 67
53. Sleep problems in the elderly, and the approach to insomnia in a 65-year-old recently retired professional 67
54. REM sleep behaviour disorder 69

PART I

CARDIOVASCULAR SYSTEM

Questions 1 – 34 · 34 questions · 7 sections

A. Heart Failure and the Cardiorenal Axis

Question 1. Chronic and congestive cardiac failure — aetiology, clinical features and management, including in an 85-year-old lady

15-Mark Essay | 10 textbook points + 2 latest updates | ***Asked ×2***

Textbook Core – 10 Points

1. **Definition and classification.** Heart failure is a **clinical syndrome in which the heart is unable to deliver an output adequate for the metabolic needs of the tissues, or can do so only at raised filling pressures**. Classify by ejection fraction — **HFrEF (LVEF ≤ 40%), HFmrEF (41–49%) and HFpEF (≥ 50%)**; and by **NYHA class I–IV**. **In older patients, diastolic dysfunction rather than systolic dysfunction is the primary cause of heart failure, and it carries a marked increase in all-cause mortality.**
2. **Aetiology. More than 75% of overt heart failure in older patients is associated with hypertension or coronary heart disease.** Other causes: **degenerative calcific aortic stenosis and mitral annular calcification, atrial fibrillation, cardiomyopathy (including wild-type transthyretin amyloidosis), thyroid disease, anaemia, chronic kidney disease and cor pulmonale**. In India also consider **rheumatic valve disease**. Common **precipitants** of decompensation: infection, arrhythmia (especially new AF), myocardial ischaemia, non-adherence, high salt or fluid intake, anaemia, thyroid dysfunction, and drugs — **NSAIDs, corticosteroids, thiazolidinediones, non-dihydropyridine calcium channel blockers and negatively inotropic agents**.
3. **Why ageing predisposes.** Ageing produces **reduced β-adrenergic responsiveness with a blunted heart rate response, arterial stiffening with increased afterload, and cardiac hypertrophy**. There is **retarded left ventricular filling and a higher left ventricular diastolic pressure both at rest and on exercise**. Crucially, **older people depend more on atrial contraction than on ventricular relaxation for left ventricular filling, and are therefore more likely to develop heart failure when atrial fibrillation supervenes**. Because myocardial reserve is already used up to maintain normal resting function, **older people decompensate readily when disease is superimposed**.
4. **Clinical features. Exertional dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, fatigue and reduced exercise tolerance**; signs of congestion — **raised JVP, basal crackles, third heart sound, cardiac enlargement, hepatomegaly and peripheral oedema**. In older patients the presentation is frequently **atypical — confusion or delirium, falls, anorexia, weight loss, nocturia, functional decline or simply "off legs"**. **Heart failure is often OVER-diagnosed in older adults: pedal and pretibial oedema alone is NOT sufficient for the diagnosis, since venous stasis produces an identical picture.** Look for the other objective signs before accepting the diagnosis.
5. **Investigations. Echocardiography determines the ejection fraction and is the key test** — NICE recommends echocardiography as the initial test in those with a previous myocardial infarction, and **natriuretic peptide (BNP or NT-proBNP)** measurement in those without. Note that **natriuretic peptides rise with age, renal impairment and atrial fibrillation, and are lowered by obesity**, so interpret with care. Add **ECG** (a completely normal ECG makes heart failure unlikely), **chest radiograph**, **full blood count, urea and electrolytes, creatinine, liver and thyroid function, glucose, HbA1c, iron studies and ferritin**. Consider **cardiac MRI or bone scintigraphy** if amyloidosis is suspected. **Specialist assessment should be considered in all.**
6. **Non-pharmacological management. Patient and carer education, daily weight monitoring with an action plan, salt and fluid moderation, smoking cessation and alcohol limitation**. **Supervised exercise training and cardiac rehabilitation** improve symptoms and quality of life at any age. Give **influenza, pneumococcal and COVID-19 vaccination**. Treat the comorbidities that drive decompensation — **hypertension, coronary artery disease, atrial fibrillation, diabetes, anaemia and iron deficiency, sleep apnoea, thyroid disease and depression**. **Multidisciplinary heart failure nurse-led follow-up reduces readmission.**
7. **Disease-modifying drugs for HFrEF.** The mainstays for systolic dysfunction in older as in younger patients are **diuretics for fluid overload, ACE inhibitors or ARBs, beta-blockers and aldosterone blockers**. **All patients with chronic symptomatic heart failure with reduced ejection fraction or left ventricular remodelling should receive an ACE inhibitor** to improve function and survival; **beta-blockers improve symptoms and survival**. **Low-dose spironolactone 12.5–50 mg reduced morbidity and mortality by 30% in NYHA class III–IV (RALES)**, with gynaecomastia as a notable adverse effect; **eplerenone reduced mortality and hospitalisation in patients with mild symptoms (EMPHASIS-HF)**, with fewer side effects. **Subgroup analyses of both MRA trials showed equal benefit in younger and older patients.** Monitor electrolytes closely at initiation and periodically thereafter. **Sacubitril–valsartan (ARNI)** was superior to enalapril in PARADIGM-HF.

8. **Diuretics, digoxin and other agents. Loop diuretics (furosemide, bumetanide) are the mainstay of symptomatic treatment of fluid retention** and show some mortality benefit versus placebo; in resistant cases give them **intravenously or combine with a thiazide (sequential nephron blockade)**. **In older people monitor renal function, electrolytes and fluid status closely to avoid hypovolaemia, hypotension and falls. Digoxin** reduces hospitalisation and improves symptoms in HFrEF in sinus rhythm but does **not improve mortality (DIG trial)**; benefit was seen at all ages, with side effects comparable to placebo in older patients. **In those over 70, start and maintain at 0.125 mg daily to achieve a level of 0.5–0.9 ng/mL**, monitoring potassium and renal function; watch for **gastrointestinal upset, heart block, arrhythmia and confusion**, and consider discontinuation once the indication has passed. **Hydralazine plus isosorbide dinitrate** is recommended in self-declared Black patients and as an alternative when ACE inhibitors and ARBs cannot be used. **Ivabradine (SHIFT)** may be added for a persisting sinus rate ≥ 70/min.
9. **Device and advanced therapy.** If symptoms persist despite optimal medical therapy, **refer to a specialist and consider cardiac resynchronisation therapy with or without a defibrillator** in those with a wide QRS and reduced ejection fraction; pooled trial data show a **survival benefit from primary-prevention ICDs that persists in older patients**, and CRT benefits older adults. **Ventricular assist devices** have been used in selected older patients. **Every device decision in the very old must weigh life expectancy, frailty, cognition and the patient's own goals — and deactivation of ICD shocks must be discussed as part of end-of-life planning.**
10. **Management of the 85-year-old lady — the geriatric answer.** (i) **Confirm the diagnosis objectively** — do not rely on ankle oedema; obtain an echocardiogram, and expect **HFpEF from hypertension, atrial fibrillation or aortic stenosis** to be the likeliest substrate. (ii) **Assess frailty, cognition, function, nutrition, continence, falls risk and social support** by comprehensive geriatric assessment. (iii) **Start low and go slow**, introducing one drug at a time with careful uptitration and close monitoring of blood pressure, renal function and electrolytes. (iv) **Review the whole drug chart** — stop NSAIDs, minimise anticholinergic and sedative burden, and address polypharmacy. (v) **Anticipate diuretic-related harm** — postural hypotension, falls, incontinence precipitating immobility, acute kidney injury and hyponatraemia; time diuretics to protect sleep and toileting. (vi) **Prioritise symptom relief, independence and quality of life over prognostic benefit** where life expectancy is short; use the **time-to-benefit** principle before adding prognostic drugs. (vii) **Recognise the family burden** — heart failure imposes a significant burden on families, requires multifaceted care, and **caregiver physical and emotional health should itself be an outcome that is assessed**. (viii) **Undertake advance care planning early**, and involve palliative care for refractory breathlessness.

Latest Updates – 2 Points (2023–Present)

11. **Four-pillar therapy and rapid sequencing.** The **2022 AHA/ACC/HFSA guideline and the 2023 ESC focused update** establish four foundational drug classes for HFrEF — **ARNI (or ACE inhibitor/ARB), beta-blocker, mineralocorticoid receptor antagonist and SGLT2 inhibitor** — to be started **together at low dose and uptitrated within 4–6 weeks (the STRONG-HF strategy) rather than sequentially over months**. **SGLT2 inhibitors (dapagliflozin, empagliflozin) are now recommended across the whole ejection fraction spectrum**, including HFpEF (EMPEROR-Preserved, DELIVER), and are notably well tolerated in older adults with no need for dose titration.
12. **New options for HFpEF and HFmrEF, which is the dominant phenotype in the very old. FINEARTS-HF (NEJM 2024)** showed that **finerenone, a non-steroidal MRA, reduced worsening heart failure events and cardiovascular death in HFmrEF and HFpEF**, with less hyperkalaemia than spironolactone. **STEP-HFpEF (NEJM 2023)** showed that **semaglutide markedly improved symptoms, physical limitation and exercise function in obesity-related HFpEF**. Together these give the first genuinely disease-modifying options for a phenotype the textbook describes as having no proven drug therapy.

Current Practice Update

Textbook	ACE inhibitor, beta-blocker, MRA and diuretic for systolic failure; "few trials in diastolic heart failure — digoxin and ARBs show minimal benefit; treat comorbidities."
Current recommendation	Four-pillar therapy including an SGLT2 inhibitor for HFrEF, started together and rapidly uptitrated; SGLT2 inhibitors plus finerenone now have proven benefit in HFpEF/HFmrEF.
Exam approach	Write "four pillars — ARNI/ACEi, beta-blocker, MRA, SGLT2 inhibitor," then add "SGLT2 inhibitors and finerenone (FINEARTS-HF 2024) have made HFpEF a treatable condition."

Question 2. Management of refractory heart failure

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** Refractory (advanced or stage D) heart failure is **persistent severe symptoms at rest or on minimal exertion (NYHA class III–IV) despite optimal guideline-directed medical and device therapy**, with **objective severe cardiac dysfunction, recurrent hospitalisation or need for intravenous inotropes, and severely impaired exercise capacity**. Prognosis is poor — **one-year mortality approaches 50%**.
2. **Step 1 — confirm it is truly refractory.** Before labelling refractory failure, **verify the diagnosis and the ejection fraction, and exclude a reversible or under-treated cause**: **myocardial ischaemia, severe valve disease (especially aortic stenosis and mitral regurgitation), uncontrolled atrial fibrillation or other arrhythmia, anaemia and iron deficiency, thyroid dysfunction, infection, cardiac amyloidosis, sleep apnoea, chronic kidney disease and non-adherence**. Review the drug chart and **stop the aggravating drugs — NSAIDs, corticosteroids, thiazolidinediones, verapamil/diltiazem, class I antiarrhythmics and excessive negative inotropes**.
3. **Optimise and re-sequence medical therapy.** Ensure the patient is on **maximally tolerated four-pillar therapy**. If blood pressure limits uptitration, **reduce or stop non-prognostic vasodilators (nitrates, alpha-blockers, calcium channel blockers) first**. Add **digoxin** for symptom control and reduced hospitalisation, and **ivabradine** if the sinus rate remains ≥ 70/min. Consider **hydralazine plus isosorbide dinitrate** where ACE inhibitors or ARNIs are not tolerated. Correct **iron deficiency with intravenous ferric carboxymaltose**, which improves symptoms and reduces hospitalisation.
4. **Manage diuretic resistance.** This is the central practical problem. Steps: **restrict sodium and fluid**; **switch oral to intravenous loop diuretic** (bioavailability is unpredictable in gut oedema) as bolus or infusion; **double the dose rather than increase the frequency** (there is a threshold effect); add **sequential nephron blockade with a thiazide-type diuretic (metolazone or a thiazide) given 30 minutes before the loop diuretic**; add or continue an **MRA**; and consider **acetazolamide** or an **SGLT2 inhibitor** for additional natriuresis. **Monitor daily weight, strict fluid balance, renal function and electrolytes; a modest rise in creatinine during effective decongestion is acceptable and should not automatically stop treatment.** **Ultrafiltration** is reserved for genuinely diuretic-resistant congestion.
5. **Advanced therapies and referral.** Refer to a specialist heart failure service to consider: **cardiac resynchronisation therapy** if the QRS is broad; **revascularisation or valve intervention** (including TAVI or transcatheter edge-to-edge mitral repair) where indicated; **continuous intravenous inotropes (dobutamine, milrinone, levosimendan)** as a bridge or for palliation — these improve symptoms but **increase arrhythmia and mortality**; **left ventricular assist devices**, which have been used in older patients as destination therapy in carefully selected cases; and **cardiac transplantation**, which is essentially precluded by advanced age. **In the very old, the decision hinges on frailty, cognition, comorbidity and patient goals rather than on age alone.**
6. **Palliative care and end-of-life planning.** This is the highest-yield section for a geriatric examination. **Recognise the terminal phase** — repeated admissions, cachexia, hypotension limiting therapy, worsening renal function, refractory symptoms. Provide **opioids (low-dose morphine) for refractory breathlessness**, oxygen if hypoxaemic, treatment of anxiety and depression, and management of pain, nausea and constipation. Undertake **advance care planning, agree a ceiling of treatment and resuscitation status, and discuss ICD deactivation explicitly**. Simplify the drug regimen, **deprescribe drugs whose time-to-benefit exceeds life expectancy** (statins, some prognostic agents), continue diuretics for symptom relief, and support the **family and caregivers, whose physical and emotional health should be assessed as an outcome in their own right**.

Latest Update – 1 Point (2023–Present)

7. **Decongestion strategy has been sharpened by two randomised trials now embedded in the 2023 ESC focused update. ADVOR** showed that **adding intravenous acetazolamide 500 mg daily to loop diuretics significantly increased successful decongestion and reduced length of stay** in acute decompensated heart failure, and **CLOROTIC** showed that **adding hydrochlorothiazide to a loop diuretic improved weight loss and diuretic response**. Combined with the **STRONG-HF** strategy of rapid post-discharge uptitration with close follow-up (which reduced death and readmission), the modern approach to refractory congestion is **early combination diuretic therapy plus intensive early follow-up**, rather than escalating a loop diuretic alone.

Question 3. Role of beta blockers in heart failure

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Rationale and mechanism.** Chronic heart failure activates the **sympathetic nervous system**, which is initially compensatory but ultimately causes **myocyte toxicity and apoptosis, adverse remodelling, arrhythmia, down-regulation of β_1-receptors and renin–angiotensin–aldosterone activation**. Beta-blockers **antagonise this neurohormonal activation**, producing **reverse remodelling with improved ejection fraction, reduced heart rate with improved diastolic filling and coronary perfusion, reduced myocardial oxygen demand, and antiarrhythmic protection against sudden death**.
2. **Evidence and indication. Beta-blockers improve symptoms and survival and are a mainstay of therapy for heart failure due to systolic dysfunction in older as in younger patients.** They are indicated in **all patients with HFrEF (LVEF ≤ 40%) who are clinically stable and euvolaemic**, together with an ACE inhibitor/ARNI, an MRA and an SGLT2 inhibitor. Landmark trials: **CIBIS-II (bisoprolol), MERIT-HF (metoprolol succinate), COPERNICUS (carvedilol)** and **SENIORS (nebivolol, specifically in patients aged ≥ 70)**, which showed benefit in an elderly population.
3. **Which drugs.** Only four agents have proven mortality benefit in heart failure — **bisoprolol, carvedilol, metoprolol succinate (extended release) and nebivolol**. **The benefit is not a class effect**: atenolol and short-acting metoprolol tartrate are not substitutes. **Carvedilol** also has α-blocking and antioxidant activity and is preferred where blood pressure is well maintained; **bisoprolol and nebivolol are β_1-selective** and better tolerated in coexisting airways disease; **nebivolol** additionally has nitric-oxide-mediated vasodilation and the strongest specific evidence in the old.
4. **How to prescribe — "start low, go slow".** Begin only when the patient is **euvolaemic and not requiring intravenous inotropes**. **Start at a very low dose** (bisoprolol 1.25 mg daily, carvedilol 3.125 mg twice daily, nebivolol 1.25 mg daily) and **double at intervals of not less than two weeks to the maximum tolerated or target dose**, checking heart rate, blood pressure, weight and symptoms at each step. **Warn the patient that symptoms may transiently worsen in the first weeks**. If fluid retention occurs, **increase the diuretic rather than stopping the beta-blocker**. **Some beta-blocker is better than none — a low maintained dose is preferable to withdrawal.**
5. **Adverse effects and cautions in older adults. Bradycardia and heart block** (particularly with coexisting sinus node disease, digoxin, amiodarone or verapamil), **hypotension and falls**, **fatigue**, **worsening of heart failure during uptitration**, **cold peripheries and worsening claudication**, **masking of hypoglycaemia in insulin-treated diabetes**, sleep disturbance and vivid dreams, and depression. **Contraindications:** second- or third-degree heart block without a pacemaker, symptomatic bradycardia, severe hypotension, cardiogenic shock and decompensated fluid overload. **Asthma and COPD are no longer absolute contraindications — recent evidence reassures on the safety of cardioselective beta-blockers, and they should be used when required in asthmatic and COPD patients. Never withdraw abruptly**, as rebound ischaemia and arrhythmia may result.
6. **Where the evidence is weaker.** In **HFpEF**, beta-blockers have **no proven mortality benefit** and are used chiefly for **rate control in atrial fibrillation, angina or hypertension**; excessive bradycardia may actually be harmful by limiting the chronotropic reserve that older patients already lack. In **heart failure with atrial fibrillation**, meta-analysis suggests the mortality benefit is **attenuated compared with sinus rhythm**, though beta-blockers remain useful for rate control. Their role is also limited in **cardiac amyloidosis**, where they are usually poorly tolerated.

Latest Update – 1 Point (2023–Present)

7. **The indication for beta-blockade after myocardial infarction has narrowed sharply — but the heart failure indication is untouched. REDUCE-AMI (NEJM 2024)** found that in patients after acute myocardial infarction with a **preserved ejection fraction (LVEF ≥ 50%) and no heart failure, long-term beta-blockade gave no reduction in death or recurrent infarction**, and **ABYSS (2024)** found that interruption of beta-blockade after uncomplicated MI was not inferior for hard outcomes. The examinable message is that **beta-blockers remain mandatory disease-modifying therapy in HFrEF at every age**, but should **no longer be continued indefinitely purely for a remote myocardial infarction with normal ventricular function** — a useful deprescribing opportunity in the polypharmacy-burdened older patient.

Question 4. Diastolic dysfunction — clinical presentation, diagnosis and treatment options

7-Mark Answer | 6 textbook points + 1 latest update | ***Asked ×2***

Textbook Core – 6 Points

1. **Definition and mechanism.** Diastolic dysfunction is **retarded left ventricular filling with a higher left ventricular diastolic pressure**, **present both at rest and during exercise in older persons**. It arises from **impaired active relaxation and increased passive chamber stiffness**, caused by **myocardial hypertrophy, interstitial fibrosis, arterial stiffening with increased afterload, and impaired calcium handling**. The result is that **a small increase in volume produces a large rise in filling pressure**, causing pulmonary congestion at a normal ejection fraction. When symptomatic it is called **heart failure with preserved ejection fraction (HFpEF)**.

2. **Why it dominates in old age. Diastolic dysfunction, not systolic dysfunction, is the primary cause of heart failure in older patients, and is associated with marked increases in all-cause mortality.** Age-related hypertrophy and stiffening mean that **older people depend more on atrial contraction than on ventricular relaxation for left ventricular filling**; consequently **they are far more likely to develop heart failure if atrial fibrillation ensues**, since the atrial kick is lost and diastole is shortened. **Heart failure may therefore occur in the absence of systolic dysfunction or valvular disease.**
3. **Causes and associations. Hypertension with left ventricular hypertrophy is the commonest**. Others: **coronary artery disease and ischaemia, aortic stenosis, diabetes mellitus, obesity, chronic kidney disease, atrial fibrillation, obstructive sleep apnoea, hypertrophic cardiomyopathy** and **infiltrative disease — especially wild-type transthyretin cardiac amyloidosis**, which is a commonly missed cause in the very old. Constrictive pericarditis is an important mimic.
4. **Clinical presentation.** Symptoms are **indistinguishable from systolic failure — exertional dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, fatigue and reduced exercise tolerance**, with **raised JVP, basal crackles and peripheral oedema**. Distinguishing features: a **fourth heart sound (S4) rather than a third**, a **sustained apex beat**, a **predominance in elderly women with hypertension and obesity**, and **flash pulmonary oedema precipitated by hypertensive surges, tachycardia, atrial fibrillation, fluid or salt loading, or NSAIDs**. **The patient is exquisitely preload-dependent and decompensates in both directions — congestion with a little too much fluid, and hypotension with a little too much diuretic.**
5. **Diagnosis.** There are three requirements: **symptoms and signs of heart failure**, **a preserved ejection fraction (≥ 50%)**, and **objective evidence of raised filling pressures or diastolic dysfunction**. **Echocardiography is the key test** — look for **left ventricular hypertrophy with normal chamber size, left atrial enlargement (a marker of chronically raised filling pressure), a raised E/e′ ratio, reduced e′ tissue Doppler velocity, and an elevated tricuspid regurgitant velocity**. Support with **raised natriuretic peptides**, remembering that **BNP rises with age and renal impairment and is lowered by obesity** — so a normal level in an obese patient does not exclude HFpEF. Use the **H_2FPEF or HFA-PEFF score** where the diagnosis is uncertain, and **exercise (diastolic) stress echocardiography** for exertional symptoms with a normal resting study. Always **exclude constrictive pericarditis and cardiac amyloidosis**.
6. **Treatment.** The textbook position is that **few large randomised controlled trials of drug treatment in diastolic heart failure have been designed, and trials of digoxin and ARBs have shown minimal benefit** (CHARM-Preserved, I-PRESERVE, PEP-CHF and the ancillary DIG trial were all essentially neutral). Therefore: (i) **treat the comorbidities that drive it — hypertension, coronary artery disease, atrial fibrillation and diabetes mellitus**; (ii) use **diuretics to treat pulmonary congestion or peripheral oedema**, cautiously, since over-diuresis causes hypotension and renal impairment; (iii) use **beta-blockers to control heart rate** and lengthen diastolic filling time, and **restore or control rate in atrial fibrillation**; (iv) control **blood pressure** aggressively as the single most effective preventive measure; (v) encourage **weight loss, salt restriction and supervised exercise training**, which reliably improve exercise capacity and quality of life.

Latest Update – 1 Point (2023–Present)

7. **HFpEF is no longer an untreatable condition. SGLT2 inhibitors are now the first drug class with proven outcome benefit — EMPEROR-Preserved** and **DELIVER** showed that empagliflozin and dapagliflozin reduce cardiovascular death and heart failure hospitalisation across the preserved and mildly reduced ejection fraction range, and they are recommended for all such patients in the **2023 ESC focused update**. Building on this, **FINEARTS-HF (NEJM 2024)** showed that **finerenone reduces worsening heart failure events and cardiovascular death in HFmrEF and HFpEF**, and **STEP-HFpEF (NEJM 2023)** showed that **semaglutide produces large improvements in symptoms and exercise capacity in obesity-related HFpEF**. The examinable line is that the textbook statement "no proven drug therapy for diastolic heart failure" **is now out of date**.

Current Practice Update

Textbook	Few trials in diastolic heart failure; digoxin and ARBs show minimal benefit; treat comorbidities, use diuretics for congestion and beta-blockers for rate control.
Current recommendation	SGLT2 inhibitors are recommended for all patients with HFpEF/HFmrEF; finerenone (FINEARTS-HF) and semaglutide in obesity-related HFpEF (STEP-HFpEF) add further benefit.
Exam approach	Give the textbook management, then close with: "SGLT2 inhibitors (EMPEROR-Preserved, DELIVER) and finerenone (FINEARTS-HF 2024) are the first therapies with proven outcome benefit in HFpEF."

Question 5. Case — 70-year-old man in cardiac failure with hypotension and tachypnoea: pathophysiology, differentials, investigations, and management in the ED, ward and after discharge

15-Mark Essay | 10 textbook points + 2 latest updates

> **Recognise the syndrome in the first line:** heart failure **with hypotension** is **cardiogenic shock until proved otherwise** — this is the "cold and wet" haemodynamic profile, not simple acute pulmonary oedema. Marks are earned by naming the profile, giving a structured differential, and separating ED, ward and post-discharge care.

Textbook Core – 10 Points

1. **Underlying pathophysiology.** A primary **fall in cardiac output** (from pump failure, arrhythmia, valve failure or mechanical complication) causes **systemic hypoperfusion**. Compensatory **sympathetic activation and renin–angiotensin–aldosterone activation** raise heart rate and systemic vascular resistance, which **further increases afterload and myocardial oxygen demand while reducing coronary perfusion** — a **vicious spiral of ischaemia → worsening contractility → lower output → more ischaemia**. Simultaneously, **raised left ventricular filling pressure is transmitted to the pulmonary capillaries, causing interstitial and alveolar oedema**; this reduces compliance and impairs gas exchange, and the resulting **hypoxaemia and metabolic (lactic) acidosis drive the tachypnoea**. Systemic hypoperfusion causes **acute kidney injury, hepatic dysfunction, delirium and a systemic inflammatory response with inappropriate vasodilatation**.

2. **Haemodynamic profiling at the bedside.** Classify immediately by **congestion ("wet or dry") and perfusion ("warm or cold")**:

Profile	Findings	Approach
Warm and wet	Congested, well perfused, normal or high BP	Diuretic ± vasodilator
Cold and wet	**Congested AND hypoperfused — cool peripheries, narrow pulse pressure, mottling, oliguria, confusion, raised lactate**	**Inotrope/vasopressor first, then diuresis once perfused — this patient**
Cold and dry	Hypoperfused, not congested	Cautious fluid challenge, then inotrope

   Cardiogenic shock = systolic BP < 90 mmHg for > 30 minutes (or vasopressor need) with **evidence of end-organ hypoperfusion** and adequate filling.

3. **Differential diagnosis — cardiac causes to consider. Acute myocardial infarction with pump failure** (the commonest cause); **mechanical complications of MI — acute mitral regurgitation from papillary muscle rupture, ventricular septal rupture, free wall rupture with tamponade**; **tachyarrhythmia or bradyarrhythmia including complete heart block**; **critical aortic stenosis**; **acute severe valvular regurgitation from infective endocarditis**; **myocarditis**; **Takotsubo cardiomyopathy**; **cardiac tamponade**; and **decompensation of known heart failure**.

4. **Differential diagnosis — non-cardiac mimics that must be excluded. Sepsis and septic shock with myocardial depression** (fever, warm periphery, high lactate, source of infection); **massive pulmonary embolism** (right ventricular failure with clear lungs, raised JVP, hypoxia with hypocapnia); **hypovolaemia and gastrointestinal bleeding**; **tension pneumothorax**; **aortic dissection** with tamponade or acute aortic regurgitation; **anaphylaxis**; **drug toxicity — beta-blocker, calcium channel blocker or digoxin overdose**; **adrenal crisis and severe hypothyroidism (myxoedema)**; and **severe anaemia or thyrotoxicosis causing high-output failure**.

5. **Investigations that discriminate between them.**

Test	What it rules in or out
12-lead ECG (immediately)	STEMI, NSTEMI, arrhythmia, complete heart block, right heart strain (S1Q3T3) in PE, low voltage in tamponade
Bedside echocardiography	**The single most discriminating test** — LV/RV function, regional wall motion, valve rupture, VSD, tamponade, aortic stenosis, IVC size (excludes hypovolaemia)
Troponin, natriuretic peptide	Myocardial injury; a normal BNP essentially excludes heart failure as the cause of breathlessness
ABG with lactate	Hypoxia, acidosis, degree of hypoperfusion; hypocapnia with hypoxia suggests PE
Chest radiograph, lung ultrasound	Pulmonary oedema (B-lines, Kerley B, upper lobe diversion), pneumothorax, consolidation, widened mediastinum
FBC, U&E, creatinine, LFT, glucose, TFT, CRP, cultures	Sepsis, anaemia, AKI, hepatic congestion, thyroid disease
CT pulmonary angiogram / CT aorta	Pulmonary embolism; aortic dissection — only once stabilised
Coronary angiography	Definitive if ACS-related shock — should not be delayed

6. **Emergency Department management — immediate stabilisation. ABCDE**, monitored bed, two cannulae, arterial line if shocked, urinary catheter for hourly output. **Sit the patient up** and give **oxygen to target SpO_2 94–98%**; escalate to **CPAP or non-invasive ventilation**, which reduces preload and afterload, improves oxygenation and reduces intubation; intubate if exhausted, obtunded or acidotic despite NIV. **Do NOT give nitrates or high-dose diuretic first in a hypotensive patient** — nitrates are contraindicated at systolic BP < 90 mmHg. Instead: give a **cautious 250 mL fluid challenge only if the IVC is collapsed and there is no pulmonary oedema**; otherwise start **noradrenaline** to restore a mean arterial pressure ≥ 65 mmHg, then add an **inotrope (dobutamine or levosimendan)** to restore perfusion. Once perfused, give **intravenous furosemide** for congestion. Correct **arrhythmia (urgent DC cardioversion for haemodynamically unstable tachyarrhythmia; pacing for complete heart block)**, and if ACS is the cause arrange **immediate primary PCI**.
7. **Ward or coronary care management.** Continue **continuous monitoring of rhythm, blood pressure, saturation, hourly urine output, daily weight and strict fluid balance**, with **daily renal function and electrolytes**. **Wean vasopressors and inotropes as perfusion recovers**, then **titrate diuretics to a negative fluid balance**, adding a **thiazide or acetazolamide for diuretic resistance**. Treat the precipitant — **revascularisation, antibiotics, rate or rhythm control, correction of anaemia and thyroid dysfunction**. **Reintroduce and uptitrate disease-modifying therapy as soon as the patient is off inotropes and euvolaemic**: ACE inhibitor or ARNI, beta-blocker, MRA and SGLT2 inhibitor. Provide **VTE prophylaxis, early mobilisation, pressure-area care, delirium prevention, nutrition and dietitian input**. Refer for **device therapy (ICD/CRT) assessment** once the ejection fraction has been reassessed at 3 months on optimal therapy.
8. **Geriatric considerations throughout.** A 70-year-old may have **reduced β-adrenergic responsiveness, arterial stiffening, diastolic dysfunction and limited renal reserve**, so he is **exquisitely preload-sensitive** and tolerates neither over-filling nor over-diuresis. **Give fluid in 250 mL aliquots with reassessment**. Actively look for and prevent **acute kidney injury, delirium, falls, hospital-acquired infection, pressure sores, constipation and deconditioning**. **Review the whole drug chart** — stop NSAIDs and other precipitants; review anticholinergic and sedative burden. Undertake a **comprehensive geriatric assessment**, and **discuss ceilings of care, escalation and resuscitation status early** with the patient and family.
9. **Discharge planning. Discharge only when the patient is euvolaemic, on stable oral therapy for at least 24 hours, with stable renal function.** Provide: a **written management plan with daily weights and an action plan for a weight gain of more than 2 kg in three days**; **education on salt and fluid moderation, medication purpose and side effects**; a **reconciled and simplified drug list**; **enrolment in cardiac rehabilitation**; **influenza, pneumococcal and COVID-19 vaccination**; and **social and functional support with an occupational therapy home assessment**. Arrange **heart failure nurse follow-up within 7 days and clinic review within 2 weeks**, with **early uptitration of the four pillars — multidisciplinary nurse-led follow-up is the intervention that most reliably reduces readmission**.
10. **Longer-term follow-up and prognosis. Repeat echocardiography at 3 months on optimal therapy** to guide ICD/CRT referral. Monitor **renal function and potassium after each dose change**. Screen and treat **iron deficiency (intravenous iron), anaemia, atrial fibrillation, sleep apnoea, depression and frailty**. **Secondary prevention** if ischaemic — antiplatelet therapy, statin, blood pressure and glycaemic control, smoking cessation. Counsel on **driving restrictions and vaccination**. Prognosis after cardiogenic shock remains poor, so **advance care planning should be revisited**, and the **caregiver's physical and emotional health should be assessed as part of ongoing review**.

Latest Updates – 2 Points (2023–Present)

11. **DanGer Shock (NEJM 2024)** — the first adequately powered randomised trial of mechanical circulatory support in cardiogenic shock. In **STEMI-related cardiogenic shock**, a **microaxial flow pump (Impella CP) reduced 180-day all-cause mortality compared with standard care**, though at the cost of significantly more **bleeding, limb ischaemia, haemolysis and renal replacement therapy**. This is the first positive mortality trial in this field (intra-aortic balloon counterpulsation was neutral in IABP-SHOCK II), and it supports early referral of selected patients to a **shock team at a centre with mechanical circulatory support** — while the complication profile makes patient selection critical in the frail older patient.
12. **Culprit-lesion-only revascularisation and rapid post-discharge uptitration. CULPRIT-SHOCK** established that in shock complicating multivessel disease, **culprit-lesion-only PCI is superior to immediate multivessel PCI** (less death and renal replacement therapy) — staged treatment of remaining lesions is the correct approach. After stabilisation, **STRONG-HF** showed that **high-intensity uptitration of guideline-directed therapy to full dose within 2 weeks of discharge, with four follow-up visits in 2 months, significantly reduced death and heart failure readmission at 180 days**, and this benefit was preserved in older patients — making the **first two weeks after discharge the highest-value period of the whole admission**.

Question 6. Cardiorenal syndrome

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** Cardiorenal syndrome (CRS) is a group of disorders of the heart and kidneys in which **acute or chronic dysfunction of one organ induces acute or chronic dysfunction of the other**. It is **bidirectional**, and its recognition matters because the presence of renal dysfunction is one of the strongest independent predictors of mortality in heart failure, and because it constrains the very treatments (diuretics, ACE inhibitors, MRAs) that heart failure requires.
2. **Classification (Ronco).**

Type	Name	Mechanism and typical example
Type 1	Acute cardiorenal	**Acute heart failure → acute kidney injury** (acute decompensated heart failure, cardiogenic shock, acute coronary syndrome)
Type 2	Chronic cardiorenal	**Chronic heart failure → progressive chronic kidney disease**
Type 3	Acute renocardiac	**Acute kidney injury → acute cardiac dysfunction** (fluid overload, hyperkalaemic arrhythmia, uraemic pericarditis)
Type 4	Chronic renocardiac	**Chronic kidney disease → cardiac disease** (LV hypertrophy, accelerated atherosclerosis, uraemic cardiomyopathy)
Type 5	Secondary	**A systemic disease damaging both organs** — sepsis, diabetes, amyloidosis, SLE, cirrhosis

3. **Pathophysiology.** The traditional model of a "low forward flow" reducing renal perfusion is now known to be secondary. **The dominant mechanism is renal VENOUS CONGESTION — a raised central venous pressure is transmitted back to the renal veins, raising renal interstitial and intracapsular pressure, reducing the transrenal perfusion gradient and hence the glomerular filtration rate.** Elevated intra-abdominal pressure from ascites and visceral oedema compounds this. Additional mechanisms: **neurohormonal activation (renin-angiotensin-aldosterone and sympathetic overactivity) causing sodium and water retention and efferent arteriolar constriction**; **systemic inflammation and oxidative stress**; **endothelial dysfunction with reduced nitric oxide**; **anaemia and iron deficiency, forming the "cardiorenal anaemia syndrome"**; and **drug-induced injury from NSAIDs, contrast media and over-diuresis**. In the older patient **reduced renal reserve, nephrosclerosis, and reduced GFR that is masked by low muscle mass** make all of this more likely.
4. **Clinical features and assessment.** Features of **congestion** — raised JVP, peripheral and sacral oedema, hepatomegaly and ascites, weight gain, orthopnoea — coexisting with features of **renal dysfunction** — rising creatinine and urea, oliguria, hyperkalaemia, metabolic acidosis, anaemia. **The critical bedside distinction is between the CONGESTED patient (raised JVP, dilated IVC, oedema — needs MORE decongestion) and the HYPOVOLAEMIC over-diuresed patient (flat JVP, postural drop, dry mucosae — needs LESS diuretic)**, because the creatinine rises in both. Assess with **daily weight, strict fluid balance, JVP, postural blood pressure, IVC diameter and lung ultrasound B-lines**. Investigations: **urea, electrolytes, creatinine and eGFR, urinalysis with urine protein-creatinine ratio, urine sodium, full blood count and iron studies, natriuretic peptides, renal ultrasound, echocardiography**, and review for nephrotoxins. **Note that a rise in creatinine during effective decongestion ("pseudo-worsening renal function") is common, is haemodynamic rather than structural, and is NOT associated with worse outcome provided congestion is being relieved**.

5. **Management — decongestion. Intravenous loop diuretics are the cornerstone.** Give as a **bolus or continuous infusion** at **1–2.5 times the usual home oral dose**; oral bioavailability is unreliable in gut oedema. For **diuretic resistance**, use **sequential nephron blockade** — add a **thiazide-type diuretic (metolazone or hydrochlorothiazide) 30 minutes before the loop diuretic**, add an **MRA**, and consider **acetazolamide**. Restrict sodium and fluid. **Ultrafiltration** is reserved for genuinely diuretic-resistant congestion; it removes isotonic fluid but has not shown superiority over stepped pharmacological care (CARRESS-HF). **Renal replacement therapy** for refractory hyperkalaemia, acidosis, uraemia or fluid overload. Monitor **daily weight, fluid balance, renal function and electrolytes**.
6. **Management — disease-modifying therapy and the drugs to keep or stop. Do NOT reflexively stop ACE inhibitors, ARBs or MRAs for a modest creatinine rise** — a rise of up to about 30% with stable potassium is acceptable and these drugs confer long-term cardiac and renal benefit; halve the dose and monitor rather than stopping outright. Do stop them for a rise beyond 30%, refractory hyperkalaemia or symptomatic hypotension. **Stop NSAIDs and other nephrotoxins, and minimise contrast exposure.** Continue or start an **SGLT2 inhibitor**, which reduces both heart failure and renal endpoints and may cause a small early reversible "dip" in eGFR that should not prompt discontinuation. Treat **anaemia and iron deficiency with intravenous iron**. Manage **hyperkalaemia** with dietary advice and a **potassium binder (patiromer or sodium zirconium cyclosilicate)** so that RAAS inhibition can be maintained. Treat the precipitant — infection, arrhythmia, ischaemia, obstruction. Involve **nephrology and cardiology jointly**, and in the frail older patient with advanced dual organ failure, undertake **advance care planning and consider a conservative, symptom-focused pathway rather than dialysis**.

Latest Update – 1 Point (2023–Present)

7. **Combination diuretic therapy up front, and non-steroidal MRAs, have changed cardiorenal management.** The **ADVOR trial** showed that **adding intravenous acetazolamide 500 mg daily to loop diuretics significantly increased successful decongestion and shortened hospital stay** in acute decompensated heart failure with volume overload, and **CLOROTIC** showed that adding hydrochlorothiazide improved weight loss and diuretic response — both are now reflected in the **2023 ESC heart failure focused update**, which endorses **early combination diuretic therapy for congestion rather than escalating a loop diuretic alone**. In parallel, **FIDELIO-DKD and FIGARO-DKD** established that **finerenone reduces both renal progression and cardiovascular events in chronic kidney disease with type 2 diabetes with less hyperkalaemia than spironolactone**, and **FINEARTS-HF (NEJM 2024)** extended this benefit to **HFmrEF and HFpEF** — giving, for the first time, a single agent that protects both organs in the cardiorenal patient.

B. Ischaemic Heart Disease and Atherosclerosis

Question 7. Unstable angina — clinical features, evaluation and management

15-Mark Essay | 10 textbook points + 2 latest updates | ***Asked ×2***

Textbook Core – 10 Points

1. **Definition and place in the ACS spectrum.** Unstable angina is **myocardial ischaemia at rest or on minimal exertion, without acute myocyte necrosis** — that is, **ischaemic symptoms with a normal (non-elevated) troponin**. It sits between stable angina and non-ST-elevation myocardial infarction (NSTEMI); together they form the **non-ST-elevation acute coronary syndromes (NSTE-ACS)**. The classical triad of presentations is **rest angina lasting more than 20 minutes, new-onset severe angina, or a crescendo pattern of previously stable angina**.
2. **Pathogenesis.** The usual mechanism is **disruption of an atheromatous plaque — rupture, fissuring, erosion or haemorrhage — with superimposed non-occlusive platelet-rich thrombus** causing a sudden reduction in coronary flow. Contributory mechanisms are **vasospasm, distal embolisation and inflammation**. In the older patient, **type 2 myocardial ischaemia** from an **oxygen supply–demand mismatch** is equally common and is precipitated by **sepsis, hypotension, tachyarrhythmia, anaemia, hypoxia, thyrotoxicosis and organ dysfunction** — this must be identified because the treatment is entirely different.
3. **Clinical features and the geriatric pitfall.** Typical features are **retrosternal chest tightness or heaviness radiating to the jaw, neck or left arm, with sweating, nausea and dyspnoea**. **In older people typical cardiac chest pain is less common and, when present, is usually less well defined or less severe.** Ischaemia may be **asymptomatic or present atypically with dyspnoea, fatigue, dizziness, syncope, confusion, lethargy or altered mental state**, especially in the frail. Because they are physically less active, **angina in this age group is less often related to exertion**. Signs may include a new S4, transient mitral regurgitation murmur, or signs of heart failure.

4. **Differential diagnosis.** Cardiac — **NSTEMI, STEMI, aortic dissection, pericarditis, myocarditis, Takotsubo, severe aortic stenosis**. Respiratory — **pulmonary embolism, pneumonia, pneumothorax, pleurisy**. Gastrointestinal — **epigastric pain may be misdiagnosed as peptic ulcer disease, and burning nocturnal or post-prandial pain as gastro-oesophageal reflux or hiatus hernia**. Musculoskeletal — **shoulder or back pain may be misdiagnosed as osteoarthritis**, costochondritis, herpes zoster. Also consider anxiety and panic disorder.
5. **Initial evaluation — ECG and biomarkers.** Obtain a **12-lead ECG within 10 minutes** and repeat it serially and with pain. Look for **ST depression, transient ST elevation and T-wave inversion**; **dynamic changes are the key finding** and confer high risk. **Note that the resting ECG is less valuable in the elderly because of common age-related changes, and a normal ECG does not exclude ACS.** Measure **high-sensitivity troponin at presentation and at 1–3 hours**: unstable angina is defined by an **absence of significant rise and fall**. Remember that troponin is **chronically elevated in renal impairment, heart failure, atrial fibrillation, sepsis, pulmonary embolism and old age**, so it is the **dynamic change, not the absolute level, that indicates infarction**.
6. **Further evaluation. Bedside echocardiography** for regional wall motion abnormality, ejection fraction, valve disease and mechanical complications. Baseline **full blood count (anaemia is a common precipitant and modifies antithrombotic choice), renal function, electrolytes, glucose, HbA1c, lipids, thyroid function and CRP**; **chest radiograph**. **The exercise treadmill test has limited diagnostic value in old age because exercise capacity is insufficient to induce ischaemia; pharmacological stress testing and imaging modalities are useful in older as in younger people.** Options include **stress echocardiography, myocardial perfusion imaging, stress cardiac MRI and CT coronary angiography**.
7. **Risk stratification.** Use the **GRACE score** (age, heart rate, systolic BP, creatinine, Killip class, cardiac arrest, ST deviation, troponin) for ischaemic risk and the **TIMI score** as a simpler alternative; use the **CRUSADE score** or **ARC-HBR criteria** for bleeding risk. **Very-high-risk features mandating immediate (< 2 h) invasive strategy: haemodynamic instability or cardiogenic shock, recurrent or refractory chest pain despite treatment, life-threatening arrhythmia, mechanical complication, acute heart failure, or recurrent dynamic ST changes**. **High risk (invasive within 24 h):** raised troponin, dynamic ST/T changes, GRACE score > 140. **Age is heavily weighted in every risk score, so almost all older patients are classified as high risk — but they are also at the highest bleeding risk, which is the central tension of the answer.**
8. **Immediate medical management. Anti-ischaemic: sublingual then intravenous nitrates** (avoid if hypotensive, in aortic stenosis or with recent phosphodiesterase-5 inhibitors), **beta-blockers** unless there is heart failure, bradycardia or cocaine use, and **a rate-limiting calcium channel blocker** if beta-blockers are contraindicated. **Oxygen only if SpO_2 < 90%. Antiplatelet: aspirin 150–300 mg loading then 75 mg daily indefinitely**, plus a **$P2Y_{12}$ inhibitor — ticagrelor or clopidogrel**; **prasugrel is contraindicated over 75 years, under 60 kg, or with prior stroke or TIA**. **Anticoagulant: fondaparinux 2.5 mg subcutaneously daily is preferred for its favourable bleeding profile**, or enoxaparin, or unfractionated heparin — all **renally dose-adjusted**. **Add a statin (high-intensity) and an ACE inhibitor**, and a proton pump inhibitor for gastroprotection with dual antiplatelet therapy.
9. **Invasive strategy and revascularisation. Coronary angiography with PCI** is the definitive treatment for high-risk patients, timed by risk as above, with **radial access preferred because it substantially reduces bleeding and mortality** — particularly valuable in older patients. Use **current-generation drug-eluting stents**. Choose **CABG** for left main or complex three-vessel disease, especially with diabetes, after Heart Team discussion. **During treatment of ACS, older people are more prone to side effects such as stroke, acute kidney injury and bleeding complications**, so contrast volume should be minimised with pre- and post-hydration, and antithrombotic doses carefully adjusted for weight and renal function. **Suboptimal timing — that is, excessively late referral — has a significant negative impact on both procedural risk and late outcome**, so decisions should not be made on a "wait and see" basis.
10. **Secondary prevention and geriatric care planning.** Long-term therapy: **aspirin indefinitely plus a $P2Y_{12}$ inhibitor for 12 months** (shortened to **1–3 months** in high bleeding risk, then single antiplatelet therapy), **high-intensity statin ± ezetimibe**, **ACE inhibitor**, and **beta-blocker where the ejection fraction is reduced**. Add **blood pressure and glycaemic control, smoking cessation, weight and diet management, and cardiac rehabilitation — in old age, cardiac rehabilitation following ischaemic events improves survival and enhances quality of life, general well-being and mental health**, and improves physical and cognitive function. Incorporate **multimorbidity, polypharmacy, physical and cognitive function, frailty and life expectancy** into decision-making, and adopt a **patient-centred rather than disease-centred plan** that focuses on **quality rather than quantity of life**. For frail patients with poor cognitive and physical function or limited life expectancy, aggressive treatment may not achieve meaningful goals, and **symptom palliation or end-of-life planning may be more appropriate**.

Latest Updates – 2 Points (2023–Present)

11. **SENIOR-RITA (NEJM 2024)** — the largest randomised trial of invasive versus conservative management in **NSTE-ACS in patients aged 75 and over** (median age 82, half frail). An invasive strategy **did NOT reduce the primary composite of cardiovascular death or non-fatal myocardial infarction, but did significantly reduce non-fatal myocardial infarction and subsequent revascularisation**, without excess procedural harm. The examinable message is nuanced and highly quotable: **routine invasive management should not be assumed beneficial for hard outcomes in the very old, but it remains reasonable for symptom control and to prevent recurrent events — the decision must be individualised by frailty, comorbidity and patient preference, not by chronological age**.
12. **2023 ESC Guidelines for Acute Coronary Syndromes** unified STEMI and NSTE-ACS into a **single guideline with a continuum-based approach**. Key changes: the **"invasive within 24 hours" recommendation for high-risk NSTE-ACS was downgraded to Class IIa** following neutral timing trials; **routine pre-treatment with a $P2Y_{12}$ inhibitor before angiography in NSTE-ACS is not recommended** (Class III); **abbreviated DAPT of 1–3 months followed by $P2Y_{12}$ monotherapy is endorsed in high-bleeding-risk patients**; and there is a dedicated section recommending that management in **older, frail patients be guided by comorbidity, frailty and estimated life expectancy**.

Current Practice Update

Textbook	Early invasive strategy for high-risk NSTE-ACS; pre-treatment with dual antiplatelet therapy before angiography; 12 months of DAPT.
Current recommendation	2023 ESC — no routine $P2Y_{12}$ pre-treatment in NSTE-ACS; 24-hour invasive timing downgraded to IIa; abbreviated DAPT in high bleeding risk; SENIOR-RITA tempers the invasive default in the very old.
Exam approach	Write "2023 ESC no longer recommends routine $P2Y_{12}$ pre-treatment in NSTE-ACS, and SENIOR-RITA (2024) shows the invasive strategy in over-75s reduces recurrent MI but not death — individualise by frailty."

Question 8. Uses and limitations of the electrocardiogram in acute coronary syndromes

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Primary use — immediate triage.** The 12-lead ECG must be obtained and interpreted **within 10 minutes of first medical contact**. Its principal function is **to separate ST-elevation myocardial infarction, which requires immediate reperfusion, from non-ST-elevation ACS, which is managed with antithrombotic therapy and risk-stratified angiography**. Because **the greatest benefit from reperfusion occurs within the first two to three hours after symptom onset**, the ECG is the single time-critical investigation in the whole pathway.
2. **STEMI criteria and localisation. New ST elevation at the J point in two contiguous leads: ≥ 1 mm in all leads except V2–V3, where the threshold is ≥ 2 mm in men ≥ 40 years, ≥ 2.5 mm in men < 40, and ≥ 1.5 mm in women. New left bundle branch block with ischaemic symptoms is treated as a STEMI equivalent.** Territory localisation: **II, III, aVF = inferior (right coronary); V1–V4 = anteroseptal (LAD); I, aVL, V5–V6 = lateral (circumflex)**. **Always record right-sided (V4R) leads in inferior infarction to detect right ventricular involvement, and posterior leads (V7–V9) when there is ST depression in V1–V3.**
3. **NSTE-ACS findings and serial recording.** Look for **ST depression (horizontal or downsloping ≥ 0.5 mm), transient ST elevation and T-wave inversion**. **Dynamic changes — appearing with pain and resolving with relief — are the most specific and confer high risk.** A single ECG is therefore inadequate: **repeat at 15–30 minute intervals, with every episode of pain, and after any change in symptoms**. Continuous ST-segment monitoring is preferable where available.
4. **Additional uses beyond diagnosis.** The ECG gives **prognostic information** — the extent of ST deviation and the number of leads involved are components of the **GRACE risk score**. It detects **arrhythmic and conduction complications** — atrial fibrillation, ventricular tachycardia, and **complete heart block, which most often complicates inferior infarction**. It suggests **mechanical and other complications** such as pericarditis (widespread saddle-shaped ST elevation with PR depression) and left ventricular aneurysm (persistent ST elevation weeks later). It also provides a **baseline against which subsequent tracings are compared**, which is why obtaining old ECGs is so valuable.

5. **Limitations in the older patient. The resting ECG is less valuable in older people because of common age-related changes.** Confounders that mask or mimic ischaemia: **left bundle branch block, paced rhythm, left ventricular hypertrophy with strain, atrial fibrillation, digoxin effect, electrolyte disturbance and pre-existing Q waves or T-wave abnormalities**. **A normal ECG does NOT exclude acute coronary syndrome** — up to a third of NSTEMIs have a normal or non-diagnostic tracing, and the **left circumflex territory and the posterior wall are electrocardiographically "silent"**. Conversely the ECG cannot distinguish **type 1 (plaque rupture) from type 2 (supply–demand mismatch) infarction**, which is a very common and important distinction in the old.
6. **Practical consequences.** Because of these limitations the ECG must always be interpreted **together with the clinical context, serial high-sensitivity troponin measurement and echocardiography**. **Compare with a previous tracing wherever one exists.** Where left bundle branch block or a paced rhythm is present, apply the **Sgarbossa (or modified Smith-Sgarbossa) criteria** and use **urgent echocardiography** to look for a regional wall motion abnormality. **Never withhold reperfusion from a patient with a convincing history and evolving symptoms merely because the ECG is non-diagnostic — repeat it, and escalate to imaging or angiography.**

Latest Update – 1 Point (2023–Present)

7. The **2023 ESC ACS guideline** formally recognises **"STEMI-equivalent" patterns that indicate acute coronary occlusion despite the absence of classical ST elevation**, and recommends an **immediate invasive strategy for these patients**. They include: **de Winter's sign** (upsloping ST depression at the J point in the precordial leads with tall symmetrical T waves — proximal LAD occlusion); **posterior infarction** (ST depression in V1–V3 with tall R waves, confirmed on posterior leads V7–V9); **ST elevation in aVR with widespread ST depression** (left main or severe three-vessel disease); and **isolated right ventricular infarction on V4R**. This reflects the wider shift in emphasis from "STEMI versus NSTEMI" toward the **occlusion myocardial infarction (OMI) concept**, and it is precisely the kind of high-yield detail examiners reward.

Question 9. Case — advice to a 65-year-old man with diabetes, hypertension, dyslipidaemia and BMI 35, seen in clinic after two coronary stents

7-Mark Answer | 6 textbook points + 1 latest update

Frame the answer as structured secondary prevention. This man has established ASCVD with four modifiable risk factors and fresh stents — every point should name a target and an action.

Textbook Core – 6 Points

1. **Antiplatelet therapy — the most urgent point. Aspirin 75 mg daily lifelong**, plus a **$P2Y_{12}$ inhibitor (ticagrelor, prasugrel or clopidogrel) for 12 months after an acute coronary syndrome** or 6 months after elective PCI; shorten to **1–3 months if bleeding risk is high**, then continue single antiplatelet therapy. **Emphasise in the strongest terms that dual antiplatelet therapy must NOT be stopped prematurely — stent thrombosis carries about 40% mortality.** Advise him to carry a **stent card**, to **consult his cardiologist before any surgical or dental procedure**, and to report bleeding rather than stopping the tablets himself. Add a **proton pump inhibitor** for gastroprotection.
2. **Lipids.** He has established ASCVD, so target **LDL-cholesterol below 55 mg/dL (1.4 mmol/L) with at least a 50% reduction from baseline**. Start or continue a **high-intensity statin — atorvastatin 40–80 mg or rosuvastatin 20–40 mg**. If the target is not met, **add ezetimibe 10 mg**, then consider a **PCSK9 inhibitor or bempedoic acid**. Check a **lipid profile and liver function at 6–12 weeks**. Explain that the statin is taken for **plaque stabilisation, not for the cholesterol number alone**, and counsel on muscle symptoms so that he reports rather than silently stops the drug.
3. **Blood pressure.** Target **below 130/80 mmHg** given diabetes and coronary disease, avoiding a diastolic pressure below 70 mmHg (the "J-curve" concern in coronary disease). Preferred agents in this patient: an **ACE inhibitor or ARB** (cardioprotective, renoprotective in diabetes) plus a **beta-blocker** if the ejection fraction is reduced or angina persists, and a **calcium channel blocker or thiazide-like diuretic** as needed. Advise **home blood pressure monitoring** and **single-pill combinations** to reduce tablet burden and improve adherence.
4. **Diabetes.** Target **HbA1c around 7% (53 mmol/mol)**, individualised and relaxed if there is hypoglycaemia risk or frailty. Because he has established cardiovascular disease and obesity, **choose glucose-lowering agents for their cardiovascular benefit, not merely for glycaemic control — metformin as background, plus an SGLT2 inhibitor (cardiovascular and renal benefit, heart failure prevention) and/or a GLP-1 receptor agonist (atherosclerotic benefit plus substantial weight loss). Avoid pioglitazone (fluid retention and heart failure) and minimise sulfonylureas and insulin because of hypoglycaemia**. Arrange annual **retinal screening, foot examination and urine albumin-creatinine ratio**.

5. **Weight, diet and exercise.** A BMI of 35 is **class II obesity**: aim for an initial **5–10% weight loss**. Advise a **Mediterranean-style or DASH diet**, salt below 5 g/day, reduced refined carbohydrate and saturated fat, more fruit, vegetables, whole grains, nuts and fish, and **alcohol limitation**. **Refer to a structured cardiac rehabilitation programme — this is one of the most strongly evidence-based interventions after PCI, improving survival, quality of life, physical and cognitive function and mental health.** Build up to **150 minutes per week of moderate aerobic activity plus resistance training twice weekly**. Screen for **obstructive sleep apnoea**, which is highly likely at this BMI.
6. **General advice, safety-netting and follow-up. Absolute smoking cessation** with pharmacological support. Give **influenza, pneumococcal and COVID-19 vaccination**. Teach him to **recognise recurrent angina and to use sublingual GTN, with clear instructions to call emergency services if pain persists beyond 15 minutes or is severe**. Advise on **driving restrictions** after PCI per local regulations, and on **safe resumption of sexual activity** (nitrates must never be combined with phosphodiesterase-5 inhibitors). **Screen for depression and anxiety**, which are common and worsen outcomes. Discuss **adherence explicitly** and simplify the regimen. Arrange **follow-up at 4–6 weeks** with repeat lipids, renal function, electrolytes, HbA1c and blood pressure, and **reassess the ejection fraction if it was reduced**.

Latest Update – 1 Point (2023–Present)

7. **SELECT (NEJM 2023)** — in patients with **established cardiovascular disease and overweight or obesity but WITHOUT diabetes**, weekly **semaglutide 2.4 mg reduced major adverse cardiovascular events by 20%**, establishing **obesity itself as a modifiable cardiovascular target and pharmacological weight loss as secondary prevention in its own right**. In a patient who also has diabetes, the parallel evidence from **SUSTAIN-6 and LEADER (GLP-1 receptor agonists)** and **EMPA-REG OUTCOME, CANVAS and DECLARE-TIMI 58 (SGLT2 inhibitors)** supports using these agents for cardiovascular protection. Current ACC/AHA and ESC guidance therefore recommends an **SGLT2 inhibitor and/or a GLP-1 receptor agonist in patients with type 2 diabetes and established ASCVD, independently of HbA1c**.

Question 10. Drug-eluting stents and in-stent restenosis

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Stent types.** A **bare-metal stent (BMS)** is a bare metallic scaffold that prevents acute recoil but has a high restenosis rate of **20–30%**. A **drug-eluting stent (DES)** has three components — a **metal platform**, an **antiproliferative drug** and a **polymer carrier**. Current-generation DES use **thin-strut cobalt-chromium or platinum-chromium platforms** eluting **everolimus, zotarolimus or sirolimus** from **biocompatible or biodegradable polymers**.
2. **Mechanism and benefit of DES.** The antiproliferative drug inhibits **vascular smooth muscle proliferation and neointimal hyperplasia**, reducing **restenosis and target-lesion revascularisation to under 5%**. Current-generation DES also have **lower stent thrombosis rates than BMS**, so **DES are now the default for virtually all patients, including the elderly and those at high bleeding risk** — BMS are essentially obsolete.
3. **In-stent restenosis (ISR) — definition and mechanism.** ISR is **renarrowing of ≥ 50% of the stented segment**. Two mechanisms: **neointimal hyperplasia** (dominant with BMS, occurs early at 3–12 months) and **neoatherosclerosis** — new atherosclerotic plaque forming inside the stent (typical of DES, occurs late, beyond 1 year, and may rupture). Usually presents as **recurrent stable angina**, but up to a third present as an **acute coronary syndrome**.
4. **Risk factors for ISR. Patient factors** — diabetes mellitus, chronic kidney disease, continued smoking. **Lesion factors** — small vessel diameter (< 2.5 mm), long lesions, **bifurcation and ostial** lesions, heavily calcified lesions, chronic total occlusion. **Procedural factors** — **stent under-expansion or malapposition**, geographic miss, residual dissection, stent fracture. **Premature discontinuation of dual antiplatelet therapy** is the key modifiable factor for stent thrombosis.
5. **Evaluation and treatment of ISR.** Coronary angiography with **intravascular imaging (IVUS or OCT)** to define the mechanism — under-expansion needs high-pressure or cutting/scoring balloon dilatation, whereas neointimal hyperplasia needs antiproliferative therapy. Definitive options: **drug-coated balloon (DCB)** or **implantation of a second DES**; plain balloon angioplasty alone has an unacceptably high recurrence rate. **CABG** is considered for recurrent or diffuse multi-vessel ISR.

6. **Antiplatelet therapy and geriatric considerations. Dual antiplatelet therapy (aspirin + a $P2Y_{12}$ inhibitor)** is given for **6 months after elective PCI** and **12 months after an acute coronary syndrome**, shortened to **1–3 months** in patients at **high bleeding risk (ARC-HBR criteria — age ≥ 75, anaemia, CKD, prior bleeding, oral anticoagulation)**, followed by single antiplatelet therapy. **Never stop DAPT prematurely — stent thrombosis carries about 40% mortality.** In the very old prefer **clopidogrel**; **prasugrel is contraindicated over 75 years, under 60 kg, or with prior stroke/TIA**. If oral anticoagulation is also needed, use **triple therapy for only about a week, then a DOAC plus clopidogrel**.

Latest Update – 1 Point (2023–Present)

7. The **AGENT IDE trial (2024)** showed that a **paclitaxel-coated balloon** was **superior to conventional balloon angioplasty** for coronary in-stent restenosis, reducing target-lesion failure — leading to the **first FDA approval of a coronary drug-coated balloon in the United States (2024)**. DCB treatment avoids adding another metal layer, which is particularly attractive in older patients with recurrent ISR and high bleeding risk. In parallel, the **2023 ESC ACS guideline** endorses **abbreviated DAPT (1–3 months) followed by $P2Y_{12}$ inhibitor monotherapy** in high-bleeding-risk patients.

Current Practice Update

Textbook	Choice between bare-metal and drug-eluting stents, with DES avoided when prolonged DAPT is undesirable; ISR treated with repeat stenting.
Current recommendation	Current-generation DES for all patients regardless of bleeding risk, with the duration of DAPT shortened instead; drug-coated balloons are a guideline-supported first-line option for ISR.
Exam approach	State "modern DES with abbreviated DAPT has replaced the BMS strategy in high-bleeding-risk elderly patients" — this single line is highly mark-earning.

Question 11. Statins in the very old — primary and secondary prevention

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Rationale. Atherosclerotic cardiovascular disease is the leading cause of death and disability in adults aged 75 and above**, and **age is the strongest single predictor of cardiovascular risk**. Because absolute risk rises steeply with age, **the absolute benefit of lipid lowering can be greater in older than in younger patients** even though the relative risk reduction is similar. Statins act by **HMG-CoA reductase inhibition**, with additional plaque-stabilising and anti-inflammatory effects.
2. **Secondary prevention — evidence is clear.** In established ASCVD (previous myocardial infarction, stroke or TIA, peripheral arterial disease, or revascularisation), statins **reduce major vascular events and mortality at all ages**. At least **moderate-intensity statin therapy is recommended regardless of age**, and existing therapy should **not be stopped merely because the patient has grown older**. This is the strongest examination point.
3. **Primary prevention — evidence is weaker.** Older adults, particularly those over 75, were **under-represented in the major trials**. **PROSPER** (pravastatin, ages 70–82) reduced coronary events but **not stroke and not mortality**; **ALLHAT-LLT** showed no benefit in older hypertensive patients. Standard risk calculators (Pooled Cohort Equations, SCORE2) **lose specificity above 75** because age dominates the score. Decisions must therefore be **individualised**.
4. **Time-to-benefit and the geriatric decision.** The average **time to benefit is about 2.5 years** for prevention of ASCVD events. **A statin is inappropriate when estimated life expectancy is shorter than the time to benefit.** Weigh **frailty, multimorbidity, cognition, polypharmacy, functional status and patient preference**, and use **shared decision-making**. Consider **deprescribing** in advanced dementia, terminal malignancy, severe frailty or when goals of care become purely palliative.
5. **Adverse effects and interactions. Statin-associated muscle symptoms** (myalgia, weakness — a cause of falls and reduced mobility; rarely rhabdomyolysis), **transaminitis**, and **new-onset diabetes**. Risk rises with **CYP3A4 interactions** — **amiodarone, verapamil, diltiazem, macrolides, azole antifungals, ciclosporin** — so **avoid high-dose simvastatin**. **Pravastatin, rosuvastatin and pitavastatin** are least CYP3A4-dependent. Evidence overall shows **neutral or even protective cognitive effects**; statins do not cause dementia.
6. **Practical prescribing. Start low and go slow** — moderate intensity (**atorvastatin 10–20 mg** or **rosuvastatin 5–10 mg**) is usually sufficient. Check **baseline LFT and CK**, exclude hypothyroidism, and repeat lipids at **6–12 weeks**. If the LDL target is not met, **add ezetimibe 10 mg** rather than escalating the statin dose — this is better tolerated in the old. For statin intolerance, try an alternative statin, alternate-day dosing, or **bempedoic acid / PCSK9 inhibitors** in selected high-risk patients.

Latest Update – 1 Point (2023–Present)

7. **2025 National Lipid Association / American Geriatrics Society Expert Clinical Consensus (JAGS 2025)** on hypercholesterolaemia in adults over 75 without ASCVD: LDL-C remains an **independent predictor of ASCVD beyond age 75**; it is **reasonable to initiate a statin for primary prevention when LDL-C is 70–189 mg/dL in the absence of life-limiting illness**; **coronary artery calcium scoring** can refine risk when the decision is uncertain; and **deprescribing is appropriate in those with life-limiting disease**. The **STAREE trial** (atorvastatin 40 mg versus placebo in ~10,000 Australians aged ≥ 70, co-primary endpoint **disability-free survival**) will settle the primary prevention question — **results awaited**.

Current Practice Update

Textbook	Statin benefit in the very old is uncertain, particularly for primary prevention; treatment individualised.
Current recommendation	2025 NLA/AGS consensus gives an explicit LDL-C threshold (70–189 mg/dL), supports CAC-guided decisions, and formalises deprescribing criteria.
Exam approach	Write "secondary prevention — statin regardless of age; primary prevention — individualise using time-to-benefit (~2.5 years) and the 2025 NLA/AGS consensus."

Question 12. Atherosclerosis and the biomarkers associated with it

7-Mark Answer | 6 textbook points + 1 latest update | ***Asked ×2***

Textbook Core – 6 Points

1. **Definition and burden.** Atherosclerotic cardiovascular disease is the **leading cause of death and disability in adults aged 75 and older**. Atherosclerosis is a **slow-developing chronic inflammatory disease that begins as early as the first decades of life, at the level of the intimal tunica of large-calibre arteries**. The presence of atherosclerosis has been positively correlated with age at death even in **ancient mummified populations**, suggesting it is an **inherent component of human ageing** — but genetic and environmental factors modulate its severity and speed of progression, among which **lipid disorders, in particular hypercholesterolaemia, are foremost**.
2. **Pathogenesis.** The sequence is: **endothelial injury and dysfunction** (from shear stress at branch points, hypertension, smoking, hyperglycaemia, oxidised LDL) → **increased permeability with subendothelial retention and oxidation of apoB-containing lipoproteins → monocyte adhesion and migration, differentiation into macrophages and uptake of oxidised LDL to form foam cells → fatty streak → smooth muscle migration and proliferation with fibrous cap formation → fibrofatty plaque with a necrotic lipid core → plaque rupture, fissuring, erosion or haemorrhage with superimposed thrombosis**, producing the acute event. In ageing, **cellular senescence primes the vessel and drives established disease forward**, and **"inflammageing"** — chronically elevated inflammatory markers — contributes through inhibition of growth factors, increased catabolism and disturbed homeostatic signalling.
3. **Risk factors. Non-modifiable:** age (the strongest single predictor of cardiovascular risk), male sex, family history and genetic predisposition, ethnicity. **Modifiable: dyslipidaemia, hypertension, diabetes mellitus, smoking, obesity and visceral adiposity, physical inactivity, chronic kidney disease**. **Emerging and geriatric-specific: frailty appears to be a cardiovascular risk factor unique to older people, sharing a pathogenetic link with ischaemic heart disease through chronic inflammation and haematological and endocrine factors**; and **loneliness, social isolation, depression and dementia** are further risk factors that increase cardiovascular events in old age.
4. **Established lipid biomarkers.**

Biomarker	Significance
LDL-cholesterol	The **causal driver and primary treatment target**; remains independently associated with ASCVD beyond the age of 75
Non-HDL-cholesterol	Total minus HDL — captures **all atherogenic apoB particles**; superior in diabetes, obesity and hypertriglyceridaemia; needs no fasting sample
Apolipoprotein B	Directly counts **atherogenic particle number**; more accurate than LDL-C when triglycerides are high or LDL-C is low
Lipoprotein(a)	**Genetically determined, largely unmodifiable by diet or statins**; causal for ASCVD and for calcific aortic stenosis; measure **once in a lifetime**
Triglycerides, HDL-C	HDL-C is a risk marker, not a treatment target — HDL-raising therapies have failed to improve outcomes

5. **Inflammatory and other circulating biomarkers. High-sensitivity CRP** — an established marker of residual inflammatory risk; a strong association exists between increasing age and increasing systemic inflammation as measured by CRP. **Interleukin-6** — an upstream driver of the inflammatory pathway and a core marker of inflammageing and frailty. **Lp-PLA2 and myeloperoxidase** — markers of plaque inflammation and instability. **Homocysteine** — associated with risk, but lowering it with B vitamins does not reduce events. **Fibrinogen and D-dimer** — thrombotic risk. **NT-proBNP and high-sensitivity troponin** — markers of subclinical myocardial injury and strain that predict events in older adults, and are increasingly used as "newer biomarkers" of cardiovascular risk. **Note that in older people a raised troponin and BNP frequently reflect chronic myocardial stress rather than acute events, so trends matter more than absolute values.**
6. **Imaging biomarkers and clinical use. Coronary artery calcium (CAC) score on non-contrast CT** is the most useful risk-refining test — a **score of zero confers a very low short-term risk** and can justify withholding or deferring a statin, whereas a high score reclassifies the patient upward. **Carotid intima-media thickness and carotid plaque on ultrasound**, **ankle brachial index** and **CT coronary angiography with plaque characterisation** are alternatives. The practical role of all these markers is to **refine risk when the decision to treat is uncertain** — this matters especially in older adults, in whom **standard risk calculators lose specificity because chronological age dominates the score**. **Management remains risk-factor modification: statin therapy to LDL targets, blood pressure and glycaemic control, smoking cessation, weight loss and exercise.**

Latest Update – 1 Point (2023–Present)

7. **Two biomarkers have moved from research interest to guideline recommendation.** First, **Lipoprotein(a)**: **ESC/EAS and 2025 AHA/ACC guidance now recommend measuring Lp(a) at least once in every adult's lifetime** for risk stratification, and the first targeted therapies — **pelacarsen (Lp(a)HORIZON), olpasiran and lepodisiran** — are in phase 3 outcome trials, with pelacarsen lowering Lp(a) by around 80%. Second, **residual inflammatory risk**: pooled analyses of over 30,000 statin-treated patients (Ridker et al., **Lancet 2023**) showed that **high-sensitivity CRP predicted future cardiovascular events and death more strongly than LDL-cholesterol did**, supporting the dual-target concept — **lower LDL for the lipid pathway and target inflammation with colchicine (LoDoCo2, COLCOT) for the inflammatory pathway**. In parallel, the **2025 AHA/ACC hypertension guideline has adopted the PREVENT risk equations**, which for the first time incorporate **eGFR, urine albumin-creatinine ratio and HbA1c** into routine cardiovascular risk estimation.

C. Hypertension and Blood Pressure Disorders

Question 13. Management of hypertension in a 65-year-old with dyslipidaemia and coronary artery disease

15-Mark Essay | 10 textbook points + 2 latest updates

Textbook Core – 10 Points

1. **Definition and the importance of the problem.** Hypertension is defined as a **systolic blood pressure of 140 mmHg or greater and/or a diastolic blood pressure of 90 mmHg or greater**. It is the **major risk factor for stroke, heart failure and coronary artery disease in older adults, all of which are important contributors to mortality and functional disability**. Because it is remediable and its control reduces the incidence of coronary heart disease and stroke, **increased efforts at detection and treatment are indicated**. In this patient, hypertension, dyslipidaemia and established coronary disease act multiplicatively, so **global cardiovascular risk reduction — not blood pressure alone — is the objective**.
2. **Accurate diagnosis and measurement.** Confirm with **repeated measurements on at least two occasions** using a validated device and correct cuff size, after 5 minutes seated rest, with the arm supported at heart level. **Measure in both arms initially and use the higher reading. Always measure standing blood pressure at 1 and 3 minutes to detect orthostatic hypotension, which is common in this age group and limits how aggressively treatment can be titrated.** Confirm the diagnosis with **home blood pressure monitoring or 24-hour ambulatory monitoring**, which also detects **white-coat hypertension, masked hypertension and non-dipping**. Exclude **pseudohypertension** from rigid calcified arteries.
3. **Evaluation — secondary causes and target-organ damage.** Screen for secondary hypertension where there is resistant or accelerated hypertension or a suggestive feature: **renal parenchymal disease, renovascular disease (renal bruit, flash pulmonary oedema, AKI on ACE inhibitor), primary aldosteronism (hypokalaemia), obstructive sleep apnoea, thyroid disease, phaeochromocytoma, Cushing's syndrome**, and **drugs — NSAIDs, corticosteroids, decongestants, ciclosporin, erythropoietin, liquorice**. Assess target-organ damage: **ECG and echocardiography for left ventricular hypertrophy, urine albumin-creatinine ratio and eGFR, fundoscopy**, and carotid or peripheral vascular assessment.

4. **Baseline investigations and risk assessment. Full blood count, urea, electrolytes, creatinine and eGFR, fasting glucose and HbA1c, fasting lipid profile, uric acid, liver and thyroid function, urinalysis and ACR, ECG**. Because he already has **established coronary artery disease, he is by definition at very high cardiovascular risk** — a risk calculator is unnecessary, and he qualifies immediately for **intensive blood pressure lowering and high-intensity statin therapy**.
5. **Blood pressure targets in this patient.** Aim for a **systolic pressure below 130 mmHg**, and generally **not below 120 mmHg**, with a **diastolic pressure of 70–80 mmHg**. **In coronary artery disease, be cautious about lowering the diastolic pressure below about 70 mmHg, because coronary perfusion occurs in diastole and excessive lowering may worsen ischaemia — the "J-curve" phenomenon.** Targets must be **individualised**: relax them in the presence of **frailty, symptomatic orthostatic hypotension, falls, cognitive impairment or limited life expectancy**. **Standing blood pressure, not seated, should be used to guide titration in patients with postural symptoms.**
6. **Non-pharmacological management.** These measures lower blood pressure and also improve lipids and glycaemia. **Salt restriction to under 5 g of sodium chloride daily** (an important and achievable target in the Indian diet); **DASH or Mediterranean dietary pattern** rich in fruit, vegetables, whole grains and low-fat dairy; **weight reduction**; **at least 150 minutes per week of moderate aerobic exercise plus resistance training**; **alcohol moderation**; **smoking cessation**; **stress reduction and adequate sleep**; and **withdrawal of drugs that raise blood pressure, especially NSAIDs**.
7. **Choice of antihypertensive drugs — driven by the coronary disease.** The comorbidity dictates the choice (a "compelling indication"):

Agent	Role in this patient
Beta-blocker	**First choice** — antianginal, reduces myocardial oxygen demand, mandatory if there is prior MI with reduced ejection fraction or heart failure
ACE inhibitor or ARB	**First choice** — reduces cardiovascular events in coronary disease (HOPE, EUROPA), regresses LV hypertrophy, renoprotective
Dihydropyridine calcium channel blocker (amlodipine)	Excellent add-on; effective in isolated systolic hypertension and in angina; ankle oedema is the limiting effect
Thiazide-like diuretic (indapamide, chlorthalidone)	Effective add-on; watch **hyponatraemia, hypokalaemia, gout and postural hypotension** in the old
Spironolactone 25 mg	Drug of choice for **resistant hypertension** (PATHWAY-2) — monitor potassium and renal function

   Avoid short-acting nifedipine, alpha-blockers as first-line therapy (postural hypotension), and the combination of an ACE inhibitor with an ARB. Verapamil and diltiazem must be avoided if there is heart failure or if a beta-blocker is co-prescribed.
8. **Prescribing principles in the older adult. Start low and go slow** — begin with a single low-dose agent or a low-dose combination, and **review at 4-weekly intervals**. **Prefer adding a second low-dose drug to maximising the dose of one, and prefer single-pill combinations, which improve adherence and reduce tablet burden.** Check **renal function and electrolytes 1–2 weeks after starting or increasing an ACE inhibitor, ARB, diuretic or MRA**. At every visit, **recheck standing blood pressure, ask about dizziness and falls, and reconcile the medication list**. Deprescribe or reduce doses if the patient becomes frail, loses weight, or develops symptomatic hypotension.
9. **Concurrent management of the dyslipidaemia.** With established coronary artery disease the LDL target is **below 55 mg/dL (1.4 mmol/L) with at least a 50% reduction from baseline**. Give a **high-intensity statin (atorvastatin 40–80 mg or rosuvastatin 20–40 mg)**, **add ezetimibe 10 mg** if the target is not reached, and consider a **PCSK9 inhibitor or bempedoic acid** thereafter. **Intensive LDL lowering has been shown to be beneficial in high-risk older patients with established cardiovascular disease.** Watch for **CYP3A4 interactions** with amlodipine, diltiazem, verapamil and amiodarone — **avoid high-dose simvastatin**. Check **lipids and liver function at 6–12 weeks** and address **statin-associated muscle symptoms** promptly rather than allowing silent discontinuation.
10. **Complete the secondary prevention package and follow up.** Add **aspirin 75 mg daily** (secondary prevention — established coronary disease), **sublingual GTN for angina with clear instructions**, and consider an **SGLT2 inhibitor or GLP-1 receptor agonist** if diabetes coexists. Arrange **cardiac rehabilitation**, **influenza, pneumococcal and COVID-19 vaccination**, and **screening for and treatment of obstructive sleep apnoea, depression and anaemia**. Follow up **monthly until controlled, then 3–6 monthly**, with **annual renal function, electrolytes, lipids and ECG**. Reinforce **adherence at every visit** — non-adherence is the commonest cause of apparent resistant hypertension. Add **Indian context**: high dietary salt, low potassium intake, early-onset and more aggressive ASCVD, and a large treatment gap — **API and Lipid Association of India consensus** recommend intensive risk factor control in this group.

Latest Updates – 2 Points (2023–Present)

11. **2025 AHA/ACC multisociety High Blood Pressure Guideline** — the first major US update since 2017, and **co-authored by the American Geriatrics Society**. Key changes: a **universal treatment target of below 130/80 mmHg with further encouragement to reach a systolic pressure below 120 mmHg**, supported by SPRINT, **STEP** (which specifically randomised patients aged 60–80), **ESPRIT** and **BPROAD**; replacement of the Pooled Cohort Equations with the **PREVENT risk calculator**; a strong endorsement of **single-pill combination therapy** and of **out-of-office (home or ambulatory) measurement for both diagnosis and titration**; a new Class IIb recommendation for **renal denervation** in uncontrolled hypertension; and **explicit individualised exceptions to the target for institutionalised patients, those with limited life expectancy and the frail**.
12. **2024 ESC Guidelines for Elevated Blood Pressure and Hypertension** introduced a **new intermediate category of "Elevated BP" (systolic 120–139 or diastolic 70–89 mmHg)**, in which treatment is considered for those at high cardiovascular risk, and set a **general on-treatment target of systolic 120–129 mmHg where tolerated**. Crucially for geriatric practice, the guideline recommends that treatment be guided by **tolerability rather than by chronological age**, mandates **routine screening for orthostatic hypotension**, and applies a **less intensive, symptom-guided target in patients with significant frailty or limited life expectancy**.

Question 14. Stages of hypertension according to JNC 8, and the JNC 8 target blood pressure in people over 60

7-Mark Answer | 6 textbook points + 1 latest update

Important framing point to state at the start of the answer: JNC 8 (2014) did not create a staging system. It was a treatment-threshold and target guideline; the stages that are conventionally quoted belong to **JNC 7 (2003)**. Stating this explicitly earns marks — many candidates conflate the two.

Textbook Core – 6 Points

1. **Classification (JNC 7 stages, retained for reference).** The textbook definition is a **systolic pressure of 140 mmHg or greater and/or a diastolic pressure of 90 mmHg or greater**.

Category	Systolic (mmHg)		Diastolic (mmHg)
Normal	< 120	and	< 80
Prehypertension	120–139	or	80–89
Stage 1 hypertension	**140–159**	or	**90–99**
Stage 2 hypertension	**≥ 160**	or	**≥ 100**
Isolated systolic hypertension	**≥ 140**	and	**< 90**

2. **What JNC 8 actually did.** JNC 8 (published in **JAMA, 2014**) was an **evidence-based panel report addressing nine questions on thresholds, targets and drug choice**, deliberately restricted to **randomised controlled trial evidence**. It **did not define stages, did not address measurement technique, secondary hypertension, lifestyle modification or resistant hypertension**, and was **not formally endorsed by the NHLBI**.
3. **The JNC 8 recommendation for people over 60 — the core of the question. In the general population aged 60 years and older, initiate pharmacological treatment when the blood pressure is ≥ 150/90 mmHg, and treat to a goal of below 150/90 mmHg (Grade A, strong recommendation).** This **relaxation of the systolic threshold from 140 to 150 mmHg** was the single most controversial and most examinable element of JNC 8, and was based chiefly on **HYVET, SHEP and Syst-Eur**. The panel added a **corollary (expert opinion)**: if treatment already achieves a lower systolic pressure without adverse effects on health or quality of life, **treatment need not be adjusted upwards**. A **minority of the panel dissented**, arguing the evidence was insufficient to raise the threshold above 140 mmHg.
4. **Other JNC 8 thresholds and targets.**

Group	Threshold to treat	Goal
General population **≥ 60 years**	**≥ 150/90**	**< 150/90**
General population < 60 years	≥ 140/90	< 140/90
Diabetes (any age)	≥ 140/90	< 140/90
Chronic kidney disease (any age)	≥ 140/90	< 140/90

Note that JNC 8 **relaxed the diabetes and CKD targets from the previous 130/80 mmHg**.

5. **JNC 8 drug recommendations.** In the **general non-Black population, including those with diabetes**, first-line treatment may be a **thiazide-type diuretic, calcium channel blocker, ACE inhibitor or ARB**. In the **general Black population, including those with diabetes**, first-line treatment should be a **thiazide-type diuretic or calcium channel blocker**. In **chronic kidney disease of any race, an ACE inhibitor or ARB should be included** for renal protection. **Beta-blockers were NOT recommended as first-line therapy** (based on the LIFE trial), which was another notable departure from JNC 7. Titration strategies: maximise the first drug, add a second before maximising the first, or start with two drugs.
6. **Criticisms and the geriatric perspective.** The over-60 target of 150/90 mmHg was criticised as **too permissive**, particularly for patients with coronary artery disease or previous stroke, and it was **overturned by SPRINT (2015)**, which showed that targeting a systolic pressure below 120 mmHg reduced cardiovascular events and all-cause mortality, including in a prespecified subgroup aged 75 and over. **The enduring, examinable geriatric principle from JNC 8 is nevertheless correct and still current: blood pressure targets in older people must be individualised and balanced against orthostatic hypotension, falls, polypharmacy, frailty and quality of life.** The important practical caveat is that **SPRINT measured unattended automated office blood pressure, which reads roughly 5–10 mmHg lower than conventional office measurement**.

Latest Update – 1 Point (2023–Present)

7. **JNC 8 is now obsolete and has been superseded twice over.** The **2025 AHA/ACC multisociety guideline** (co-authored by the American Geriatrics Society) **retires and replaces the 2017 ACC/AHA guideline and sets a universal target of below 130/80 mmHg, with encouragement to reach a systolic pressure below 120 mmHg**, supported by SPRINT, **STEP** (in patients aged 60–80), **ESPRIT** and **BPROAD**. It also introduces the **PREVENT risk calculator** in place of the Pooled Cohort Equations, endorses **single-pill combinations** and **home/ambulatory measurement**, and provides **explicit individualised exceptions for institutionalised patients, the frail and those with limited life expectancy**. In parallel the **2024 ESC guideline** introduced the intermediate category of **"Elevated BP" (120–139/70–89 mmHg)** and a target of **120–129 mmHg systolic where tolerated**.

Current Practice Update

Textbook / JNC 8	Age ≥ 60 — treat at ≥ 150/90 mmHg to a goal of < 150/90 mmHg; diabetes and CKD goal < 140/90 mmHg.
Current recommendation	2025 AHA/ACC — universal target < 130/80 mmHg with encouragement toward < 120 mmHg systolic; 2024 ESC — 120–129 mmHg systolic where tolerated; both individualise for frailty.
Exam approach	Answer the question as asked (JNC 8: < 150/90 over 60), then add one line: "JNC 8 has been superseded — SPRINT, STEP and the 2025 AHA/ACC guideline now recommend < 130/80 mmHg, individualised for frailty."

Question 15. Accelerated hypertension

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definitions and terminology. Accelerated hypertension** is a **severe elevation of blood pressure (usually diastolic > 120–130 mmHg) with grade III retinopathy — flame haemorrhages, cotton-wool spots and hard exudates**. **Malignant hypertension** is the same picture **with grade IV retinopathy, that is, papilloedema**. The modern classification is more useful:

Term	Definition	Management
Hypertensive urgency	Severe hypertension (usually ≥ 180/120) **WITHOUT acute target-organ damage**	**Oral** agents, lower over 24–48 h, outpatient or short observation
Hypertensive emergency	Severe hypertension **WITH acute, ongoing target-organ damage**	**Intravenous** therapy in a monitored setting

The presence of acute target-organ damage, not the absolute number, defines the emergency.

2. **Pathophysiology.** A rapid rise in blood pressure overwhelms **vascular autoregulation**, causing **endothelial injury, loss of vasomotor tone and increased permeability**. The histological hallmarks are **fibrinoid necrosis of arterioles and proliferative (onion-skin) endarteritis**. This triggers a self-perpetuating cycle: ischaemia → renin–angiotensin activation → further vasoconstriction and pressure natriuresis → volume depletion → more renin release. In the brain, breakthrough of cerebral autoregulation produces **vasogenic cerebral oedema (hypertensive encephalopathy, PRES)**; in small vessels it causes **microangiopathic haemolytic anaemia with thrombocytopenia**.

3. **Causes. Essential hypertension that is untreated or where treatment has been abruptly stopped** (the commonest scenario, and abrupt clonidine or beta-blocker withdrawal is a classic trigger). Secondary causes are disproportionately represented: **renal parenchymal disease, renovascular disease (bilateral renal artery stenosis, fibromuscular dysplasia), primary aldosteronism, phaeochromocytoma, Cushing's syndrome, coarctation, systemic sclerosis renal crisis, and eclampsia**. Drugs and toxins: **cocaine, amphetamines, sympathomimetics and decongestants, ciclosporin and tacrolimus, erythropoietin, NSAIDs, corticosteroids, VEGF inhibitors and tyrosine kinase inhibitors, MAOI–tyramine interaction, and steroid or liquorice excess**.
4. **Clinical features by target organ. Eye** — blurred vision, visual loss; grade III/IV retinopathy on fundoscopy. **Brain** — **hypertensive encephalopathy** with headache, nausea, vomiting, visual disturbance, confusion, seizures and coma; also **intracerebral haemorrhage, subarachnoid haemorrhage and ischaemic stroke**. **Heart** — **acute pulmonary oedema, acute coronary syndrome, aortic dissection**. **Kidney** — **acute kidney injury with haematuria, proteinuria and red cell casts**. **Blood** — **microangiopathic haemolytic anaemia with schistocytes and thrombocytopenia**. **In older patients, presentation may be non-specific — delirium, falls or unexplained deterioration — so fundoscopy and urinalysis must be performed in every severely hypertensive older patient.**
5. **Investigations. Fundoscopy is mandatory and is the single most important bedside investigation.** Also: **urinalysis and urine microscopy for haematuria, proteinuria and casts; urea, electrolytes and creatinine; full blood count with a blood film for schistocytes; LDH, haptoglobin and reticulocyte count; ECG and troponin; chest radiograph; and echocardiography**. Imaging as indicated: **CT or MRI brain** for neurological features (PRES shows posterior white-matter oedema), **CT aortogram** for suspected dissection. Investigate for **secondary causes once stabilised** — renal ultrasound with Doppler, plasma aldosterone-to-renin ratio, plasma or urinary metanephrines, and a full drug and substance history.
6. **Management. Hypertensive urgency:** treat with **oral agents (amlodipine, an ACE inhibitor, a beta-blocker) and reduce the pressure gradually over 24–48 hours**, with close outpatient follow-up. **Never use sublingual short-acting nifedipine — the uncontrolled fall in pressure precipitates stroke and myocardial infarction, a particular danger in the older patient with impaired cerebral autoregulation. Hypertensive emergency:** admit to a monitored bed with **intra-arterial pressure monitoring** and use titratable **intravenous** agents. The general rule is to **reduce the mean arterial pressure by no more than 20–25% in the first hour, then to about 160/100 mmHg over the next 2–6 hours, and to normal over 24–48 hours**. **Important exceptions:** in **aortic dissection**, reduce systolic pressure to **< 120 mmHg and heart rate < 60/min within 20 minutes** using a **beta-blocker (esmolol or labetalol) FIRST, then a vasodilator**; in **acute ischaemic stroke**, do not lower unless > 220/120 mmHg (or thrombolysis is planned, when the target is < 185/110 mmHg). Drug choice by context: **labetalol or nicardipine** for encephalopathy and stroke; **glyceryl trinitrate** for acute pulmonary oedema or ACS; **esmolol plus a vasodilator** for dissection; **phentolamine** for phaeochromocytoma; **labetalol or hydralazine with magnesium** for eclampsia. **Avoid diuretics unless there is pulmonary oedema**, since these patients are often volume-depleted from pressure natriuresis.

Latest Update – 1 Point (2023–Present)

7. The **2024 ESC hypertension guideline and the 2025 AHA/ACC guideline** both reinforce a shift away from treating a number toward **treating the presence of acute target-organ damage**. Specific practice points: for **hypertensive urgency without organ damage there is no benefit and potential harm from rapid parenteral lowering** — oral therapy with follow-up within days is preferred, and **routine admission is discouraged**; the **2025 AHA/ACC guideline provides drug- and condition-specific intravenous protocols** (labetalol, nicardipine, clevidipine, esmolol, enalaprilat, fenoldopam) rather than a single generic target; and both guidelines **advise against short-acting oral or sublingual agents in any setting**. The 2025 guideline also adds a Class IIb recommendation for **renal denervation** in patients whose hypertension remains uncontrolled despite optimal therapy or who cannot tolerate medication.

Question 16. Isolated systolic hypertension — cut-off value, treatment and prognosis

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and cut-off. Isolated systolic hypertension (ISH) is defined as a systolic pressure of 140 mmHg or greater WITH a diastolic pressure of less than 90 mmHg.** It is the **commonest form of hypertension in older adults**, accounting for the majority of hypertension after the age of 60, and its prevalence rises steadily with age. A **wide pulse pressure (systolic minus diastolic, normally < 60 mmHg)** is its defining haemodynamic feature and is itself a strong independent predictor of cardiovascular events.

2. **Pathophysiology.** ISH results from **age-related stiffening of the large conduit arteries** — degeneration and fragmentation of **elastin** with increased **collagen** deposition, calcification, endothelial dysfunction and reduced nitric oxide availability. Loss of the aortic "Windkessel" cushioning function means the **stroke volume is ejected into a rigid tube, raising systolic pressure**, while **faster pulse-wave velocity causes the reflected wave to return during systole rather than diastole, further augmenting systolic pressure and lowering diastolic pressure**. Contributory factors: high salt intake, obesity, diabetes, chronic kidney disease, and high-output states such as anaemia, thyrotoxicosis, aortic regurgitation, arteriovenous fistula and Paget's disease.
3. **Clinical assessment and pitfalls.** Most patients are asymptomatic. Confirm with repeated measurements and **home or ambulatory monitoring**. **Three specific pitfalls in the old: (i) always measure standing blood pressure, since orthostatic hypotension coexists in up to a third and limits treatment; (ii) exclude pseudohypertension from rigid calcified arteries, suggested by a palpable radial artery despite cuff occlusion (Osler's sign) and by high readings without target-organ damage; (iii) look for white-coat and masked hypertension.** Assess target-organ damage — **ECG and echocardiography for left ventricular hypertrophy, eGFR and urine ACR, fundoscopy**.
4. **Treatment thresholds and targets.** Treat when the systolic pressure is **persistently ≥ 140 mmHg** (or lower in high-risk patients), aiming for a **systolic pressure below 130 mmHg where tolerated**. **The critical caution is that lowering systolic pressure inevitably lowers diastolic pressure further, and a diastolic pressure below about 60–65 mmHg may compromise coronary perfusion, which occurs in diastole — the "J-curve".** Therefore titrate to **symptoms and standing blood pressure**, accept a higher systolic target in those with symptomatic postural hypotension, and relax targets in **frailty, dementia, recurrent falls or limited life expectancy**. Begin with **lifestyle measures — salt restriction below 5 g daily, weight reduction, DASH-type diet, aerobic exercise, alcohol moderation and withdrawal of NSAIDs**.
5. **Drug treatment. Thiazide-like diuretics (indapamide, chlorthalidone) and dihydropyridine calcium channel blockers (amlodipine) are first-line**, because they are the agents proven in the ISH trials and they specifically reduce arterial stiffness and central pressure. **ACE inhibitors and ARBs** are effective alternatives and are preferred with diabetes, chronic kidney disease, heart failure or previous myocardial infarction. **Beta-blockers are less effective in ISH** — by slowing the heart they increase stroke volume and, through wave reflection, may raise central aortic pressure — so they are used only for a compelling indication such as angina, prior MI or rate control. **Start with one low-dose agent (or a low-dose single-pill combination), review 4-weekly, and add rather than maximise.** Monitor **electrolytes and renal function, and check for hyponatraemia, hypokalaemia, gout and postural dizziness**.
6. **Prognosis.** ISH is **not a benign consequence of ageing**. **Systolic pressure and pulse pressure are stronger predictors of cardiovascular events in older adults than diastolic pressure**, and ISH carries an increased risk of **stroke, heart failure, coronary events, atrial fibrillation, chronic kidney disease, cognitive decline and vascular dementia**. The benefit of treatment is well established: **SHEP** reduced stroke by about 36%, **Syst-Eur** reduced stroke by about 42% and also reduced incident dementia, and **HYVET**, in patients aged 80 and over, showed reductions in stroke, heart failure and **all-cause mortality** — establishing that **treating hypertension is worthwhile even in the very old**. The counterweight is that over-treatment causes **falls, syncope, fractures, acute kidney injury and electrolyte disturbance**, so the outcome depends on careful individualised titration.

Latest Update – 1 Point (2023–Present)

7. **Intensive systolic lowering is now supported by trials conducted specifically in older adults.** The **STEP trial** randomised Chinese patients **aged 60–80** to a systolic target of 110–130 versus 130–150 mmHg and found **a significant reduction in cardiovascular events in the intensive group, with no increase in falls, syncope or acute kidney injury**; **ESPRIT** (2024) and **BPROAD** (2024, in diabetes) reached concordant conclusions. On this basis the **2025 AHA/ACC guideline** sets a universal target of **below 130/80 mmHg with encouragement toward below 120 mmHg systolic**, and the **2024 ESC guideline** targets **120–129 mmHg systolic where tolerated** — both explicitly stating that **chronological age alone should not raise the target, but frailty, symptomatic orthostatic hypotension and limited life expectancy should**.

Question 17. Postural hypotension in the elderly — evaluation and management

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and prevalence.** Orthostatic (postural) hypotension is a **sustained fall in systolic blood pressure of at least 20 mmHg, or in diastolic pressure of at least 10 mmHg, within 3 minutes of standing** (or of head-up tilt to 60°). Variants: **initial OH** (a transient fall within 15 seconds), **delayed OH** (beyond 3 minutes, requiring prolonged standing or tilt to detect), and **post-prandial hypotension** (a fall within 2 hours of a meal). **It is very common: a postural fall of more than 20 mmHg is found in about 30% of a large elderly population, and a fall of more than 40 mmHg in 10%. Baroreceptor responses become more sluggish with age**, giving an increased tendency to postural syncope.
2. **Causes — drugs first. Drugs are the commonest and most reversible cause.** Implicated agents include **ganglion blockers, diuretics, phenothiazines, antihistamines, antidepressants, benzodiazepines, barbiturates and antiparkinsonian drugs**; cardiovascular drugs are particularly important — **nitrates, beta-blockers and nifedipine** — and **donepezil may increase the risk of syncope**. Also alpha-blockers, ACE inhibitors, ARBs, opioids and alcohol. **Non-neurogenic causes: volume depletion (dehydration, haemorrhage, diarrhoea, vomiting, poor oral intake), sepsis, anaemia, adrenal insufficiency, prolonged bed rest and deconditioning, varicose veins, and haemodialysis** — orthostatic hypotension and syncope are common in the elderly following haemodialysis. **Neurogenic causes: autonomic neuropathy (diabetes, amyloidosis, Guillain–Barré, Shy–Drager/multiple system atrophy), Parkinson's disease, dementia with Lewy bodies, pure autonomic failure and spinal cord disease, particularly traumatic cervical cord lesions**.
3. **Clinical features. Light-headedness, dizziness, blurred or tunnel vision, "coat-hanger" ache across the neck and shoulders, generalised weakness, fatigue and cognitive slowing on standing**, progressing to **presyncope and syncope**. **In the older patient the presentation is frequently NOT dizziness but unexplained falls, drop attacks, transient confusion or functional decline, with no recall of loss of consciousness — so orthostatic hypotension must be actively sought in every faller. Symptoms are typically worst on rising in the morning, after meals, in hot weather, after exertion, after alcohol, and during intercurrent illness.**
4. **Evaluation.** Measure blood pressure and heart rate **supine after 5 minutes rest, then at 1 and 3 minutes of standing**; extend to 5–10 minutes if delayed OH is suspected. **A compensatory rise in heart rate suggests a non-neurogenic cause such as volume depletion, whereas a blunted or absent heart rate response suggests neurogenic autonomic failure.** Perform a **head-up tilt table test** if standing measurements are negative but the history is suggestive. Take a complete **drug history** and examine for **dehydration, anaemia, parkinsonism, peripheral neuropathy and cognitive impairment**. Investigations: **full blood count, urea, electrolytes, creatinine, glucose and HbA1c, B12, morning cortisol or short Synacthen test, thyroid function, ECG** and, where relevant, serum and urine electrophoresis for amyloid. **Exclude treatable conditions such as Addison's disease.** Screen for **supine hypertension**, which frequently coexists and complicates treatment.
5. **Non-pharmacological management — always first. Review the medication**; **it is not always possible to discontinue the relevant drugs — for example in Parkinson's disease the effect of dopaminergic drugs in aggravating the postural fall must be balanced against their therapeutic benefit.** Then: **avoid factors causing vasodilatation — high temperatures, marked exertion and alcohol**; eat **small frequent meals rather than large ones** (to limit post-prandial splanchnic pooling), and reduce refined carbohydrate; **avoid dehydration** and liberalise salt and fluid intake where not contraindicated. **Change posture slowly and reverse the change temporarily if symptoms supervene.** Teach **physical counter-manoeuvres — crossing the legs, tensing the calf muscles and abdominal compression**, which transiently ameliorate symptoms. **Elastic compression stockings** (or an abdominal binder) contribute significantly, though patients may need help putting them on and they are hard to tolerate in hot weather. **Sleeping with a slight head-up tilt** helps, possibly by expanding plasma volume, but more than about 10° is poorly tolerated. Encourage patients to **remain as active as possible**, since chronic exposure to low blood pressure appears to improve cerebral autoregulation.
6. **Drug treatment.** Add only if the above measures fail. **Most drugs are used outside their licence and the benefits may be limited. Fludrocortisone 100–200 µg at night is usually started first**, acting by salt and water retention — monitor for **hypokalaemia, oedema, heart failure and supine hypertension**. **Ephedrine**, a sympathomimetic, can be added at **15 mg three times daily, increasing if necessary to 30 mg three times daily**; higher doses cause **tremor, tachycardia and agitation**. Other agents used include **midodrine** (an α_1-agonist, given three times daily with the last dose at least 4 hours before lying down), **desmopressin** for nocturnal polyuria and morning postural hypotension, and **erythropoietin** where there is anaemia. **Supine hypertension is the main risk of all drug treatment** — manage it by head-up sleeping, avoiding daytime recumbency, and a short-acting nocturnal antihypertensive if needed. **Cardiac pacing does not help.** Finally, because **the risks of serious injury from falls are very high in this population**, the patient must understand the risks and take precautions to avoid attacks wherever possible.

Latest Update – 1 Point (2023–Present)

7. The **2024 ESC hypertension guideline** makes **routine screening for orthostatic hypotension a standard part of hypertension assessment in older adults**, recommending that standing blood pressure be measured at every visit and that **treatment be titrated to the standing rather than the seated pressure** where postural symptoms exist. Importantly, it also states that **orthostatic hypotension is not in itself a reason to leave hypertension untreated** — analyses from SPRINT and pooled trial data showed that intensive blood pressure lowering did **not** increase orthostatic hypotension with symptoms, and that **treating the underlying hypertension often improves rather than worsens orthostatic tolerance**. In parallel, the **AGS Beers Criteria 2023** continue to list drugs to avoid in patients with a history of syncope or falls, reinforcing medication review as the first therapeutic step.

D. Valvular and Myocardial Disease

Question 18. Aortic stenosis — clinical presentation, diagnosis and management

7-Mark Answer | 6 textbook points + 1 latest update | ***Asked ×3***

Textbook Core – 6 Points

1. **Epidemiology and aetiology. Acquired calcific degenerative aortic stenosis is the commonest valve disease in the elderly, with a prevalence of 2.8% in those aged 75 and over**, and it is found at autopsy in about 4–6% of those over 65. **Aortic valve cusp sclerosis or calcification is present in 26–29% of adults older than 65.** Isolated aortic stenosis is commoner in men except over the age of 80, where women predominate. Degenerative calcification was formerly thought to be passive calcium deposition, but is now known to share the **pathophysiology of vascular atherosclerosis** — lipid deposition, inflammatory cell infiltration, basement membrane disruption and calcification, a concept termed **"valvulo-metabolic risk"**. Other causes: **bicuspid valve** (presents in the 50s–60s) and **rheumatic disease**, still important in India.
2. **Clinical presentation.** The usual presentation in older adults is **fatigue, syncope, angina pectoris and congestive heart failure**; exertional dyspnoea is often the earliest symptom. **The development of symptoms — angina, syncope or heart failure — identifies the critical point in the natural history, because symptomatic aortic stenosis without intervention has only a 20% three-year survival.** Other features: exertional dizziness, sudden death, and **gastrointestinal bleeding from angiodysplasia with acquired von Willebrand disease (Heyde's syndrome)**. Note that **the asymptomatic state is difficult to establish in the elderly because of a gradual reduction in activity or a sedentary lifestyle** — patients unconsciously limit themselves.
3. **Physical signs and their unreliability in the old.** The classical findings are a **slow-rising, low-volume pulse (pulsus parvus et tardus), a narrow pulse pressure, a heaving sustained apex beat, a soft or absent second heart sound, an S4, and an ejection systolic murmur radiating to the carotids**. **However, the typical murmur and pulse of aortic stenosis may be modified in older adults: systemic hypertension may shorten the systolic murmur, giving it the character of an aortic sclerosis murmur, and loss of vascular elasticity may modify the pulse pressure so that the typical pulse contour is absent.** The murmur may also be maximal at the apex and fail to radiate (Gallavardin phenomenon), mimicking mitral regurgitation. **Physical examination alone is therefore not reliable for diagnosing aortic stenosis in older adults**, and because systolic murmurs are so common in this age group, differentiating mitral regurgitation, aortic sclerosis and aortic stenosis by auscultation is a genuine challenge.
4. **Diagnosis. The addition of Doppler flow studies to echocardiography has greatly improved diagnostic accuracy.** Severe aortic stenosis is defined by an **aortic valve area < 1.0 cm² (or < 0.6 cm²/m² indexed), a peak transvalvular velocity ≥ 4.0 m/s, and a mean gradient ≥ 40 mmHg**. Be alert to **low-flow, low-gradient severe aortic stenosis** (small valve area with a low gradient) — with a **reduced ejection fraction**, use **dobutamine stress echocardiography** to distinguish true severe stenosis from pseudo-severe; with a **preserved ejection fraction**, use the **calcium score on CT**. **Left ventricular catheterisation remains the most reliable method of assessing aortic stenosis in older adults but should be reserved for patients who are symptomatic (angina, syncope or dyspnoea) and in whom surgery is contemplated.** An **exercise test is recommended to determine whether an apparently asymptomatic patient is truly asymptomatic** — but is **contraindicated once symptoms are present**. Add **BNP** and coronary angiography before intervention.
5. **Management — general. There is no effective medical therapy that alters the natural history; valve replacement is the only definitive treatment.** Medical care is supportive: cautious diuretics for congestion, control of hypertension (avoid excessive vasodilatation), rate control and prompt cardioversion of atrial fibrillation, and treatment of coexisting coronary disease. **Avoid nitrates and high-dose vasodilators in severe stenosis** because a fixed cardiac output makes profound hypotension likely. Statins do not slow progression. **Follow asymptomatic patients with serial echocardiography** and educate them to report symptoms immediately.

6. **Intervention — SAVR versus TAVI. Survival of the elderly patient after successful surgical aortic valve replacement is similar to that of the general population and enables return to an independent, active life.** Operative mortality approaches that of younger patients, and **it is not until patients reach their 80s that age alone becomes a risk factor**; five-year survival for UK octogenarians undergoing SAVR is about 65% (about 55% with concomitant CABG). **Once symptomatic aortic valve disease is diagnosed in a patient aged 80 or more, early referral for valve replacement avoids the hazards of falling LV function, loss of contractile reserve, urgent surgery and sudden death. TAVI** improves five-year survival compared with medical treatment in inoperable patients, is equivalent to SAVR in high-risk patients with possible peri-procedural advantage, and is now used in intermediate and lower-risk patients; **the choice between SAVR and TAVI must be made by the Heart Team** on clinical, anatomical and technical grounds. Considerations favouring one over the other include the **lower rate of paravalvular leak with SAVR, the higher pacemaker requirement with TAVI, and uncertain long-term TAVI valve durability**. A **bioprosthesis is generally preferred over a mechanical valve above 65 years**, since mortality from thromboembolism and anticoagulant-related haemorrhage is three times higher with mechanical valves in this group. **Balloon aortic valvuloplasty is no longer a definitive option** — mortality 3–10%, stroke 10–25%, 66% restenosis within six months, and fewer than 20% surviving a year — but retains a role as a **bridge** in very sick patients. Finally, **identify futility**: life expectancy under two years from malignancy, severe airways disease, established dementia or severe frailty, an STS score > 15%, dialysis dependence or home oxygen dependence all predict that even TAVI will not benefit the patient.

Latest Update – 1 Point (2023–Present)

7. **EARLY TAVR (NEJM 2024)** challenged the long-standing rule of watchful waiting in asymptomatic disease. In patients with **asymptomatic severe aortic stenosis and a normal ejection fraction**, **early TAVI significantly reduced the composite of death, stroke or unplanned cardiovascular hospitalisation compared with clinical surveillance**, driven largely by fewer unplanned hospitalisations — and notably **26% of the surveillance group required valve replacement within six months**, underlining how quickly these patients declare themselves. This supports a strategy of **earlier intervention in selected asymptomatic patients**, and is particularly relevant in older adults in whom, as the textbook notes, **the "asymptomatic" state is unreliable because activity is self-limited**.

Question 19. Aortic sclerosis

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** Aortic sclerosis is **focal thickening, fibrosis and calcification of the aortic valve leaflets WITHOUT significant obstruction to left ventricular outflow** — by convention a **peak transvalvular velocity below 2.5 m/s with normal leaflet excursion**. It is the **earliest, non-obstructive stage of the same disease process that culminates in calcific degenerative aortic stenosis**.
2. **Prevalence.** It is very common. **Aortic valve cusp sclerosis or calcification is present in 26% of adults older than 65**, and in the Cardiovascular Health Study the prevalence was **29% of the elderly**, rising to about **40–50% of those over 80**. Roughly **10–15% progress to haemodynamically significant aortic stenosis over 5–10 years**, at an average rate of about 1–2% per year.
3. **Pathogenesis — an atherosclerosis-like process.** Degenerative aortic valve disease was for many years thought to result from the **passive accumulation of calcium on the surface of the valve leaflet**; it is now established that its **aetiology has a pathophysiology similar to that of vascular atherosclerosis**. Early stages resemble active atherosclerotic inflammation — **basement membrane disruption, lipid deposition, inflammatory cell infiltration and calcification**, with later osteoblastic differentiation of valve interstitial cells. Shared risk factors — **age, male sex, smoking, hypertension, diabetes, dyslipidaemia (particularly raised Lp(a)), chronic kidney disease and visceral obesity** — give rise to the concept of **valvulo-metabolic risk**. Note that **only about 50% of patients with degenerative aortic valve disease have significant coronary disease, and most patients with coronary disease do not have valve disease**, so additional factors must be involved.
4. **Clinical features.** Aortic sclerosis is **asymptomatic by definition** and is usually found incidentally. The sign is an **ejection systolic murmur, loudest at the aortic area, typically early-peaking, short and grade 1–2/6**, and crucially it is accompanied by a **normal carotid upstroke, a normal pulse pressure and a normally preserved (often accentuated) aortic component of the second heart sound**. There is no left ventricular hypertrophy attributable to the valve.

5. **Distinguishing sclerosis from stenosis.** This is the crux of the answer, and **it can be difficult in older adults on clinical grounds alone**.

Feature	Aortic sclerosis	Aortic stenosis
Symptoms	None	Angina, syncope, heart failure
Carotid upstroke	**Normal**	**Slow-rising, low volume (parvus et tardus)**
Murmur peak	Early systolic, short	Mid-to-late peaking, long, harsh
Second heart sound (A2)	Normal or accentuated	Soft, single or absent
Apex beat	Normal	Sustained, heaving
Peak velocity / gradient	**< 2.5 m/s**, no gradient	**≥ 2.5 m/s**; severe if ≥ 4.0 m/s or mean gradient ≥ 40 mmHg

   Two textbook caveats make the clinical distinction unreliable: **systemic hypertension may shorten the systolic murmur of stenosis, giving it the character of a sclerosis murmur**, and **loss of vascular elasticity may modify the pulse pressure so that the typical pulse contour of stenosis is absent**. **Doppler echocardiography is therefore mandatory in any older patient with a systolic murmur.** Bedside manoeuvres also help differentiate the systolic murmurs of the elderly: the murmurs of both sclerosis and stenosis **increase after a premature ventricular contraction and with amyl nitrite and squatting, and decrease with Valsalva**, whereas the murmur of **hypertrophic obstructive cardiomyopathy increases with Valsalva and decreases with squatting**, and **mitral regurgitation does not increase after a premature beat**.

6. **Prognostic significance and management. Aortic sclerosis is NOT a benign incidental finding: it is associated with an increase in the risk of death from cardiovascular causes and the risk of myocardial infarction, even in the absence of haemodynamically significant obstruction of left ventricular outflow — an approximately 50% relative increase in cardiovascular death and myocardial infarction in the Cardiovascular Health Study. It should therefore be treated as a marker of systemic atherosclerotic burden and a trigger for comprehensive cardiovascular risk assessment: assess and treat blood pressure, lipids, diabetes, smoking, weight and renal function. No treatment retards progression of the valve lesion itself — statins have been shown not to slow progression despite the atherosclerotic pathogenesis, since 60–70% of patients with degenerative valve disease are already dyslipidaemic and on statins yet still progress rapidly, suggesting that targeting the entire metabolic risk rather than lipids alone may be more effective. Management is therefore risk factor modification plus surveillance: repeat echocardiography every 3–5 years, or sooner if symptoms develop or the murmur changes. Antibiotic prophylaxis for infective endocarditis is not recommended for aortic sclerosis.**

Latest Update – 1 Point (2023–Present)

7. **Lipoprotein(a) has emerged as the strongest causal lipid driver of calcific aortic valve disease**, and it is the one modifiable factor that distinguishes valve disease from ordinary atherosclerosis. Mendelian randomisation and cohort data show that **elevated Lp(a) and the LPA risk genotype are causally associated with aortic valve calcification, incident aortic stenosis and faster progression from sclerosis to stenosis** — which explains why statins, which do not lower Lp(a), have repeatedly failed to slow valve disease. Current **ESC/EAS and 2025 AHA/ACC guidance recommends measuring Lp(a) at least once in every adult**, and **Lp(a)-lowering agents (pelacarsen in Lp(a)HORIZON, olpasiran, lepodisiran) are in phase 3 trials**, offering the first prospect of disease-modifying therapy for calcific aortic valve disease.

Question 20. Mitral regurgitation in the elderly

6-Mark Answer | 5 textbook points + 1 latest update

Textbook Core – 5 Points

1. **Definition and classification.** Mitral regurgitation (MR) is **systolic backflow from the left ventricle into the left atrium** through an incompetent mitral valve. Classify as **PRIMARY (degenerative/organic) — a structural abnormality of the leaflets, chordae or annulus**, versus **SECONDARY (functional) — a structurally normal valve failing because of left ventricular or left atrial remodelling**. This distinction determines the entire management pathway. Also classify by **acute versus chronic**.

2. **Causes in older adults. Primary: mucoid (myxomatous) degeneration with mitral valve prolapse** — mucoid degeneration affects mainly the mitral valve, allowing the leaflet to stretch under normal intracardiac pressure and prolapse into the left atrium in systole; it is found in about **1% of autopsies over the age of 65**. Also **mitral annular calcification**, a disease of older adults found in **9% of autopsies over 50, rising strikingly with age and particularly in women — from 3.2% under 70 to 44% over 90** — which **often results in mitral insufficiency or conduction abnormalities and rarely stenosis, is an important contributor to congestive heart failure in older adults, and is a site for endocarditis**. Other primary causes: **infective endocarditis, rheumatic disease (important in India), and chordal rupture**, which is the usual mechanism of death directly from mucoid degeneration. **Secondary: ischaemic MR after myocardial infarction, dilated cardiomyopathy, and atrial functional MR from long-standing atrial fibrillation with left atrial and annular dilatation** — increasingly recognised as a distinct and common entity in the very old.
3. **Clinical features. Chronic MR** is often long asymptomatic, then presents with **exertional dyspnoea, fatigue, orthostatic intolerance, palpitations and atrial fibrillation**, and finally with **pulmonary hypertension and right heart failure**. **Acute severe MR** — from papillary muscle rupture after myocardial infarction or from endocarditis — presents as **abrupt pulmonary oedema and cardiogenic shock, often with only a soft or absent murmur** because atrial and ventricular pressures rapidly equalise. Signs of chronic MR: a **pansystolic murmur at the apex radiating to the axilla, a soft S1, a third heart sound, a displaced hyperdynamic apex beat** and, in mitral valve prolapse, a **mid-systolic click with a late systolic murmur** — though the murmur of prolapse can occur at any time in systole. Distinguishing features on manoeuvres: **the murmur of mitral regurgitation does NOT increase after a premature ventricular contraction and decreases with amyl nitrite and Valsalva**, unlike the aortic murmurs. **Mitral insufficiency caused by mucoid degeneration is usually well tolerated and rarely requires surgery**; with mitral annular calcification the regurgitation is **usually mild to moderate**, and **as many as two-thirds of patients with mitral annular calcification present with an apical systolic murmur of mitral regurgitation**.
4. **Investigations. Echocardiography is the best technique for diagnosing mitral annular calcification** and for assessing MR overall — it defines the **mechanism, severity (regurgitant volume, effective regurgitant orifice area, vena contracta), left ventricular size and ejection fraction, left atrial size and pulmonary artery pressure**. **Transoesophageal echocardiography** is used to define anatomy before intervention and to detect endocarditis. Add **ECG** (atrial fibrillation, left atrial enlargement, conduction abnormality with annular calcification), **chest radiograph**, **BNP**, **exercise echocardiography** for exertional symptoms with apparently moderate MR, and **coronary angiography** before surgery. **In severe chronic MR the ejection fraction is spuriously flattered by the low-impedance leak, so an EF below 60% already indicates significant left ventricular dysfunction.**
5. **Management. Acute severe MR** is a surgical emergency: stabilise with **afterload reduction (nitroprusside), diuretics and an intra-aortic balloon pump if hypotensive**, and proceed to urgent surgery. **Chronic primary MR:** there is no medical therapy that alters the natural history — **surgery (mitral valve repair in preference to replacement) is indicated for symptomatic severe MR, or for asymptomatic severe MR with an ejection fraction ≤ 60%, an end-systolic diameter ≥ 40 mm, new atrial fibrillation or pulmonary hypertension**. **Chronic secondary MR:** the first step is **optimal guideline-directed heart failure therapy plus cardiac resynchronisation and revascularisation where indicated**, because functional MR frequently improves with successful treatment of the ventricle. **Surgery is indicated only after this has failed**, and there is a well-established survival benefit from **correcting coexistent moderate or greater ischaemic mitral regurgitation at the time of CABG surgery**. Additional geriatric points: **anticoagulate for atrial fibrillation**; note that **mitral annular calcification carries a higher incidence of cerebral embolism, so anticoagulation with warfarin may be indicated**; **surgery for annular calcification is usually indicated only if endocarditis is superimposed**; and **a bioprosthesis is preferred over 70 years for a valve in the mitral position**. Subacute bacterial endocarditis prophylaxis is no longer recommended for mitral valve prolapse.

Latest Update – 1 Point (2023–Present)

6. **Transcatheter edge-to-edge repair (TEER, "MitraClip") is now established for older patients who are unsuitable for surgery.** Building on COAPT, two 2024 randomised trials in **secondary MR with heart failure** — **RESHAPE-HF2** and **MATTERHORN (both NEJM 2024)** — showed that **TEER added to guideline-directed medical therapy reduced heart failure hospitalisation and improved symptoms and quality of life**, with MATTERHORN additionally showing non-inferiority to surgery for the composite of death, hospitalisation, reintervention and assist device implantation, but with **significantly fewer major adverse events**. Because it is performed percutaneously without cardiopulmonary bypass, TEER is **especially attractive in the frail elderly**, and current ACC/AHA and ESC valve guidance recommends it for appropriately selected patients with severe symptomatic MR at high or prohibitive surgical risk, after Heart Team assessment.

Question 21. Infective endocarditis in the elderly

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and burden.** Infective endocarditis (IE) is infection of the **endocardium**, usually of the heart valves. In people over 65 the incidence is about **four times** that of the general population and mortality is about **twice** that of younger patients.
2. **Predisposing factors. Undiagnosed degenerative (calcific) aortic valve disease** and increased use of **invasive procedures and implanted devices** (pacemakers, prosthetic valves, intravascular catheters) are the main reasons for the rise. Other risks are **diabetes** and **gastrointestinal and genitourinary tract cancers**. Mitral annular calcification and mucoid mitral valve degeneration also predispose. In India, **rheumatic valvular disease** remains an important substrate.
3. **Microbiology changes with age.** The proportion due to **Staphylococcus aureus falls with age**, while **enterococci** and **Streptococcus bovis (gallolyticus)** emerge as major pathogens. Isolation of **S. bovis mandates colonoscopy** to look for colonic neoplasm. Viridans streptococci still predominate where rheumatic heart disease is common; coagulase-negative staphylococci cause device-related IE.
4. **Atypical presentation.** Fever may be **absent or low grade**. The older patient often presents with **delirium, anorexia, weight loss, falls, fatigue or unexplained anaemia** with a raised ESR/CRP. A **new or changing murmur** may be the only sign. Classical peripheral stigmata (Osler nodes, Janeway lesions, Roth spots, splinter haemorrhages) are **uncommon**, so diagnosis is frequently delayed.
5. **Diagnosis.** Take **three sets of blood cultures** from separate sites before antibiotics. **Transthoracic echocardiography** first; proceed to **transoesophageal echocardiography** if TTE is negative, or if there is a prosthetic valve or intracardiac device. Apply the **modified Duke criteria**. Send serology for culture-negative causes (Coxiella burnetii, Bartonella, Brucella).
6. **Management. Prolonged intravenous bactericidal antibiotics for 4–6 weeks**, guided by culture and sensitivity, with careful **renal-adjusted aminoglycoside dosing**. **Surgery** is indicated for heart failure, uncontrolled infection/abscess, prosthetic valve dehiscence, and large mobile vegetations with embolism — **age alone is not a contraindication**, though frailty raises operative risk. **Antibiotic prophylaxis strategy should take age into account** in global risk assessment before invasive gastrointestinal or genitourinary procedures.

Latest Update – 1 Point (2023–Present)

7. **2023 ESC Guidelines on Infective Endocarditis** adopt the **2023 Duke–ISCVID criteria**, which add **cardiac CT angiography** and **^{18}F-FDG PET/CT** as major imaging criteria (especially valuable for prosthetic valve and device infection in older adults). They also endorse **partial oral step-down antibiotic therapy** after at least 10 days of intravenous treatment in stabilised left-sided IE (**POET trial**), and **outpatient parenteral antibiotic therapy** — both reduce prolonged hospitalisation and deconditioning in frail elderly patients.

Current Practice Update

Textbook	Diagnosis by blood cultures, echocardiography and the modified Duke criteria; full course of intravenous antibiotics.
Current recommendation	2023 ESC / Duke–ISCVID criteria include cardiac CT and FDG-PET/CT as major criteria; partial oral therapy and OPAT are accepted in stabilised patients.
Exam approach	Write the modified Duke criteria, then add one line: "2023 ESC now incorporates the Duke–ISCVID criteria with advanced imaging and permits partial oral therapy (POET)."

Question 22. Cardiomyopathies — classification and management

7-Mark Answer | 6 textbook points + 1 latest update

Source note: Cardiomyopathy is **not covered adequately as a standalone topic in the uploaded textbook** (Pathy's refers to dilated and hypertrophic cardiomyopathy mainly as causes of sudden cardiac death; Essentials of Clinical Geriatrics covers idiopathic hypertrophic subaortic stenosis). Points 1–6 below are constructed from those textbook references supplemented by current standard guidance, which is clearly labelled.

Textbook Core – 6 Points

1. **Definition and classification.** A cardiomyopathy is a **myocardial disorder with structural and functional abnormality not explained by coronary disease, hypertension or valve disease**. Morphological types: **Dilated (DCM)**, **Hypertrophic (HCM)**, **Restrictive (RCM)**, **Arrhythmogenic right ventricular (ARVC)**, and **unclassified** (Takotsubo, left-ventricular non-compaction).

2. **Geriatric relevance. Dilated and hypertrophic cardiomyopathy are important causes of sudden cardiac death** in older people after coronary disease. **Wild-type transthyretin cardiac amyloidosis (ATTR-wt)** is the commonest restrictive cardiomyopathy of old age — suspect it in **HFpEF with left ventricular hypertrophy but low-voltage ECG**, bilateral carpal tunnel syndrome, lumbar canal stenosis, biceps tendon rupture and intolerance of antihypertensives.
3. **Dilated cardiomyopathy.** Dilated left ventricle with **systolic dysfunction**. Causes: ischaemic, **alcohol**, chemotherapy (**anthracyclines, trastuzumab**), thyroid disease, tachycardia-mediated, myocarditis, peripartum. Treatment is **four-pillar heart failure therapy — ARNI or ACE inhibitor, beta-blocker, MRA and SGLT2 inhibitor** — titrated slowly, with diuretics for congestion.
4. **Hypertrophic cardiomyopathy.** Asymmetric septal hypertrophy with **dynamic left ventricular outflow tract obstruction**; in older adults it may be mistaken for aortic stenosis and is described as **idiopathic hypertrophic subaortic stenosis (IHSS)**. The murmur **increases with Valsalva and standing** and **decreases with squatting**; a **bisferiens pulse** with no aortic regurgitant murmur is a clue. Diagnosis is by **echocardiography**. Therapy relies on **beta-blockers**; **avoid digoxin, diuretics, nitrates and vasodilators** which worsen obstruction. **Atrial fibrillation is poorly tolerated** and may need cardioversion.
5. **Restrictive cardiomyopathy. Impaired ventricular filling with normal or near-normal ejection fraction** and biatrial enlargement. Causes: **amyloidosis**, haemochromatosis, radiation, sarcoidosis and **endomyocardial fibrosis** (relevant in India). Diagnosis: echocardiography with **apical sparing on strain imaging**, cardiac MRI, **^{99m}Tc-PYP/DPD bone scintigraphy** for ATTR, and exclusion of a monoclonal protein (serum free light chains, immunofixation). Must be distinguished from **constrictive pericarditis**.
6. **Management principles in older adults.** Treat heart failure cautiously with attention to **preload dependence**; control and anticoagulate **atrial fibrillation**; correct anaemia and thyroid dysfunction. **ICD for sudden death prevention** only after weighing life expectancy, frailty and patient wishes. In amyloidosis **avoid digoxin, calcium channel blockers and high-dose beta-blockers**; use **tafamidis** as disease-modifying therapy in ATTR-CM. Genetic counselling and family screening for inherited forms.

Latest Update – 1 Point (2023–Present)

7. The **2023 ESC Guidelines on Cardiomyopathies** — the first standalone ESC cardiomyopathy guideline — adopt a **phenotype-based approach** with multimodality imaging and genetic testing for all patients and relatives. For the older patient, disease-modifying therapy for **ATTR cardiac amyloidosis** has expanded rapidly: after tafamidis (ATTR-ACT), the **ATTRibute-CM** trial (acoramidis, NEJM 2024) and **HELIOS-B** (vutrisiran, NEJM 2025) both reduced death and cardiovascular hospitalisation; and **mavacamten**, a cardiac myosin inhibitor (EXPLORER-HCM), is now approved for symptomatic obstructive HCM.

E. Arrhythmias and Cardiac Pacing

Question 23. Complete heart block and pacemaker indications

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** Third-degree (complete) heart block is **complete failure of conduction between atria and ventricles**, producing regular atrial activity with an **independent escape rhythm**. The escape is usually ventricular — **wide QRS at 30–40 beats per minute**. A nodal or junctional escape (narrow QRS, faster) means the block is higher, within the AV node or bundle of His. **The lower the origin of the escape rhythm, the less reliable it is.**
2. **Causes in the elderly. Idiopathic age-related fibrosis of the conduction system** (Lev and Lenègre disease) is commonest. Others: **ischaemic heart disease and inferior myocardial infarction**, drugs (**beta-blockers, digoxin, verapamil, diltiazem, amiodarone**), **hyperkalaemia**, calcific aortic valve disease and post-TAVI, infiltrative disease (**sarcoidosis, amyloidosis**), **neuromuscular disease** (myotonic dystrophy type 1, Kearns–Sayre syndrome), and cardiac surgery or AV junction ablation.
3. **Clinical features. Stokes–Adams attacks** (abrupt syncope without warning), presyncope, **falls**, fatigue, dyspnoea, angina and heart failure. Signs: slow regular pulse, **cannon 'a' waves** in the JVP, **variable intensity of the first heart sound** and a wide pulse pressure. Complete heart block is a classic cardiac cause of syncope in old age.
4. **Class I indications for permanent pacing.** (i) **Acquired complete heart block not attributable to a reversible or physiological cause — regardless of symptoms**. (ii) Complete heart block due to **neuromuscular disease with conduction disorder** (myotonic dystrophy type 1, Kearns–Sayre). (iii) **Symptomatic complete heart block occurring as a consequence of guideline-directed drug therapy that must be continued**.

5. **Related Class I / IIa indications. Mobitz type II second-degree block** not attributable to reversible causes should be paced **regardless of symptoms** (Class I); so should **unresolving advanced second-degree block after cardiac surgery or AV junction ablation** (Class I). Pacing is **reasonable (Class IIa)** in **infiltrative cardiomyopathy such as cardiac sarcoidosis with Mobitz type II block**, and in **Mobitz type I block when symptoms are clearly attributable to the block**.
6. **Pacemaker choice and complications. DDD (dual-chamber)** pacing preserves AV synchrony and is preferred in complete heart block with sinus rhythm; **VVI/R** is used when there is permanent atrial fibrillation. Pacing that maintains physiological ventricular activation (**CRT or His-bundle pacing**) should be considered when the **ejection fraction is below 50% and ventricular pacing is expected more than 40% of the time** (Class IIa). Complications: **pneumothorax 1–2% with the subclavian approach but under 0.1% with cephalic or axillary access**, tamponade under 0.2%, infection under 1%, lead displacement; early complications occur in about **7% within two weeks** and later complications in up to 10%. Risk factors are **female sex and low body mass index** — **increasing age itself is not associated with higher complication risk**. In cachectic patients with thin skin or skeletal deformity, a **sub-pectoral** position reduces erosion.

Latest Update – 1 Point (2023–Present)

7. The **2023 HRS/APHRS/LAHRS Guideline on Cardiac Physiologic Pacing** establishes **conduction system pacing** as a recommended alternative to conventional right-ventricular pacing when a **high ventricular pacing burden is anticipated** — as in complete heart block. **Left bundle branch area pacing (LBBAP)** has largely superseded His-bundle pacing because of better capture thresholds and lead stability. **Leadless pacemakers** (Micra AV2, Aveir) are an option for AV block in frail older patients with poor venous access, thin skin or high infection risk.

Current Practice Update

Textbook	Choice lies between VVI/R, AAI, DDD and CRT; direct His-bundle pacing is "increasingly popular" but technically challenging.
Current recommendation	2023 HRS physiologic pacing guideline — left bundle branch area pacing is the preferred conduction system pacing technique; leadless devices are established for selected patients.
Exam approach	Give the classical mode selection, then add: "2023 HRS guideline now recommends conduction system pacing (LBBAP) when high ventricular pacing burden is expected."

Question 24. Sick sinus syndrome

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** Sick sinus syndrome (**sinus node dysfunction**) is a spectrum of **inappropriate sinus bradycardia, sinus arrest or pause, sinoatrial exit block, chronotropic incompetence**, and **tachycardia-bradycardia syndrome**. Dysfunction may progress until **no sinus beats occur** and a junctional escape rhythm takes over. It is **primarily a disease of older people**, resulting from **degenerative or ischaemic change** that may also involve the AV node.
2. **Causes. Idiopathic age-related fibrosis** of the sinus node is commonest. Others: **ischaemic heart disease**, drugs (**beta-blockers, verapamil, diltiazem, digoxin, amiodarone, ivabradine, lithium, donepezil**), **hypothyroidism**, hyperkalaemia, infiltrative disease (amyloid, sarcoid), obstructive sleep apnoea, and cardiac surgery. **Always exclude a drug cause before implanting a pacemaker.**
3. **Clinical features. Recurrent syncope** from sinus pauses with an inadequate escape rhythm, presyncope, dizziness, **unexplained falls**, fatigue, confusion, and **exercise intolerance from chronotropic incompetence**. In **tachy-brady syndrome**, palpitations from atrial fibrillation or flutter are followed by a **long post-tachycardia pause** and syncope on termination. Many older patients are asymptomatic. **Both paroxysmal and chronic atrial fibrillation are commonly associated** with sinus node disease.
4. **Diagnosis.** Resting ECG, then **ambulatory Holter monitoring**; if symptoms are infrequent use **prolonged external monitoring or an implantable loop recorder**. **Symptom–rhythm correlation is essential** — an abnormal ECG without symptoms does not justify pacing. **Exercise testing** demonstrates chronotropic incompetence. Electrophysiological study (sinus node recovery time) is rarely required. Check **thyroid function, electrolytes and the drug chart**.
5. **Prognosis. Mortality appears to be unaffected by sinus node dysfunction itself**; survival is determined by **associated pathology such as ischaemic heart disease**. The main morbidity is **syncope with injury** and **thromboembolic stroke from associated atrial fibrillation** — assess stroke risk and anticoagulate accordingly, independently of the pacing decision.

6. **Management and pacing indications.** First **withdraw culprit drugs** and correct reversible causes. Pacing is **Class I** when (i) **symptoms are directly attributable to sinus node dysfunction**, and (ii) **sinus bradycardia develops secondary to guideline-directed treatment of another condition which must be continued**. Pacing **should be considered (Class IIa)** in **tachy–brady syndrome where symptoms are attributable to the bradycardia**, and **rate-responsive pacing** should be considered for **symptomatic chronotropic incompetence**. **AAI pacing** is used only in pure sinus node disease with no existing or expected disease elsewhere in the conduction system; otherwise **DDD(R)** is preferred, since VVI pacing causes pacemaker syndrome and more atrial fibrillation.

Latest Update – 1 Point (2023–Present)

7. The **2023 HRS/APHRS/LAHRS Cardiac Physiologic Pacing Guideline** reinforces that in sinus node dysfunction with intact AV conduction the aim is to **preserve intrinsic ventricular activation** — use **atrial-based (AAI/DDD) pacing** and enable **algorithms that minimise unnecessary right-ventricular pacing**, since a high right-ventricular pacing burden increases atrial fibrillation and heart failure. Conduction system pacing is reserved for those who also need ventricular pacing.

Question 25. Atrial fibrillation

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and epidemiology.** Atrial fibrillation (AF) is the **most common sustained cardiac arrhythmia**, characterised by **uncoordinated atrial activation with consequent loss of atrial mechanical function**. It is now regarded as a **multifactorial disease** caused by an interplay of cardiovascular and metabolic risk factors, systemic inflammation, and anatomical and electrical substrates. In 2016 more than **43 million people** were estimated to have AF; the **lifetime risk at age 55 is about 35%**. It is **1.5 times more common in men**, though onset is later in women (65 versus 60 years).
2. **Risk factors. All the classical cardiovascular risk factors are significantly associated with incident AF.** Each **10 mmHg rise in systolic blood pressure increases the risk of developing AF by 11–16%**; in diabetes there is a **dose–response relationship between HbA1c and incident AF**; and there is a **strong association between increasing age and increasing systemic inflammation as measured by C-reactive protein**. Others: heart failure, valvular disease (especially rheumatic mitral disease in India), obesity, obstructive sleep apnoea, alcohol, thyrotoxicosis, chronic kidney disease and cardiac surgery. **The risk of incident AF is directly related to the total burden of risk factors, rising progressively with the number present.**
3. **Clinical features and consequences.** Presentation may be with **palpitations, breathlessness, fatigue, chest pain, dizziness or syncope**, but AF is frequently **asymptomatic and detected incidentally** — or presents first as **stroke, heart failure or falls**. In older people the loss of the atrial contribution to ventricular filling is critical, because **they depend more on atrial contraction than on ventricular relaxation for left ventricular filling and therefore decompensate rapidly into heart failure**. Consequences: **up to 30% of all ischaemic strokes are due to AF**; **20–30% of AF patients develop heart failure**; there is an **up to 60% relative increase in risk of significant cognitive decline**; **more than 60% report impaired quality of life**; and AF causes an **up to 3.5-fold increase in cardiovascular and all-cause death**. The pulse is **irregularly irregular** with an apex–radial deficit — but note that **frequent atrial ectopic beats, common in the old, can produce a pulse that is confused with AF**, so confirm with an ECG and obtain a transthoracic echocardiogram if not previously done.
4. **Diagnosis and assessment.** Confirm with a **12-lead ECG showing absent P waves, an irregularly irregular QRS rhythm and a fibrillatory baseline**. For paroxysmal AF use **Holter monitoring, extended patch monitoring, an implantable loop recorder or a smartphone/wearable single-lead ECG**. Classify as **first-diagnosed, paroxysmal, persistent, long-standing persistent or permanent**. Investigate with **echocardiography** (left atrial size, valve disease, ejection fraction, left ventricular hypertrophy), **thyroid function, full blood count, renal and liver function, electrolytes**, and screen for **sleep apnoea and alcohol excess**.
5. **Anticoagulation — the priority.** Assess stroke risk with **CHA_2DS_2-VASc** and bleeding risk with **HAS-BLED**. Anticoagulate men scoring ≥ 2 and women ≥ 3. **A high HAS-BLED score is not a reason to withhold anticoagulation — it identifies modifiable risk factors to correct and prompts earlier review. DOACs are preferred over warfarin** in non-valvular AF; **apixaban has the best geriatric profile** (lowest major and gastrointestinal bleeding, safest in chronic kidney disease). **Warfarin is mandatory in mechanical prosthetic valves and moderate-to-severe rheumatic mitral stenosis.** Falls risk is a poor reason to withhold treatment — a patient would need to fall about **295 times a year** for the bleeding risk to outweigh the stroke benefit. Consider **left atrial appendage occlusion** when anticoagulation is absolutely contraindicated. In practice virtually every patient aged 75 or over already scores ≥ 2, so **anticoagulation is the default**.

6. **Rate versus rhythm control and integrated care. Rate control** is the usual first strategy in the elderly, with a resting target of **< 110/min (lenient) tightened to < 80/min if symptoms persist**: use a **beta-blocker or a rate-limiting calcium channel blocker (diltiazem, verapamil — avoid in heart failure)**, with **digoxin** as an add-on, particularly in the sedentary or hypotensive, at reduced dose with level monitoring. **Rhythm control** is indicated for persistent symptoms despite rate control, recent-onset AF, AF-related heart failure, or a young patient: options are **DC cardioversion (with 3 weeks of anticoagulation before and 4 weeks after, or a TOE-guided approach), antiarrhythmic drugs (amiodarone is the most usable in structural heart disease but has thyroid, hepatic, pulmonary, ocular and neurological toxicity in long-term use; flecainide and propafenone only with structurally normal hearts), and catheter ablation**, which is more effective than drugs and is reasonable in selected fitter older patients. **Pace-and-ablate (AV node ablation with pacing)** is an option for refractory rapid AF. Manage the whole patient with the **ABC pathway — Avoid stroke with anticoagulation, Better symptom control, Comorbidity and risk factor management**, which has been shown to improve outcomes.

Latest Update – 1 Point (2023–Present)

7. The **2024 ESC Guidelines for the Management of Atrial Fibrillation** made three examinable changes. First, **CHA_2DS_2-VASc has been replaced by CHA_2DS_2-VA — sex category is removed (maximum 7)**, with anticoagulation recommended at a score of ≥ 2 and considered at 1, on the grounds that female sex is an age-dependent risk modifier rather than an independent risk factor. Second, the ABC pathway has been reframed as the **AF-CARE pathway** — **C**omorbidity and risk factor management, **A**void stroke and thromboembolism, **R**educe symptoms by rate and rhythm control, and **E**valuation with dynamic reassessment — deliberately placing **comorbidity management first**. Third, following **EAST-AFNET 4** and **CASTLE-AF**, there is stronger support for **early rhythm control within 12 months of diagnosis** and for **catheter ablation as first-line therapy in paroxysmal AF and in AF with heart failure and reduced ejection fraction**.

Current Practice Update

Textbook	CHA_2DS_2-VASc with sex category; ABC pathway; rate control as the default strategy.
Current recommendation	2024 ESC — CHA_2DS_2-VA (sex removed); AF-CARE pathway with comorbidity management first; early rhythm control and first-line ablation in selected patients.
Exam approach	Draw CHA_2DS_2-VASc (still examinable), then add: "2024 ESC has replaced it with CHA_2DS_2-VA and the ABC pathway with AF-CARE."

Question 26. CHA2DS2-VASc and HAS-BLED scores in atrial fibrillation

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Purpose. CHA_2DS_2-VASc** estimates the annual risk of **ischaemic stroke and systemic thromboembolism** in non-valvular atrial fibrillation and decides who needs **oral anticoagulation**. **HAS-BLED** estimates **major bleeding risk** on anticoagulation. Atrial fibrillation causes **up to 30% of all ischaemic strokes** and a **3.5-fold increase** in cardiovascular and all-cause death.
2. **CHA_2DS_2-VASc components (maximum 9).**

Letter	Risk factor	Score
C	Congestive heart failure / LV dysfunction	1
H	Hypertension	1
A_2	**Age ≥ 75 years**	**2**
D	Diabetes mellitus	1
S_2	**Prior Stroke / TIA / thromboembolism**	**2**
V	Vascular disease (prior MI, PAD, aortic plaque)	1
A	Age 65–74 years	1
Sc	Sex category (female)	1

3. **Interpretation of CHA_2DS_2-VASc. Men ≥ 2 and women ≥ 3** → oral anticoagulation **recommended**. Men = 1, women = 2 → anticoagulation **should be considered**. Men = 0, women = 1 → **no antithrombotic therapy**. **Aspirin is not an acceptable alternative to anticoagulation.** Practically, almost every patient aged 75 or over already scores 2 or more — **age alone makes anticoagulation the default in geriatric practice**.

4. **HAS-BLED components (maximum 9). H**ypertension (uncontrolled systolic BP > 160 mmHg) 1; **A**bnormal renal **or** liver function, 1 each; **S**troke 1; **B**leeding history or predisposition (including anaemia) 1; **L**abile INR (time in therapeutic range < 60%) 1; **E**lderly (age > 65) 1; **D**rugs (antiplatelets, NSAIDs) **or** alcohol excess, 1 each.
5. **Interpretation of HAS-BLED.** A score of **≥ 3 indicates high bleeding risk**. **A high HAS-BLED score is NOT a reason to withhold anticoagulation.** Its purpose is to (i) identify and **correct modifiable risk factors** — control blood pressure, stop NSAIDs and unnecessary antiplatelets, limit alcohol, review renal function, avoid labile INR — and (ii) **schedule earlier and more frequent review**.
6. **Geriatric considerations. Falls risk is a very poor reason to withhold anticoagulation** — a patient would need to fall roughly **295 times a year** for the bleeding risk to outweigh the stroke benefit. Assess **frailty, cognition, adherence, swallowing, renal function and drug interactions** instead. Use the integrated **ABC pathway** (**A**void stroke with anticoagulation, **B**etter symptom control, **C**omorbidity and risk factor management), which improves outcomes in anticoagulated patients.

Latest Update – 1 Point (2023–Present)

7. The **2024 ESC Guidelines for the Management of Atrial Fibrillation** replaced CHA_2DS_2-VASc with the **CHA_2DS_2-VA score** — **sex category has been removed** (maximum 7) because female sex is an age-dependent risk modifier rather than an independent risk factor. Anticoagulation is **recommended at a score ≥ 2** and **should be considered at a score of 1**. The ABC pathway has been reframed as the **AF-CARE pathway** (**C**omorbidity and risk factor management, **A**void stroke and thromboembolism, **R**educe symptoms by rate and rhythm control, **E**valuation and dynamic reassessment).

Current Practice Update

Textbook	CHA_2DS_2-VASc including sex category; sex-specific thresholds (men ≥2, women ≥3); ABC pathway.
Current recommendation	2024 ESC — CHA_2DS_2-VA (sex removed, maximum 7), single threshold of ≥2 for both sexes; AF-CARE pathway.
Exam approach	Draw the full CHA_2DS_2-VASc table (still examinable), then write one line: "2024 ESC has replaced this with CHA_2DS_2-VA by removing sex category."

Question 27. Tachyarrhythmias

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and classification.** A tachyarrhythmia is a rhythm with a **ventricular rate above 100 beats per minute**. Classify first by **QRS width** — this is the practical bedside division:

Narrow complex (QRS < 120 ms) — supraventricular	Broad complex (QRS ≥ 120 ms)
Sinus tachycardia; **atrial fibrillation**; atrial flutter; atrial tachycardia; **multifocal atrial tachycardia** (classically in COPD); AV nodal re-entrant tachycardia (AVNRT); AV re-entrant tachycardia (AVRT)	**Ventricular tachycardia (monomorphic or polymorphic)**; **torsades de pointes**; **ventricular fibrillation**; SVT with aberrant conduction or pre-existing bundle branch block; pre-excited AF; paced rhythm

Any broad-complex tachycardia in an older patient with structural heart disease must be treated as ventricular tachycardia until proved otherwise.

2. **Epidemiology and substrate in old age. Abnormal heart rhythm increases with age even in those with normal hearts — the prevalence of atrial and ventricular ectopy reaches up to 100% in older people**, and **ventricular arrhythmias can be found in 70–80% of people over 60**. Age-related **fibrosis of the conduction system and atrial myocardium, chamber dilatation, ischaemic scar and hypertrophy** provide the substrate. For a ventricular tachyarrhythmia to develop, both a **substrate** — structural (infarcted or hypertrophic myocardium creating myocytes of differing refractory periods and a re-entrant circuit) or electrical (early or delayed after-depolarisations) — and a **trigger** are required; the trigger is typically transient, such as **electrolyte imbalance, acute ischaemia or an antiarrhythmic drug** (as in torsades de pointes). **Channelopathies such as congenital long QT and Brugada syndrome are uncommon in older age groups.**
3. **Clinical features. Palpitations, breathlessness, chest pain, dizziness, presyncope, syncope** or, in sustained VT, **cardiac arrest**. In older patients presentation is frequently atypical — **falls, confusion, fatigue, decompensated heart failure or an incidental finding**. Assess **haemodynamic stability** immediately, looking for the adverse features: **shock, syncope, myocardial ischaemia and heart failure**. Examine for **cannon 'a' waves and variable intensity of the first heart sound, which indicate AV dissociation and therefore VT**.

4. **Diagnosis.** Obtain a **12-lead ECG during the tachycardia wherever possible**, plus a rhythm strip; a **previous ECG in sinus rhythm** is invaluable for comparison. ECG features favouring **VT** over SVT with aberrancy: **AV dissociation, capture and fusion beats, QRS > 140 ms, extreme (northwest) axis, concordance across the precordial leads, and a history of previous myocardial infarction** — the last being the single most useful clinical discriminator. For intermittent arrhythmia use **Holter monitoring, an event recorder, an implantable loop recorder or wearable ECG**. Always check **potassium, magnesium, calcium, renal and thyroid function, troponin and digoxin level**, review the drug chart for **QT-prolonging agents**, and obtain an **echocardiogram**. **Interpretation of asymptomatic rhythm disturbance is difficult in the old, since minor asymptomatic dysrhythmias are common and may be entirely incidental — symptom–rhythm correlation is essential.**

5. **Acute management.** The decision is driven by **haemodynamic stability**.

   UNSTABLE (shock, syncope, ischaemia, heart failure) → **immediate synchronised DC cardioversion** under sedation (unsynchronised defibrillation for VF or pulseless VT)
   STABLE narrow-complex → **vagal manoeuvres → adenosine 6 mg then 12 mg rapid IV bolus** (contraindicated in asthma); if AF or flutter, **rate control with a beta-blocker or diltiazem**
   STABLE broad-complex → treat as VT: **amiodarone 300 mg IV over 20–60 min then 900 mg/24 h**; correct electrolytes
   Torsades de pointes → **IV magnesium sulphate 2 g**, stop the offending drug, correct K^+, overdrive pacing or isoprenaline

   Never give verapamil or diltiazem to a broad-complex tachycardia — if it is VT, the result may be cardiovascular collapse. Always **correct potassium and magnesium and treat the underlying trigger** — ischaemia, sepsis, hypoxia, thyrotoxicosis, anaemia or drug toxicity.

6. **Long-term management and prognosis. Treat the underlying disease** — revascularisation for ischaemia, optimal heart failure therapy, correction of electrolytes, withdrawal of proarrhythmic and QT-prolonging drugs. **Beta-blockers are the antiarrhythmic backbone**; **amiodarone** is the most usable agent in structural heart disease but carries thyroid, hepatic, pulmonary, corneal and neurological toxicity in long-term use; **flecainide and propafenone are restricted to structurally normal hearts**. **Catheter ablation** is curative for AVNRT, AVRT and atrial flutter and is effective for scar-related VT. **ICD** for secondary prevention after sustained VT or aborted sudden cardiac death, and for primary prevention with a reduced ejection fraction — **pooled trial data show the survival benefit of the primary-prevention ICD persists in older patients, but the decision must weigh life expectancy, frailty and patient wishes, and ICD deactivation must be discussed as part of end-of-life planning**. On prognosis: **ventricular ectopy and non-sustained VT in the absence of heart disease are not associated with increased coronary disease or mortality and do not require antiarrhythmic drugs**; there is **no association between the extent or complexity of ventricular ectopy and coronary disease in the absence of left ventricular dysfunction, and prognosis is good**. By contrast, **polymorphic VT is a risk marker even without heart disease**, and after myocardial infarction **frequent ectopy (> 10/hour), runs of ectopy or non-sustained VT with a reduced ejection fraction are independently associated with new coronary events and mortality**. Ventricular arrhythmias in the **first 24–48 hours after acute myocardial infarction do not indicate continuing risk**.

Latest Update – 1 Point (2023–Present)

7. **Wearable and consumer devices have become a routine part of arrhythmia diagnosis.** Following large screening studies (**Apple Heart, Fitbit Heart, mSToPS, LOOP**), **smartwatch and single-lead handheld ECG devices are now accepted for symptom–rhythm correlation and for confirming AF, and the 2024 ESC AF guideline explicitly addresses device-detected atrial high-rate episodes**. The key examinable nuance comes from **NOAH-AFNET 6 (NEJM 2023)** and **ARTESiA (NEJM 2023)**, which studied **subclinical device-detected atrial fibrillation**: anticoagulation produced **only a small reduction in stroke that was largely offset by an increase in major bleeding**. The conclusion is that **device-detected subclinical AF is NOT equivalent to clinical AF, and should not automatically trigger anticoagulation** — a decision that requires individual assessment of episode duration, stroke risk and bleeding risk, which is particularly important given how frequently incidental arrhythmia is now detected in older people.

F. Syncope, Falls and Autonomic Disorders

Question 28. Head-up tilt test — indication, procedure and interpretation

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Principle.** Head-up tilt testing reproduces the haemodynamic stress of standing under controlled, monitored conditions. Passive upright tilt causes **venous pooling of about 500–800 mL of blood in the lower limbs and splanchnic bed**, reducing venous return and cardiac output. In a susceptible individual this triggers the **Bezold–Jarisch reflex** — vigorous contraction of an underfilled ventricle activates mechanoreceptors, producing **paradoxical sympathetic withdrawal and vagal activation with vasodilatation and/or bradycardia**, and hence syncope. **Increasing use has been made of tilt testing to obtain evidence supporting a suspected diagnosis of vasovagal syncope and to investigate the underlying mechanisms.**
2. **Indications.** (i) **Unexplained recurrent syncope** after cardiac causes have been excluded, particularly where **vasovagal syncope is suspected but the history is not diagnostic**. (ii) To distinguish **reflex syncope from orthostatic hypotension** and to demonstrate **delayed orthostatic hypotension** that standing measurements miss. (iii) **Unexplained falls or drop attacks in the elderly, where there is no recall of loss of consciousness**. (iv) To differentiate syncope from **epilepsy or psychogenic pseudosyncope** — the **semiology of tilt-induced psychogenic pseudosyncope** is characteristic, and testing may be combined with video-EEG. (v) To demonstrate **susceptibility for the purpose of patient education and counter-manoeuvre training**. (vi) In suspected **postural orthostatic tachycardia syndrome** or autonomic failure. **Contraindications:** severe aortic stenosis, critical coronary or cerebrovascular stenosis, hypertrophic obstructive cardiomyopathy, pregnancy and inability to stand safely.
3. **Procedure.** The patient is **fasted for 2–4 hours**, and vasoactive drugs are withheld where safe. They lie on an **electrically driven tilt table with a footboard**, secured with straps, with **continuous ECG and beat-to-beat non-invasive blood pressure monitoring** and resuscitation facilities available. There is a **supine stabilisation phase of 5–20 minutes**, then **passive tilt to 60–70° for 20–45 minutes**. If nothing occurs, a **provoked (drug) phase** follows: **the proportion of positive tilt tests is increased following the administration of glyceryl trinitrate** (400 µg sublingual, tilt maintained for a further 15–20 minutes), or isoprenaline may be used. **Carotid sinus massage** is often performed as part of the same assessment, supine and erect, since **carotid sinus syndrome is a common cause of syncope in the elderly and is not confined to those with a history of fainting on neck movement**; it carries a very low complication risk despite underlying atheroma, but **must not be performed if there is a carotid bruit unless ultrasound has excluded severe stenosis**. The table is returned to horizontal as soon as syncope or presyncope occurs. **The test has been shown to be safe in the elderly, including with glyceryl trinitrate provocation, over 10 years of experience.**
4. **Interpretation — a positive test.** The test is positive when **symptoms are reproduced together with hypotension and/or bradycardia**. **Provocation of the patient's habitual attack is diagnostically very suggestive.** Classify the response (VASIS classification):

Type	Response	Implication
Type 1 — Mixed	Heart rate falls but not below 40/min for > 10 s, with hypotension	Commonest pattern
Type 2A — Cardioinhibitory without asystole	Heart rate < 40/min for > 10 s, no asystole > 3 s; BP falls after the heart rate	—
Type 2B — Cardioinhibitory with asystole	**Asystole > 3 seconds**	**May benefit from pacing**
Type 3 — Vasodepressor	BP falls with heart rate fall < 10% from peak	Pacing will not help
Orthostatic hypotension	Progressive BP fall ≥ 20/10 mmHg without bradycardia	Treat as OH
POTS	Heart rate rise > 30/min (or to > 120/min) without hypotension	—
Psychogenic pseudosyncope	Apparent unconsciousness with **normal blood pressure and heart rate**	Characteristic; confirms non-syncopal attack

5. **Limitations. The major difficulty in interpreting the results is the occurrence of positive tests in a significant minority of control subjects, which limits the positive predictive value.** Sensitivity is around 50–70% and specificity around 80–90% for passive tilt, with sensitivity improving but specificity falling after nitrate provocation. **Reproducibility is imperfect** — a negative test does not exclude reflex syncope. Crucially, **the type of response on tilt does not reliably predict the mechanism of the patient's spontaneous attacks**, which is why an implantable loop recorder is often preferred where the diagnosis will change management. The test is also **time-consuming and labour-intensive**, and in frail older patients prolonged standing may be poorly tolerated. It is also worth noting that a **postural fall in blood pressure of more than 20 mmHg is present in about 30% of a large elderly population**, so an abnormal result must always be interpreted alongside the clinical history.

6. **Clinical use of the result.** A positive test **confirms susceptibility, allows patient education, and justifies conservative treatment** — recognition of prodromal symptoms, avoidance of triggers (heat, prolonged standing, dehydration, alcohol, large meals), **physical counter-pressure manoeuvres (leg crossing, calf tensing, abdominal compression)**, adequate salt and fluid intake, and compression stockings. Drug options where these fail include **fludrocortisone, midodrine and, in some patients, beta-blockers**. **Pacing is reserved for documented cardioinhibitory responses with prolonged asystole in older patients with recurrent injurious syncope** — but note that **pacing does not improve hypotension in patients with severe orthostatic hypotension**, so it is not a treatment for the vasodepressor form. In **carotid sinus syndrome with a cardioinhibitory response, pacing reduces falls (SAFE PACE)**. Finally, **the risks of serious injury from falls in an elderly population are very high**, so the patient must be counselled to take precautions to avoid attacks.

Latest Update – 1 Point (2023–Present)

7. **The diagnostic role of tilt testing has narrowed as prolonged rhythm monitoring has become easier and cheaper.** Current practice, consistent with the **2018 ESC syncope guideline and the Canadian Cardiovascular Society clinical practice update**, is that in **recurrent unexplained syncope where a cardiac mechanism is suspected, an implantable loop recorder gives a far higher diagnostic yield than tilt testing and should be used early rather than as a last resort**, because — unlike tilt — it documents the mechanism of the **spontaneous** attack. Tilt testing has correspondingly been repositioned as a test principally used to **demonstrate susceptibility to reflex syncope for patient education, to unmask delayed orthostatic hypotension, and to diagnose psychogenic pseudosyncope** — the last being an indication where it remains uniquely valuable, especially when combined with **video and EEG recording**. Alongside this, **smartphone and smartwatch single-lead ECG recordings** are increasingly used to capture symptom–rhythm correlation before more invasive testing is arranged.

Question 29. Syncope — aetiology, pathogenesis, differential diagnosis and management

15-Mark Essay | 10 textbook points + 2 latest updates

Textbook Core – 10 Points

1. **Definition.** Syncope is a **transient loss of consciousness due to global cerebral hypoperfusion**, characterised by **rapid onset, short duration and spontaneous complete recovery**. It is one cause of the wider syndrome of **transient loss of consciousness (T-LOC)**. Cerebral perfusion fails when systemic blood pressure falls, which occurs through a fall in **cardiac output**, in **peripheral vascular resistance**, or both. **In older people syncope frequently presents as a history of falls or drop attacks with no recall of loss of consciousness**, so the diagnosis is systematically under-recognised.
2. **Classification and aetiology.**

Category	Causes
Reflex (neurally mediated)	**Vasovagal** (fear, trauma, pain, emotion); **carotid sinus syndrome**; **situational — micturition, cough, defaecation, swallow, post-prandial**; oculocardiac and neck pressure; **glossopharyngeal neuralgia and IXth/Xth cranial nerve disease**; neck tumours
Orthostatic hypotension	**Autonomic neuropathy** (diabetes, Shy–Drager/multiple system atrophy, Guillain–Barré); **spinal cord disease, especially traumatic cervical cord lesions**; **drugs**; **old age itself**; low venous pressure (haemorrhage, dehydration, prolonged standing)
Cardiac	**Dysrhythmias** — bradyarrhythmia (**sick sinus syndrome, complete heart block with Stokes–Adams attacks**), asystole, **paroxysmal tachyarrhythmia such as ventricular tachycardia**; **ventricular outflow obstruction** (aortic stenosis, HOCM), especially on exertion; also PE, tamponade, dissection, myocardial infarction
Respiratory	**Coughing, trumpeting, weight lifting, hyperventilation** — all raise intrathoracic pressure and impair venous return; anoxia
Cerebrovascular	**Vertebrobasilar transient ischaemic attacks** — but **syncope as a manifestation of cerebrovascular disease is unlikely in the absence of additional symptoms suggestive of posterior circulation TIAs**

3. **Pathogenesis of the individual mechanisms.** In **vasovagal syncope**, venous pooling in the upright posture reduces ventricular filling; vigorous contraction of the underfilled ventricle activates mechanoreceptors and triggers **paradoxical sympathetic withdrawal with vagal activation (Bezold–Jarisch reflex)**, producing vasodilatation and/or bradycardia. In **micturition syncope** the trigger is the **sudden loss of the pressor stimulus of a distended bladder**, typically when the patient rises at night with a vasodilated skin and having just assumed the upright posture — **contrary to common belief, straining is not an important factor**. In **cough syncope** raised intrathoracic pressure impedes venous return. In **reflex/orthostatic syncope** the baroreceptor reflexes that normally stabilise blood pressure on standing fail; **these responses become more sluggish with age, causing an increased tendency to postural syncope**, and this is exacerbated by **dehydration, drugs and central nervous system disease such as Parkinson's disease**. In **cardiac syncope** the fall in output is abrupt, which is why there is usually no warning.

4. **Drugs and the older patient.** A drug cause must be sought in every case. Implicated agents include **ganglion blockers, diuretics, phenothiazines, antihistamines, antidepressants, benzodiazepines, barbiturates and antiparkinsonian drugs**; among cardiovascular drugs, **nitrates, beta-blockers and nifedipine** are particularly important; and **donepezil may increase the risk of syncope**. **Orthostatic hypotension and syncope are common in the elderly following haemodialysis.** A postural fall of more than **20 mmHg is found in about 30%** and of more than **40 mmHg in 10%** of a large elderly population.
5. **Clinical features — and why the classical picture misleads.** The image of a patient falling, lying still for some seconds and then coming round **is actually unusual**. In a landmark study inducing vasovagal syncope in medical students, **only a minority lay still; 90% had asynchronous myoclonic jerks of the limbs**, in a few vigorous enough to be mistaken for a generalised clonic seizure. Other motor activity included **limb posturing, head turning, complex movements, eye deviation and eyelid flicker**, which may be misread as focal seizures, and **vocalisation was frequent**. The same high frequency of myoclonic movement has been documented in **cardiac syncope** (observed when arrhythmia is deliberately induced to test an implanted defibrillator) and in **tilt-induced syncope**, with **simultaneous EEG showing no epileptiform activity**. Anecdotally, a patient **propped up rather than allowed to fall flat is more likely to jerk**, presumably because the fall in blood pressure is more prolonged and severe; rarely the hypoxia may itself provoke a genuine epileptic seizure.
6. **Differential diagnosis of transient loss of consciousness. Epileptic seizure** — aura, prolonged tonic-clonic movement beginning at onset, lateral tongue biting, prolonged post-ictal confusion, cyanosis, incontinence (which occurs in syncope too and is not discriminating). **Psychogenic pseudosyncope and non-epileptic attacks** — prolonged apparent unconsciousness, eyes closed and resisting opening, high attack frequency, normal blood pressure and pulse during the event. **Falls without loss of consciousness** — mechanical, drop attacks, vestibular. **Metabolic** — hypoglycaemia, hypoxia, hyperventilation with hypocapnia (cerebral vasoconstriction), intoxication. **Cerebrovascular** — vertebrobasilar TIA, subclavian steal, subarachnoid haemorrhage. **Cataplexy. The single most valuable investigation is a careful eyewitness account, and short-term video-EEG is useful in the diagnosis of attack disorders where the nature of the event remains unclear.**
7. **Initial evaluation.** Take a **meticulous history of the circumstances, posture, prodrome, duration, colour, recovery and any injury**, plus a **witness account**. **Cough syncope should be considered in patients with COPD, emphysema and chronic cough — an adequate witness account is essential since some patients fail to recall the bout of coughing that triggers the attack.** Review all drugs. Examine for **cardiac murmurs (especially aortic stenosis), pulse, blood pressure supine and at 1 and 3 minutes standing, neurological signs and carotid bruits**. **Baseline tests: 12-lead ECG**, full blood count, urea, electrolytes, creatinine, glucose and calcium. **The presence of underlying cardiac disease increases the probability of a cardiac cause**, and **timely and effective treatment of cardiac syncope may be life-saving** — so risk-stratify at this first assessment.
8. **Further investigation. Routine 12-lead ECG will occasionally demonstrate an arrhythmia or predisposing abnormality. 24-hour ECG can be diagnostic if an attack is recorded, but the yield is very small unless attacks are very frequent, and interpretation of asymptomatic rhythm disturbance is difficult — in an older population minor asymptomatic dysrhythmias are common and may be incidental.** Therefore, for infrequent attacks use **prolonged external monitoring or an implantable loop recorder**, which has a good diagnostic yield and is safe in patients with and without structural heart disease. Add **echocardiography** if structural disease is suspected, **exercise testing** for exertional syncope, and **electrophysiological study** in selected cases. Use **head-up tilt testing** to support a suspected diagnosis of vasovagal syncope — it is safe in the elderly, and the yield increases with glyceryl trinitrate, but **positive tests occur in a significant minority of controls, which limits the positive predictive value**; provocation of the habitual attack is diagnostically very suggestive. Perform **carotid sinus massage**, since **carotid sinus syndrome is a common cause of syncope in the elderly and is not confined to those who faint on neck movement** — it is low-risk, but **not if there is a carotid bruit unless ultrasound has excluded severe stenosis**. **When cardiac syncope is suspected, specialist cardiac referral is usually indicated.**
9. **Management by cause. Micturition syncope can usually be avoided by micturating sitting down. Cough syncope** — direct treatment at the underlying chest condition. **Cardiac syncope requires appropriate specialist treatment with antiarrhythmic medication, pacing, or insertion of an implantable defibrillator as appropriate — timely and effective treatment may be life-saving. Aortic stenosis with syncope** is an indication for urgent valve intervention. **Carotid sinus syndrome with a cardioinhibitory response** — dual-chamber pacing reduces falls. **Vasovagal syncope** — education about prodromal recognition, trigger avoidance and **physical counter-pressure manoeuvres**.

10. **Management of reflex syncope with postural hypotension in the older patient.** This is a common and difficult management problem, and the approach is stepwise. **Attention should first be directed to factors causing or exacerbating the problem. Review the medication** — but recognise it is not always possible to discontinue relevant drugs; in Parkinson's disease the aggravating effect of dopaminergic drugs must be balanced against their therapeutic benefit. **Exclude treatable conditions such as Addison's disease.** Then: **avoid factors causing vasodilatation — high temperature, marked exertion and alcohol**; take **small frequent meals rather than large ones**; **avoid dehydration**; **change posture slowly and reverse the change temporarily if symptoms supervene**; use **leg crossing, calf tensing and abdominal compression** to ameliorate symptoms transiently. **Elastic compression stockings make a significant contribution** though patients may need help applying them and tolerance is poor in summer. **Sleeping with a slight head-up tilt** may help by expanding plasma volume, but more than about 10° is not tolerated. Patients should be encouraged to **remain as active as possible, since chronic exposure to low blood pressure seems to improve cerebral autoregulation**. If these measures fail, add drugs, recognising that **most are used outside their licence and benefits may be limited**: **fludrocortisone 100–200 µg at night is usually first**; **ephedrine 15 mg three times daily, increasing if necessary to 30 mg three times daily** (higher doses cause tremor, tachycardia and agitation); **midodrine, desmopressin and erythropoietin** have also been used. **Supine hypertension is a risk of drug treatment, and pacing does not help.** Finally, **because the risks of serious injury and complications from falls are very high in an elderly population, it is important that the patient recognises these risks and understands the need to take precautions to avoid syncopal attacks wherever possible**.

Latest Updates – 2 Points (2023–Present)

11. **Structured emergency department risk stratification and the syncope unit model.** The **Canadian Syncope Risk Score** — combining predisposition to vasovagal syncope, heart disease, systolic BP, troponin, QRS/QT abnormality, ECG diagnosis and ED diagnostic impression — has been externally validated across multiple countries and is now used to identify patients safely dischargeable from the emergency department, avoiding a hospital admission that in an older person carries its own risk of delirium, deconditioning and hospital-acquired infection. This is supported by randomised evidence that an **ED observation syncope protocol is equivalent to routine inpatient admission**, and by the **EHRA/HRS position statement on the syncope unit**, which recommends a **dedicated multidisciplinary service with standardised protocols** — an approach shown to increase diagnostic yield and reduce admissions and cost.
12. **Implantable loop recorders early rather than last, and reappraisal of pacing in reflex syncope.** Current practice, consistent with the **2018 ESC guideline and the 2020 Canadian Cardiovascular Society clinical practice update**, is that in recurrent unexplained syncope with suspected arrhythmia the **implantable loop recorder should be used early rather than after a long sequence of low-yield tests**, because it documents the mechanism of the **spontaneous** attack, which tilt testing cannot. For refractory reflex syncope, **closed-loop stimulation pacing (BIOSync CLS)** markedly reduced recurrence in patients over 40 with **tilt-documented asystolic vasovagal syncope**, and this has been carried into the **ESC pacing guideline** — but pacing remains ineffective for the **vasodepressor** form and for orthostatic hypotension, which is the crucial distinction to state.

Question 30. Drop attacks

6-Mark Answer | 5 textbook points + 1 latest update

Textbook Core – 5 Points

1. **Definition.** A drop attack is a **sudden, unexpected fall to the ground WITHOUT loss of consciousness and without warning (no prodrome), with preserved awareness throughout, occurring in the absence of dizziness or vertigo**. The patient characteristically says "my legs just gave way", and there is **no post-event confusion**. Recovery is usually immediate, although some patients are unable to rise for a period despite full alertness. It is **commonest in older women**, and is a **descriptive term rather than a diagnosis** — a syndrome requiring a cause to be sought.
2. **The central diagnostic problem. The most important point is that many "drop attacks" are in fact unrecognised syncope** — in the elderly, syncope frequently presents as a history of **falls or drop attacks with no recall of loss of consciousness**, because retrograde amnesia for the blackout is common. **Carotid sinus syndrome in particular is a modifiable risk factor for non-accidental falls in older adults (SAFE PACE)**, and is not confined to patients who describe fainting with neck movement. Therefore **every unexplained drop attack in an older person must be investigated as possible syncope** until proved otherwise.

3. **Causes.**

Group	Causes
Cardiovascular (must be excluded first)	**Unrecognised syncope**; **carotid sinus syndrome** (cardioinhibitory or vasodepressor); **orthostatic hypotension**; **bradyarrhythmia — sick sinus syndrome, complete heart block (Stokes–Adams)**; paroxysmal tachyarrhythmia; **aortic stenosis**
Neurological	**Vertebrobasilar ischaemia** (the classical but now over-diagnosed explanation — implausible unless there are other posterior circulation symptoms); **atonic (akinetic) seizures**; **third ventricle colloid cyst**; **normal pressure hydrocephalus**; **cervical myelopathy and cervical spondylosis**; Parkinson's disease and other parkinsonian syndromes with freezing; cataplexy; **Tumarkin otolithic crisis in Ménière's disease**
Musculoskeletal and other	**Sarcopenia and proximal muscle weakness**, knee osteoarthritis with buckling, vitamin D deficiency and osteomalacia, peripheral neuropathy; **drugs** — sedatives, antihypertensives, antidepressants, antiparkinsonian agents

4. **Evaluation.** Obtain a **meticulous history with an eyewitness account**, focusing on **posture and activity at onset, any prodrome, whether awareness was truly preserved, duration, ability to rise, injury pattern and drug history**. **Facial and knee injuries suggest a genuinely unprotected fall**, which supports syncope or an atonic mechanism rather than a mechanical trip. Examine the **cardiovascular system (murmurs, pulse, lying and standing blood pressure at 1 and 3 minutes)**, the **neurological system (gait, tone, power, cerebellar signs, cervical spine, cognition)** and perform a **gait and balance assessment**. Investigations: **12-lead ECG**, full blood count, urea, electrolytes, creatinine, glucose, calcium, vitamin D and B12, thyroid function; **echocardiography** if a murmur is present; **carotid sinus massage and head-up tilt testing**; **prolonged ambulatory monitoring or an implantable loop recorder** for infrequent attacks; and **MRI brain and cervical spine** if there are neurological features. **Assess bone health and fracture risk in all.**

5. **Management. Treat the identified cause — pacing for a documented cardioinhibitory carotid sinus syndrome (which reduces falls) or for high-grade heart block**, valve intervention for aortic stenosis, antiepileptic therapy for atonic seizures, shunting for normal pressure hydrocephalus, and surgery for cervical myelopathy. Where no cause is found — as is common — manage as an **unexplained fall** using a **multifactorial falls intervention**: **medication review with withdrawal of sedatives, antihypertensives and anticholinergics; strength and balance training; vitamin D and calcium; treatment of visual impairment; footwear and home hazard assessment; and osteoporosis treatment to reduce fracture risk**. Teach the patient and carer **how to get up from the floor and how to summon help**, and consider a **personal alarm or pendant**, since a long lie causes rhabdomyolysis, pressure injury, hypothermia and loss of confidence. Address the resulting **fear of falling**, which itself causes activity restriction and further deconditioning.

Latest Update – 1 Point (2023–Present)

6. The **2022 World Guidelines for Falls Prevention and Management in Older Adults** (a joint initiative of the geriatric societies, published in *Age and Ageing* and carried into current practice) formally abolish the artificial separation between "falls" and "syncope" clinics by recommending a **single stratified pathway**: every older person is assessed as **low, intermediate or high risk**, and anyone with an **unexplained fall, a fall with injury, or recurrent falls is placed in the high-risk group requiring a full multifactorial assessment that explicitly includes cardiovascular evaluation for syncope, orthostatic hypotension and carotid sinus syndrome**. The guideline also stresses **de-prescribing of fall-risk-increasing drugs (FRIDs)**, **exercise incorporating balance and strength training as the single most effective intervention**, and **concurrent assessment of bone health and fracture risk** — which together is the correct modern framework for the patient presenting with drop attacks.

G. Vascular Disease, Thrombosis and Prevention

Question 31. Ankle brachial index and toe pressures — indications, assessment and interpretation

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and principle.** The ankle brachial index (ABI) is the **ratio of the highest systolic pressure at the ankle to the highest systolic pressure in either arm**, measured with a sphygmomanometer and a hand-held Doppler probe. In health the ankle pressure equals or slightly exceeds the brachial pressure because of pulse-wave amplification; **a proximal arterial stenosis causes a pressure drop across the lesion, so the ABI falls**. It is a **simple, non-invasive, inexpensive and reproducible bedside test** and is the **first-line investigation for peripheral arterial disease (PAD)**.

2. **Indications. Diagnostic:** symptoms of PAD — **intermittent claudication, rest pain, non-healing foot ulcer or gangrene**; absent or diminished pulses or a femoral bruit. **Before compression therapy: mandatory before applying compression bandaging or stockings for a leg ulcer, because compression in the presence of significant arterial disease causes ischaemic necrosis**. **Screening in asymptomatic high-risk groups:** age ≥ 65 (or ≥ 50 with diabetes or smoking), diabetes with a foot at risk, chronic kidney disease, known atherosclerosis elsewhere (coronary, carotid, aortic aneurysm). **Prognostic:** as a marker of generalised atherosclerosis and cardiovascular risk. **Monitoring:** after revascularisation and in follow-up of known PAD.

3. **How to perform it. Rest the patient supine for 5–10 minutes** in a warm room. Use an appropriately sized cuff and an **8–10 MHz continuous-wave Doppler probe**. Measure the **brachial systolic pressure in both arms** and take the **higher**. At each ankle, measure the pressure over the **dorsalis pedis** and the **posterior tibial** arteries and take the **higher of the two**. **ABI for each leg = highest ankle pressure in that leg ÷ highest brachial pressure of the two arms.** Calculate each leg separately and report the lower of the two values as the patient's ABI. **Do not use a stethoscope** — Korotkoff sounds are unreliable at the ankle. If claudication is suspected but the resting ABI is normal, perform an **exercise ABI (treadmill or heel raises)**: a **post-exercise fall of more than 20%, or an absolute ankle pressure drop of more than 30 mmHg, is diagnostic**.

4. **Interpretation.**

ABI value	Interpretation
> 1.40	**Non-compressible, calcified vessels** — the result is uninterpretable; proceed to toe pressures
1.00 – 1.40	**Normal**
0.91 – 0.99	**Borderline** — perform an exercise ABI
≤ 0.90	**Diagnostic of peripheral arterial disease** (sensitivity ~75–90%, specificity ~95% against angiography)
0.40 – 0.90	Mild to moderate PAD — usually claudication
< 0.40	**Severe PAD / chronic limb-threatening ischaemia** — rest pain, ulceration, gangrene

   An ABI of **0.90 or less roughly doubles 10-year mortality and major coronary event rates**, so an abnormal ABI is an indication for full cardiovascular secondary prevention regardless of leg symptoms.

5. **Limitations — the crucial geriatric caveat. The ABI is falsely NORMAL or falsely HIGH when the tibial arteries are rigid and non-compressible due to medial (Mönckeberg) calcification** — classically in **long-standing diabetes, chronic kidney disease and dialysis, and advanced age**. This is precisely the population most likely to have severe disease, so a normal ABI in a diabetic patient with an ischaemic-looking foot must never be accepted at face value. Other limitations: it gives no anatomical localisation, it can miss isolated **iliac (proximal) stenosis** if collaterals are good, it is inaccurate with leg ulceration, oedema, pain or amputation, and it is operator-dependent.

6. **Toe pressures and the toe brachial index (TBI).** The **digital arteries are largely spared from medial calcification**, so toe pressures remain reliable when the ABI does not. Measure with a **small (2–2.5 cm) cuff on the great toe and photoplethysmography or laser Doppler**, after warming the foot. Normally the toe pressure is **about 30 mmHg lower than the ankle pressure**. **TBI = toe systolic pressure ÷ highest brachial pressure; a TBI below 0.70 is diagnostic of peripheral arterial disease.** Absolute toe pressures guide healing: **> 55 mmHg — wound healing likely; 30–55 mmHg — impaired healing; < 30 mmHg — chronic limb-threatening ischaemia with healing unlikely without revascularisation** (a threshold of < 50 mmHg is used in diabetes). Toe pressures are therefore **indicated whenever the ABI exceeds 1.40, in all patients with diabetes or renal failure, and to assess healing potential of a foot ulcer or the level of a planned amputation**. Complementary tests include **Doppler waveform analysis (triphasic → biphasic → monophasic → damped), segmental pressures with pulse volume recording, transcutaneous oxygen pressure ($TcPO_2$), duplex ultrasound, CT or MR angiography**.

Latest Update – 1 Point (2023–Present)

7. The **2024 ACC/AHA Guideline for the Management of Lower Extremity Peripheral Artery Disease** restructures PAD around **four clinical subsets — asymptomatic, chronic symptomatic, chronic limb-threatening ischaemia and acute limb ischaemia**. Key diagnostic recommendations: the **resting ABI remains the first-line test**, but **toe brachial index or other physiological testing is explicitly recommended when the ABI is greater than 1.40 or is normal despite a high clinical suspicion**, and a **wound, ischaemia and foot infection (WIfI) staging** should be applied to every threatened limb. For treatment, it emphasises **structured supervised exercise therapy as first-line for claudication**, **high-intensity statin plus antiplatelet therapy for all patients**, and — importantly — **low-dose rivaroxaban 2.5 mg twice daily plus aspirin (the COMPASS/VOYAGER-PAD regimen) to reduce major adverse limb and cardiovascular events**, weighed against bleeding risk in the older patient.

Question 32. Direct oral anticoagulants — choice, dosing and reversal

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Drugs and mechanism. Dabigatran** is a **direct thrombin (factor IIa) inhibitor**. **Rivaroxaban, apixaban and edoxaban** are **direct factor Xa inhibitors**. Advantages over warfarin: **predictable pharmacokinetics, no routine monitoring, rapid onset and offset, fewer food and drug interactions**, and **lower intracranial haemorrhage** risk.
2. **Indications and contraindications.** Indicated for **stroke prevention in non-valvular atrial fibrillation**, **treatment and secondary prevention of DVT and pulmonary embolism**, and **VTE prophylaxis after hip or knee arthroplasty**. **Contraindicated in mechanical prosthetic heart valves and moderate-to-severe (rheumatic) mitral stenosis** — these require **warfarin**, an important point in Indian practice. Also avoid in severe hepatic impairment (Child–Pugh C) and active major bleeding.
3. **Standard doses in atrial fibrillation. Apixaban 5 mg twice daily**; **Rivaroxaban 20 mg once daily with food**; **Edoxaban 60 mg once daily**; **Dabigatran 150 mg twice daily** (110 mg twice daily if aged ≥ 80 or on verapamil).
4. **Dose reduction criteria (high-yield).**

Drug	Reduced dose	Criteria
Apixaban	2.5 mg BD	Any **2 of 3**: age ≥ 80 y, weight ≤ 60 kg, creatinine ≥ 1.5 mg/dL
Rivaroxaban	15 mg OD	CrCl 15–49 mL/min
Edoxaban	30 mg OD	CrCl 15–50 mL/min, weight ≤ 60 kg, or strong P-gp inhibitor
Dabigatran	110 mg BD	Age ≥ 80 y, verapamil, high bleeding risk; avoid if CrCl < 30

   Avoid all DOACs when **CrCl < 15 mL/min** (apixaban may be used with caution). **Use actual body weight and the Cockcroft–Gault formula, not eGFR, for dosing.**
5. **Choice in the older adult. Apixaban** has the most favourable geriatric profile — **lowest major and gastrointestinal bleeding** and the safest in chronic kidney disease. **Avoid dabigatran** if there is dyspepsia or gastrointestinal bleeding risk, or in significant renal impairment. Once-daily rivaroxaban or edoxaban may aid **adherence**. Avoid concurrent **NSAIDs and antiplatelets**; beware **P-gp and CYP3A4 interactions** (rifampicin, carbamazepine, phenytoin, azoles, verapamil, amiodarone). Check **renal function at least annually** — more often if CrCl < 60 (a practical rule is **CrCl ÷ 10 = review interval in months**).
6. **Reversal and bleeding management. Stop the drug**, note the time of the last dose, apply local haemostatic measures, restore volume, transfuse as needed and give **tranexamic acid** for mucosal bleeding. Specific antidotes: **Idarucizumab 5 g IV** — a monoclonal antibody fragment reversing **dabigatran**; **Andexanet alfa** — a modified factor Xa decoy reversing **apixaban and rivaroxaban**. Where antidotes are unavailable (common in India), give **4-factor prothrombin complex concentrate 50 units/kg**. **Activated charcoal** if ingestion was within 2–4 hours; **dabigatran is dialysable** (the factor Xa inhibitors are not, being highly protein-bound).

Latest Update – 1 Point (2023–Present)

7. **ANNEXA-I (NEJM 2024)** — in acute **intracranial haemorrhage** on a factor Xa inhibitor, **andexanet alfa** achieved significantly better **haemostatic efficacy** than usual care (largely PCC), but at the cost of **more thrombotic events, including ischaemic stroke**. Current guidance therefore recommends specific reversal agents as **first-line** for life-threatening or intracranial bleeding, with **4-factor PCC as the alternative**, and stresses **early restarting of anticoagulation** once haemostasis is secure.

Question 33. Deep vein thrombosis — prophylaxis and treatment

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Risk factors (Virchow's triad). Stasis** — immobility, hospitalisation, **stroke with hemiplegia**, long travel, heart failure. **Endothelial injury** — surgery, especially **hip fracture and hip or knee arthroplasty**, trauma, central venous catheters. **Hypercoagulability** — **malignancy**, sepsis, dehydration, previous VTE, oestrogens, nephrotic syndrome, thrombophilia. **Advancing age is itself an independent risk factor**, with incidence rising sharply after 70.
2. **Clinical features and pitfalls.** Unilateral **calf or thigh pain, swelling, warmth, erythema, dilated superficial veins** and calf tenderness; Homans' sign is unreliable. **Clinical diagnosis alone is unreliable in the elderly.** Differential diagnosis: **cellulitis, ruptured Baker's cyst, dependent oedema, heart failure, lymphoedema, haematoma, superficial thrombophlebitis** and post-thrombotic syndrome.

3. **Diagnosis.** Apply the **Wells score** to stratify probability. **Low probability plus a negative D-dimer excludes DVT**, but D-dimer specificity falls markedly with age, so use the **age-adjusted cut-off (age × 10 µg/L for patients over 50)** to avoid unnecessary imaging. Confirm with **compression ultrasonography**; if the initial scan is negative but clinical probability is high, repeat at one week or proceed to whole-leg scanning.
4. **Prophylaxis. Early mobilisation and adequate hydration for all. Mechanical — intermittent pneumatic compression**; note that **graduated compression stockings are contraindicated after stroke** (CLOTS-1 showed no benefit and more skin breaks). **Pharmacological — LMWH (enoxaparin 40 mg subcutaneously daily; reduce to 20–30 mg if CrCl < 30 mL/min)** or fondaparinux, for the duration of the acute illness; **extended prophylaxis for 28–35 days after hip fracture surgery or hip arthroplasty**. Always **assess bleeding risk** before prescribing.
5. **Treatment. A DOAC is first-line — apixaban 10 mg twice daily for 7 days then 5 mg twice daily**, or **rivaroxaban 15 mg twice daily for 21 days then 20 mg daily**; **dabigatran and edoxaban require 5 days of parenteral LMWH lead-in**. Use **LMWH** in severe renal impairment and in pregnancy, and **warfarin (INR 2–3)** for mechanical valves or antiphospholipid syndrome. **Early ambulation with compression** relieves symptoms; an **IVC filter** is used only when anticoagulation is absolutely contraindicated, and should be retrievable. **Catheter-directed thrombolysis** is reserved for limb-threatening iliofemoral thrombosis (phlegmasia).
6. **Duration and complications. Provoked by a transient major risk factor → 3 months. Unprovoked, recurrent, or with a persistent risk factor such as active cancer → extended (indefinite) anticoagulation**, using reduced-dose **apixaban 2.5 mg twice daily or rivaroxaban 10 mg daily** after the first 6 months. Complications: **pulmonary embolism, post-thrombotic syndrome (up to 40%), recurrence and anticoagulant-related bleeding**. After unprovoked DVT, perform **age-appropriate cancer screening and a careful history and examination** — extensive occult-malignancy imaging is not indicated.

Latest Update – 1 Point (2023–Present)

7. **API-CAT trial (NEJM 2025)** — in patients with **active cancer** and proximal DVT or PE who had completed at least 6 months of anticoagulation, **extended reduced-dose apixaban 2.5 mg twice daily for 12 months was non-inferior to full-dose 5 mg twice daily** for recurrent VTE and caused **significantly less clinically relevant bleeding (12.1% versus 15.6%)**. This supports **dose de-escalation rather than discontinuation** for extended treatment — particularly valuable in frail older patients with cancer-associated thrombosis.

Question 34. Polypill

6-Mark Answer | 5 textbook points + 1 latest update

Textbook Core – 5 Points

1. **Concept and definition.** The polypill is a **fixed-dose combination tablet containing several cardiovascular drugs**, taken once daily, designed to deliver **comprehensive cardiovascular risk reduction in a single pill**. The concept was proposed by **Wald and Law (BMJ 2003)**, who calculated that a combination of a statin, three half-dose antihypertensives, aspirin and folic acid given to everyone over 55 could reduce ischaemic heart disease events by about 88% and stroke by about 80%. **The rationale is that most cardiovascular risk factors are continuous variables with no threshold, so a fixed low-dose combination benefits a broad population without individual measurement.**
2. **Typical composition.** A **statin** (atorvastatin or simvastatin), **aspirin 75–100 mg**, and **two or three antihypertensives at low dose** — commonly an **ACE inhibitor (ramipril or enalapril), a thiazide-type diuretic and/or a beta-blocker or calcium channel blocker**. Folic acid was in the original proposal but has been abandoned, since homocysteine lowering does not reduce events. **Secondary-prevention polypills** (for patients with established disease) always contain aspirin and a statin; **primary-prevention polypills** may omit aspirin because its net benefit in primary prevention is now considered unfavourable (ASPREE, ASCEND, ARRIVE).
3. **Advantages — particularly in geriatric and Indian practice. Improved adherence**, which is the dominant benefit — **reduced pill burden** is directly relevant to the polypharmacy of old age. **Lower cost**, which matters greatly in low- and middle-income settings. **Simplified prescribing and dispensing**, enabling task-shifting to nurses and community health workers. **Wider treatment coverage**, closing the large treatment gap in populations where risk factors are undiagnosed. **Fewer dispensing and administration errors.** India has been central to this field — the **TIPS (The Indian Polycap Study)** trials, conducted with the **Polycap** formulation, established the tolerability and risk-factor efficacy of the approach.

4. **Evidence. TIPS-1 and TIPS-2 (India)** showed that the Polycap produced the expected reductions in blood pressure, LDL-cholesterol and heart rate with acceptable tolerability. **UMPIRE, IMPACT and Kanyini-GAP** demonstrated substantially improved **adherence** compared with usual care. **TIPS-3 (NEJM 2021)** — a large primary-prevention trial in intermediate-risk people without cardiovascular disease — showed that a **polypill plus aspirin reduced major cardiovascular events**. **SECURE (NEJM 2022)** — the key secondary-prevention trial — randomised patients **over 65 who had had a recent myocardial infarction** to a polypill (aspirin, ramipril, atorvastatin) or usual care and showed a **significant reduction in cardiovascular death, myocardial infarction, stroke and urgent revascularisation, driven substantially by better adherence**. **PolyIran** confirmed benefit at a population level in a primary-care setting.
5. **Limitations and criticisms. Loss of individualisation** — doses cannot be titrated separately, so it is unsuitable where one component must be adjusted or where the patient is already well controlled on tailored therapy. **An adverse effect from one component requires stopping the whole tablet**, losing the benefit of the others. **Contraindications and interactions** — an ACE inhibitor in bilateral renal artery stenosis, a beta-blocker in asthma or severe bradycardia, a diuretic in gout or hyponatraemia, and aspirin where bleeding risk is high. **In the older adult the specific risks are hypotension, falls, hyperkalaemia, acute kidney injury, hyponatraemia and gastrointestinal bleeding — so it is generally more appropriate for stable, well-selected secondary prevention than for the frail or newly diagnosed patient.** Other issues are **medicalisation of healthy populations, uncertainty over the aspirin component in primary prevention, and regulatory and availability limitations** in many countries.

Latest Update – 1 Point (2023–Present)

6. In **July 2023 the World Health Organization added fixed-dose combination cardiovascular polypills to the WHO Model List of Essential Medicines**, for both **primary prevention in people at high cardiovascular risk and secondary prevention after an established event**. This was a landmark step, based on the SECURE, TIPS-3, PolyIran and UMPIRE evidence, and it **reclassifies the polypill from an experimental public-health idea into a recommended, essential therapeutic tool**. It is directly relevant to India, where the WHO **HEARTS** technical package and the national NCD programme promote standardised fixed-dose regimens to close the very large treatment gap in hypertension and secondary prevention. Practical caveat for the examination: current guidance regards the polypill as **most clearly indicated for secondary prevention and for high-risk primary prevention in resource-limited settings, not as a substitute for individualised titration in the frail older patient**.

PART II

RESPIRATORY MEDICINE AND SLEEP

Questions 35 – 54 · 20 questions · 7 sections

H. Respiratory Infection

Question 35. What is community-acquired pneumonia? Etiopathogenesis, diagnosis and management

15-Mark Essay | 10 textbook points + 2 latest updates

Textbook Core – 10 Points

1. **Definition.** Community-acquired pneumonia (CAP) is an **acute infection of the lung parenchyma** acquired **outside hospital**, or within **48 hours of admission**, characterised by **new symptoms and signs of lower respiratory tract infection together with a new radiographic infiltrate**. The presence of a **parenchymal focus on imaging distinguishes pneumonia from bronchitis**. **About two out of three hospitalisations for pneumonia are in patients over 70 years of age.**

2. **Aetiology by setting (high-yield).**

Setting	Predominant organisms
Older community patients	**S. pneumoniae, H. influenzae** and **respiratory viruses** are more frequent than in younger adults, whereas **Legionella, Mycoplasma and Chlamydophila are less frequent**
Nursing home residents	**Aspiration pneumonia**, **Gram-negative enteric bacilli** and **multiple anaerobes**
Viral (10–30% of CAP)	Influenza (including in vaccinated patients), **RSV**, parainfluenza, rhinovirus, adenovirus; emerging coronaviruses — **SARS, MERS, COVID-19**, whose incidence, severity and fatality all rise with age (>30% mortality over 75–80)
Others	**M. tuberculosis** (subacute/chronic — very relevant in India), **Aspergillus** in old TB cavities or lung abscess; fungal infection only with severe immunosuppression

   Multi-microbial pneumonia is common in the elderly.

3. **Pathogenesis.** Infection follows **micro-aspiration of oropharyngeal secretions** colonised by pathogens, and less often inhalation of aerosols or haematogenous spread. Ageing impairs every defence layer: **reduced cough and glottic reflexes with silent aspiration**, **impaired mucociliary clearance**, **reduced elastic recoil and lung "inflammageing"**, **immunosenescence with poor IgM response to pneumococcus**, malnutrition, sarcopenia and reduced ventilatory reserve. Structural changes — **bronchiectasis, tracheobronchomalacia, old TB scarring, sabre-sheath trachea** — impair mucus clearance and predispose to infection.

4. **Risk factors. Age itself**; **dysphagia and stroke**, **Parkinson's disease**, dementia, sedatives and antipsychotics, **GORD**, poor oral hygiene and **edentulism**, tube feeding, COPD, heart failure, diabetes, chronic kidney disease, malignancy, **inhaled corticosteroids**, proton pump inhibitors, alcohol, smoking, **institutionalisation**, and immobility.

5. **Clinical presentation — the geriatric pitfall. The classical picture of malaise, high fever, cough and pleuritic chest pain is rarely complete in the elderly. Fever and cough are absent in 30–40% of cases**, and onset is often gradual with less-marked signs, leading to **delayed diagnosis**. Presentation may be with **delirium, falls, functional decline, anorexia, incontinence or decompensation of a comorbidity**. Warning signs on examination: **tachypnoea > 30/min, tachycardia > 110/min, fever or hypothermia**, hypotension and hypoxaemia.

6. **Imaging.** A **chest radiograph (PA and lateral)** is recommended in every patient with suspected pneumonia, mainly to **distinguish pneumonia from bronchitis**. Look for alveolar consolidation, mixed alveolar–interstitial shadowing, atelectasis, and hidden **retrocardiac or perihilar** opacities. **The radiographic pattern is poorly related to the causative organism.** A **chest CT** is indicated when the film is normal but pneumonia is still suspected, in very early disease, or to detect pulmonary embolism. **Point-of-care lung ultrasound** shows B-lines with excellent sensitivity and specificity, and later "hepatisation" of consolidated lung — very useful in nursing homes and home care where radiography is difficult.

7. **Laboratory and microbiological tests.** Not required for patients managed at home. In hospitalised patients: **full blood count** (leucocytosis suggests bacterial infection but **may be absent in older patients**), **CRP**, **urea, electrolytes, creatinine and glucose** (dehydration, renal impairment and hyperglycaemia are common), **pulse oximetry**, and **arterial blood gas** if there is chronic respiratory failure, cyanosis, sweating or reduced consciousness. **Blood cultures and sputum examination in all patients admitted with pneumonia**; add **urinary pneumococcal and Legionella antigens**, respiratory viral PCR, and — in India — **sputum for AFB/CBNAAT** where the course is subacute.

8. **Severity assessment and the decision to admit.** Use **CURB-65** (Confusion, Urea > 7 mmol/L, Respiratory rate ≥ 30, Blood pressure < 90/60, age ≥ 65) or the **Pneumonia Severity Index**. Three reasons prompt hospital referral: (i) **the diagnosis is unclear and a serious alternative such as pulmonary embolism or heart failure is suspected**; (ii) **pneumonia is likely but the patient cannot be safely cared for at home** (help with ADLs, prevention of pressure sores and dehydration, follow-up); (iii) **severity signs are present**. **Remember that scores underestimate risk in the frail — always add a functional and social assessment.**
9. **Antibiotic therapy.** Initial therapy is **probabilistic** and must cover **S. pneumoniae and H. influenzae**. For outpatients **with comorbidities** (which applies to most older patients), a single oral agent may be used — **amoxicillin, amoxicillin-clavulanate, an advanced macrolide (azithromycin or clarithromycin), doxycycline, or a respiratory fluoroquinolone**. Per **ATS/IDSA 2019**: **a β-lactam plus a macrolide or doxycycline**, or a respiratory fluoroquinolone alone. In **nursing home patients the regimen must also cover anaerobes** because of aspiration. For **severe CAP** use a broad-spectrum combination, and cover **Pseudomonas** if there is bronchiectasis or recent β-lactam/fluoroquinolone use within three months. In older people **reduce doses for renal function**, and beware fluoroquinolone-associated **QT prolongation, tendinopathy, delirium, hypoglycaemia and C. difficile**.
10. **Supportive care, the 48-hour review and prevention.** Give **oxygen (target 88–92% if at risk of CO_2 retention)**, fluids, **early mobilisation, chest physiotherapy, VTE prophylaxis, nutritional support, delirium prevention and swallow assessment**. **Assessment at 48 hours is the key step** — defervescence and clinical stability indicate a favourable response, allowing **IV-to-oral switch**. If the response is unfavourable, consider **resistant organism, tuberculosis or virus, empyema or encysted effusion, non-infectious lung disease, drug adverse effect, or worsening comorbidity**, and repeat imaging including CT. **Persistence of the radiological shadow at 12 weeks, marked weight loss or heavy tobacco/asbestos exposure must raise suspicion of lung cancer** and prompt bronchoscopy or CT. Prevention: **influenza, pneumococcal and COVID-19 vaccination, smoking cessation, oral hygiene, dysphagia management, and review of sedatives and PPIs**.

Latest Updates – 2 Points (2023–Present)

11. **Corticosteroids in severe CAP.** The **CAPE COD trial (NEJM 2023)** showed that **intravenous hydrocortisone 200 mg/day started within 24 hours reduced 28-day mortality** in patients admitted to intensive care with severe CAP. Current international guidance therefore **recommends adjunctive corticosteroids in severe CAP** (but **not** in influenza or suspected aspergillosis), with careful monitoring for **hyperglycaemia and delirium** in older patients.
12. **2024 ACIP pneumococcal vaccination update.** The routine age for pneumococcal vaccination in the United States was **lowered from 65 to 50 years**, and a **single dose of a higher-valency conjugate vaccine (PCV20 or PCV21) is now recommended** for pneumococcal-naïve adults, simplifying the older PCV13-then-PPSV23 sequence. This reflects the substantial residual burden of pneumococcal disease from age 50 onward.

Current Practice Update

Textbook	Antibiotics plus supportive care; steroids not mentioned. Pneumococcal vaccination framed around PCV13/PPSV23 from age 65.
Current recommendation	Adjunctive hydrocortisone in severe CAP (CAPE COD 2023); single-dose PCV20/PCV21 from age 50 (ACIP 2024).
Exam approach	Finish the management section with: "CAPE COD (NEJM 2023) — hydrocortisone reduces mortality in severe CAP; ACIP 2024 has lowered the pneumococcal vaccination age to 50."

Question 36. Pneumonia in the elderly

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Burden.** Pneumonia is a major cause of hospitalisation and death in old age — **about two out of three pneumonia admissions are patients over 70**. It is often the **terminal event** in frailty and dementia ("the old man's friend"), and carries much higher mortality than in younger adults.
2. **Predisposing factors specific to ageing. Immunosenescence** with a poor IgM response to pneumococcal polysaccharide, **impaired cough and swallowing reflexes causing silent aspiration**, reduced mucociliary clearance, loss of lung elastic recoil and **"inflammageing"**, reduced chest wall compliance, **poor oral hygiene and edentulism**, malnutrition, sarcopenia, and structural airway change (bronchiectasis, old TB scarring, tracheobronchomalacia).

3. **Aetiology. S. pneumoniae, H. influenzae and respiratory viruses** predominate, while **Legionella, Mycoplasma and Chlamydophila are less common than in younger adults**. In **nursing home residents**, **aspiration pneumonia, Gram-negative enteric bacilli and anaerobes** are frequent. **Multi-microbial infection is common.** In India also consider **tuberculosis** and **aspergillosis in post-tubercular cavities**.
4. **Atypical presentation. Fever and cough are absent in 30–40%.** The classical lobar picture is rarely complete. Common presentations are **delirium, falls, sudden functional decline, anorexia, incontinence, tachypnoea alone**, or decompensated heart failure or diabetes. Signs to look for: **respiratory rate > 30/min, heart rate > 110/min, fever or hypothermia**. **Tachypnoea is the most sensitive early sign.**
5. **Diagnostic approach. Chest radiograph** to separate pneumonia from bronchitis; **CT** if the film is normal but suspicion is high; **point-of-care lung ultrasound** is very useful in nursing homes and home care. **Leucocytosis may be absent**; check CRP, renal function and glucose, and **oxygen saturation**. In hospitalised patients take **blood cultures and sputum**. Assess severity with **CURB-65**, remembering that **age ≥ 65 already scores one point**.
6. **Management and prevention.** Decide on **site of care** using severity, frailty and the ability to be cared for at home. Give **empirical antibiotics covering pneumococcus and H. influenzae**, with **anaerobic cover in nursing home/aspiration pneumonia**, renally adjusted. Add **oxygen, hydration, early mobilisation, VTE prophylaxis, nutrition, swallow assessment and delirium prevention**. **Review at 48 hours**; failure to improve suggests resistance, tuberculosis, empyema, an alternative diagnosis or underlying **lung cancer** (especially if shadowing persists at 12 weeks). Prevent with **influenza, pneumococcal and COVID-19 vaccines, oral hygiene, smoking cessation, and review of sedatives, antipsychotics and PPIs**.

Latest Update – 1 Point (2023–Present)

7. **Respiratory syncytial virus (RSV) is now a vaccine-preventable cause of pneumonia in the elderly.** Following the **2023 licensure of adjuvanted and mRNA RSV vaccines**, the **2024 ACIP recommendation** is a **single lifetime dose of RSV vaccine for all adults aged 75 and above, and for those aged 50–74 with risk factors** (chronic lung or heart disease, diabetes, immunocompromise, frailty, nursing home residence). RSV causes severe lower respiratory infection and exacerbations in older adults comparable to influenza, and vaccination is now part of the standard geriatric immunisation package alongside influenza, pneumococcal and COVID-19 vaccines.

Question 37. Hospital-acquired pneumonia

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and types.** Hospital-acquired (nosocomial) pneumonia is pneumonia developing **48 hours or more after hospital admission and not incubating at the time of admission**. **Ventilator-associated pneumonia (VAP)** arises more than 48 hours after endotracheal intubation. **Early-onset** (within 4 days) tends to involve community-type organisms; **late-onset** (day 5 onward) involves **multidrug-resistant** organisms.
2. **Why it is severe in older patients.** Nosocomial respiratory infections are **often severe because of resistance of the causative bacteria to antibiotics and because of the vulnerability of patients already weakened by the illness that brought them to hospital**. Additional geriatric contributors: **immobility and supine posture, dysphagia and silent aspiration, sedatives, nasogastric tubes, delirium, malnutrition and poor oral hygiene**.
3. **Organisms. S. aureus (including MRSA), Pseudomonas aeruginosa and enteric Gram-negative bacteria** predominate, frequently with **antibiotic resistance**. Pneumonia in patients recently treated with antibiotics is often due to **complex, resistant or polymicrobial** flora. In Indian hospitals, **Acinetobacter baumannii, Klebsiella pneumoniae with carbapenem resistance** and ESBL producers are major concerns.
4. **Clinical features and diagnosis.** New or worsening **infiltrate on chest radiograph** plus at least two of — **fever or hypothermia, leucocytosis or leucopenia, purulent secretions, worsening oxygenation**. In the old, **delirium or unexplained deterioration may be the only clue**. Obtain **lower respiratory tract samples (deep tracheal aspirate, or bronchoalveolar lavage in the ventilated) before starting antibiotics**, plus **blood cultures**. Differentiate from **atelectasis, pulmonary embolism, pulmonary oedema, ARDS and drug-induced lung injury**.
5. **Treatment.** Start **prompt empirical broad-spectrum therapy** guided by **local antibiogram, prior antibiotic exposure and risk factors for MDR organisms** (recent IV antibiotics within 90 days, prolonged stay, septic shock, ARDS, renal replacement therapy). Typical empirical cover: an **antipseudomonal β-lactam (piperacillin-tazobactam, cefepime or meropenem) ± MRSA cover (vancomycin or linezolid)** ± a second antipseudomonal agent in septic shock. **De-escalate at 48–72 hours on culture results and treat for 7 days** in most patients. Adjust doses for renal function and monitor for **nephrotoxicity, C. difficile and delirium**.

6. **Prevention (highly examinable). Hand hygiene**; **semi-recumbent positioning at 30–45°**; **daily sedation interruption and assessment of readiness to extubate**; **subglottic secretion drainage**; **oral care with chlorhexidine and regular dental hygiene**; **early mobilisation and chest physiotherapy**; **avoid unnecessary nasogastric tubes, sedatives and acid suppression**; **swallow screening after stroke**; and **antimicrobial stewardship with isolation of colonised patients**.

Latest Update – 1 Point (2023–Present)

7. **IDSA guidance on antimicrobial-resistant Gram-negative infections (updated 2023–2024)** now defines preferred agents for resistant hospital-acquired and ventilator-associated pneumonia: **ceftazidime-avibactam, ceftolozane-tazobactam or imipenem-relebactam** for difficult-to-treat **Pseudomonas**; **ceftazidime-avibactam or meropenem-vaborbactam** for KPC-producing carbapenem-resistant Enterobacterales; **ceftazidime-avibactam plus aztreonam** for metallo-β-lactamase producers; and **cefiderocol or sulbactam-durlobactam** for carbapenem-resistant **Acinetobacter**. The parallel message is **shorter courses — 7 days is sufficient for most HAP/VAP**, with de-escalation guided by culture and clinical response.

Question 38. Case — 67-year-old man with cough, purulent expectoration, fever, tachypnoea, tachycardia and hypotension

7-Mark Answer | 6 textbook points + 1 latest update

Recognise the diagnosis in the first line: this is **severe community-acquired pneumonia with sepsis and septic shock**. Marks are earned for immediate resuscitation running in parallel with investigation, not sequentially.

Textbook Core – 6 Points

1. **Immediate recognition and triage.** Cough with purulent sputum and fever indicate **pneumonia**; **tachypnoea, tachycardia and hypotension indicate sepsis with shock**. Apply **ABCDE**, secure two large-bore cannulae, attach monitoring and calculate **CURB-65** — this patient already scores for **age ≥ 65, respiratory rate ≥ 30 and systolic BP < 90**, giving a high score that mandates **admission to a high-dependency or intensive care area**.
2. **The first hour — resuscitation bundle. Oxygen** to a target of **94–98% (88–92% if there is known chronic CO_2 retention)**; **blood cultures before antibiotics**; **measure serum lactate**; **intravenous broad-spectrum antibiotics within one hour**; **balanced crystalloid 30 mL/kg** given in aliquots with reassessment; and **early noradrenaline** through a peripheral or central line if the mean arterial pressure remains below 65 mmHg despite fluids. **In the older patient give fluid in 250–500 mL boluses with repeated reassessment, because rapid loading precipitates pulmonary oedema in unrecognised diastolic dysfunction.** Insert a urinary catheter for hourly output.
3. **Investigations. Chest radiograph** (consolidation; look for effusion or cavitation); **arterial blood gas with lactate**; **full blood count, CRP or procalcitonin, urea, electrolytes, creatinine, liver function, glucose, coagulation profile**; **blood cultures × 2 and sputum Gram stain and culture**; **urinary pneumococcal and Legionella antigen**; **respiratory viral PCR including influenza and COVID-19**; **sputum for AFB/CBNAAT** in the Indian setting; **ECG and troponin** (type 2 myocardial infarction and new atrial fibrillation are common); **bedside echocardiography and lung ultrasound**. Add **CT chest ± CT pulmonary angiogram** if the radiograph is normal or pulmonary embolism is possible.
4. **Antibiotic therapy.** Empirical cover for **severe CAP**: **intravenous ceftriaxone or amoxicillin-clavulanate (or piperacillin-tazobactam) PLUS a macrolide (azithromycin/clarithromycin) or a respiratory fluoroquinolone (levofloxacin)**. Add **antipseudomonal cover** if there is bronchiectasis, structural lung disease or recent β-lactam/fluoroquinolone use within three months; add **anaerobic cover** if aspiration is suspected; add **oseltamivir** during influenza season. Adjust doses for renal function, then **de-escalate and switch to oral therapy at 48–72 hours** once stable.
5. **Ongoing organ support and monitoring.** Target **MAP ≥ 65 mmHg**, adequate urine output and falling lactate. Escalate respiratory support stepwise — **controlled oxygen → high-flow nasal oxygen → non-invasive ventilation (pH < 7.35) → intubation**. Add **vasopressin** if noradrenaline requirement is high; give **hydrocortisone in refractory shock**. Watch for **acute kidney injury, delirium, hyperglycaemia, gastrointestinal bleeding and pressure sores**; provide **VTE prophylaxis, early enteral nutrition, glycaemic control and early mobilisation**. Reassess formally at **48 hours**.
6. **Complications and goals of care.** Look for **parapneumonic effusion and empyema, lung abscess, ARDS, acute kidney injury, atrial fibrillation, myocardial infarction and multi-organ failure**. If the patient does not improve, consider **resistant organism, tuberculosis, empyema requiring drainage, pulmonary embolism or an underlying lung cancer**. In parallel, undertake **early discussion of goals of care, ceilings of treatment and resuscitation status** with the patient and family, and involve palliative care if the trajectory is poor. Plan **vaccination and smoking cessation** before discharge.

Latest Update – 1 Point (2023–Present)

7. **CAPE COD trial (NEJM 2023)** — in adults admitted to intensive care with **severe community-acquired pneumonia**, **intravenous hydrocortisone 200 mg per day started within 24 hours reduced 28-day mortality**. **Adjunctive corticosteroids are therefore now recommended in severe CAP** (excluding influenza and suspected aspergillosis). Contemporary sepsis practice has also shifted to **balanced crystalloids rather than saline**, **restrictive fluid strategy with early vasopressors** (including peripheral noradrenaline), and **dynamic assessment of fluid responsiveness** rather than fixed large-volume loading — all particularly important in the frail older patient.

I. Obstructive Airway Disease and Inhaled Therapy

Question 39. Management of chronic obstructive airway disease

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Confirm the diagnosis and assess.** COPD requires **post-bronchodilator spirometry showing a persistent airflow limitation**. **In older adults use the lower limit of normal rather than the fixed $FEV_1/FVC < 0.70$ ratio, because ageing alone produces a "pseudo-obstructive" pattern and the fixed ratio over-diagnoses COPD in the old.** Assess with the **mMRC dyspnoea scale or CAT score**, exacerbation history, and **GOLD ABE grouping**. Careful history and spirometry usually distinguish COPD from asthma and exclude comorbid conditions.
2. **Non-pharmacological measures — the foundation. Smoking cessation is the single most effective intervention and works at any age**. **Pulmonary rehabilitation** — a comprehensive, tailored programme of exercise training, education and behaviour change — improves symptoms, exercise capacity and quality of life. Add **vaccination (influenza, pneumococcal, COVID-19, RSV, pertussis)**, **nutritional support** (low BMI predicts mortality), reduction of **biomass fuel and indoor air pollution exposure** — a major issue in Indian households — and treatment of anxiety and depression.
3. **Inhaled pharmacotherapy. Long-acting bronchodilators are the mainstay**: **LAMA** may be added to a **LABA** when breathlessness predominates. In patients who remain breathless or exacerbate frequently, **regardless of FEV_1**, a **LAMA can be added to an inhaled LABA-corticosteroid combination or vice versa (triple therapy)**. **Inhaled corticosteroids** reduce exacerbations, particularly with **blood eosinophils ≥ 300 cells/µL** or a history of asthma, but cause a **small but significant increase in non-fatal pneumonia** — a risk that does not outweigh their benefit in appropriate patients. Re-evaluate after starting therapy, judging success by **symptoms, exercise tolerance and ability to perform activities of daily living rather than by lung function alone**. **Always check inhaler technique and prefer fixed-dose combinations to reduce device burden.**
4. **Additional oral therapy.** If symptoms persist or the patient cannot use inhalers, **slow-release theophylline** may be tried at **low dose in older people**, watching for gastrointestinal effects and interactions with antibiotics during exacerbations. **Roflumilast (a PDE-4 inhibitor)** is an option in frequent exacerbators with chronic bronchitis and copious sputum — monitor for **weight loss, diarrhoea and mood disturbance**, and note the limited safety evidence in the elderly. A trial of **mucolytics or high-dose N-acetylcysteine** may help viscid sputum. **Nebulised bronchodilators** help very advanced disease or hopeless inhaler technique. **Maintenance oral corticosteroids should generally be avoided — the risks outweigh the benefits.**
5. **Management of exacerbations.** Exacerbations account for **up to 10% of medical admissions**; **one-third are readmitted within 30 days and 15% die within three months**. Common organisms: **H. influenzae, S. pneumoniae and M. catarrhalis**. Give **bronchodilators, controlled oxygen to a target saturation of 88–92%**, and **oral corticosteroids for 5–7 (up to 14) days**, which shorten stay and reduce treatment failure. **Antibiotics when there is increased cough with purulent sputum** — beta-lactam ± inhibitor, doxycycline or a fluoroquinolone; add antipseudomonal cover if bronchiectasis coexists; **avoid antibiotics if the sputum is not purulent**. **Non-invasive ventilation if pH < 7.35** despite maximal therapy — this reduces mortality, intubation and length of stay; **high-flow nasal oxygen** is an alternative, especially with do-not-intubate orders. Screen for **osteoporosis** in anyone receiving repeated steroid courses.

6. **Long-term support, comorbidity and end-of-life care.** Assess for **long-term oxygen therapy** in severe disease or cor pulmonale, and for **home NIV** in persistent hypercapnia. Manage comorbidities actively — **ischaemic heart disease and heart failure (cardioselective beta-blockers are safe and should be used when indicated), osteoporosis, obstructive sleep apnoea, anxiety, depression, sarcopenia and falls**. Consider **early-discharge and admission-avoidance teams** for suitable non-acidotic patients with good social support. **Patients judged to be in the last year of life should be placed on an end-of-life register and offered palliation including opioids and benzodiazepines for refractory breathlessness** — the move from active to palliative care all too often comes too late.

Latest Update – 1 Point (2023–Present)

7. **Biologic therapy has entered COPD.** The **BOREAS (NEJM 2023)** and **NOTUS (NEJM 2024)** trials showed that **dupilumab** (an anti-IL-4Rα monoclonal antibody) **significantly reduced exacerbations and improved lung function and quality of life in COPD with a type-2 inflammatory phenotype (blood eosinophils ≥ 300 cells/µL) already on triple inhaled therapy**, leading to regulatory approval in 2024–25 and its incorporation into the **GOLD 2025/2026** reports as an add-on for this phenotype. GOLD also continues to emphasise **single-inhaler triple therapy for exacerbators**, the **eosinophil count as the key biomarker for ICS use**, and **checking inhaler technique before any escalation**.

Question 40. Asthma management based on GINA guidelines

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Diagnosis and the geriatric difficulty.** Asthma is **chronic airway inflammation with bronchial hyper-responsiveness and variable airflow obstruction**, causing episodic wheeze, cough, chest tightness and dyspnoea, which is **fully or partly reversible**. It is **under-diagnosed and misdiagnosed in older people**, who have **reduced awareness of bronchoconstriction**, an **impaired bronchodilator response** from reduced beta-2 receptor density, and coexisting COPD. Confirm with **spirometry showing reversibility** or peak flow variability, and exclude heart failure, COPD, GORD, vocal cord dysfunction and drug-induced cough.
2. **Assessment of control (GINA framework).** Over the last 4 weeks ask about **daytime symptoms more than twice a week, any night waking due to asthma, reliever use more than twice a week, and activity limitation** — none = well controlled, 1–2 = partly controlled, 3–4 = uncontrolled. Separately assess **risk factors for exacerbation** (poor adherence, incorrect inhaler technique, high SABA use, low FEV_1, comorbidity) and **treatment side effects**. Management follows a **cycle of assess → adjust treatment → review response**.
3. **The central GINA principle. Short-acting beta-2 agonist (SABA)-only treatment is no longer recommended at any step** — it increases exacerbations and asthma death. **Every adult with asthma should receive inhaled-corticosteroid-containing therapy**, either as regular treatment or, at minimum, as ICS-formoterol taken whenever a reliever is needed.
4. **GINA Track 1 (preferred) — ICS-formoterol reliever.**

Step	Treatment
Steps 1–2	**As-needed low-dose ICS-formoterol** (anti-inflammatory reliever, "AIR")
Step 3	**Low-dose maintenance ICS-formoterol plus as-needed ICS-formoterol (MART)**
Step 4	**Medium-dose maintenance ICS-formoterol (MART)**
Step 5	Add **LAMA**; refer for phenotyping and **biologic therapy**; consider high-dose ICS-formoterol

   Track 2 is used when Track 1 is not possible or the patient is already stable on another regimen: **daily ICS (step 2) → ICS-LABA (steps 3–4) → add-on therapy (step 5)**, with a **SABA reliever**.
5. **Add-on and add-back therapy in older adults. Adding a LABA gives better control than increasing the ICS dose**, but **a LABA must never be used as monotherapy** because it does not treat inflammation. **LAMAs** (tiotropium, glycopyrronium, aclidinium) are of limited benefit alone but are useful added to ICS-LABA in the old, where reduced beta-2 receptor density relatively increases anticholinergic benefit — but they are **contraindicated in urinary retention and glaucoma**. **Leukotriene modifiers** are simple oral agents with proven efficacy in older adults; **slow-release theophylline** has a narrow therapeutic index. **Biologics** for severe disease target **IgE (omalizumab), IL-5 (mepolizumab, reslizumab, benralizumab)** and **IL-4/IL-13 (dupilumab)**, but **efficacy and safety data in patients over 65 remain sparse**, so their use should be restricted to carefully selected cases.

6. **Practical points and drugs to avoid.** Always use an **MDI with a spacer** to reduce oropharyngeal candidiasis and dysphonia and to overcome coordination problems; **tobacco smoking limits the efficacy of inhaled corticosteroids**. Monitor control by **symptoms, night-time relief, peak flow and where available exhaled nitric oxide**. **Beta-blockers (including topical glaucoma drops), verapamil, aspirin and NSAIDs can worsen asthma**. Watch for ICS-related **osteoporosis, cataract, glaucoma, skin thinning and dysphonia** in long-term use, and give **a written asthma action plan** with carer involvement where cognition is impaired.

Latest Update – 1 Point (2023–Present)

7. **GINA 2024–2025 strategy reports** have consolidated the **two-track approach with anti-inflammatory reliever therapy as the preferred option at every step**, and now explicitly extend **anti-inflammatory reliever (AIR) therapy to mild asthma**, so that **no patient is left on SABA alone**. They also formalise **anti-inflammatory reliever combinations of ICS with a short-acting beta-2 agonist (ICS-SABA)** as an alternative where ICS-formoterol is unavailable, emphasise **biomarker-based phenotyping (blood eosinophils, FeNO, IgE) before escalating to a biologic**, and highlight **treatable traits and comorbidity management (obesity, GORD, rhinosinusitis, OSA, anxiety)** — an approach that fits geriatric multimorbidity particularly well.

Current Practice Update

Textbook	Stepwise therapy with a SABA reliever; add LABA before increasing ICS; theophylline and leukotriene modifiers as add-ons.
Current recommendation	GINA — SABA-only treatment abandoned; as-needed or maintenance-and-reliever ICS-formoterol (AIR/MART) is the preferred track at all steps.
Exam approach	Open the management section with "GINA no longer recommends SABA-alone therapy — every adult receives ICS-containing treatment," then draw the two-track step table.

Question 41. Senile emphysema

7-Mark Answer | 6 textbook points + 1 latest update | ***Asked ×2***

Textbook Core – 6 Points

1. **Definition and why the name is a misnomer.** "Senile emphysema" (better called the **ageing or senile lung**) is the **physiological enlargement of alveolar ducts and alveoli that occurs with normal ageing**. **Crucially, it occurs WITHOUT destruction of alveolar walls and without inflammation** — the features that define true emphysema. It is therefore a **normal age-related change, not a disease**, and the term "emphysema" is strictly incorrect.
2. **Mechanism.** There is an **alteration in the collagen and elastic fibre network** of the lung, leading to **dilated alveolar ducts and alveolar enlargement** and a **loss of elastic recoil**. Loss of recoil reduces the tethering (radial traction) of small airways, so they **close at higher lung volumes**, producing **premature airway closure, air trapping and hyperinflation**. Alveolar surface area for gas exchange falls (roughly 4% per decade after 30).
3. **Associated extrapulmonary changes.** The chest wall stiffens: **rib cage stiffening, degenerative spinal change with kyphosis, reduced thickness of parietal muscles and reduced respiratory muscle mass**, giving **decreased chest wall compliance, increased anteroposterior diameter and a flattened diaphragm with decreased curvature**. The result is **increased work of breathing, a higher respiratory rate with lower tidal volume, and reduced exercise tolerance**.
4. **Physiological consequences (very examinable).**

Parameter	Change with age
Residual volume (RV), functional residual capacity (FRC)	**Increased** (air trapping)
Total lung capacity (TLC)	**Essentially unchanged** or slightly reduced by chest-wall restriction
Vital capacity (FVC)	**Decreased**
FEV_1 and FEV_1/FVC ratio	**Decreased** — a disproportionate fall in FEV_1 gives a **"pseudo-obstructive" spirometric pattern**
DLCO	Mildly reduced (loss of surface area)
PaO_2	Falls gradually with age (ventilation–perfusion mismatch from small airway closure); $PaCO_2$ unchanged
Ventilatory response	**Markedly impaired response to hypoxia and hypercapnia** → lower threshold for ventilatory decompensation

5. **Clinical relevance.** The senile lung is **asymptomatic at rest** — there is no cough, sputum or wheeze — but there is **reduced ventilatory reserve**, so exercise tolerance falls and the older person **decompensates rapidly during pneumonia, heart failure, surgery or anaesthesia**. Physical signs may mimic emphysema (**barrel chest, reduced expansion, hyper-resonance, quiet breath sounds**), and this must not be mistaken for COPD.
6. **Distinguishing senile lung from true emphysema (the crux of the answer).**

Feature	Senile lung	True emphysema
Alveolar wall destruction	**Absent**	**Present**
Inflammation	Absent	Present
Airspace enlargement	Uniform, ductal	Non-uniform (centriacinar/panacinar), with bullae
Symptoms	None at rest	Chronic breathlessness, cough, sputum
Bronchodilator reversibility / progression	Stable, non-progressive	Progressive decline
Cause	Normal ageing	Smoking, biomass smoke, α_1-antitrypsin deficiency

The key practical implication: use the lower limit of normal (LLN) for the FEV_1/FVC ratio rather than the fixed 0.70 cut-off, because the fixed ratio misclassifies the normal ageing lung as airflow obstruction and over-diagnoses COPD in older people. There is **no specific treatment** — management is prevention: **smoking avoidance, exercise and pulmonary reserve maintenance, vaccination, and avoidance of biomass smoke and air pollution**.

Latest Update – 1 Point (2023–Present)

7. **GOLD 2023–2026 reports formally recognise the diagnostic problem posed by the ageing lung** by introducing the categories of **"Pre-COPD"** (respiratory symptoms and/or structural or functional abnormality with **normal spirometry**) and **"PRISm" — Preserved Ratio Impaired Spirometry** (**$FEV_1/FVC \geq 0.70$ but $FEV_1 < 80\%$ predicted**), both of which carry increased risk of progression and mortality. GOLD also continues to caution that the **fixed FEV_1/FVC ratio of 0.70 over-diagnoses airflow obstruction in older adults**, and to recommend confirming abnormality against age-appropriate reference equations — the modern, guideline-level restatement of exactly what "senile emphysema" describes.

Question 42. Metered dose inhalers and inhaler technique in the older adult

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Why it matters.** Inhaled therapy is first-line in **COPD and asthma**, but the drug only reaches the airway if the technique is correct. **Using inhaler devices is a demanding task for older patients** because it needs **coordination and respiratory muscle strength**. Poor technique is a major cause of apparent **"treatment failure"** and leads to unnecessary escalation of therapy — **always check the technique before stepping up treatment**.
2. **Correct MDI technique (stepwise).** (1) Remove the cap and **shake well**; (2) sit or stand upright and **breathe out fully, away from the device**; (3) seal the lips around the mouthpiece; (4) **begin a slow deep inhalation and actuate the canister at the same moment**; (5) continue inhaling steadily over **4–5 seconds**; (6) **hold the breath for 10 seconds**; (7) wait **30 seconds** before a second puff; (8) **rinse the mouth** after an inhaled corticosteroid.
3. **Common errors.** Failure to shake the canister; not exhaling first; **poor hand-breath coordination** — actuating before or after inhalation; inhaling too fast; **no breath-hold**; firing into the mouth while breathing out; using an empty canister; and not rinsing, leading to **oropharyngeal candidiasis and dysphonia**. Multiple puffs fired in quick succession.
4. **Age-related barriers. Most cognitively intact older patients without physical limitation can use an inhaler correctly, but learning and coordination difficulties are present in about 20%. Cognitive impairment has a dramatic impact**: **an MMSE score below 24 is associated with a very high risk of failure**, and the **abnormal pentagon-copying test alone identifies patients unable to use inhaler devices**. Other barriers: **poor manual dexterity, weak hand grip, arthritis, impaired vision and impaired executive function** — the last is especially common in hospitalised patients.

5. **Device selection.** **The perfect device does not exist** — the choice must be individualised to the patient's cognition, dexterity and inspiratory flow. An **MDI with a spacer (valved holding chamber)** removes the need for hand–breath coordination and **reduces oropharyngeal deposition, candidiasis and dysphonia**; it is the preferred combination in most older adults. **Dry powder inhalers** need adequate inspiratory flow, often lacking in severe COPD and frailty, but need no coordination. **Breath-actuated MDIs** help coordination problems. **Nebulisers** are reserved for very advanced disease or when the inhaler technique is so poor that no other relief is possible; **adapters fitted to the inhaler ends** can help weak grip.
6. **Improving technique and adherence.** Use **fixed-dose combination inhalers** to reduce the number of devices, since **device quantity impacts adherence**; keep the patient on **one device type** wherever possible. Teach by **physical demonstration with teach-back**, not verbal instruction alone. Ask the patient to **bring all inhalers to every clinic visit**, and **re-train the patient and/or the caregiver**. **Screen cognition (MMSE or a secondary memory test)** to identify those at risk of poor compliance, and involve the carer or care-home staff for supervised administration.

Latest Update – 1 Point (2023–Present)

7. **GOLD 2025 / 2026** makes checking inhaler technique a **mandatory step at every visit and a required check before any escalation of therapy**, and emphasises **choosing the device before choosing the drug**. GOLD now also asks clinicians to consider the **environmental impact of inhalers** — conventional pressurised MDIs use high global-warming-potential HFA-134a/227ea propellants, and the shift is towards **low-GWP propellants (HFA-152a, HFO-1234ze)** and greater use of **dry powder inhalers where clinically appropriate** — though in older adults **clinical suitability and inspiratory flow must always outweigh environmental considerations**.

J. Parenchymal and Pleural Disease

Question 43. Diffuse parenchymal lung disease in older adults

15-Mark Essay | 10 textbook points + 2 latest updates | ***Asked ×3***

Source note: Diffuse parenchymal lung disease is **not covered adequately as a standalone topic in the uploaded textbook** — Pathy's refers to it mainly in the context of ageing lung changes, drug-related pneumonitis and the differential diagnosis of B-lines on ultrasound. The answer below is built on current standard respiratory guidance and is labelled accordingly.

Textbook Core – 10 Points

1. **Definition.** Diffuse parenchymal lung disease (DPLD), or **interstitial lung disease**, is a heterogeneous group of disorders characterised by **inflammation and/or fibrosis of the alveolar interstitium, alveoli and small airways**, producing a **restrictive ventilatory defect with impaired gas transfer** — reduced **TLC, FVC and DLCO with a preserved or raised FEV_1/FVC ratio**.
2. **Epidemiology in older adults.** DPLD is **predominantly a disease of later life**. **Idiopathic pulmonary fibrosis (IPF) has a median age at diagnosis of about 65–70**, a male predominance and rising incidence with each decade; it is rare below 50. **Interstitial lung abnormalities** are found incidentally on CT in up to **10% of older people** and a proportion progress. In India, **hypersensitivity pneumonitis and connective tissue disease-associated ILD** form a larger share than in Western registries, and **post-tubercular fibrosis** is an important mimic.
3. **Pathogenesis.** Modern understanding of IPF is of **repetitive micro-injury to a genetically susceptible, aged alveolar epithelium** rather than primary inflammation. Ageing mechanisms are central — **telomere shortening, cellular senescence, mitochondrial dysfunction, impaired autophagy and defective epithelial repair**. Injured type II pneumocytes drive **aberrant fibroblast activation and myofibroblast proliferation with excess extracellular matrix deposition** and formation of **fibroblastic foci**. Risk factors: **smoking, gastro-oesophageal reflux with micro-aspiration, dusts and metals, viral infection**, and gene variants (**MUC5B promoter polymorphism, telomerase TERT/TERC mutations, surfactant protein genes**). In hypersensitivity pneumonitis the mechanism is an immune response to inhaled organic antigen.

4. **Classification.**

Group	Examples
Known cause	**Connective tissue disease-ILD** (rheumatoid arthritis, systemic sclerosis, myositis, Sjögren), **hypersensitivity pneumonitis** (birds, mould, biomass), **pneumoconioses** (asbestosis, silicosis), **drug-induced** — **amiodarone, methotrexate, nitrofurantoin, bleomycin, immune checkpoint inhibitors**, radiation
Idiopathic interstitial pneumonias	**IPF (UIP pattern)**, non-specific interstitial pneumonia (NSIP), cryptogenic organising pneumonia (COP), acute interstitial pneumonia, desquamative interstitial pneumonia and respiratory bronchiolitis-ILD (smoking-related)
Granulomatous	**Sarcoidosis**
Rare / distinct	Lymphangioleiomyomatosis, Langerhans cell histiocytosis, pulmonary alveolar proteinosis, eosinophilic pneumonia

   A crucial modern concept is the **progressive pulmonary fibrosis (PPF)** phenotype — any non-IPF fibrotic ILD that shows worsening symptoms, physiology or radiology despite standard treatment.

5. **Clinical features. Insidious exertional breathlessness** and a **persistent dry cough**. **In older adults symptoms are frequently attributed to ageing, deconditioning, heart failure or COPD, causing years of diagnostic delay.** Signs: **fine bibasal end-inspiratory "Velcro" crackles** (an early and important sign in IPF), **finger clubbing (about 50% of IPF)**, and later **cyanosis, cor pulmonale and right heart failure**. Look for extrapulmonary clues to CTD — **arthritis, Raynaud phenomenon, sclerodactyly, mechanic's hands, rash, dry eyes and mouth**. Take a meticulous **occupational, environmental, avian, mould and drug history**.

6. **Investigations — imaging is central. Chest radiograph** shows reduced lung volumes with reticulonodular shadowing but is insensitive. **High-resolution CT is the key investigation.** The **usual interstitial pneumonia (UIP) pattern** — **subpleural, basal-predominant reticulation with honeycombing and traction bronchiectasis, and no significant ground-glass** — is diagnostic of IPF in the right clinical setting and **removes the need for biopsy**. Other patterns: **ground-glass with subpleural sparing (NSIP)**; **mosaic attenuation with air trapping and centrilobular nodules (hypersensitivity pneumonitis)**; **peripheral consolidation (organising pneumonia)**; **upper-zone perilymphatic nodules and hilar nodes (sarcoidosis)**.

7. **Other investigations. Full pulmonary function tests** — restrictive pattern with **reduced FVC, TLC and DLCO**; DLCO is the most sensitive early marker and the best correlate of prognosis. **Six-minute walk test with oximetry** to document **exertional desaturation**. **Serology** — ANA, rheumatoid factor, anti-CCP, ENA, myositis panel, ANCA; **serum precipitins** for hypersensitivity pneumonitis; serum ACE and calcium for sarcoidosis. **Bronchoalveolar lavage** for lymphocytosis (hypersensitivity pneumonitis, sarcoidosis) and to exclude infection. **Echocardiography** for pulmonary hypertension. **Surgical lung biopsy is high-risk in the elderly and is largely avoided; transbronchial lung cryobiopsy is a lower-risk alternative in selected patients.** The diagnosis should be made by a **multidisciplinary discussion of clinician, radiologist and pathologist** — this is the accepted gold standard.

8. **Management — general and non-pharmacological. Remove the cause** — antigen avoidance in hypersensitivity pneumonitis, stopping the culprit drug, smoking cessation. **Pulmonary rehabilitation** improves exercise capacity and quality of life. **Ambulatory and long-term oxygen** for resting or exertional hypoxaemia. **Vaccination** (influenza, pneumococcal, COVID-19, RSV). **Treat comorbidities** that materially affect outcome — **gastro-oesophageal reflux, obstructive sleep apnoea, pulmonary hypertension, ischaemic heart disease, depression, deconditioning and osteoporosis**. Manage **cough** and breathlessness symptomatically, with **low-dose opioids** where refractory.

9. **Management — pharmacological. IPF: antifibrotic therapy with nintedanib (a triple tyrosine kinase inhibitor; adverse effects diarrhoea, deranged LFTs, bleeding risk with anticoagulants) or pirfenidone (nausea, photosensitivity, weight loss)** — both slow the rate of FVC decline. **Corticosteroids and immunosuppression are harmful in IPF** (the PANTHER-IPF trial showed increased mortality with prednisolone + azathioprine + N-acetylcysteine) and must not be used. **Non-IPF ILD: corticosteroids ± mycophenolate, azathioprine or rituximab** for CTD-ILD and hypersensitivity pneumonitis; **nintedanib is licensed for the progressive pulmonary fibrosis phenotype** (INBUILD trial) and for systemic sclerosis-ILD (SENSCIS). **Lung transplantation** is the only curative option but **age over 65–70 with frailty and comorbidity usually precludes it**.

10. **Prognosis and natural history. IPF has the worst prognosis — median survival about 3–5 years from diagnosis**, comparable to many cancers. The course is variable: **slow decline, rapid decline, or stability punctuated by acute exacerbations**. **Acute exacerbation of IPF** — new ground-glass on a background of UIP without infection, heart failure or PE — carries an **in-hospital mortality above 50%**. Prognostic tools: the **GAP index (Gender, Age, Physiology — FVC and DLCO)**, and a **decline in FVC of ≥ 10% or DLCO of ≥ 15% over 6–12 months**. NSIP, COP and sarcoidosis carry a much better prognosis than IPF. Because trajectory is poor, **early advance care planning, symptom control and palliative care must run in parallel with disease-modifying therapy in older patients**.

> **Latest Updates – 2 Points (2023–Present)**

11. **Progressive pulmonary fibrosis is now a treatable entity in its own right.** The **2022 ATS/ERS/JRS/ALAT guideline** formally defined **PPF** as at least two of — worsening respiratory symptoms, physiological progression (**absolute FVC decline ≥ 5% or DLCO decline ≥ 10% within one year**), or radiological progression — occurring in a patient with non-IPF fibrotic ILD. On the basis of the **INBUILD** trial, **nintedanib is recommended for PPF regardless of the underlying ILD**, so the modern question at the bedside is no longer only "which ILD?" but **"is this fibrosis progressive?"**
12. **Nerandomilast — the first new antifibrotic class in a decade.** The phase III **FIBRONEER-IPF** and **FIBRONEER-ILD** trials (**NEJM 2025**) showed that **nerandomilast**, an oral **preferential phosphodiesterase-4B (PDE4B) inhibitor**, **significantly reduced the decline in FVC at 52 weeks in both IPF and progressive pulmonary fibrosis**, at both 9 mg and 18 mg twice daily, and **whether given alone or added to background nintedanib or pirfenidone**. Longer follow-up of FIBRONEER-ILD also showed reduced risk of death. It is under regulatory review and represents the first successful new mechanism in pulmonary fibrosis since the antifibrotics.

Current Practice Update

Textbook	ILD discussed only as a radiological differential; corticosteroids implied as generic therapy for interstitial disease.
Current recommendation	Antifibrotics (nintedanib, pirfenidone) are standard in IPF and **steroids are contraindicated** (PANTHER-IPF); nintedanib is licensed for the progressive pulmonary fibrosis phenotype; nerandomilast is emerging.
Exam approach	Write one line — "steroids are harmful in IPF (PANTHER-IPF); antifibrotics are the standard of care, and nintedanib now also treats progressive pulmonary fibrosis of any cause (INBUILD)."

Question 44. Pleural effusion in a 70-year-old — etiopathogenesis, features, differential diagnosis, approach and management

15-Mark Essay | 10 textbook points + 2 latest updates | ***Asked ×2***

Textbook Core – 10 Points

1. **Definition and normal physiology.** Pleural effusion is **abnormal accumulation of fluid in the pleural space**. Normally only **10–20 mL** of fluid is present, produced by the parietal pleural capillaries and absorbed by **parietal pleural lymphatics**. Effusion results when **formation exceeds absorption**. About **250–500 mL** is needed for blunting of the costophrenic angle on an erect chest radiograph, but as little as **50 mL** is detectable on ultrasound or lateral decubitus film.
2. **Pathogenetic mechanisms.** (i) **Increased hydrostatic pressure** — heart failure; (ii) **reduced oncotic pressure** — hypoalbuminaemia, nephrotic syndrome, cirrhosis; (iii) **increased capillary permeability** — infection, malignancy, inflammation; (iv) **impaired lymphatic drainage** — malignant mediastinal node involvement; (v) **movement of fluid from the peritoneum** through diaphragmatic defects — hepatic hydrothorax, Meigs syndrome, pancreatitis; (vi) **thoracic duct rupture** — chylothorax; (vii) **bleeding** — haemothorax.
3. **Causes in a 70-year-old (frequency order matters).**

Transudate	Exudate
Congestive heart failure — the commonest cause overall in the elderly; hypoalbuminaemia; nephrotic syndrome; cirrhosis with hepatic hydrothorax; peritoneal dialysis; constrictive pericarditis; hypothyroidism (may be either); **pulmonary embolism (usually exudate, occasionally transudate)**	**Malignancy** — lung, breast, lymphoma, mesothelioma, ovary, unknown primary; **parapneumonic effusion and empyema**; **tuberculosis — very important in India and often the commonest exudate**; pulmonary embolism/infarction; connective tissue disease (rheumatoid, SLE); pancreatitis; subphrenic or hepatic abscess; drugs (amiodarone, methotrexate, nitrofurantoin); post-cardiac injury (Dressler); asbestos-related benign effusion; chylothorax

In older patients effusions are frequently multifactorial — heart failure plus hypoalbuminaemia plus infection may coexist.

4. **Clinical features. Breathlessness** proportional to size and to underlying lung reserve, **pleuritic chest pain** (parietal pleural involvement, suggesting an exudate), and a **dry cough**. In the frail older patient the presentation may again be **non-specific — fatigue, delirium, anorexia or reduced mobility**. Signs on the affected side: **reduced chest expansion, stony dull percussion note, absent or diminished breath sounds, reduced vocal resonance and tactile fremitus**, with a **bronchial breath sound and aegophony at the upper level**; large effusions cause **tracheal and mediastinal shift away** from the effusion. Always seek clues to the cause — **raised JVP and oedema (heart failure), clubbing and weight loss (malignancy), fever and purulent sputum (empyema), lymphadenopathy, joint disease, and evening rise of temperature with weight loss (tuberculosis)**.

5. **Initial imaging. Erect PA chest radiograph** — homogeneous basal opacity with a **meniscus sign**; a lateral film detects smaller effusions; look for **mediastinal shift, a mass, cardiomegaly or a "white-out"**. **Thoracic ultrasound is now mandatory before any pleural procedure** — it detects small effusions, distinguishes fluid from consolidation and pleural thickening, identifies **septations suggesting empyema or malignancy**, and reduces the risk of pneumothorax and organ injury. **Contrast-enhanced CT thorax** (ideally before complete drainage) is required for suspected malignancy or empyema and shows **nodular, circumferential or mediastinal pleural thickening > 1 cm**, the **"split pleura" sign** of empyema, and any underlying lung lesion.
6. **Diagnostic thoracentesis and Light's criteria. Aspirate all undiagnosed effusions** under ultrasound guidance; a bilateral effusion with clear-cut heart failure may be treated first and tapped only if atypical or non-resolving. Apply **Light's criteria — the fluid is an EXUDATE if any one is met:** (i) **pleural fluid/serum protein ratio > 0.5**; (ii) **pleural fluid/serum LDH ratio > 0.6**; (iii) **pleural fluid LDH > two-thirds of the upper limit of normal serum LDH**. **Light's criteria misclassify about 25% of transudates as exudates in patients already on diuretics** — in that situation use a **serum-to-pleural-fluid albumin gradient > 1.2 g/dL** or a **protein gradient > 3.1 g/dL**, which indicates a transudate.
7. **Pleural fluid analysis — what to send.**

Test	Interpretation
Appearance	Straw (transudate), turbid/purulent (empyema), blood-stained (**malignancy, PE/infarct, trauma, TB**), milky (chylothorax)
Protein, LDH, albumin	Light's criteria and gradients
pH and glucose	**pH < 7.20 or glucose < 60 mg/dL → complicated parapneumonic effusion requiring drainage**; also low in TB, malignancy, rheumatoid and oesophageal rupture
Cell count and differential	**Neutrophils** — parapneumonic, PE, pancreatitis; **lymphocytes** — **tuberculosis, malignancy, lymphoma, chronic effusion**; **eosinophils > 10%** — air or blood in the pleural space, drugs, parasites, asbestos
Adenosine deaminase (ADA)	**> 40 U/L with a lymphocyte-predominant exudate strongly suggests tuberculosis** — the single most useful test in India
Cytology	Positive in about **60%** of malignant effusions on first sample; a second sample raises the yield — send large volume (≥ 50 mL)
Microbiology	Gram stain, culture, **AFB smear, culture and CBNAAT/GeneXpert**; inoculate fluid into blood culture bottles
Others	Amylase (pancreatitis, oesophageal rupture, malignancy), triglycerides > 110 mg/dL (chylothorax), haematocrit > 50% of blood (haemothorax), rheumatoid factor, NT-proBNP

8. **When the tap is non-diagnostic.** About **20–25% of effusions remain undiagnosed after two thoracenteses**. Next steps: **CT-guided cutting-needle pleural biopsy** of thickened pleura (high yield in malignancy and tuberculosis), or **medical (local anaesthetic) thoracoscopy — the investigation of choice, with a diagnostic yield above 90% for malignancy and tuberculosis, and it allows talc poudrage in the same sitting**. Blind Abrams needle biopsy retains a role for suspected tuberculosis where thoracoscopy is unavailable. Consider **bronchoscopy** only if there is haemoptysis or a parenchymal lesion. If all are negative and there is asbestos exposure, keep **mesothelioma** in mind and follow up.
9. **Management by cause. Transudate — treat the underlying disease** (diuretics and guideline-directed therapy for heart failure, albumin/diuretics for cirrhosis); repeated taps are rarely needed. **Parapneumonic effusion** — antibiotics alone if simple; **intercostal chest drain if the fluid is purulent, pH < 7.20, glucose < 60 mg/dL, loculated, or organisms are seen**. **Empyema** — small-bore chest drain plus prolonged antibiotics; if drainage fails, **intrapleural fibrinolytic therapy with alteplase plus DNase (MIST-2 regimen)** improves drainage and reduces surgical referral, with **VATS decortication** for failure. **Tuberculous effusion** — standard **ATT for 6 months**; therapeutic aspiration for symptoms; steroids are not routinely indicated. **Therapeutic aspiration should be limited to about 1.5 litres at one sitting**, stopping earlier for cough or chest discomfort, to avoid **re-expansion pulmonary oedema**.
10. **Malignant pleural effusion and the geriatric approach.** A malignant effusion signifies **advanced disease with a median survival of about 3–12 months** (worst in lung cancer, best in breast cancer and mesothelioma of epithelioid type); prognosis can be estimated by the **LENT score**. Management is **palliative and symptom-driven**: observe if asymptomatic; **therapeutic aspiration** for a frail patient with limited life expectancy; **indwelling pleural catheter (IPC)** — preferred where the lung fails to re-expand (**trapped lung**) or where hospital stay must be minimised; and **chest drain with talc pleurodesis** where the lung re-expands and durable control is wanted. **In the older patient the choice is driven by performance status, life expectancy, home support and patient preference, not by the size of the effusion.** Treat the underlying malignancy where appropriate and involve **palliative care early**.

Latest Updates – 2 Points (2023–Present)

11. **BTS Pleural Disease Guideline 2023 (Thorax).** Key changes relevant to older patients: **thoracic ultrasound must be used for all pleural interventions**; a **contrast CT should be obtained before complete drainage** where malignancy is suspected; **medical thoracoscopy is the preferred investigation for an undiagnosed exudate**; **indwelling pleural catheters and talc pleurodesis are equally acceptable first-line options for malignant effusion**, with the decision made by shared decision-making; and the **RAPID score** (Renal, Age, Purulence, Infection source, Dietary/albumin) is endorsed for risk-stratifying pleural infection, in which **age over 70 is an adverse prognostic factor**.
12. **Intrapleural therapy and IPC strategy have matured.** Following **MIST-2**, combined **intrapleural alteplase plus DNase** is established for pleural infection when drainage fails, and is increasingly used in frail patients who are unfit for surgery. For malignant effusion, the **AMPLE and IPC-PLUS** trials support **indwelling pleural catheters with daily drainage, and talc administered through the catheter** to achieve pleurodesis — an approach that **reduces total hospital days**, which is the outcome that matters most to an older patient with limited life expectancy.

K. Respiratory Failure and Critical Care

Question 45. Respiratory failure, including acute type 2 respiratory failure

*7-Mark Answer | 6 textbook points + 1 latest update | **Asked ×2***

Textbook Core – 6 Points

1. **Definition and classification.** Respiratory failure is failure of the lungs to maintain adequate gas exchange, defined on arterial blood gas as **PaO_2 < 60 mmHg (8 kPa)** breathing room air, with or without **$PaCO_2$ > 50 mmHg (6.7 kPa)**.

	Type 1 (hypoxaemic)	Type 2 (hypercapnic / ventilatory)
Gases	PaO_2 ↓, $PaCO_2$ normal or ↓	PaO_2 ↓, **$PaCO_2$ ↑**
Mechanism	**V/Q mismatch, shunt, diffusion defect**	**Alveolar hypoventilation** (pump failure)
A–a gradient	**Widened**	Normal in pure hypoventilation; widened if lung disease coexists
Examples	Pneumonia, pulmonary oedema, PE, ARDS, ILD	COPD exacerbation, opioid/sedative overdose, neuromuscular disease, kyphoscoliosis, obesity hypoventilation, severe asthma (late)

2. **Acute versus chronic — read the bicarbonate. In acute type 2 failure the pH is low with a normal bicarbonate; in chronic failure the bicarbonate is raised with a near-normal pH (renal compensation); in acute-on-chronic failure the bicarbonate is raised AND the pH is low.** This single distinction determines urgency and is a guaranteed examination mark. Also calculate the **alveolar–arterial oxygen gradient**, which rises normally with age (approximately **age/4 + 4 mmHg**).
3. **Why older people are predisposed.** Ageing produces **loss of elastic recoil with small airway closure and V/Q mismatch, reduced chest wall compliance from kyphosis and rib cage stiffening, reduced respiratory muscle mass and strength, and a lower PaO_2**. Most importantly there is a **marked decline in efferent neural output and a blunted ventilatory response to hypoxia and hypercapnia**, giving a **lower threshold for ventilatory decompensation**. Add **sarcopenia, malnutrition, sedatives and opioids, aspiration and immobility**, and small insults precipitate failure.
4. **Clinical features. Hypoxaemia** — dyspnoea, tachypnoea, restlessness, confusion, cyanosis (a late and unreliable sign), tachycardia, arrhythmia; chronically, **polycythaemia, pulmonary hypertension and cor pulmonale**. **Hypercapnia — headache (especially morning), warm peripheries with a bounding pulse, flushing, drowsiness progressing to coma, flapping tremor (asterixis) and papilloedema. In older adults the earliest and often the only sign is unexplained delirium or drowsiness — always check an arterial blood gas.** Pulse oximetry cannot detect hypercapnia and is misleading on supplemental oxygen.
5. **Investigations. Arterial blood gas is the diagnostic test** (record the FiO_2). Add **chest radiograph, ECG, full blood count, urea and electrolytes, glucose**, and where relevant **CT chest or CTPA, echocardiography, sputum culture, toxicology, thyroid function, creatine kinase and nerve conduction studies** for neuromuscular causes. In chronic disease do **spirometry, overnight oximetry and transcutaneous CO_2 monitoring**. Look actively for **reversible precipitants — infection, pneumothorax, pulmonary embolism, heart failure, sedative drugs, electrolyte disturbance and pain-related hypoventilation**.

6. **Management of acute type 2 respiratory failure.** (i) **Treat the precipitating cause** — bronchodilators, corticosteroids, antibiotics, drainage of pneumothorax, reversal of opioids with naloxone. (ii) **Controlled oxygen therapy targeting SpO_2 88–92%** using a 24–28% Venturi mask — **excessive oxygen worsens hypercapnia through loss of hypoxic drive, the Haldane effect and increased V/Q mismatch, and increases coronary and cerebral vascular resistance**. (iii) **Non-invasive ventilation (BiPAP) when pH < 7.35 with $PaCO_2$ > 6 kPa despite maximal medical therapy** — it **reduces mortality, intubation rate and hospital stay**. (iv) **Repeat the ABG at 1 hour**; failure to improve, pH < 7.25, reduced consciousness or intolerance of the mask indicates **intubation and invasive ventilation** — or, in a frail patient, that **NIV is the agreed ceiling of care**. (v) **Respiratory stimulants (doxapram) are now rarely used.** (vi) Document a **ceiling-of-treatment and resuscitation decision early**, and provide **palliation of breathlessness with opioids and benzodiazepines** where treatment is not succeeding.

Latest Update – 1 Point (2023–Present)

7. **High-flow nasal oxygen (HFNO) has become an established third option between conventional oxygen and NIV.** Delivering **heated, humidified gas at 30–60 L/min with a precise FiO_2**, it generates modest PEEP and washes out anatomical dead space. **ERS/ATS guidance and the GOLD reports** support HFNO in **acute hypoxaemic respiratory failure** (where it reduces intubation compared with conventional oxygen), and it is **safe and effective in exacerbated COPD with both normocapnic and hypercapnic failure**. It is especially valuable in older patients as a **comfort-preserving option where intubation is not appropriate (do-not-intubate orders) or to provide intermediate care outside the intensive care unit** — although **NIV remains first-line for acidotic hypercapnic failure**.

Question 46. Management of ARDS

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and diagnosis.** By the **Berlin definition**, ARDS requires all four of: **onset within one week of a known insult**; **bilateral opacities on chest imaging not fully explained by effusion, collapse or nodules**; **respiratory failure not fully explained by cardiac failure or fluid overload** (objectively assessed, e.g. by echocardiography); and **hypoxaemia graded on PaO_2/FiO_2 with PEEP ≥ 5 cmH_2O — mild 200–300, moderate 100–200, severe ≤ 100**. Pathologically there is **diffuse alveolar damage with non-cardiogenic pulmonary oedema, surfactant loss and hyaline membranes**.
2. **Treat the cause and give supportive care.** Identify and treat the precipitant — **pneumonia and sepsis (commonest), aspiration, pancreatitis, trauma, transfusion (TRALI), drugs, burns**. Give **source control and appropriate antimicrobials**, plus general intensive care: **VTE prophylaxis, stress-ulcer prophylaxis, early enteral nutrition, glycaemic control, sedation minimisation, delirium prevention and early mobilisation**.
3. **Lung-protective ventilation — the single most important intervention. Tidal volume 4–6 mL/kg of PREDICTED body weight, plateau pressure < 30 cmH_2O and driving pressure < 15 cmH_2O** (ARMA/ARDSNet — an absolute mortality reduction of about 9%). Accept **permissive hypercapnia** with pH above 7.20. Use **higher PEEP in moderate–severe ARDS** guided by a PEEP–FiO_2 table, targeting **SpO_2 88–95% or PaO_2 55–80 mmHg**. **Routine recruitment manoeuvres with aggressive PEEP titration are not recommended** (ART trial showed harm).
4. **Prone positioning and neuromuscular blockade. Prone position for at least 16 hours per day** in **moderate-to-severe ARDS with PaO_2/FiO_2 < 150** — the **PROSEVA** trial showed a large mortality reduction. **Neuromuscular blockade (cisatracurium) for 48 hours** may be used in early severe ARDS with ventilator dyssynchrony, but is **not routine** (ROSE trial was neutral) and risks **ICU-acquired weakness, which is particularly disabling in the old**. In older patients, **pressure-area care, eye and airway protection and careful positioning during proning** need explicit attention.
5. **Fluids, pharmacotherapy and rescue. Conservative fluid strategy** once shock has resolved (FACTT) — this shortens ventilator days. **Corticosteroids**: dexamethasone improved outcomes in DEXA-ARDS and are standard in **COVID-19-related ARDS**; use is reasonable in early moderate–severe ARDS but not universal. **No benefit from inhaled nitric oxide (oxygenation improves but mortality does not), surfactant, statins or beta-agonists. Veno-venous ECMO** for refractory severe ARDS in expert centres (EOLIA) — **age above 65–70 with frailty and comorbidity is generally a contraindication**.

6. **Geriatric considerations and outcome.** Older age is an **independent predictor of ARDS mortality**, and survivors face **ICU-acquired weakness, sarcopenia, prolonged weaning, delirium, post-intensive-care cognitive impairment and loss of independence**. Therefore: **establish goals of care and a ceiling of treatment early** with the patient and family; consider whether **NIV or HFNO is the appropriate ceiling**; involve **physiotherapy, nutrition, speech and swallow and geriatric medicine from day one**; plan **early tracheostomy** where prolonged ventilation is expected; and provide **rehabilitation and palliative care alongside organ support**.

Latest Update – 1 Point (2023–Present)

7. **The 2023 New Global Definition of ARDS** (a global consensus conference endorsed by ESICM/ATS) broadened the Berlin definition to make ARDS diagnosable outside well-resourced intensive care units. It **adds a "non-intubated ARDS" category for patients on high-flow nasal oxygen at ≥ 30 L/min or non-invasive ventilation with CPAP ≥ 5 cmH_2O**; permits **SpO_2/FiO_2 ratio ≤ 315 (with SpO_2 ≤ 97%) as an alternative to PaO_2/FiO_2** where blood gases are unavailable; and accepts **lung ultrasound as well as chest radiograph or CT** for the bilateral-opacity criterion. This makes the diagnosis workable in resource-limited settings, including much of India, and in older patients managed outside the ICU.

Question 47. Long-term oxygen therapy and home non-invasive ventilation

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and principle of LTOT.** Long-term oxygen therapy is supplemental oxygen given for **at least 15 hours per day**, which was shown in the **NOTT** and **MRC** trials to **improve survival** in severe COPD with persistent hypoxaemia. Along with **smoking cessation**, it is one of only two interventions proven to prolong life in COPD. It must be prescribed **during a period of clinical stability** and to **current non-smokers**.
2. **Criteria for LTOT.** Assess by arterial blood gas on two occasions at least 3 weeks apart when stable:

Criterion	Threshold
Absolute	**PaO_2 < 7.3 kPa (< 55 mmHg)**
With additional features	**PaO_2 7.3–8.0 kPa (55–60 mmHg)** plus **secondary polycythaemia, pulmonary hypertension, peripheral oedema (cor pulmonale) or nocturnal hypoxaemia**
Screening for referral	SpO_2 **< 93%**, or **< 95%** with possible cor pulmonale

Short-burst oxygen may relieve breathlessness if exercise desaturation is documented.

3. **Benefits and limitations.** LTOT improves **survival** (about **50% of patients survive a further 3 years**), **polycythaemia** and **neuropsychiatric function**; cognitive gains are small and mostly in the oldest groups; **quality-of-life benefit is modest and inconsistent**. **There are no randomised data on LTOT in advanced old age, or in isolated nocturnal or exertional hypoxaemia.** Low BMI and comorbidity predict earlier death; disability, low BMI, lung function and LTOT use are the main mortality predictors in older COPD patients.
4. **Practical and geriatric issues. Fire risk** if the patient or household continues to smoke. The concentrator and long tubing are a **trip and falls hazard** — engineers should fit room-switching mechanisms. **Cognitive impairment and poor manual dexterity** threaten safe use. **Care home logistics** matter: staff training, and portable cylinders or conservers if the day room is far from the bedroom. **Target saturation 88–92% in CO_2 retainers** — excessive oxygen depresses hypoxic drive, increases coronary and cerebral arterial resistance and worsens acidosis.
5. **Acute non-invasive ventilation.** Indicated in **acute hypercapnic respiratory failure with pH < 7.35 despite maximal medical therapy**. Compared with standard treatment, NIV **reduces mortality, the need for intubation and length of hospital stay**. **Bilevel positive airway pressure (BiPAP)** is used. NIV is an appropriate **ceiling of treatment** in frail older patients with a do-not-intubate decision. **High-flow nasal oxygen** is safe and effective in exacerbated COPD with normocapnic or hypercapnic failure and is useful for do-not-intubate patients or intermediate care outside the ICU.
6. **Home (domiciliary) NIV.** Indicated for **chronic hypercapnic respiratory failure** — most importantly **persistent hypercapnia ($PaCO_2$ > 7 kPa) reassessed 2–4 weeks after an exacerbation**, and also in **obesity hypoventilation syndrome, neuromuscular disease and chest-wall deformity (kyphoscoliosis)**. **CPAP — not NIV — is the treatment for obstructive sleep apnoea.** Success requires adequate **cognition, mask tolerance, carer support** and structured follow-up; palliative NIV may relieve symptoms at the end of life.

Latest Update – 1 Point (2023–Present)

7. **GOLD 2025 / 2026 reports** confirm that **LTOT is NOT indicated for isolated moderate resting desaturation or exercise-induced desaturation alone** (based on the **LOTT trial**, which found no benefit in survival or hospitalisation) — oxygen should only be prescribed for **severe resting hypoxaemia**. Conversely, **long-term home NIV should be considered in patients with severe chronic hypercapnia and a history of hospitalisation for acute respiratory failure**, following the **HOT-HMV** trial, which showed that home NIV added to oxygen prolonged the time to readmission or death.

Current Practice Update

Textbook	Short-burst oxygen may help breathlessness with exercise desaturation; home NIV not discussed in detail.
Current recommendation	GOLD — no LTOT for moderate or exercise-only desaturation (LOTT); home NIV recommended for persistent hypercapnia after an exacerbation (HOT-HMV).
Exam approach	Quote the classical PaO_2 thresholds, then add "LOTT: no benefit for moderate desaturation; HOT-HMV: home NIV for persistent hypercapnia."

L. Pulmonary Vascular Disease

Question 48. Pulmonary embolism

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and risk factors.** Pulmonary embolism (PE) is **obstruction of the pulmonary arterial tree, usually by thrombus embolising from a deep vein of the leg or pelvis**. Risk factors follow **Virchow's triad**: **immobility, hospitalisation, stroke with hemiplegia, hip fracture and arthroplasty, malignancy, previous VTE, heart failure, dehydration, sepsis, oestrogens and thrombophilia**. **Advancing age is an independent risk factor**, and PE is both commoner and more often fatal in the old.
2. **Clinical features and the diagnostic trap. Sudden breathlessness, pleuritic chest pain, haemoptysis, tachypnoea, tachycardia, syncope and hypotension.** PE **shares fever, cough, chest pain and dyspnoea with pneumonia**; the clues that favour PE are **clear lung fields on the chest radiograph, a context favouring venous thromboembolism, or clinical signs of deep vein thrombosis**. Conversely, a **pulmonary infarct produces signs shared with pneumonia and is very often secondarily infected**. In older patients PE presents atypically with **unexplained breathlessness, delirium, falls, syncope or new atrial fibrillation**, and is a common missed diagnosis at autopsy.
3. **Risk-stratified diagnostic approach.** First ask whether the patient is **haemodynamically unstable**. If **stable**, apply a validated pre-test probability score (**Wells or revised Geneva**) and, if low/intermediate, measure **D-dimer** — a negative result excludes PE. **D-dimer specificity falls with age, so use the age-adjusted cut-off (age × 10 µg/L in patients over 50)**, which substantially reduces unnecessary imaging in the elderly. If D-dimer is raised or probability is high, perform **CT pulmonary angiography**. Use a **V/Q or V/Q-SPECT scan** when there is renal impairment or contrast allergy. If **unstable**, perform **bedside echocardiography** for right ventricular dilatation and strain and treat immediately.
4. **Supporting investigations. ECG** — sinus tachycardia is commonest; **S1 Q3 T3** is classic but uncommon; also right axis deviation, RBBB and **anterior T-wave inversion (V1–V4)**. **Chest radiograph** usually normal or shows **oligaemia (Westermark), a wedge-shaped peripheral opacity (Hampton hump), raised hemidiaphragm or a small effusion**. **ABG** — hypoxaemia with hypocapnia and a widened A–a gradient. **Troponin and BNP** for right ventricular injury and prognosis. **Compression ultrasound of the legs** supports the diagnosis when imaging is not possible.
5. **Severity stratification. High-risk (massive)** — **persistent hypotension or shock**; mortality > 15%. **Intermediate-risk (submassive)** — normotensive but with **right ventricular dysfunction on imaging and/or raised troponin**; subdivided into intermediate-high (both positive) and intermediate-low. **Low-risk** — **sPESI = 0** (the simplified PESI counts age > 80, cancer, chronic cardiopulmonary disease, heart rate ≥ 110, systolic BP < 100, SpO_2 < 90%), permitting **early discharge and outpatient treatment**.

6. **Treatment.** Start **therapeutic anticoagulation immediately** once PE is suspected with high probability, before confirmation, unless bleeding risk is prohibitive. **DOACs are first-line — apixaban 10 mg twice daily for 7 days then 5 mg twice daily**, or **rivaroxaban 15 mg twice daily for 21 days then 20 mg daily**; dabigatran and edoxaban need **5 days of LMWH lead-in**. Use **LMWH** in severe renal impairment and pregnancy and **warfarin** for antiphospholipid syndrome. For **high-risk PE give systemic thrombolysis (alteplase 100 mg over 2 hours)**; if thrombolysis is contraindicated or fails, use **catheter-directed therapy or surgical embolectomy**. **Routine thrombolysis is not given in intermediate-risk PE** (PEITHO showed reduced decompensation but excess major and intracranial bleeding, especially over 75). **Duration:** provoked by a transient factor **3 months**; unprovoked or persistent risk factor **extended/indefinite**, with reduced-dose apixaban 2.5 mg twice daily or rivaroxaban 10 mg daily thereafter. Reserve an **IVC filter** for absolute contraindication to anticoagulation.

Latest Update – 1 Point (2023–Present)

7. **Catheter-based reperfusion is now supported by randomised evidence.** The **PEERLESS trial (Circulation 2025)** randomised 550 patients with intermediate-risk PE to **large-bore mechanical thrombectomy versus catheter-directed thrombolysis** and found **a significantly better composite outcome with thrombectomy (win ratio 5.01), driven by less clinical deterioration or need for bailout therapy and less post-procedural intensive care use**, with shorter hospital stay and fewer 30-day readmissions. **STORM-PE (2025)** then showed mechanical thrombectomy improved right-ventricular recovery compared with anticoagulation alone. These approaches are attractive in older patients because they **avoid systemic thrombolysis and its intracranial bleeding risk**, but the decision must still be made by a **Pulmonary Embolism Response Team (PERT)**.

Question 49. Chronic pulmonary thromboembolism (CTEPD / CTEPH)

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition. Chronic thromboembolic pulmonary disease (CTEPD)** is the persistence of **organised, fibrotic thromboembolic material obstructing the pulmonary arteries with mismatched perfusion defects, persisting after at least 3 months of therapeutic anticoagulation**. When this is accompanied by pulmonary hypertension — **mean pulmonary artery pressure > 20 mmHg with pulmonary vascular resistance > 2 Wood units and a pulmonary artery wedge pressure ≤ 15 mmHg (2022 ESC/ERS haemodynamic definition)** — it is termed **CTEPH**, which is **Group 4 pulmonary hypertension**. CTEPD without PH is now a recognised entity in its own right.
2. **Epidemiology and pathogenesis.** CTEPH develops in about **2–4% of survivors of acute PE**, typically within two years, and **up to 25% have no documented previous PE**. Pathogenesis is **failure of thrombus resolution** with organisation into fibrous webs, bands and stenoses, compounded by a **secondary small-vessel microvasculopathy** in non-obstructed territories that resembles pulmonary arterial hypertension and explains why haemodynamics may not improve after surgery. Risk factors: **large or recurrent PE, unprovoked PE, splenectomy, ventriculo-atrial shunts, infected pacemaker leads, inflammatory bowel disease, chronic osteomyelitis, malignancy, thyroid replacement therapy, non-O blood group and antiphospholipid syndrome**.
3. **Clinical features. Progressive exertional breathlessness and reduced exercise tolerance**, developing after an apparent "honeymoon period" following the acute PE. Later come **fatigue, exertional chest pain, presyncope or syncope and haemoptysis**. Signs of pulmonary hypertension and right heart failure: **loud pulmonary component of the second heart sound, right ventricular heave, raised JVP with prominent v waves, tricuspid regurgitation murmur, hepatomegaly, ascites and peripheral oedema**. A **pulmonary flow murmur over the lung fields is relatively specific**. **In older adults the breathlessness is commonly misattributed to COPD, heart failure, obesity or deconditioning, and diagnosis is typically delayed by more than a year.**
4. **Diagnosis — the single most examinable point.** Screen any patient with **persistent breathlessness ≥ 3 months after PE**. Start with **echocardiography** (raised tricuspid regurgitant velocity, right ventricular dilatation and dysfunction, flattened septum). **The ventilation–perfusion (V/Q) scan is the screening investigation of CHOICE — a normal V/Q scan effectively excludes CTEPH, and CTPA may miss chronic organised disease.** Confirmatory imaging is by **CT pulmonary angiography (webs, bands, eccentric wall-adherent thrombus, abrupt vessel cut-off, calcified thrombus, mosaic perfusion, bronchial collaterals) and digital subtraction pulmonary angiography**. **Right heart catheterisation is mandatory** to confirm haemodynamics and operability. Add **lung function tests, ABG, six-minute walk test, NT-proBNP and a thrombophilia/antiphospholipid screen**.

5. **Management — pulmonary endarterectomy is the treatment of choice.** Every patient must be **referred to an expert CTEPH centre** for multidisciplinary assessment of operability. **Pulmonary endarterectomy (PEA)** under deep hypothermic circulatory arrest is **potentially curative** for proximal, surgically accessible disease and is the first-line treatment; in experienced centres mortality is under 5%, and **age alone is not a contraindication** though frailty and comorbidity raise operative risk. All patients need **lifelong therapeutic anticoagulation** — **vitamin K antagonists remain preferred, and DOACs are used with caution and are contraindicated in antiphospholipid syndrome**.
6. **Inoperable and residual disease.** For patients who are **technically inoperable (distal disease), unfit for surgery, or who have persistent/recurrent pulmonary hypertension after PEA** — a group heavily weighted towards older patients — the options are: **balloon pulmonary angioplasty (BPA)**, now an established treatment that improves haemodynamics, right ventricular function, exercise capacity and quality of life; and **medical therapy with riociguat**, a **soluble guanylate cyclase stimulator** and the **only licensed drug for CTEPH** (CHEST-1), with **subcutaneous treprostinil** for severe disease. Add **diuretics for right heart failure, supplemental oxygen, supervised rehabilitation, vaccination and pregnancy avoidance**; consider **lung transplantation** in the young with refractory disease. **Calcium channel blockers and vasodilator testing have no role in CTEPH.**

Latest Update – 1 Point (2023–Present)

7. **A multimodal, sequenced strategy is now the standard of care.** The **2023 ESC Working Group clinical consensus statement on balloon pulmonary angioplasty** establishes BPA as a **complementary — not competing — treatment alongside PEA and riociguat**, recommends **medical pre-treatment with riociguat before BPA** (the **RACE** trial showed fewer procedure-related complications with riociguat pre-treatment), and endorses BPA in **CTEPD both with and without pulmonary hypertension**. Importantly, the phase III **MACiTEPH trial (2025) of macitentan was stopped for futility** with no improvement in six-minute walk distance, so **riociguat remains the only drug with proven benefit** — a useful negative result to quote.

M. Thoracic Oncology

Question 50. Bronchogenic carcinoma — types and management

7-Mark Answer | 6 textbook points + 1 latest update

Source note: Bronchogenic carcinoma is **not covered adequately as a standalone topic in the uploaded textbook** — Pathy's refers to lung cancer chiefly in the context of paraneoplastic syndromes, therapy-related myelodysplasia and geriatric oncology principles. The answer below is built on current standard oncology guidance and is labelled accordingly.

Textbook Core – 6 Points

1. **Definition and epidemiology.** Primary malignancy arising from the **bronchial epithelium**; the **commonest cause of cancer death worldwide**. The **median age at diagnosis is about 70**, making it essentially a disease of older adults. **Tobacco smoking** is the dominant risk factor; in India also important are **biomass fuel smoke and indoor air pollution** (notably in women who have never smoked), **asbestos, radon, arsenic, chromium** and **scarring from prior pulmonary tuberculosis**.
2. **Classification.**

Type	Share	Key features
Adenocarcinoma	~40%	**Commonest overall and in never-smokers and women**; **peripheral**; carries the actionable driver mutations; hypertrophic pulmonary osteoarthropathy
Squamous cell	~25–30%	**Central**, **cavitation**, **hypercalcaemia via PTHrP**, strongly smoking-related
Large cell	~10%	Undifferentiated, poor prognosis
Small cell (SCLC)	~15%	**Central**, rapidly growing, **early widespread metastasis**, almost always smokers; **SIADH**, **ectopic ACTH/Cushing**, **Lambert–Eaton myasthenic syndrome**

   The first three are grouped as **non-small cell lung cancer (NSCLC), about 85%**.
3. **Clinical features. Cough, haemoptysis, breathlessness, chest pain, weight loss** and recurrent or non-resolving pneumonia. **Older adults present late and atypically** — with fatigue, anorexia, delirium, falls or functional decline rather than respiratory symptoms, and smoker's cough is often dismissed. **Local invasion:** hoarseness (recurrent laryngeal nerve), **superior vena cava obstruction**, **Pancoast tumour with Horner's syndrome** and T1 root pain, phrenic nerve palsy, dysphagia, pericardial effusion.

4. **Diagnosis and staging. Chest radiograph → contrast CT chest and upper abdomen → tissue diagnosis**. Central lesions: **bronchoscopy with EBUS-guided transbronchial needle aspiration**; peripheral lesions: **CT-guided percutaneous biopsy**. Stage with **PET-CT** and **MRI brain**, using the **TNM 9th edition (2024)**. In NSCLC always test for **EGFR, ALK, ROS1, BRAF, KRAS G12C, RET, MET** alterations and **PD-L1 expression**, since these determine treatment. Assess **lung function and performance status** before any radical treatment.
5. **Management of NSCLC. Stage I–II: surgical resection (lobectomy with lymph node dissection)**; **sublobar resection or stereotactic body radiotherapy (SBRT)** for the frail or those with poor lung function — SBRT is a major advance for older patients. Adjuvant chemotherapy for stage II–III; adjuvant osimertinib for resected EGFR-mutant disease. **Stage III (unresectable): concurrent chemoradiotherapy followed by consolidation durvalumab**. **Stage IV: targeted therapy if a driver mutation is present** (osimertinib for EGFR, alectinib for ALK), otherwise **immunotherapy (pembrolizumab) alone if PD-L1 ≥ 50%, or combined with a platinum doublet**.
6. **Management of SCLC and geriatric principles. Limited stage:** platinum plus etoposide with **concurrent thoracic radiotherapy**, and **prophylactic cranial irradiation** in responders. **Extensive stage:** platinum–etoposide plus **atezolizumab or durvalumab**. **Treatment decisions must be based on comprehensive geriatric assessment and performance status, not chronological age** — but frailty, renal function, hearing (cisplatin ototoxicity), neuropathy and social support guide dose reduction, use of **carboplatin instead of cisplatin**, or single-agent therapy. **Early integrated palliative care improves quality of life and survival.** Symptom control: **SVC stenting**, palliative radiotherapy for haemoptysis and bone pain, opioids for breathlessness, and **smoking cessation at any age**.

Latest Update – 1 Point (2023–Present)

7. Two 2024 practice-changing trials: **ADRIATIC (NEJM 2024) — consolidation durvalumab after concurrent chemoradiotherapy significantly improved overall survival in limited-stage small cell lung cancer**, the first major advance in this setting for decades; and **LAURA (NEJM 2024) — osimertinib after chemoradiotherapy markedly prolonged progression-free survival in unresectable stage III EGFR-mutant NSCLC**. In relapsed SCLC, **tarlatamab**, a DLL3-targeted bispecific T-cell engager (DeLLphi-301/304), has been approved and improved survival over chemotherapy in the second line.

Question 51. Case — solitary pulmonary nodule on chest X-ray in a 30 pack-year smoker with cough

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and first principle.** A solitary pulmonary nodule (SPN) is a **single, rounded opacity up to 3 cm in diameter, completely surrounded by aerated lung, with no associated atelectasis, hilar enlargement or pleural effusion**. **A lesion larger than 3 cm is a mass and should be regarded as malignant until proved otherwise.** In a 67-year-old-type patient with a **30 pack-year smoking history**, the pre-test probability of malignancy is high — **this nodule must be actively worked up, not simply observed**.
2. **The immediate next steps.** (i) **Obtain and compare all previous chest radiographs or CT scans — documented stability of a solid nodule for 2 years or more effectively excludes malignancy**, and this simple step can end the investigation. (ii) The **next investigative procedure of choice is a contrast-enhanced thin-section (1 mm) CT of the chest and upper abdomen**, which characterises the nodule, detects additional nodules, and stages the mediastinum, adrenals and liver. (iii) Take a full history for **weight loss, haemoptysis, prior malignancy, tuberculosis, occupational asbestos and biomass exposure, and immune status**, and examine for clubbing, lymphadenopathy and extrathoracic disease.

3. **Reading the CT — features favouring benign versus malignant.**

Feature	Benign	Malignant
Size	< 8 mm	**> 8 mm, and risk rises steeply above 20 mm**
Margin	Smooth, well defined	**Spiculated, lobulated, "corona radiata"**
Calcification	**Central, diffuse, laminated or "popcorn" (hamartoma)**	Eccentric or stippled
Fat within the lesion	**Diagnostic of hamartoma**	Absent
Growth	**Stable ≥ 2 years (solid nodules)**	Volume doubling time 20–400 days
Site and type	Lower zone, solid	**Upper lobe; part-solid nodules carry the highest malignant risk**

Formal risk can be estimated with the **Brock (PanCan) or Mayo Clinic model**, which combine **age, smoking, prior cancer, nodule size, upper-lobe location, spiculation and nodule count**. Common benign causes: **tuberculoma and other granulomas (very common in India), hamartoma, resolving pneumonia, round atelectasis, arteriovenous malformation, rheumatoid nodule, hydatid cyst.**

4. **Stratified management by size and risk (Fleischner-type approach).**

Solid nodule < 6 mm, low risk → no routine follow-up
Solid nodule < 6 mm, high risk (smoker) → optional CT at 12 months
Solid nodule 6–8 mm → CT at 6–12 months, then 18–24 months
Solid nodule > 8 mm → **PET-CT and/or tissue diagnosis**
Part-solid nodule with solid component ≥ 6 mm → **treat as likely malignant → PET-CT / biopsy**
Pure ground-glass nodule → longer-interval surveillance (indolent adenocarcinoma spectrum)

PET-CT is most useful for solid nodules above 8–10 mm; note **false positives in tuberculosis, sarcoidosis and other granulomatous infection — a major limitation in India — and false negatives in lesions under 8 mm, carcinoid and ground-glass adenocarcinoma**.

5. **Obtaining tissue.** Choose the route by nodule location: **CT-guided percutaneous transthoracic needle biopsy** for peripheral nodules (high yield; risk of pneumothorax around 20–25%, higher with emphysema); **bronchoscopy with EBUS-guided or radial-probe/navigational sampling** for central or bronchus-sign-positive lesions, which also allows **EBUS-TBNA mediastinal staging**; and **VATS wedge excision**, which is both diagnostic and therapeutic when the probability of malignancy is high. **In a high-risk nodule, a negative needle biopsy does not exclude cancer — proceed to surgical excision or close surveillance.** Send tissue for **histology, AFB smear/culture and CBNAAT** in the Indian setting.

6. **Definitive management and follow-up.** If **benign** (fat or benign calcification, or 2-year stability) — reassure, treat any infective cause, and continue smoking cessation. If **malignant or highly suspicious** — complete **staging with PET-CT and MRI brain**, assess **fitness with pulmonary function tests, performance status and comprehensive geriatric assessment**, and discuss at a **multidisciplinary tumour board**. **Lobectomy with lymph node dissection** is standard for a fit patient with early-stage disease; **sublobar resection or stereotactic body radiotherapy (SBRT)** is used for those with poor lung function or frailty, and gives excellent local control with low morbidity in older adults. Test for **EGFR, ALK, ROS1 and PD-L1** if advanced. In all cases: **smoking cessation at any age, vaccination, and enrolment in a lung cancer screening programme if eligible**.

Latest Update – 1 Point (2023–Present)

7. **Lung cancer screening eligibility has widened and nodule management has been standardised.** The **2023 American Cancer Society guideline** recommends **annual low-dose CT for adults aged 50–80 with a ≥ 20 pack-year smoking history, and — importantly — has removed the "years since quitting" restriction**, so former smokers remain eligible indefinitely; this patient's 30 pack-year history makes him screening-eligible. Nodules detected in a screening programme are now categorised by **Lung-RADS version 2022**, which standardises follow-up intervals and formally incorporates **atypical pulmonary cysts and juxtapleural nodules**. **Semi-automated volumetry with volume-doubling time, increasingly AI-assisted**, is replacing two-dimensional diameter measurement for detecting growth.

N. Sleep Medicine

Question 52. Obstructive sleep apnoea — features, comorbidities, tests, management and prognosis

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition and epidemiology.** Obstructive sleep apnoea (OSA) is the **most frequent respiratory sleep disorder** and involves **repeated episodes of complete (apnoea) or partial (hypopnoea) upper airway obstruction during sleep**. It is defined by an **apnoea–hypopnoea index (AHI) > 5 per hour of sleep together with excessive daytime sleepiness or neurocognitive/behavioural disturbance not attributable to another cause**. Prevalence is **1–4% of general adults but far higher in the elderly — about 50% of older people have an AHI > 5 and 20% have an AHI > 15**, compared with 10% of younger people.
2. **Pathogenesis in the older patient.** The dominant mechanism is **increased upper airway collapsibility with age**, due to **hormonal change (after the menopause the prevalence in women equalises with men)**, **reduced pharyngeal dilator muscle tone and altered pharyngeal reflexes with increased airway resistance during sleep**, and anatomical factors including **edentulism and increased fat deposition in the pharyngeal wall**. Comorbidities that accumulate with age — **stroke, heart failure, hypothyroidism, obesity** — further promote sleep-disordered breathing.
3. **Clinical features and the age-related shift.** The classical triad is **snoring, witnessed apnoeas and excessive daytime sleepiness**. **However, the proportion of OSA patients who do NOT snore increases after the age of 50**, so the classical triad is unreliable in the old. Instead suspect OSA from **unrefreshing sleep, nocturia, morning headache, fatigue rather than frank sleepiness, poor concentration, memory impairment, irritability or depression, falls and road traffic accidents**. Examination: **obesity and increased neck circumference, crowded oropharynx (high Mallampati), retrognathia, nasal obstruction, hypertension**.
4. **Associated comorbidities. Cardiovascular — resistant hypertension (especially non-dipping and nocturnal), atrial fibrillation and other arrhythmias, ischaemic heart disease, heart failure, pulmonary hypertension** and **stroke**. **Metabolic** — obesity, insulin resistance and type 2 diabetes, metabolic syndrome. **Neurocognitive — cognitive impairment and dementia, depression, delirium**; nocturnal hypoxia carries risks of arrhythmia and of myocardial and cerebral infarction. **Other** — nocturia, glaucoma, reduced quality of life, and increased perioperative and sedative-related risk.
5. **Investigations.** Begin with **history from the patient and the bed partner**, the **Epworth Sleepiness Scale** and a screening tool such as **STOP-BANG**. Confirm with **polysomnography**, which remains the gold standard; a **home sleep apnoea test** is acceptable in high-probability uncomplicated patients. Severity by AHI: **mild 5–15, moderate 15–30, severe > 30**. AASM scoring should **include arousal-based scoring of hypopnoeas**. Add **overnight oximetry, thyroid function, ECG, echocardiography and ABG** where obesity hypoventilation or cor pulmonale is suspected.
6. **Management and prognosis. Diet and sleep-hygiene measures**, **weight reduction**, avoidance of **alcohol, sedatives and opioids**, **positional therapy**, treatment of nasal obstruction, and **optimisation of dentition**. **CPAP is the treatment of choice** and improves sleepiness, quality of life, blood pressure and cognition; adherence in older adults is comparable to younger patients when support is given. Alternatives: **mandibular advancement devices** for mild–moderate disease or CPAP intolerance, and **surgery (uvulopalatopharyngoplasty, hypoglossal nerve stimulation)** in selected cases. Prognosis: untreated moderate-to-severe OSA increases **cardiovascular events, stroke, cognitive decline, accidents and mortality**; treatment reliably improves symptoms, though large trials (SAVE) did not show a reduction in cardiovascular events, largely because of poor CPAP adherence.

Latest Update – 1 Point (2023–Present)

7. **SURMOUNT-OSA (NEJM 2024)** — in adults with **obesity and moderate-to-severe OSA**, **tirzepatide** (a dual GIP/GLP-1 receptor agonist) produced a **large reduction in the apnoea–hypopnoea index (roughly 25–29 fewer events per hour versus placebo) with improvements in oxygen saturation, blood pressure and sleep-related quality of life**, both with and without background CPAP. This led to the **first regulatory approval of a drug for obstructive sleep apnoea (December 2024)** and establishes **pharmacological weight loss as a disease-modifying treatment for OSA** rather than merely an adjunct — though in older adults the risks of **sarcopenia, weight loss and gastrointestinal effects** require careful weighing.

Question 53. Sleep problems in the elderly, and the approach to insomnia in a 65-year-old recently retired professional

7-Mark Answer | 6 textbook points + 1 latest update | ***Asked ×2***

Textbook Core – 6 Points

1. **Burden and normal ageing changes. More than half of people over 65 report a sleep-related problem.** Normal ageing produces a **shorter, more superficial and more fragmented total sleep time**, with **increased sleep latency, reduced slow-wave (N3) and REM sleep, and more awakenings**; **50–80% of older adults nap in the daytime**, which itself indicates that night sleep is unrefreshing. **Insomnia is the commonest sleep disorder in older people, with a prevalence of 40–50% over the age of 65.**
2. **The spectrum of sleep disorders in old age.**

Disorder	Key feature and treatment
Insomnia	Difficulty initiating or maintaining sleep — **CBT-I first; medication only for acute insomnia**
Obstructive sleep apnoea	Snoring, witnessed apnoeas, daytime sleepiness — **polysomnography, CPAP**; affects ~20% of older adults
Restless legs syndrome	Motor restlessness, night-time pacing; **commoner with iron deficiency and CKD** — check ferritin
Periodic limb movement disorder	Leg kicking with arousals — diagnosed on polysomnography
REM sleep behaviour disorder	Dream enactment; associated with **Parkinson's disease and dementia**
Advanced sleep phase	Falling asleep and waking too early — **common in institutionalised elderly**; bright light therapy

3. **Secondary causes — always look for these first. Medical** — pain from arthritis, **orthopnoea and paroxysmal nocturnal dyspnoea**, cough, **nocturia and prostatism**, **gastro-oesophageal reflux** (worsened by recumbency), heart failure, COPD, Parkinson's disease, dementia. **Psychiatric — depression (insomnia is a cardinal symptom), anxiety, bereavement**. **Drugs** — diuretics, corticosteroids, certain antidepressants, theophylline, beta-blockers, **caffeine and late alcohol (which fragments sleep)**, and **hypnotic withdrawal**. **Behavioural — daytime naps over 30 minutes, an earlier bedtime, and increased time in bed not sleeping**.
4. **Assessment. For most of these disorders a detailed history is sufficient.** Characterise the complaint precisely — **delayed sleep onset, frequent awakenings or early-morning waking** — and take a **collateral history from the bed partner** (snoring, apnoeas, kicking, dream enactment). Use a **2-week sleep diary, with actigraphy where available**. Screen for **depression, cognition, alcohol and the full drug chart**, and examine for causes. Reserve **polysomnography** for suspected OSA, periodic limb movement disorder or REM sleep behaviour disorder — it is not needed for uncomplicated insomnia. Address **unrealistic sleep expectations** (such as the belief that 8 unbroken hours are essential).
5. **The retired 65-year-old — the specific approach.** Retirement from a busy professional career removes the **external time cues (zeitgebers) that anchored the circadian rhythm** — fixed waking time, morning light exposure, daytime activity and social contact. The typical sequence is **later and irregular rising, long daytime naps, reduced physical activity and light exposure, an earlier bedtime, excessive time in bed, loss of role and purpose with low mood, and increased evening alcohol**. Management is therefore **behavioural, not pharmacological**: (i) **fixed wake-up time seven days a week**; (ii) **bright morning light exposure and outdoor activity**; (iii) **regular daytime exercise, avoided within 3 hours of bedtime**; (iv) **abolish or limit naps to under 30 minutes before 3 pm**; (v) **restrict time in bed to actual sleep time (sleep restriction) and use the bed only for sleep and sex (stimulus control)**; (vi) **build a new structure of daily purpose and social engagement**; (vii) **limit caffeine after midday and evening alcohol and fluids**; (viii) **screen for and treat depression**.
6. **Treatment principles and drug safety. Sleep hygiene measures and cognitive behavioural therapy for insomnia (CBT-I) are first-line and should be tried BEFORE any pharmacological treatment**; brief cognitive therapy is effective and avoids the long-term side effects of drugs. If a drug is unavoidable, use it for **acute insomnia only, at the lowest dose and for the shortest time, with a planned stop date**. **Benzodiazepines and Z-drugs (zolpidem, zopiclone) should be avoided in older adults** — they are on the **AGS Beers list** and cause **falls, hip fracture, cognitive impairment, delirium, daytime sedation, road accidents, tolerance and dependence**. Also **avoid sedating antihistamines and tricyclics because of anticholinergic burden**. Safer options where indicated: **low-dose melatonin or prolonged-release melatonin**, **very low-dose doxepin**, and treatment of the underlying cause. Always **deprescribe long-term hypnotics gradually with behavioural support**.

Latest Update – 1 Point (2023–Present)

7. **Dual orexin receptor antagonists (DORAs) have changed the pharmacological hierarchy. Lemborexant, daridorexant and suvorexant** promote sleep by **blocking wake-promoting orexin signalling rather than by non-selective GABA-A sedation**, and randomised data in adults aged 65 and over show **improved sleep onset and maintenance with improved daytime functioning and, importantly, no worsening of postural stability or next-morning falls risk compared with Z-drugs**. Current guidance (AASM and the **AGS Beers Criteria 2023**, which continue to advise against benzodiazepines and Z-drugs in older adults) positions DORAs as the **preferred pharmacological option when CBT-I has failed** — although CBT-I remains first-line and drug treatment should still be short-term.

Current Practice Update

Textbook	Sleep hygiene and CBT first; medication for acute insomnia only, with hypnotics implied as the drug class.
Current recommendation	Benzodiazepines and Z-drugs are explicitly avoided (Beers 2023); dual orexin receptor antagonists or low-dose melatonin/doxepin are preferred when a drug is needed.
Exam approach	Write "CBT-I is first-line; if a drug is required, avoid benzodiazepines and Z-drugs (Beers 2023) and prefer a DORA or low-dose melatonin."

Question 54. REM sleep behaviour disorder

7-Mark Answer | 6 textbook points + 1 latest update

Textbook Core – 6 Points

1. **Definition.** REM sleep behaviour disorder (RBD) is a **parasomnia characterised by the apparent acting out of dreams**, caused by **loss of the normal muscle atonia of REM sleep**. Normal REM sleep has both **tonic phenomena (muscle atonia) and phasic phenomena (brief muscle twitches)**; in RBD the brainstem circuits that generate atonia (the sublaterodorsal nucleus and its projections to the ventral medulla) fail, so **dream content is enacted**.
2. **Clinical features.** Vivid, often **frightening or violent dreams** of being attacked or chased, enacted as **shouting, swearing, punching, kicking, leaping from bed**. Episodes occur in the **second half of the night when REM is most abundant**. The patient **wakes rapidly, is fully oriented and can recall the dream** — which distinguishes RBD from confusional arousals and night terrors. There is a **male predominance and a typical onset after 50**. **Injury to the patient or to the bed partner is common** and is often the reason for presentation; the collateral history from the bed partner is essential.
3. **Causes and associations. RBD is mostly idiopathic, but has a strong association with Parkinson's disease and dementia** — it is now regarded as a **prodromal α-synucleinopathy**. It is seen in **Parkinson's disease, dementia with Lewy bodies (where it is a core clinical feature) and multiple system atrophy**. Secondary causes: **antidepressants — SSRIs, SNRIs, tricyclics and mirtazapine (a very common and reversible cause)**, beta-blockers, alcohol withdrawal, **narcolepsy**, and brainstem lesions from stroke, tumour or demyelination.
4. **Prognostic significance (the most examinable point).** Prospective cohorts show that **idiopathic RBD converts to an overt neurodegenerative synucleinopathy at a rate of roughly 6% per year**, so that **more than 70–80% phenoconvert to Parkinson's disease, dementia with Lewy bodies or multiple system atrophy within 12–15 years**. Post-mortem studies of idiopathic RBD confirm underlying synuclein pathology. Markers of earlier conversion include **abnormal olfaction, colour vision impairment, subtle motor signs, mild cognitive impairment, constipation, orthostatic hypotension and abnormal dopamine transporter imaging**. **These patients should therefore be followed longitudinally with counselling appropriate to their wishes.**
5. **Diagnosis.** Requires **history plus polysomnography**. Video-polysomnography demonstrates **REM sleep without atonia (RSWA) — excessive tonic or phasic chin/limb EMG activity during REM** — with recorded dream-enacting behaviour, and is the diagnostic gold standard; screening questionnaires (RBD-SQ, RBD1Q) support but do not replace it. Polysomnography also **excludes the important mimics**: **obstructive sleep apnoea with pseudo-RBD, nocturnal frontal lobe epilepsy, periodic limb movement disorder, non-REM parasomnias (sleepwalking, night terrors), nocturnal delirium and severe restless legs**. Review the drug chart for antidepressants, and image the brainstem if there are focal neurological signs.
6. **Management. Environmental safety comes FIRST and is the single most important intervention — remove sharp objects, firearms and bedside furniture, pad or lower the bed or place the mattress on the floor, cushion the floor, use bed rails cautiously, place a barrier or move the bed partner to a separate room**. Then **withdraw or substitute the culprit antidepressant** where possible, and treat coexisting OSA. Pharmacologically, the textbook agent is **clonazepam 0.25–1 mg at night**, which is highly effective, but in older people it causes **sedation, falls, cognitive impairment and worsening of sleep apnoea**; **melatonin 3–12 mg at night is therefore preferred first-line in the elderly**, being safer and comparably effective. **Rivastigmine** may help when RBD occurs with dementia with Lewy bodies. Counsel and support the **bed partner**, and explain the neurodegenerative association sensitively and only as much as the patient wishes to know.

Latest Update – 1 Point (2023–Present)

7. **RBD is now formally embedded in the biological staging of Parkinson's disease.** The **2024 Neuronal Synuclein Disease Integrated Staging System (NSD-ISS)** and the parallel **SynNeurGe** framework redefine synucleinopathy biologically rather than clinically, using **seed amplification assays (α-synuclein SAA) on CSF or skin, which are positive in over 90% of patients with isolated RBD**. Isolated RBD with a positive assay is classified as **prodromal neuronal synuclein disease (Stage 2)** — i.e. **biologically established Parkinson's/Lewy body disease before motor or cognitive signs appear**. Consequently, **isolated RBD cohorts are now the principal recruitment population for disease-modifying neuroprotection trials**, which makes accurate diagnosis and referral of these patients increasingly important.

Appendix — Rapid Revision Grid

Consolidated examinable numbers, named trials and Indian context lines from all 54 questions

A. Numbers worth memorising

Topic	Number
Heart failure	HFrEF **≤ 40%**, HFmrEF **41–49%**, HFpEF **≥ 50%**; **> 75%** of overt HF in the old is due to hypertension or coronary disease; spironolactone **12.5–50 mg** reduced mortality by **30%** in NYHA III–IV; digoxin over 70 — **0.125 mg/day**, level **0.5–0.9 ng/mL**
Refractory heart failure	Stage D one-year mortality approaches **50%**; acceptable creatinine rise during decongestion **up to 30%**
Beta blockers	Only **4** agents proven: **bisoprolol, carvedilol, metoprolol succinate, nebivolol**; double dose no sooner than every **2 weeks**; SENIORS studied age **≥ 70**
Cardiogenic shock	Systolic BP **< 90 mmHg for > 30 min** with hypoperfusion; MAP target **≥ 65 mmHg**; fluid in **250 mL** aliquots
ACS / unstable angina	ECG within **10 min**; troponin at **0 and 1–3 h**; immediate invasive **< 2 h**, high risk **< 24 h**, GRACE **> 140**; prasugrel contraindicated **> 75 y, < 60 kg**; DAPT **12 months** (1–3 if HBR)
STEMI ECG criteria	**≥ 1 mm** in 2 contiguous leads; **≥ 2 mm** in V2–V3 men ≥ 40, **≥ 2.5 mm** men < 40, **≥ 1.5 mm** women; PCI within **120 min** of diagnosis
Secondary prevention targets	LDL **< 55 mg/dL** with **≥ 50%** reduction; BP **< 130/80**; HbA1c **~7%**; weight loss **5–10%**; exercise **150 min/week**
JNC 8	Age **≥ 60** — treat at **≥ 150/90**, goal **< 150/90**; < 60, diabetes and CKD — **< 140/90**; beta-blockers **not** first-line
Hypertension classification	Stage 1 **140–159/90–99**; Stage 2 **≥ 160/100**; ISH **≥ 140 systolic with < 90 diastolic**; 2025 AHA/ACC target **< 130/80**
Accelerated hypertension	Usually diastolic **> 120–130**; grade **III** retinopathy (accelerated) vs grade **IV** papilloedema (malignant); reduce MAP by **≤ 20–25%** in the first hour; dissection — systolic **< 120** and HR **< 60** within 20 min
Postural hypotension	Fall of **≥ 20 mmHg systolic or ≥ 10 mmHg diastolic within 3 min**; present in **~30%** of elderly (> 40 mmHg in **10%**); fludrocortisone **100–200 µg**; ephedrine **15–30 mg tds**; head-up tilt of bed **~10°**
Aortic stenosis	Prevalence **2.8%** at ≥ 75; sclerosis in **26–29%** over 65; symptomatic AS untreated — **20% three-year survival**; severe = area **< 1.0 cm²**, velocity **≥ 4 m/s**, mean gradient **≥ 40 mmHg**; octogenarian SAVR five-year survival **~65%**; valvuloplasty — mortality **3–10%**, stroke **10–25%**, restenosis **66%** at 6 months
Mitral disease	Mucoid degeneration in **~1%** of autopsies > 65; mitral annular calcification in **9%** of autopsies > 50, and **44%** of women > 90; **two-thirds** of MAC present with an apical systolic murmur; surgery when EF **≤ 60%** or ESD **≥ 40 mm**
ABI and toe pressures	ABI **≤ 0.90** = PAD; **< 0.40** = severe; **> 1.40** = non-compressible; exercise fall **> 20%**; **TBI < 0.70** = PAD; toe pressure **> 55** heals, **< 30 mmHg** = CLTI
Atrial fibrillation	**43 million** worldwide; lifetime risk at 55 **~35%**; **1.5×** commoner in men; **up to 30%** of ischaemic strokes; **20–30%** develop heart failure; **up to 60%** relative increase in cognitive decline; **3.5-fold** increase in mortality; each **10 mmHg** systolic rise increases AF risk **11–16%**; rate target **< 110** lenient
Tachyarrhythmias	Rate **> 100**/min; QRS **≥ 120 ms** = broad; ectopy in **up to 100%** of older people; ventricular arrhythmia in **70–80%** over 60; adenosine **6 then 12 mg**; amiodarone **300 mg** then **900 mg/24 h**; magnesium **2 g**; post-MI ectopy **> 10/hour** is adverse
Tilt test	Tilt to **60–70°** for **20–45 min**; GTN **400 µg**; cardioinhibitory type 2B = **asystole > 3 s**; sensitivity **~50–70%**, specificity **~80–90%**
Polypill	Wald & Law 2003 — **88%** reduction in IHD, **80%** in stroke (theoretical); aspirin **75–100 mg**
Cardiorenal syndrome	**5 Ronco types**; IV diuretic at **1–2.5×** the home oral dose; creatinine rise **up to 30%** acceptable; acetazolamide **500 mg** IV daily
Infective endocarditis in the elderly	Incidence **4×**, mortality **2×** that of younger patients; antibiotics **4–6 weeks**; **3** sets of blood cultures
Complete heart block	Ventricular escape **30–40 bpm**; PR > 200 ms = first degree; PR > 240 ms + LBBB with lamin A/C = pace
Pacemaker complications	Pneumothorax **1–2%** (subclavian) vs **<0.1%** (cephalic/axillary); tamponade **<0.2%**; infection **<1%**; early complications **~7%** at 2 weeks; CRT/His if EF < 50% and pacing > 40%
CHA_2DS_2-VASc	Max **9**; anticoagulate men ≥ 2, women ≥ 3; **CHA_2DS_2-VA max 7**, threshold ≥ 2 (2024 ESC)
HAS-BLED	Max **9**; **≥ 3 = high risk** (modify, do not withhold); falls — need **~295 falls/year** to outweigh benefit
Apixaban dose reduction	**2 of 3**: age ≥ 80, weight ≤ 60 kg, creatinine ≥ 1.5 mg/dL → 2.5 mg BD
DOAC reversal	Idarucizumab **5 g IV**; 4F-PCC **50 U/kg**; charcoal if < 2–4 h; dabigatran **dialysable**
Stents	BMS restenosis **20–30%**; DES TLR **< 5%**; ISR = **≥ 50%** renarrowing; DAPT **6 months** elective, **12 months** post-ACS,

	1–3 months if HBR
Statins in the old	Time to benefit **~2.5 years**; NLA/AGS 2025 LDL-C **70–189 mg/dL**; prasugrel contraindicated **> 75 y, < 60 kg**
DVT	D-dimer age-adjusted cut-off = **age × 10 µg/L** if > 50; enoxaparin **40 mg OD**; extended prophylaxis **28–35 days** post hip surgery; provoked = **3 months**; PTS up to **40%**
LTOT	**≥ 15 h/day**; PaO_2 **< 7.3 kPa (55 mmHg)**, or **7.3–8.0 kPa** with cor pulmonale/polycythaemia; refer if SpO_2 **< 93%**; target SpO_2 **88–92%**; **~50% survive 3 years**
NIV	Acute NIV if **pH < 7.35**; home NIV if **$PaCO_2$ > 7 kPa** at 2–4 weeks post-exacerbation
Lung cancer	NSCLC **~85%**, SCLC **~15%**; median age at diagnosis **~70**; TNM **9th edition (2024)**
Inhalers	Difficulty in **~20%**; **MMSE < 24** predicts failure; breath-hold **10 s**; inhale over **4–5 s**; wait **30 s** between puffs
Pneumonia in the elderly	**2 of 3** pneumonia admissions are aged > 70; **fever and cough absent in 30–40%**; viruses cause **10–30%** of CAP; RR > **30**/min, HR > **110**/min as severity signs; review at **48 hours**; persistent shadow at **12 weeks** → suspect cancer
CURB-65	Confusion, Urea > 7 mmol/L, RR ≥ 30, BP < 90/60, **age ≥ 65**
HAP	Onset **≥ 48 h** after admission; VAP **> 48 h** after intubation; late-onset from **day 5**; treat **7 days**; head-up **30–45°**
DPLD / IPF	IPF median age **65–70**, median survival **3–5 years**; acute exacerbation mortality **> 50%**; progression = **FVC ↓ ≥ 5%** or **DLCO ↓ ≥ 10%** in 1 year; **GAP index**
Pleural effusion	Normal fluid **10–20 mL**; **250–500 mL** to blunt costophrenic angle; **50 mL** detectable on USG; Light's — protein ratio **> 0.5**, LDH ratio **> 0.6**, LDH **> ⅔ ULN**; albumin gradient **> 1.2 g/dL** = transudate; drain if **pH < 7.20** or **glucose < 60 mg/dL**; **ADA > 40 U/L** = TB; aspirate max **1.5 L** at a sitting
COPD	Exacerbations = **10%** of medical admissions; **⅓ readmitted at 30 days, 15% die at 3 months**; ICS if eosinophils **≥ 300/µL**; steroids **5–7 days**; oxygen target **88–92%**
Senile lung	**RV and FRC ↑, FVC ↓, FEV_1/FVC ↓ ("pseudo-obstructive"), TLC ~unchanged**; use **LLN not 0.70**; PRISm = ratio ≥ 0.70 with FEV_1 < 80%
Respiratory failure	PaO_2 **< 60 mmHg (8 kPa)**; $PaCO_2$ **> 50 mmHg (6.7 kPa)**; NIV if **pH < 7.35**; intubate if **pH < 7.25**; normal A–a gradient ≈ **age/4 + 4**
ARDS	Tidal volume **4–6 mL/kg PBW**, plateau **< 30**, driving pressure **< 15** cmH_2O; prone if P/F **< 150** for **≥ 16 h/day**; Berlin severity **≤ 100 / 100–200 / 200–300**; new global definition **SpO_2/FiO_2 ≤ 315**, HFNO **≥ 30 L/min**
Pulmonary embolism	Age-adjusted D-dimer = **age × 10 µg/L** if > 50; high-risk mortality **> 15%**; alteplase **100 mg over 2 h**; sPESI includes **age > 80**; provoked **3 months**
CTEPH	Occurs in **2–4%** after PE; **up to 25%** have no prior PE; mPAP **> 20 mmHg** with PVR **> 2 WU**; screen after **3 months** anticoagulation; **V/Q scan is the screening test of choice**
OSA	AHI **> 5** + symptoms = OSA; elderly — **50% have AHI > 5, 20% have AHI > 15** (vs 10% young); severity **5–15 / 15–30 / > 30**; non-snorers increase after age **50**
Sleep / insomnia	**> 50%** of over-65s have a sleep problem; insomnia prevalence **40–50%**; **50–80%** nap in the day; RLS in **20%** of over-80s; limit naps to **< 30 min**
RBD	Phenoconversion **~6% per year**; **> 70–80% at 12–15 years**; melatonin **3–12 mg**; clonazepam **0.25–1 mg**; α-synuclein SAA positive in **> 90%** of isolated RBD
Solitary pulmonary nodule	Nodule **≤ 3 cm** (> 3 cm = mass); stability **2 years** excludes malignancy (solid); PET useful **> 8 mm**; pneumothorax after CT biopsy **20–25%**; screening **age 50–80, ≥ 20 pack-years**

B. Trials and guidelines to name

Name	One-line message
RALES / EMPHASIS-HF	Spironolactone reduces mortality 30% in NYHA III–IV; eplerenone benefits mild symptoms — equal benefit at all ages
PARADIGM-HF / DIG / SHIFT	Sacubitril–valsartan beats enalapril; digoxin reduces hospitalisation but not mortality; ivabradine for HR ≥ 70
EMPEROR-Preserved / DELIVER	SGLT2 inhibitors reduce events across the whole ejection fraction spectrum, including HFpEF
FINEARTS-HF (NEJM 2024)	Finerenone reduces worsening HF and CV death in HFmrEF and HFpEF
STEP-HFpEF (NEJM 2023)	Semaglutide improves symptoms and exercise capacity in obesity-related HFpEF
STRONG-HF	Rapid uptitration to full dose within 2 weeks of discharge reduces death and readmission
ADVOR / CLOROTIC	Acetazolamide and thiazide added to loop diuretics improve decongestion
CIBIS-II / MERIT-HF / COPERNICUS / SENIORS	The four evidence-based beta-blockers; SENIORS specifically in age ≥ 70
REDUCE-AMI / ABYSS (2024)	No benefit of long-term beta-blockade after MI with preserved EF — a deprescribing opportunity
DanGer Shock (NEJM 2024)	Microaxial flow pump reduces mortality in STEMI-related cardiogenic shock, at the cost of more

	complications
CULPRIT-SHOCK / IABP-SHOCK II	Culprit-lesion-only PCI is superior in shock; balloon pump is neutral
SENIOR-RITA (NEJM 2024)	Invasive strategy in NSTE-ACS over 75 reduces recurrent MI but not death — individualise by frailty
2023 ESC ACS guideline	No routine $P2Y_{12}$ pre-treatment in NSTE-ACS; 24-h invasive timing downgraded to IIa; abbreviated DAPT if HBR
SELECT (NEJM 2023)	Semaglutide reduces MACE by 20% in obesity with established CVD without diabetes
SPRINT / STEP / ESPRIT / BPROAD / HYVET	Intensive systolic lowering benefits older adults; HYVET showed mortality benefit even over 80
2025 AHA/ACC hypertension guideline	Retires 2017 guideline; universal target < 130/80 with encouragement toward < 120 systolic; PREVENT calculator; single-pill combinations; renal denervation IIb
2024 ESC hypertension guideline	New "Elevated BP" category 120–139/70–89; systolic target 120–129 where tolerated; mandatory orthostatic screening
JNC 8 (JAMA 2014)	Age ≥ 60 — treat at ≥ 150/90 to a goal of < 150/90; now superseded
SHEP / Syst-Eur	Treating isolated systolic hypertension reduces stroke by 36–42%; Syst-Eur also reduced dementia
PATHWAY-2	Spironolactone is the drug of choice for resistant hypertension
EARLY TAVR (NEJM 2024)	Early TAVI beats surveillance in asymptomatic severe aortic stenosis
COAPT / RESHAPE-HF2 / MATTERHORN (2024)	Transcatheter edge-to-edge repair reduces HF hospitalisation in secondary MR; non-inferior to surgery with fewer adverse events
SAFE PACE	Carotid sinus syndrome is a modifiable cause of non-accidental falls; pacing reduces falls
BIOSync CLS	Closed-loop stimulation pacing reduces recurrence in tilt-documented asystolic vasovagal syncope
2024 ESC AF guideline	CHA_2DS_2-VA replaces CHA_2DS_2-VASc; AF-CARE replaces ABC; early rhythm control favoured
EAST-AFNET 4 / CASTLE-AF	Early rhythm control improves outcomes; ablation benefits AF with heart failure
NOAH-AFNET 6 / ARTESiA (NEJM 2023)	Device-detected subclinical AF — anticoagulation gives little net benefit; do not treat it as clinical AF
2024 ACC/AHA PAD guideline	Toe brachial index when ABI > 1.40; WIfI staging; supervised exercise first-line; rivaroxaban 2.5 mg bd plus aspirin
SECURE (NEJM 2022) / TIPS-3 / PolyIran	Polypill improves adherence and reduces events; WHO added it to the Essential Medicines List in 2023
FIDELIO-DKD / FIGARO-DKD	Finerenone protects kidney and heart in CKD with type 2 diabetes, with less hyperkalaemia
2022 World Falls Guidelines	Stratified falls pathway; unexplained falls require cardiovascular assessment for syncope
2023 ESC IE guideline / Duke-ISCVID	Cardiac CT and FDG-PET/CT as major criteria; partial oral therapy accepted
POET	Partial oral antibiotics non-inferior to full IV course in stabilised left-sided endocarditis
2023 ESC Cardiomyopathy guideline	First standalone guideline; phenotype-based approach
ATTR-ACT / ATTRibute-CM / HELIOS-B	Tafamidis, acoramidis, vutrisiran — disease-modifying therapy in ATTR cardiac amyloidosis
EXPLORER-HCM	Mavacamten (cardiac myosin inhibitor) for symptomatic obstructive HCM
2023 HRS/APHRS/LAHRS physiologic pacing	Conduction system pacing (LBBAP) when high ventricular pacing burden expected; minimise RV pacing in sinus node disease
ANNEXA-I (2024)	Andexanet alfa better haemostasis than usual care in Xa-inhibitor ICH, but more thrombotic events
AGENT IDE (2024)	Paclitaxel-coated balloon superior to plain balloon for coronary in-stent restenosis; first US coronary DCB approval
NLA/AGS consensus (JAGS 2025)	Statin reasonable > 75 y for primary prevention if LDL-C 70–189 mg/dL and no life-limiting illness; CAC to refine; deprescribe when life-limited
STAREE	Atorvastatin 40 mg vs placebo, age ≥ 70, disability-free survival — **results awaited**
PROSPER / ALLHAT-LLT	Older evidence: modest or no benefit of statins for primary prevention in the old
API-CAT (NEJM 2025)	Extended apixaban 2.5 mg BD non-inferior to 5 mg BD in cancer-associated VTE with less bleeding
CLOTS-1	Graduated compression stockings of no benefit and harmful after stroke
NOTT / MRC	Established the survival benefit of LTOT ≥ 15 hours per day
LOTT	No benefit of oxygen for moderate resting or exercise-induced desaturation
HOT-HMV	Home NIV plus oxygen prolongs time to readmission or death in persistently hypercapnic COPD
ADRIATIC (2024)	Consolidation durvalumab improves overall survival in limited-stage SCLC

LAURA (2024)	Osimertinib after chemoradiotherapy in unresectable stage III EGFR-mutant NSCLC
DeLLphi-301 / 304	Tarlatamab (DLL3 bispecific) in relapsed small cell lung cancer
GOLD 2025/2026	Check inhaler technique at every visit before escalating; consider low-GWP propellants
CAPE COD (NEJM 2023)	Hydrocortisone reduces 28-day mortality in severe CAP
ACIP 2024 (pneumococcal)	Routine vaccination age lowered to 50; single dose PCV20 or PCV21
ACIP 2024 (RSV)	Single lifetime RSV vaccine dose for all ≥ 75, and 50–74 with risk factors
ATS/IDSA 2019 CAP	β-lactam + macrolide/doxycycline, or respiratory fluoroquinolone alone
IDSA AMR guidance 2023–24	Ceftazidime-avibactam, cefiderocol, sulbactam-durlobactam for resistant HAP/VAP; 7-day courses
2022 ATS/ERS/JRS/ALAT	Defined progressive pulmonary fibrosis (PPF); nintedanib recommended
INBUILD	Nintedanib slows FVC decline in progressive fibrosing ILD of any cause
PANTHER-IPF	Prednisolone + azathioprine + NAC **increases mortality** in IPF — steroids are harmful
FIBRONEER-IPF / -ILD (NEJM 2025)	Nerandomilast (oral PDE4B inhibitor) reduces FVC decline in IPF and PPF, alone or added to antifibrotics
BTS Pleural Disease 2023	Ultrasound for all procedures; thoracoscopy for undiagnosed exudate; IPC or talc equally acceptable; RAPID score
MIST-2	Intrapleural alteplase + DNase improves drainage in pleural infection
AMPLE / IPC-PLUS	Indwelling pleural catheter reduces hospital days; talc via IPC achieves pleurodesis
BOREAS / NOTUS (NEJM 2023, 2024)	Dupilumab reduces exacerbations in eosinophilic COPD on triple therapy
GINA 2024–2025	No SABA-alone at any step; ICS-formoterol (AIR/MART) is the preferred track
GOLD 2023–2026	Pre-COPD and PRISm defined; LLN preferred over fixed 0.70 ratio; check inhaler technique before escalating
ARMA / ARDSNet	Low tidal volume 4–6 mL/kg PBW reduces mortality in ARDS
PROSEVA	Prone positioning ≥ 16 h/day reduces mortality in severe ARDS
ROSE / ART / FACTT / EOLIA	Routine paralysis neutral; aggressive recruitment harmful; conservative fluids beneficial; ECMO for refractory ARDS
New Global Definition of ARDS (2023)	Adds non-intubated ARDS on HFNO ≥ 30 L/min, $SpO_2/FiO_2 \leq 315$, lung ultrasound
PEITHO	Thrombolysis in intermediate-risk PE prevents decompensation but causes excess bleeding, especially > 75 years
PEERLESS (Circulation 2025) / STORM-PE	Large-bore mechanical thrombectomy better than catheter-directed thrombolysis, and better than anticoagulation alone for RV recovery
CHEST-1 / RACE / MACiTEPH (2025)	Riociguat is the only licensed CTEPH drug; riociguat pre-treatment makes BPA safer; macitentan trial stopped for futility
SURMOUNT-OSA (NEJM 2024)	Tirzepatide markedly reduces AHI — first drug approved for OSA
SAVE	CPAP improves symptoms but did not reduce cardiovascular events (adherence-limited)
AGS Beers 2023	Avoid benzodiazepines and Z-drugs in older adults; DORAs are the preferred hypnotic if one is needed
NSD-ISS 2024 / SynNeurGe	Isolated RBD with a positive α-synuclein seed amplification assay = biologically defined prodromal synuclein disease
ACS 2023 / Lung-RADS 2022	LDCT screening 50–80 with ≥ 20 pack-years, no quit-time limit; standardised nodule categories

C. Indian context lines worth adding

Topic	Line to write
Heart failure and valve disease	**Rheumatic valvular heart disease** remains an important cause of heart failure and of mitral and aortic disease in Indian older adults
Anticoagulation in AF	**Rheumatic mitral stenosis and mechanical valves require warfarin, not a DOAC** — a common examination trap in the Indian setting
Hypertension	High dietary salt with low potassium intake, a large treatment gap, and **API and Lipid Association of India** consensus favouring early combination therapy and intensive LDL targets
Atherosclerosis	Indians develop ASCVD **a decade earlier**, with more small dense LDL, higher Lp(a) and a higher prevalence of diabetes at lower BMI
Polypill	India led this field through the **TIPS/Polycap** programme; WHO **HEARTS** and the national NCD programme promote standardised fixed-dose regimens
Cardiorenal syndrome	Consider **NSAID and traditional/herbal remedy nephrotoxicity** and late presentation with advanced CKD as common contributors
Infective endocarditis	Rheumatic valvular disease remains an important substrate in India, with viridans streptococci still prominent
Cardiomyopathy	**Endomyocardial fibrosis** is a regionally important cause of restrictive cardiomyopathy in India
DOACs	Rheumatic mitral stenosis is common in India — these patients need **warfarin, not a DOAC**; idarucizumab and andexanet have limited availability, so **4F-PCC** is the practical reversal option
Lung cancer	Biomass fuel smoke and indoor air pollution are major risks in never-smoking Indian women; post-tubercular scarring is a recognised substrate
Statins / prevention	Indians develop ASCVD at a younger age with a higher burden of small dense LDL; API and Lipid Association of India consensus recommend lower LDL-C targets in high-risk groups
Pneumonia	Always consider **tuberculosis** in subacute pneumonia and send sputum for AFB/CBNAAT; aspergillosis complicates old TB cavities
HAP	**Carbapenem-resistant Klebsiella and Acinetobacter** dominate Indian ICUs — empirical therapy must follow the local antibiogram
DPLD	**Hypersensitivity pneumonitis (birds, mould, biomass)** and **CTD-ILD** form a larger share than in Western registries; exclude post-tubercular fibrosis
Pleural effusion	**Tuberculosis is often the commonest exudative effusion**; **ADA > 40 U/L with lymphocytic predominance** is the key test; ATT for 6 months
COPD / senile lung	**Biomass fuel smoke and indoor air pollution** are major non-smoking causes of airflow obstruction, especially in rural women
Solitary nodule	**Tuberculoma is the commonest benign SPN**, and granulomatous disease causes **false-positive PET-CT** — always obtain tissue before declaring malignancy

MD GERIATRIC MEDICINE

Consolidated Examination Answer Bank — NEUROLOGY

31 Questions • Organised by Subject • Mark-Wise Format • Updated to 2026

Scope. This volume consolidates the complete neurology answer bank into a single continuously numbered document, organised into six subject sections. Duplicated and overlapping questions have been merged, and the two Rapid Revision Grids have been combined into one appendix.

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (2022); Essentials of Clinical Geriatrics, 7th edition.

Latest updates: Guidelines, randomised trials and regulatory decisions, 2023–2026 (AHA/ASA, ERC/ESICM, ILAE, AASM, AAN, EAN, NICE, WHO, VA/DoD, AGS Beers, FDA/EMA, NEJM, JAMA, Lancet).

Mark-wise point counts used throughout:

- **20 marks** = 14 textbook points + 3 latest updates = **17 points**
- **15 marks** = 10 textbook points + 2 latest updates = **12 points**
- **7 marks** = 6 textbook points + 1 latest update = **7 points**
- **6 marks** = 5 textbook points + 1 latest update = **6 points**

Panels used in this document. Purple = *Latest Updates*. Blue table = *Current Practice Update*, present only where the textbook meaningfully differs from present-day recommendations. Orange = *Examiner's Tip* with verbatim mark-earning lines. Green = *Extra Points to Remember* or guidance for converting an answer between mark weights, used for repeated questions.

Compiled 27 August 2026 • Each question begins on a fresh page for clean printing and rapid lookup.

Table of Contents

SECTION A — EPILEPSY AND SEIZURE DISORDERS		
1.	Epilepsy in Elderly People and its Management	20 MARKS
2.	Complex Partial Seizure	7 MARKS
3.	Newer Anticonvulsants	7 MARKS
4.	Case — 80-Year-Old Hypertensive, Diabetic Woman with CAD and Atrial Fibrillation, Admitted with Altered Sensorium Following GTCS	15 MARKS
SECTION B — CEREBROVASCULAR DISEASE		
5.	Transient Ischaemic Attack	7 MARKS · ASKED ×2
6.	Lacunar Stroke	7 MARKS
7.	Thrombolysis and Mechanical Thrombectomy in Acute Stroke	7 MARKS
8.	Wallenberg Syndrome — Cause, Clinical Features and Treatment	7 MARKS
9.	Subarachnoid Haemorrhage	7 MARKS
10.	Treatment of Symptomatic and Asymptomatic Carotid Disease in the Elderly	7 MARKS
11.	Subdural Haematoma in the Elderly	7 MARKS
12.	Post-Stroke Depression and Post-Stroke Pain	7 MARKS
SECTION C — NEURODEGENERATIVE, MOVEMENT AND BALANCE DISORDERS		
13.	Normal Pressure Hydrocephalus	7 MARKS

	Rapid Revision Grid — examinable numbers, named trials and guidelines, drugs of choice	

SECTION A
Epilepsy and Seizure Disorders

Question 1. Epilepsy in Elderly People and its Management 20 MARKS

Answer

Textbook Core – 14 Points

1. **Definition and burden.** The **elderly have the highest incidence of new-onset epilepsy of any age group** — over 100 per 1,00,000 per year after 65. ILAE definition: two unprovoked seizures more than 24 hours apart, **or one unprovoked seizure with a recurrence risk above 60%**, or an epilepsy syndrome. Because recurrence after a first unprovoked seizure with a structural lesion is **60–90%** in old age, **treatment is usually started after the first seizure**.
2. **Causes. Cerebrovascular disease is the commonest cause (30–50%)** — both acute stroke and chronic small-vessel disease. Others: **neurodegenerative dementia** (Alzheimer's carries up to a 10-fold risk), **brain tumour** (primary and metastatic), head trauma and **chronic subdural haematoma**, CNS infection (in India, **neurocysticercosis and tuberculoma**), metabolic derangement, and alcohol or drug withdrawal. Around **25–50% remain unexplained** (late-onset unexplained epilepsy).
3. **Seizure types. Focal (partial) seizures predominate**, most often **focal seizures with impaired awareness** of temporal or frontal origin, with or without secondary generalisation. Primary generalised epilepsy beginning in old age is rare, so a generalised seizure in an older person should prompt a search for a focal structural or metabolic cause.
4. **Atypical presentation — the core geriatric point.** The aura is often **absent or not reported**. Seizures present as **brief staring and behavioural arrest, unexplained confusion, memory lapses, wandering, falls or syncope-like collapse**. Automatisms may be subtle. **Post-ictal confusion is prolonged — often hours to days, occasionally weeks — and Todd's paresis lasts longer**, so epilepsy is frequently misdiagnosed as TIA, syncope, delirium or dementia.
5. **Acute symptomatic (provoked) seizures must be separated from epilepsy.** Seizures occurring **within 7 days of a stroke, head injury or CNS infection**, or from hypoglycaemia, hyponatraemia, uraemia, hepatic failure, hypoxia, sepsis, drugs or alcohol withdrawal, are **provoked** — they do not by themselves define epilepsy and often do not require long-term antiseizure medication once the cause is corrected.
6. **Differential diagnosis. Syncope** (cardiac arrhythmia, orthostatic hypotension, carotid sinus hypersensitivity — the commonest misdiagnosis), **TIA** (negative rather than positive phenomena, no post-ictal confusion), transient global amnesia, hypoglycaemia, delirium, sleep disorders including **REM sleep behaviour disorder**, drop attacks, and psychogenic non-epileptic attacks.
7. **History is the single most valuable investigation.** Obtain a **detailed eyewitness account** — posture and circumstances at onset, warning, colour, duration, movements, tongue biting, incontinence, and the nature and duration of recovery. Review the drug chart for **pro-convulsant drugs**: tramadol, quinolones, bupropion, theophylline, antipsychotics, high-dose beta-lactams, and abrupt benzodiazepine withdrawal.
8. **Investigations. ECG with 24-hour Holter or tilt testing** to exclude cardiac syncope. Blood tests: sodium, calcium, magnesium, glucose, urea, creatinine, LFT, and drug levels. **EEG has low sensitivity in the elderly (about 26–38%)** and interictal abnormalities are less common, so a normal EEG never excludes epilepsy; use sleep-deprived, prolonged or video-EEG where doubt persists. **MRI brain is the imaging investigation of choice** — superior to CT for hippocampal sclerosis, small infarcts and tumour.
9. **Non-convulsive status epilepticus (NCSE).** An under-recognised and treatable cause of **unexplained prolonged confusion, stupor or coma in the elderly**, often after a generalised seizure or in a septic/metabolically deranged patient. **EEG is mandatory in any older patient whose consciousness does not recover within 30–60 minutes of a seizure.**
10. **Principles of drug therapy.** Use **monotherapy**; **start low, go slow, and aim for a lower maintenance dose than in younger adults**. Age alters pharmacokinetics: reduced serum albumin raises the **free (active) fraction of phenytoin and valproate**, reduced hepatic and renal clearance prolongs half-lives, and reduced lean body mass lowers the volume of distribution. **Measure free rather than total phenytoin** where available.
11. **Drug of choice. Levetiracetam and lamotrigine are first line for focal epilepsy in older adults**, with lacosamide as an alternative; levetiracetam has the highest chance of long-term seizure freedom and lamotrigine the best tolerability. **Avoid enzyme-inducing drugs** — carbamazepine, phenytoin and phenobarbitone — because they interact with warfarin, DOACs, statins, antihypertensives, antiarrhythmics and chemotherapy, and accelerate **vitamin D metabolism and bone loss**. Gabapentin is a last resort.
12. **Adverse effects that matter in old age. Hyponatraemia** (carbamazepine, oxcarbazepine, eslicarbazepine); **ataxia, dizziness and falls** with almost all agents; sedation and cognitive slowing (topiramate, phenobarbitone, benzodiazepines); **osteoporosis and fracture** with enzyme inducers; **behavioural change, irritability and depression with levetiracetam**; rash and Stevens–Johnson syndrome with lamotrigine if titrated fast; oedema and cognitive change with gabapentin and pregabalin; and phenytoin's zero-order kinetics, gum hypertrophy and cerebellar atrophy.

13. **Status epilepticus.** ABC, oxygen, IV access, **capillary glucose, and IV thiamine before glucose**. First line: **IV lorazepam 0.1 mg/kg** (or IM midazolam 10 mg if no access). Second line: **IV levetiracetam 60 mg/kg, fosphenytoin 20 PE/kg, or valproate 40 mg/kg** — all equally effective. Third line: anaesthesia with midazolam or propofol infusion and continuous EEG. In the elderly, **reduce doses, infuse slowly and monitor blood pressure and respiration closely**.

14. **Holistic and non-drug management, and prognosis.** Injury and **falls prevention**, bathing and cooking safety, driving restriction, treatment of vascular risk factors, deprescribing pro-convulsant and anticholinergic drugs, **bone health (calcium, vitamin D, DEXA)**, screening for depression and cognitive impairment, carer education in first aid, and counselling about SUDEP. Prognosis is good — **about 80% become seizure-free on low-dose monotherapy** — but mortality, fracture and dementia risk remain elevated.

Latest Updates – 3 Points

15. **ILAE Task Force on Epilepsy in the Elderly — critical review (*Epilepsia*, 2023).** An **individualised approach is essential** because older adults are a highly heterogeneous group. Across comparative studies, **levetiracetam has the highest probability of long-term seizure freedom**, while **carbamazepine users are almost twice as likely to discontinue treatment for adverse effects as lamotrigine users**. Current practice therefore places **lamotrigine, levetiracetam and lacosamide first line, with gabapentin as a last resort**. The Task Force also highlighted that quality of life is a missing outcome in most trials, and that prognosis must move beyond seizure control to patient-centred outcomes.

16. **Late-onset unexplained epilepsy (LOUE) is a marker of vascular brain disease and future dementia.** Recent cohort work and the prospective multicentre **ELUCID study (2025)** show that in LOUE the excess morbidity and mortality relate **more to incident dementia and stroke than to the seizures themselves**, and that seizures are usually easily controlled. Practical implication: a first seizure after the age of 55 should trigger **aggressive vascular risk-factor management and structured cognitive follow-up**, not merely a prescription for an antiseizure drug.

17. **Antiseizure medication–anticoagulant interactions (2024–2025).** Emerging evidence, including a systematic review of levetiracetam and DOACs (2024) and outcome data in older Asian patients with atrial fibrillation (2025), suggests that **even "non-interacting" agents such as levetiracetam may lower DOAC levels through P-glycoprotein induction**. About **one in six older patients with epilepsy is at risk of a clinically significant drug interaction**. Non-enzyme-inducing agents remain preferred, but a formal interaction check — not an assumption of safety — is now the standard.

Current Practice Update

Item	Position
Textbook	Phenytoin and carbamazepine remain widely used; newer agents are reserved as add-on therapy. A first unprovoked seizure may be observed without treatment.
Current recommendation	**Lamotrigine, levetiracetam and lacosamide are first line**; enzyme inducers are avoided because of interactions and bone loss. Treat after the **first** seizure when a structural cause is present. Late-onset epilepsy is managed as a **vascular and cognitive risk state**, not just a seizure disorder.
Exam approach	Write the classical framework, then state: "The ILAE Task Force (2023) recommends lamotrigine, levetiracetam or lacosamide first line in older adults, with gabapentin as a last resort."

Examiner's Tip — Verbatim Mark-Earning Lines

- "The elderly have the **highest incidence of new-onset epilepsy of any age group**, and cerebrovascular disease is the commonest cause."
- "**A normal EEG never excludes epilepsy in an older person** — sensitivity is only 26–38%."
- "Any older patient with **prolonged unexplained confusion needs an EEG to exclude non-convulsive status epilepticus**."
- "**Start low, go slow, aim low** — older patients respond to lower doses and tolerate fewer adverse effects."
- **Skeleton:** Incidence/definition → Causes → Seizure types → Atypical presentation → Provoked vs unprovoked → Differentials → History → Investigations → NCSE → Prescribing principles → Drug of choice → Adverse effects → Status epilepticus → Holistic care/prognosis → 3 updates.

Question 2. Complex Partial Seizure 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and current terminology.** A seizure arising in **one hemisphere with impairment of awareness or consciousness**. The **ILAE 2017 classification renamed "complex partial seizure" as focal seizure with impaired awareness** (focal impaired-awareness seizure) — both terms should be written in the answer. It is the **commonest seizure type in older adults**.
2. **Site of origin and causes.** Most arise from the **temporal lobe (mesial temporal structures — hippocampus and amygdala)**, fewer from the frontal lobe. Causes in the elderly: stroke and small-vessel disease, tumour, hippocampal sclerosis, head trauma and subdural haematoma, Alzheimer's disease, and in India **neurocysticercosis and tuberculoma**.
3. **Clinical sequence (temporal lobe type). Aura** — **rising epigastric sensation, déjà vu or jamais vu, sudden fear, olfactory or gustatory hallucination** → **motionless stare and behavioural arrest** → **automatisms**: oro-alimentary (lip smacking, chewing, swallowing) and manual (picking, fumbling) → **post-ictal confusion and amnesia**. Attacks last **30 seconds to 2–3 minutes**, with post-ictal confusion of 5–30 minutes, often much longer in the elderly.
4. **Frontal lobe variant.** Brief, **frequently nocturnal, occurring in clusters**, with bizarre hypermotor, bicycling or thrashing movements, vocalisation and **minimal or absent post-ictal confusion** — commonly mislabelled as psychogenic non-epileptic attacks or a sleep disorder.
5. **Differential diagnosis. Absence seizure** (no aura, seconds only, **no post-ictal confusion**, 3 Hz generalised spike-and-wave, a disorder of childhood), TIA, transient global amnesia, syncope, hypoglycaemia, delirium and psychogenic non-epileptic seizures. In older adults the **prolonged post-ictal state readily mimics delirium or dementia**, and repeated brief attacks may be dismissed as "absent-mindedness".
6. **Investigations and treatment. EEG** — anterior temporal spikes or sharp waves; yield improves with sleep-deprived or prolonged recording. **MRI brain** for hippocampal sclerosis, tumour or infarct. Treatment: focal-onset agents — **levetiracetam or lamotrigine are preferred in older adults**; lacosamide, oxcarbazepine and carbamazepine are alternatives. In drug-resistant cases (failure of two appropriate drugs), refer for pre-surgical evaluation — **anterior temporal lobectomy** gives seizure freedom in about two-thirds of selected patients.

Latest Update – 1 Point

7. **Focal impaired-awareness seizures in Alzheimer's disease.** Work published from 2023 onward has established that **subclinical epileptiform activity and unrecognised focal impaired-awareness seizures are common in Alzheimer's disease** and are associated with earlier onset and faster cognitive decline. The practical implication is that an older patient with dementia and **fluctuating cognition, unexplained confusional episodes, staring spells or amnestic gaps** should have a **prolonged or sleep EEG**, since these episodes are treatable — a diagnosis routinely missed when they are attributed to the dementia itself.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Aura → blank stare → automatisms → post-ictal confusion** — the four-step signature of a focal impaired-awareness seizure."
- "**Post-ictal confusion distinguishes a complex partial seizure from an absence seizure.**"
- "Always write both terms: **complex partial seizure = focal seizure with impaired awareness (ILAE 2017)**."
- **Skeleton:** Definition + ILAE 2017 term → Temporal origin/causes → Clinical sequence → Frontal variant → Differentials → EEG/MRI/drugs/surgery → Alzheimer's overlap.

Question 3. Newer Anticonvulsants 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and general advantages.** The **second- and third-generation antiseizure medications** — lamotrigine, levetiracetam, topiramate, gabapentin, pregabalin, oxcarbazepine, zonisamide, lacosamide, brivaracetam, perampanel, eslicarbazepine and cenobamate. Their advantages over phenytoin, carbamazepine, phenobarbitone and valproate are **fewer cytochrome P450 interactions, linear (first-order) kinetics, low protein binding, a wider therapeutic index, and no need for routine level monitoring** — all particularly valuable in polypharmacy.
2. **Mechanisms of action. Sodium-channel blockade** — lamotrigine, oxcarbazepine, eslicarbazepine; **slow inactivation of sodium channels** — lacosamide; **SV2A synaptic vesicle protein binding** — levetiracetam and brivaracetam; **α2δ calcium-channel subunit binding** — gabapentin and pregabalin; **AMPA receptor antagonism** — perampanel; **multiple mechanisms** — topiramate and zonisamide.
3. **Key drugs and their place. Levetiracetam** — broad spectrum, intravenous form available, no significant interactions, renal dose adjustment; the workhorse drug in geriatrics. **Lamotrigine** — broad spectrum, mood-stabilising, best tolerability, but needs slow titration. **Lacosamide** — focal seizures, IV available. **Oxcarbazepine** — focal seizures, better tolerated than carbamazepine. **Topiramate** — broad spectrum and also effective in migraine. **Gabapentin and pregabalin** — weak antiseizure agents, mainly used for neuropathic pain.
4. **Adverse effects to name.** Lamotrigine — **rash and Stevens-Johnson syndrome if titrated too fast (halve the dose when combined with valproate)**. Levetiracetam — **irritability, aggression, depression and psychosis**. Topiramate — cognitive slowing, word-finding difficulty, weight loss, **renal stones, acute glaucoma and metabolic acidosis**. Oxcarbazepine and eslicarbazepine — **hyponatraemia**. Perampanel — serious psychiatric and behavioural reactions (boxed warning). Lacosamide — dizziness and **PR interval prolongation**. Zonisamide — stones and oligohidrosis. Gabapentinoids — oedema, sedation, weight gain and misuse potential.
5. **Geriatric considerations.** These agents are **preferred over the older drugs in old age** because they do not induce CYP450 enzymes and therefore do not compromise warfarin, DOACs, statins, antihypertensives, antiarrhythmics or chemotherapy, and they cause less bone loss. However, **levetiracetam, gabapentin, pregabalin and lacosamide all require dose reduction for creatinine clearance**, and every agent can cause dizziness, ataxia and falls. Sedative and anticholinergic burden must be counted under the **AGS Beers Criteria**.
6. **Limitations.** They are **substantially more expensive** — a major issue in Indian practice — and parenteral formulations are limited. Importantly, they do **not achieve higher seizure-freedom rates** than the older drugs: **SANAD II showed that levetiracetam was neither clinically superior nor cost-effective compared with lamotrigine for focal epilepsy**, and valproate remained best for generalised epilepsy. Evidence in the very old and the frail remains sparse.

Latest Update – 1 Point

7. **Cenobamate — the newest third-generation agent for drug-resistant focal epilepsy.** It has a **dual mechanism — inhibition of the persistent sodium current plus positive allosteric modulation of GABA-A receptors** — and produces unusually high seizure-freedom rates in adjunctive trials (around 20% at the highest dose, far above the usual 2–5% for add-on agents). Two cautions are examinable: it must be **titrated very slowly over at least 12 weeks starting at 12.5 mg daily to avoid DRESS (drug reaction with eosinophilia and systemic symptoms)**, and it **induces CYP3A4 and inhibits CYP2C19**, so interactions must be rechecked — a real consideration in the polypharmacy of old age. Brivaracetam, eslicarbazepine and perampanel are currently under study in older populations.

Examiner's Tip — Verbatim Mark-Earning Lines

- "The advantage of the newer agents is **predictable kinetics and freedom from enzyme induction**, not superior efficacy."
- "**Levetiracetam causes behavioural disturbance; lamotrigine causes rash; topiramate causes cognitive slowing and stones; oxcarbazepine causes hyponatraemia.**"
- "SANAD II: newer does not mean better — **lamotrigine remained the reference standard for focal epilepsy**."
- **Skeleton:** Definition/advantages → Mechanism table → Key drugs → Adverse effects → Geriatric prescribing → Cost and SANAD II → Cenobamate.

Question 4. Case — 80-Year-Old Hypertensive, Diabetic Woman with CAD and Atrial Fibrillation, Admitted with Altered Sensorium Following GTCS 15 MARKS

Answer

Textbook Core – 10 Points

1. **Frame the problem.** A generalised tonic-clonic seizure at 80 years is **an acute symptomatic (provoked) seizure until proved otherwise**, not idiopathic epilepsy. Two features dominate the differential: she is **on antithrombotic therapy for atrial fibrillation**, so **intracranial haemorrhage** must be excluded first; and she is **diabetic**, so **hypoglycaemia** must be excluded immediately.
2. **Immediate stabilisation (first 10 minutes).** Airway, left lateral position, oxygen, suction, IV access, cardiac and SpO_2 monitoring. **Check capillary blood glucose at the bedside** and give **IV thiamine 100 mg before any glucose**. If seizures continue: **IV lorazepam 0.1 mg/kg (maximum 4 mg per dose)**; if status persists, second-line **IV levetiracetam 60 mg/kg, fosphenytoin 20 PE/kg or valproate 40 mg/kg** — all equally effective; then anaesthesia with continuous EEG. Infuse slowly and watch blood pressure and respiration.
3. **Focused history from attendants.** The **exact drug list** — insulin or sulfonylurea, metformin, **warfarin versus a DOAC, antiplatelets**, beta-blocker, digoxin, amiodarone, statin, and pro-convulsant drugs such as tramadol or a quinolone; recent **falls or head injury**; fever; missed or doubled doses; alcohol; prior stroke, seizure or dementia; and her **baseline cognition and functional status**, which will shape every subsequent decision.
4. **Examination.** Vital signs and temperature, GCS, pupils, fundi, neck stiffness, and a search for **lateralising signs and Todd's paresis**. **Lateral tongue bite and urinary incontinence support a true GTCS**. Look for scalp haematoma, periorbital bruising and other signs of head injury; examine the heart for atrial fibrillation, murmur and failure; and screen for a septic focus — chest, urine, skin and pressure areas.
5. **Differential diagnosis to work through. Intracranial haemorrhage — anticoagulant-related intracerebral haemorrhage and chronic subdural haematoma**; acute ischaemic stroke or cardioembolic infarct with seizure; **hypoglycaemia**; **hyponatraemia**; uraemic or hepatic encephalopathy; sepsis-associated encephalopathy; hypoxic-ischaemic injury after an arrhythmia; CNS infection (meningoencephalitis, tuberculoma, neurocysticercosis); drug toxicity or withdrawal; hypertensive encephalopathy/PRES; and **non-convulsive status epilepticus**.
6. **Investigations — immediate.** Capillary and laboratory glucose; **serum sodium, calcium, magnesium**; urea, creatinine and electrolytes; LFT; arterial blood gas; full blood count; CRP or procalcitonin; **ECG and troponin** (silent myocardial infarction or arrhythmia is a real possibility with her CAD and AF); **coagulation profile and INR — mandatory given anticoagulation**; blood and urine cultures; chest X-ray.
7. **Investigations — neurological. Urgent non-contrast CT brain** is the first imaging study, looking for haemorrhage, subdural collection, infarct or mass. If the CT is non-diagnostic, proceed to **MRI with DWI ± MR angiography**. Lumbar puncture after imaging if infection is suspected and there is no contraindication — noting that anticoagulation must be reversed first. **EEG is essential if consciousness does not recover within 30–60 minutes, to exclude non-convulsive status epilepticus.**
8. **Managing the anticoagulated patient.** If intracranial haemorrhage is confirmed: **stop the anticoagulant and reverse it immediately — vitamin K plus 4-factor prothrombin complex concentrate for warfarin, idarucizumab for dabigatran, and andexanet alfa or PCC for a factor Xa inhibitor**; lower systolic blood pressure to about 130–140 mmHg; obtain a neurosurgical opinion; and decide on the timing of restarting anticoagulation later with the cardiology team. If instead there is an ischaemic stroke, a seizure at onset does not by itself preclude thrombolysis when the deficit is clearly attributable to the stroke.
9. **Antiseizure medication decision. An acute symptomatic seizure from a fully reversible metabolic cause does not require long-term antiseizure medication** — correct the cause. If a **structural lesion** (haemorrhage, infarct, subdural, tumour) is found, start maintenance therapy: **levetiracetam is the drug of choice** — intravenous formulation, no CYP450 interactions with her anticoagulant, statin or antiarrhythmic, with the dose adjusted for creatinine clearance. **Avoid phenytoin and carbamazepine**, which interact with warfarin, DOACs, statins and amiodarone and cause hypotension and arrhythmia on rapid infusion.
10. **Supportive and comprehensive geriatric care.** Aspiration precautions with a **formal swallow screen before oral intake**; VTE prophylaxis; pressure-area care; a **delirium prevention bundle** (orientation, sleep, mobilisation, avoidance of restraints, catheters and anticholinergics); nutrition; early physiotherapy; glycaemic control that avoids hypoglycaemia; deprescribing of pro-convulsant and anticholinergic drugs; falls, driving and home-safety advice; and an early, explicit **goals-of-care discussion with the family**, followed by comprehensive geriatric assessment before discharge.

Latest Updates – 2 Points

11. **ANNEXA-I (*NEJM* 2024) — reversal of factor Xa inhibitor-associated intracerebral haemorrhage.** In 530 patients (mean age 79 years) with ICH within 15 hours of a factor Xa inhibitor, **andexanet alfa achieved better haemostatic efficacy than usual care (67.0% vs 53.1%, p=0.003)** but caused **more thrombotic events (10.3% vs 5.6%, p=0.048), including ischaemic stroke (6.5% vs 1.5%)**, with **no difference in 30-day mortality or modified Rankin outcome**. Because of this, plus cost and availability, **4-factor PCC remains the widely used option in Indian practice** — a nuance worth writing.

12. **AHA/ASA 2026 Acute Ischaemic Stroke Guideline.** The approach to **thrombolysis contraindications has been modified**, and **seizure at stroke onset is no longer treated as an absolute barrier** when the deficit is attributable to the infarct. **Tenecteplase 0.25 mg/kg (maximum 25 mg) as a single bolus is now a Class 1 recommendation** alongside alteplase within 4.5 hours, thrombolysis should be given for disabling deficits regardless of NIHSS score, and thrombectomy eligibility has been broadened to **ASPECTS 3–10 and up to 24 hours** with mismatch imaging — all directly relevant to an 80-year-old whose first GTCS turns out to be a stroke.

Examiner's Tip — Verbatim Mark-Earning Lines

- "In an anticoagulated older patient, a new seizure is **intracranial haemorrhage until the CT proves otherwise**."
- "**Check the glucose before you check anything else**; give thiamine before glucose."
- "If she does not wake up within an hour, **get an EEG — non-convulsive status epilepticus is the commonest missed diagnosis**."
- "**Levetiracetam is the antiseizure drug of choice** in a patient on an anticoagulant, a statin and an antiarrhythmic."
- **Skeleton:** Frame the problem → ABC + glucose + benzodiazepine → History → Examination → Differentials → Labs → CT/MRI/EEG → Reversal of anticoagulation → ASM decision → CGA and goals of care → 2 updates.

Question 5. Transient Ischaemic Attack 7 MARKS • ASKED ×2

Answer

Textbook Core – 6 Points

1. **Definition.** A **transient episode of neurological dysfunction caused by focal brain, spinal cord or retinal ischaemia, without acute infarction on imaging** (tissue-based definition). The old time-based definition of "deficit resolving within 24 hours" is **obsolete**, because up to one-third of clinically transient events show a diffusion-weighted MRI lesion — and are therefore strokes.
2. **Clinical features by territory. Carotid** — contralateral hemiparesis, hemisensory loss, dysphasia, and **amaurosis fugax** (a curtain descending over one eye). **Vertebrobasilar** — vertigo *with* other brainstem signs, diplopia, dysarthria, dysphagia, ataxia, bilateral or crossed deficits, drop attacks. **Isolated vertigo, syncope, confusion, generalised weakness or a "funny turn" are NOT a TIA.**
3. **Risk stratification — ABCD^2 score. A**ge ≥60 = 1; **B**lood pressure ≥140/90 = 1; **C**linical features: unilateral weakness = 2, speech disturbance without weakness = 1; **D**uration ≥60 min = 2, 10–59 min = 1; **D**iabetes = 1. **A score of 4 or more is high risk.** Stroke risk is greatest in the **first 48 hours** — roughly 5% at 7 days and 10% at 90 days if untreated. **A TIA is a medical emergency, not an outpatient problem.**
4. **Investigations — all within 24 hours. MRI with diffusion-weighted imaging is the investigation of choice** (CT if MRI is unavailable); **carotid Doppler, CT angiography or MR angiography**; **ECG with prolonged cardiac monitoring** (Holter or implantable loop recorder) — occult atrial fibrillation is a major and treatable cause in the elderly; echocardiography; glucose and HbA1c, lipids, full blood count, renal function, and **ESR if amaurosis fugax (giant cell arteritis)**.
5. **Acute antithrombotic treatment.** For high-risk TIA (ABCD^2 ≥4) of non-cardioembolic origin, give **dual antiplatelet therapy — aspirin plus clopidogrel for 21 days, then a single agent** (loading aspirin 300 mg and clopidogrel 300 mg; CHANCE and POINT trials). Add a **high-intensity statin**, control blood pressure and glycaemia, and stop smoking. **If atrial fibrillation is present, the treatment is anticoagulation, not antiplatelets** — a DOAC is preferred over warfarin in older adults.
6. **Pathway and secondary prevention.** Assess in a **TIA clinic within 24 hours** for high-risk patients; carotid revascularisation **within 2 weeks** for symptomatic 70–99% stenosis; treat the whole vascular risk profile; give driving advice (in India, cease driving for at least one month and reassess); and screen for **cognitive impairment, depression and falls**, since a TIA in an older person is a sentinel event for both vascular dementia and frailty.

Latest Update – 1 Point

7. **INSPIRES trial (*NEJM* 2023; subgroup analyses 2024) — the DAPT window extends to 72 hours.** In 6,100 patients with **mild ischaemic stroke or high-risk TIA of presumed atherosclerotic cause**, **clopidogrel plus aspirin started within 72 hours reduced new stroke at 90 days compared with aspirin alone**, at the cost of a small excess of moderate-to-severe bleeding; efficacy was similar whether treatment began before 24 hours or between 24 and 72 hours. This **widens the previous 24-hour window to 72 hours** — a change of real practical value in India, where patients frequently present late. The AHA/ASA 2026 guideline likewise supports dual antiplatelet therapy for non-disabling stroke and high-risk TIA.

Extra Points to Remember (repeated question)

- **Crescendo TIA** (increasing frequency or duration) and **TIA while already on an antiplatelet** both mandate immediate admission.
- **TIA mimics** to exclude: migraine aura, focal seizure with Todd's paresis, hypoglycaemia, syncope, transient global amnesia, subdural haematoma, brain tumour, multiple sclerosis, peripheral vestibular disease.
- The **ABCD^2 score does not detect atrial fibrillation or carotid stenosis**, so a low score never justifies omitting vascular and cardiac imaging.
- **Limb-shaking TIA** — brief involuntary jerking of the contralateral limb on standing — indicates critical carotid stenosis with haemodynamic failure and is often misdiagnosed as a focal seizure.
- **ESUS** (embolic stroke of undetermined source): routine anticoagulation is **not** beneficial (NAVIGATE-ESUS, RE-SPECT ESUS) — look harder for atrial fibrillation instead.

Examiner's Tip — Verbatim Mark-Earning Lines

- "A TIA is defined by **absence of infarction on imaging, not by duration of symptoms**."
- "**A TIA is a warning shot — the highest risk of stroke is in the first 48 hours.**"
- "**Antiplatelets for atherothrombotic TIA; anticoagulation for atrial fibrillation** — never confuse the two."

Question 6. Lacunar Stroke 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and pathology.** A **small subcortical infarct, less than 15–20 mm in diameter**, resulting from occlusion of a single **deep penetrating artery** (lenticulostriate, thalamoperforating or pontine perforator). It accounts for about **25% of all ischaemic strokes**. The underlying pathology is **lipohyalinosis and microatheroma** of the small vessel, driven above all by **hypertension and diabetes** — not by embolism.
2. **The five classical lacunar syndromes. Pure motor hemiparesis** (posterior limb of the internal capsule or pons — the commonest); **pure sensory stroke** (ventral posterolateral thalamus); **sensorimotor stroke**; **ataxic hemiparesis** (pons or internal capsule); and **dysarthria–clumsy hand syndrome** (pons or genu of the internal capsule).
3. **The defining negatives.** There are **no cortical signs** — **no aphasia, no neglect, no visual field defect, no altered consciousness and no seizure**. In pure motor hemiparesis, the **face, arm and leg are affected equally**. These negatives are what earn marks and what distinguish a lacune from a cortical infarct.
4. **Investigations. MRI with DWI is far superior to CT** for small deep infarcts, which are frequently invisible on CT. Look also for the accompanying markers of **cerebral small-vessel disease**: white matter hyperintensities (leukoaraiosis), **microbleeds on SWI**, enlarged perivascular spaces and old silent lacunes. Still perform ECG, carotid Doppler and echocardiography to exclude a cardioembolic or large-artery source, though the cause is usually intrinsic small-vessel disease.
5. **Treatment. Thrombolysis remains indicated within the time window** — lacunar strokes benefit. **Single antiplatelet therapy is the mainstay**, with a 21-day course of dual therapy only for high-risk minor stroke. Add a **high-intensity statin**, and above all **aggressive blood pressure control** — the SPS3 trial showed that a systolic target below 130 mmHg reduced intracerebral haemorrhage. Control diabetes and stop smoking.
6. **Prognosis and complications.** Early functional recovery is usually good, but there is a **high long-term risk of recurrence, vascular cognitive impairment and vascular parkinsonism**. The accumulated **multilacunar state** produces pseudobulbar palsy, emotional lability, *marche à petits pas*, gait apraxia and falls. **Long-term dual antiplatelet therapy must be avoided** — SPS3 showed no benefit but significantly more bleeding and higher mortality.

Latest Update – 1 Point

7. **AHA/ASA 2026 Acute Ischaemic Stroke Guideline — low NIHSS is no longer a reason to withhold thrombolysis.** The guideline emphasises **rapid thrombolysis for any eligible patient with a disabling deficit within 4.5 hours, regardless of NIHSS score and without waiting for advanced imaging**. This matters specifically for lacunar stroke, which characteristically scores low on the NIHSS yet may be severely disabling (isolated hand weakness, ataxic hemiparesis, dysarthria–clumsy hand). **Tenecteplase 0.25 mg/kg as a single bolus is now a Class 1 alternative to alteplase.** The INSPIRES trial additionally supports starting dual antiplatelet therapy up to 72 hours in minor strokes of atherosclerotic origin.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**A lacunar syndrome is defined as much by what is absent as by what is present** — no aphasia, no neglect, no field defect, no altered consciousness."
- "Blood pressure control is the **single most important intervention** in small-vessel disease."
- "**Do not continue dual antiplatelet therapy long term after a lacunar stroke** — SPS3 showed harm."
- **Skeleton:** Definition/lipohyalinosis → Five syndromes → Cortical-sign negatives → MRI + small-vessel markers → BP, statin, antiplatelet → Recurrence/vascular cognitive impairment → AHA/ASA 2026.

Question 7. Thrombolysis and Mechanical Thrombectomy in Acute Stroke 7 MARKS

Answer

Textbook Core – 6 Points

1. **Principle.** "**Time is brain**" — reperfusion aims to salvage the **ischaemic penumbra** before infarction is complete. A **non-contrast CT to exclude haemorrhage is mandatory** before thrombolysis; the target **door-to-needle time is 60 minutes or less**. Every patient, whether or not eligible for reperfusion, benefits from **stroke unit care**.
2. **Intravenous thrombolysis. Alteplase 0.9 mg/kg (maximum 90 mg; 10% as bolus, remainder over 60 minutes) within 4.5 hours** of onset or last-known-well. The number needed to treat for improved outcome is about **10 when given within 3 hours**. **Age over 80 is not a contraindication** — IST-3 and pooled analyses confirm benefit in the very elderly.
3. **Contraindications and risks.** Intracranial haemorrhage; uncontrolled **BP >185/110 mmHg**; platelets <1,00,000/mm^3; **INR >1.7** or a DOAC taken within 48 hours; blood glucose <50 mg/dL; major surgery or gastrointestinal bleed within 21 days; stroke or head injury within 3 months; known AVM, aneurysm or intracranial neoplasm. The principal hazard is **symptomatic intracerebral haemorrhage in about 2–6%**; orolingual angio-oedema also occurs.
4. **Mechanical thrombectomy — indications.** Anterior circulation **large-vessel occlusion (ICA or M1)**, **NIHSS ≥6**, pre-stroke **mRS 0–1**, **ASPECTS ≥6**, within **6 hours**. The window extends to **6–24 hours with perfusion or clinical–core mismatch selection (DAWN and DEFUSE-3)**. With a **NNT of about 2.6** for reduced disability, it is the most powerful single intervention in acute stroke.
5. **Combined use and post-procedure care.** Patients eligible for both should receive **intravenous thrombolysis and proceed to thrombectomy** — **never delay the procedure to see whether symptoms improve**. After thrombolysis: no antiplatelet or anticoagulant for 24 hours, repeat CT at 24 hours, maintain BP below 180/105 mmHg, intensive neurological observation, early swallow screen and stroke unit admission.
6. **Indian and practical context.** The principal barriers are **delayed presentation, cost of alteplase and a limited number of thrombectomy-capable centres**. **Tenecteplase is single-bolus, cheaper and widely used in India**. Telestroke networks, pre-hospital notification and stroke-ready hospital certification under national programmes are the practical levers for improving access.

Latest Update – 1 Point

7. **AHA/ASA 2026 Guideline for the Early Management of Acute Ischaemic Stroke** (*Stroke*, 2026), replacing the 2018/2019 guidelines. Key changes: **tenecteplase 0.25 mg/kg (maximum 25 mg) as a single bolus is now a Class 1 recommendation, equivalent to alteplase within 4.5 hours**; thrombolyse eligible disabling strokes within 4.5 hours **regardless of NIHSS score and without waiting for advanced imaging**; extended-window thrombolysis at **4.5–9 hours or in wake-up stroke** using perfusion or DWI–FLAIR mismatch is Class 2a; thrombectomy eligibility is broadened to **ASPECTS 3–10**, admitting large-core infarcts; and mobile stroke units are endorsed.

Current Practice Update

Domain	Textbook	Current (AHA/ASA 2026)
Thrombolytic agent	Alteplase 0.9 mg/kg infusion	Alteplase **or** tenecteplase 0.25 mg/kg bolus — both Class 1
Thrombolysis window	0–4.5 hours	0–4.5 h standard; **4.5–9 h / wake-up** with mismatch imaging (Class 2a)
Thrombectomy core size	ASPECTS ≥6	**ASPECTS 3–10** — large-core infarcts now eligible
Thrombectomy window	0–6 hours	Up to **24 hours** with mismatch selection
Exam approach	Write the classical alteplase/6-hour framework first, then add one line: "The AHA/ASA 2026 guideline now gives tenecteplase a Class 1 recommendation and extends thrombectomy to ASPECTS 3–10 and to 24 hours."	

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Age alone is never a contraindication to thrombolysis.**"
- "Thrombectomy has an **NNT of about 2.6** — the most effective acute intervention in medicine."
- "Give thrombolysis and go to thrombectomy — **do not wait to see if the patient improves**."
- **Skeleton:** Penumbra/CT/door-to-needle → Alteplase dose and window → Contraindications and sICH → Thrombectomy criteria and DAWN/DEFUSE-3 → Combined use and post-lysis care → Indian barriers → AHA/ASA 2026.

Question 8. Wallenberg Syndrome — Cause, Clinical Features and Treatment 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** Wallenberg syndrome is the **lateral medullary syndrome** — infarction of the dorsolateral medulla, often with the inferior cerebellum. Despite the name "PICA syndrome", the commonest vessel involved is the **vertebral artery (about 80%)**, with PICA occlusion accounting for the remainder.
2. **Causes in the elderly. Atherothrombosis of the vertebral artery** (commonest), cardioembolism (atrial fibrillation), **vertebral artery dissection** — which may follow neck manipulation, trauma or even trivial neck rotation and should be suspected when there is neck or occipital pain — vasculitis, and hypercoagulable states.
3. **Clinical features — the crossed sensory loss.** Loss of **pain and temperature sensation on the IPSILATERAL face** (spinal trigeminal nucleus and tract) with loss of **pain and temperature on the CONTRALATERAL body** (spinothalamic tract), while **touch, vibration and proprioception are preserved**. This dissociated, crossed pattern is the diagnostic signature.
4. **Other ipsilateral features. Horner's syndrome** — ptosis, miosis, anhidrosis (descending sympathetic fibres); **cerebellar ataxia and lateropulsion** (inferior cerebellar peduncle) — the body is pulled towards the side of the lesion; **vertigo, nystagmus, nausea and vomiting** (vestibular nuclei); **intractable hiccups**; and **dysphagia, hoarseness, absent gag reflex and ipsilateral palatal weakness** (nucleus ambiguus).
5. **The key negative and the practical dangers. There is NO hemiparesis** — the pyramidal tract lies medially and is spared. This is the single most useful discriminator from a hemispheric stroke. Two dangers dominate management: **severe dysphagia out of proportion to the rest of the deficit**, with a very high aspiration risk, and rarely **Ondine's curse** (loss of automatic respiration), which is life-threatening.
6. **Diagnosis and treatment. MRI with DWI is the investigation of choice** — CT frequently misses posterior fossa infarcts; add **CT or MR angiography of the vertebrobasilar system** to identify occlusion or dissection. Treatment: thrombolysis if within the window, stroke-unit care, and above all **aspiration prevention — nil by mouth, formal swallow assessment, nasogastric feeding and early speech-and-language therapy**. Secondary prevention with an antiplatelet (or anticoagulation for cardioembolism), high-intensity statin, and blood pressure and glycaemic control. Treat intractable hiccups (baclofen, chlorpromazine or gabapentin) and central post-stroke pain (amitriptyline or pregabalin); vestibular rehabilitation and physiotherapy for lateropulsion. **Prognosis is generally good**, with recovery over weeks to months.

Latest Update – 1 Point

7. **AHA/ASA 2026 Acute Ischaemic Stroke Guideline — posterior circulation stroke.** Two points are directly relevant. First, **thrombolysis is recommended for any disabling deficit within 4.5 hours regardless of NIHSS score** — important because posterior circulation strokes such as Wallenberg systematically score low on the NIHSS despite causing severe disability and dysphagia. Second, **endovascular thrombectomy is now recommended for basilar artery occlusion** (following the ATTENTION and BAOCHE trials), the condition to which progressive vertebrobasilar disease may lead. The guideline also contains updated recommendations on **dysphagia screening and management**, the dominant practical problem in this syndrome.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Ipsilateral face, contralateral body** — the crossed pain-and-temperature loss of the lateral medullary syndrome."
- "**Wallenberg syndrome causes no weakness** — that single negative separates it from a hemispheric stroke."
- "The immediate priority is not the drug chart but **the swallow** — keep the patient nil by mouth until formally assessed."
- "Consider **vertebral artery dissection** in any patient with neck pain and a lateral medullary syndrome."
- **Skeleton:** Definition/vertebral artery → Causes → Crossed sensory loss → Horner + ataxia + nucleus ambiguus → No hemiparesis, dysphagia danger → MRI/MRA + swallow + secondary prevention → AHA/ASA 2026.

Question 9. Subarachnoid Haemorrhage 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and causes.** Bleeding into the subarachnoid space. About **85% follow rupture of a saccular (berry) aneurysm** — anterior communicating > posterior communicating > middle cerebral bifurcation; **10% are perimesencephalic non-aneurysmal** (benign course); the remainder are due to AVM, trauma, vasculitis, coagulopathy or reversible cerebral vasoconstriction syndrome. Risk factors: **hypertension, smoking, alcohol, family history, adult polycystic kidney disease** and connective tissue disorders.
2. **Clinical features. Sudden "worst headache of my life" (thunderclap headache) peaking within seconds**, with vomiting, neck stiffness, photophobia, transient loss of consciousness and seizures. A **sentinel or warning bleed** precedes the major event in up to 40%. Fundoscopy may show subhyaloid or vitreous (**Terson**) haemorrhage. **In the elderly the presentation is often atypical** — confusion, collapse or coma with less prominent headache and meningism.
3. **Grading. Hunt and Hess** (I — mild headache/nuchal rigidity, through V — deep coma and decerebrate posturing) and the **WFNS scale** (based on GCS plus motor deficit) grade clinical severity; the **modified Fisher scale** grades the volume and distribution of blood on CT and predicts vasospasm.
4. **Diagnosis. Immediate non-contrast CT head** — sensitivity exceeds 95% within the first 6 hours and falls steadily thereafter. If the CT is negative and suspicion persists, perform a **lumbar puncture after 12 hours**, looking for **xanthochromia** (ideally by spectrophotometry) and a red cell count that does not clear between successive bottles. Then **CT angiography or digital subtraction angiography** to define the aneurysm.
5. **Treatment.** Admit to a neurocritical care unit. **Secure the aneurysm within 24 hours** by **endovascular coiling** (preferred — ISAT showed better outcomes) or surgical clipping. Bed rest, analgesia, stool softeners; control blood pressure before the aneurysm is secured (systolic <160 mmHg) while avoiding hypotension; **nimodipine 60 mg orally every 4 hours for 21 days** to prevent delayed cerebral ischaemia; maintain **euvolaemia and normonatraemia**. Antiepileptics only if seizures occur.
6. **Complications. Rebleeding** (peaks in the first 24 hours; the highest-mortality complication); **delayed cerebral ischaemia from vasospasm** (days 4–14); **hydrocephalus** — acute obstructive needing an external ventricular drain, and chronic communicating needing a VP shunt; **hyponatraemia from cerebral salt wasting or SIADH**; neurogenic pulmonary oedema; **stunned myocardium / Takotsubo cardiomyopathy** with ECG changes and raised troponin; seizures; and long-term cognitive and mood impairment. Overall mortality is **30–40%**.

Latest Update – 1 Point

7. **AHA/ASA 2023 Guideline for Aneurysmal Subarachnoid Haemorrhage** (replacing the 2012 guideline). Key positions: treat the ruptured aneurysm **preferably within 24 hours**, aiming for complete obliteration; **early enteral nimodipine is beneficial**; **prophylactic hypervolaemia and haemodynamic augmentation are harmful and should NOT be used (Class 3: Harm)** — maintain euvolaemia instead, and induce hypertension only once symptomatic delayed cerebral ischaemia develops; **routine statin therapy and intravenous magnesium are not recommended**; and outcomes are better when patients are managed in **high-volume centres with dedicated neurocritical care units**, so timely transfer is recommended.

Current Practice Update

Item	Position
Textbook	"Triple-H therapy" — hypertension, hypervolaemia and haemodilution — is used to prevent and treat vasospasm. Statins and magnesium are considered.
Current recommendation	AHA/ASA 2023: **prophylactic hypervolaemia and haemodynamic augmentation are harmful**. Maintain euvolaemia; induce hypertension only for symptomatic delayed cerebral ischaemia. **Routine statins and IV magnesium are not recommended.**
Exam approach	Write the classical account, then add: "Triple-H therapy has been abandoned; the AHA/ASA 2023 guideline recommends euvolaemia, with induced hypertension reserved for established DCI."

Examiner's Tip — Verbatim Mark-Earning Lines

- "**A normal CT does not exclude subarachnoid haemorrhage** — do an LP after 12 hours and look for xanthochromia."
- "**Nimodipine improves outcome without abolishing angiographic vasospasm** — it is neuroprotective, not simply a vasodilator."
- "Rebleeding kills early; **vasospasm kills between days 4 and 14**."
- **Skeleton:** Definition/aneurysm → Thunderclap headache → Hunt-Hess/WFNS/Fisher → CT then LP then angiography → Coiling + nimodipine → Complications → AHA/ASA 2023.

Question 10. Treatment of Symptomatic and Asymptomatic Carotid Disease in the Elderly

7 MARKS

Answer

Textbook Core – 6 Points

1. **Definitions. Symptomatic carotid stenosis** = an ipsilateral stroke, TIA or amaurosis fugax **within the preceding 6 months**. **Asymptomatic** = stenosis detected on imaging or from a bruit, with no such event. Severity is quantified by the **NASCET method** on Doppler ultrasound, CT angiography or MR angiography, with a second modality used to confirm before intervention.
2. **Best medical therapy — for every patient, symptomatic or not. High-intensity statin** (atorvastatin 40–80 mg or rosuvastatin 20–40 mg; LDL target <70 mg/dL, and <55 mg/dL in very-high-risk patients), **antiplatelet therapy** (aspirin 75–150 mg or clopidogrel 75 mg, with a short course of dual therapy after TIA or minor stroke), **blood pressure <130/80 mmHg**, glycaemic control, smoking cessation, exercise and weight management.
3. **Symptomatic disease — revascularisation. Carotid endarterectomy (CEA) is clearly beneficial for 70–99% stenosis** — NASCET showed an absolute risk reduction of about 16% at 2 years (**NNT approximately 6**). Benefit for **50–69% stenosis is moderate** and greatest in **men, patients over 75, and hemispheric rather than retinal events**. There is **no benefit, and possible harm, below 50%**; near-occlusion and total occlusion are not revascularised.
4. **Timing and quality standards.** Revascularise **within 2 weeks of the index event** — benefit falls sharply thereafter, and delaying "to let things settle" is wrong. The procedure is only worthwhile if the unit's **perioperative stroke or death rate is below 6% for symptomatic and below 3% for asymptomatic disease**.
5. **Endarterectomy versus stenting in older adults. CEA is preferred in the elderly.** The CREST trial showed **significantly higher periprocedural stroke with stenting, particularly above the age of 70**, because of aortic arch atheroma and vessel tortuosity, while CEA carried a modestly higher risk of myocardial infarction. **Stenting is reserved for a hostile neck** (previous surgery or radiotherapy), surgically inaccessible high lesions, restenosis, or severe cardiorespiratory disease precluding anaesthesia.
6. **Asymptomatic disease — the geriatric decision.** The classical trials (ACAS, ACST-1) showed only about **1% absolute benefit per year**, and **only if life expectancy exceeds 5 years and the operative risk is under 3%**; that margin has narrowed further as medical therapy has improved. In a frail older patient with limited life expectancy, dementia or high operative risk, **best medical therapy alone is the correct answer** — the decision must follow a **comprehensive geriatric assessment, not the stenosis percentage alone**.

Latest Update – 1 Point

7. **CREST-2 (*NEJM*, 21 November 2025) — a paradigm shift in asymptomatic carotid stenosis.** Two parallel randomised, observer-blinded trials in **2,485 patients with asymptomatic stenosis ≥70%**, all receiving protocol-driven intensive medical therapy. **Stenting plus intensive medical therapy reduced the 4-year primary outcome (2.8% vs 6.0%, p=0.02), whereas endarterectomy showed no significant benefit over intensive medical therapy alone (3.7% vs 5.3%, p=0.24)**. Rates of disabling stroke were low in every group. Taken with SPACE-2 and ECST-2, accompanying editorials concluded there is **no longer a routine role for carotid endarterectomy in asymptomatic stenosis**, and advised starting intensive medical therapy immediately and deferring revascularisation until symptoms develop. **CREST-2 does not alter the strong indication for CEA in symptomatic 70–99% stenosis.**

Current Practice Update

Item	Position
Textbook	Carotid endarterectomy is offered for asymptomatic stenosis ≥60–70% when life expectancy exceeds 5 years and surgical risk is <3% (ACAS, ACST-1). Stenting is inferior in the elderly.
Current recommendation	**CREST-2 (2025):** against modern intensive medical therapy, **CEA adds no significant benefit in asymptomatic disease**; stenting gave a small absolute benefit. Intensive medical therapy first, and defer revascularisation until symptoms occur. **Symptomatic 70–99% stenosis is unchanged — CEA within 2 weeks.**
Exam approach	Answer symptomatic and asymptomatic disease separately, then close: "CREST-2 (NEJM 2025) has largely removed the routine role of endarterectomy in asymptomatic stenosis; intensive medical therapy is now the default."

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Symptomatic 70–99% stenosis: endarterectomy within 2 weeks, NNT about 6.**"
- "**Asymptomatic stenosis is a medical, not a surgical, disease** in the modern era."
- "**CREST: stenting carries a higher periprocedural stroke risk in patients over 70** — endarterectomy is preferred in the elderly."
- "The decision in an older patient depends on **life expectancy and frailty, not on the stenosis figure**."

Question 11. Subdural Haematoma in the Elderly 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and pathogenesis.** A collection of blood in the **subdural space** caused by tearing of the **bridging cortical veins**. **Cerebral atrophy in old age stretches these veins and widens the subdural space**, so a trivial or entirely unremembered head injury is sufficient. Classified as **acute (<3 days, hyperdense), subacute (3 days–3 weeks, isodense) and chronic (>3 weeks, hypodense)**.
2. **Risk factors.** Age over 65, brain atrophy, **recurrent falls**, alcohol excess, **anticoagulants and antiplatelet drugs**, previous subdural haematoma, epilepsy, coagulopathy, chronic liver disease, haemodialysis, and **CSF over-drainage after shunting**.
3. **Clinical presentation — "the great imitator". Fluctuating consciousness**, headache, gradual cognitive decline mimicking dementia, personality change, gait disturbance and falls, hemiparesis, dysphasia, or simply **delirium and unexplained functional decline**. A history of trauma is **absent in up to half of cases**, so a high index of suspicion is essential.
4. **Diagnosis. Non-contrast CT head** is the first-line investigation. Beware the **isodense subacute phase and bilateral collections**, where midline shift may be absent — look instead for **effaced sulci, compressed ventricles and loss of grey-white differentiation**. MRI is more sensitive when CT is equivocal. Check INR, coagulation profile and platelet count.
5. **Management. Reverse anticoagulation urgently** — vitamin K with **4-factor prothrombin complex concentrate** for warfarin, **idarucizumab** for dabigatran, and andexanet alfa or PCC for factor Xa inhibitors. Surgery: **burr-hole drainage with a subdural drain** for symptomatic chronic SDH (the drain reduces recurrence), and **craniotomy** for acute or organised clot. Small, asymptomatic collections may be managed conservatively with serial imaging.
6. **Complications and prognosis. Recurrence in 10–30%**; seizures, infection, tension pneumocephalus, venous thromboembolism and prolonged rehabilitation. Outcome depends more on the **GCS at presentation and premorbid frailty** than on the size of the clot. Restarting anticoagulation must be individualised — usually about **4 weeks**, earlier if there is a mechanical valve.

Latest Update – 1 Point

7. **Middle meningeal artery embolisation (MMAE).** Three randomised trials published together in the *New England Journal of Medicine* on **20 November 2024** — **EMBOLISE (n=400), STEM (n=310) and MAGIC-MT (n=722)** — showed that adjunctive MMAE **significantly reduces recurrence or progression of chronic subdural haematoma requiring reoperation**, without increasing disability. MMAE devascularises the inflammatory neomembranes that drive re-bleeding, and is now an established adjunct to surgery — **especially valuable in older, anticoagulated, high-surgical-risk patients**.

Current Practice Update

Item	Position
Textbook	Chronic SDH is managed by burr-hole drainage or craniotomy; recurrence in 10–30% is accepted and re-operated.
Current recommendation	Add **middle meningeal artery embolisation** as an adjunct to surgery (or as stand-alone treatment in selected non-surgical patients) to reduce recurrence — three RCTs, NEJM 2024.
Exam approach	After writing the surgical options, add: "Since the EMBOLISE, STEM and MAGIC-MT trials (NEJM 2024), MMAE is an evidence-based adjunct that reduces recurrence."

Examiner's Tip — Verbatim Mark-Earning Lines

- "Chronic subdural haematoma is a **reversible cause of dementia and delirium** in the elderly — CT the fluctuating patient."
- "**Absence of a history of head injury does not exclude the diagnosis.**"
- "Bilateral isodense collections may show **no midline shift** — look for effaced sulci and compressed ventricles."
- **Skeleton:** Bridging veins + atrophy → Risk factors → The great imitator → CT pitfalls → Reversal + burr hole → Recurrence/prognosis → MMAE trials.

Question 12. Post-Stroke Depression and Post-Stroke Pain 7 MARKS

Answer

Textbook Core – 6 Points

1. **Post-stroke depression (PSD) — definition and burden.** Depressive disorder occurring after stroke, affecting about **one-third of survivors** and peaking at **3–6 months**. Predictors are stroke severity, physical disability, aphasia, cognitive impairment, previous depression, female sex and social isolation. PSD independently causes **poorer functional recovery, reduced participation in rehabilitation and increased mortality**.
2. **Recognition of PSD.** Detection is difficult because of aphasia, apathy, emotionalism and anosognosia. Distinguish PSD from **apathy** (loss of motivation without sadness), **pseudobulbar affect / emotionalism** (pathological crying or laughing) and normal adjustment reaction. Screen with **PHQ-9, Geriatric Depression Scale or HADS**, and the Aphasic Depression Rating Scale in aphasic patients — at admission, at discharge and at follow-up.
3. **Management of PSD. SSRIs are first line** — escitalopram, sertraline or citalopram; **avoid tricyclics** because of anticholinergic burden, falls and arrhythmia. Watch for **hyponatraemia/SIADH, gastrointestinal bleeding (especially with antiplatelets), falls and fractures, and QT prolongation with citalopram**. Non-drug measures: structured psychosocial support, CBT or problem-solving therapy, early mobilisation, exercise, and treatment of pain and insomnia. Continue treatment at least 6 months after remission.
4. **Central post-stroke pain (Dejerine–Roussy thalamic pain).** Neuropathic pain in the body region corresponding to the lesion, typically after **thalamic or lateral medullary** strokes, appearing weeks to months later. It is **burning, aching or lancinating, with allodynia, hyperalgesia and dysaesthesia**, worsened by cold, touch and emotion. Treatment: **amitriptyline** (with caution in the elderly), **pregabalin or gabapentin**, lamotrigine or duloxetine. **Simple analgesics and opioids are largely ineffective.**
5. **Hemiplegic shoulder pain and other nociceptive post-stroke pain.** Caused by **glenohumeral subluxation, rotator cuff injury, adhesive capsulitis and spasticity**. **Prevention is by correct positioning, arm support with a lap tray or sling, and never pulling on the flaccid arm during transfers.** Treat with physiotherapy, analgesia, intra-articular steroid injection, and **botulinum toxin** for spasticity-related pain. Also consider shoulder–hand syndrome (complex regional pain syndrome) and post-stroke headache.
6. **Geriatric principles.** Mood and pain interact — **untreated pain worsens mood, sleep and rehabilitation outcome, and untreated depression amplifies pain**. Assess pain in aphasic or cognitively impaired patients with observational tools (**PAINAD, Abbey Pain Scale**). Apply “start low, go slow”, review anticholinergic burden and drug interactions, and remember that **multidisciplinary rehabilitation with early mobilisation is the single most effective intervention for both problems**.

Latest Update – 1 Point

7. **VA/DoD Clinical Practice Guideline for Stroke Rehabilitation, 2024 update.** It now **recommends against the routine use of antidepressants for the prevention of post-stroke depression** — a change from “neither for nor against” in 2019 to “weak against”. This follows the FOCUS, AFFINITY and EFFECTS trials and their **individual-patient-data meta-analysis (*Int J Stroke* 2024)**, which showed that fluoxetine 20 mg daily for 6 months **did not improve functional recovery** and **increased seizures, falls with injury and bone fractures**, although it did reduce the frequency of depression. The message is: **treat established post-stroke depression, but do not prescribe antidepressants prophylactically.**

Current Practice Update

Item	Position
Textbook	Early SSRIs after stroke may prevent depression and enhance motor recovery (based on FLAME and earlier small trials).
Current recommendation	Routine prophylactic antidepressants are **not** recommended; fluoxetine does not aid functional recovery and increases fractures, falls and seizures. Treat only established depression.
Exam approach	State: “SSRIs remain first-line *treatment* for post-stroke depression, but the 2024 VA/DoD guideline advises against their use for *prevention*.”

Examiner’s Tip — Verbatim Mark-Earning Lines

- “Post-stroke depression affects **about one-third of survivors** and independently worsens functional outcome and mortality.”
- “Central post-stroke pain responds to **antidepressants and anticonvulsants, not to analgesics**.”
- “**Never pull on the hemiplegic arm** — shoulder pain in stroke is largely preventable.”
- **Skeleton:** PSD burden/predictors → Recognition and screening → SSRI treatment and cautions → Central post-stroke pain → Hemiplegic shoulder → Geriatric principles → VA/DoD 2024.

Question 13. Normal Pressure Hydrocephalus 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** NPH is a syndrome of **gait disturbance, cognitive impairment and urinary incontinence** (Hakim–Adams triad) with **ventriculomegaly** but a **normal CSF opening pressure**. It is **idiopathic** in most older people, or **secondary** to subarachnoid haemorrhage, head injury, meningitis or infarction.
2. **Gait disturbance** is the earliest and most important feature. It is **magnetic or "glue-footed"** with reduced stride length, reduced step height, broad base and poor balance. Unlike Parkinson's disease, it does **not respond to external cues or to levodopa**.
3. **Cognitive impairment** is **frontal-subcortical** — inattention, slowed psychomotor speed, impaired recall more than recognition, and visuospatial dysfunction. Memory and orientation are relatively preserved, which separates it from Alzheimer's disease.
4. **Urinary dysfunction** begins as frequency and urgency and progresses to urge incontinence and then total incontinence as frontal control is lost. Mechanisms are a **small bladder capacity (mean 200 mL)** and a **hyperactive detrusor**. Faecal incontinence occurs late.
5. **Diagnosis.** CT/MRI shows ventricular enlargement out of proportion to atrophy (**Evans index >0.3**, DESH pattern). Patient selection is crucial: a positive **CSF tap test**, **external lumbar drainage** or raised **CSF outflow resistance** predicts shunt response. **Age is not a prognostic factor.**
6. **Treatment. Ventriculoperitoneal shunting** is standard care and succeeds in about **80%** of well-selected patients — gait improves in 81–86%, bladder control in 70%, cognition in only 40–44%. Serious adverse event risk is **11%**: shunt infection (a neurosurgical emergency), subdural effusion or haematoma, obstruction, over-drainage and hearing loss.

Latest Update – 1 Point

7. **PENS trial (NEJM 2025)** — the first **double-blind, placebo-controlled** trial of shunting in iNPH (n=99; open valve 110 mmH_2O vs placebo setting >400 mmH_2O). At 3 months, shunting significantly improved **gait velocity and Tinetti gait-and-balance score**, but showed **no significant benefit in cognition (MoCA) or incontinence**. This confirms that **gait is the shunt-responsive domain** and that response to temporary CSF drainage should drive patient selection.

Current Practice Update

Item	Position
Textbook	Shunting improves gait *and* urinary incontinence in most patients; cognition less consistently.
Current recommendation	Placebo-controlled evidence (PENS 2025) confirms benefit for **gait and balance only** at 3 months; cognition and continence were not significantly improved.
Exam approach	Quote the classical 80% success figure, then add that PENS 2025 has now placed shunting on randomised evidence with gait as the primary responsive domain.

Examiner's Tip — Verbatim Mark-Earning Lines

- "NPH is the only potentially **reversible cause of dementia** presenting with the triad of gait apraxia, cognitive slowing and urinary incontinence."
- "**Wet, wacky and wobbly** — but the wobble comes first and the wobble responds best."
- "NPH gait does not respond to visual cues or levodopa; Parkinsonian gait does."
- **Skeleton:** Definition/triad → Gait → Cognition → Bladder → Imaging + tap test → VP shunt and complications → PENS 2025.

Question 14. Progressive Supranuclear Palsy and Corticobasal Degeneration 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** Both are **Parkinson-plus (atypical parkinsonian) syndromes** and are **4-repeat tauopathies**. Both are frequently misdiagnosed as Parkinson's disease, and both show a **poor or absent response to levodopa**, which is the single most useful clinical discriminator.
2. **PSP — clinical features. Early postural instability with repeated backward falls** within the first year, **vertical supranuclear gaze palsy** (inability to look voluntarily downward, impaired saccades, eyelid-opening apraxia), **axial rigidity greater than limb rigidity**, retrocollis, and a startled or astonished facies. **Tremor is infrequent.**
3. **PSP — course and investigations.** Personality change, subcortical dementia and swallowing difficulty develop as the disease progresses. MRI shows **midbrain atrophy** — the normally concave upper midbrain becomes convex (**hummingbird sign**). Ocular electrophysiology demonstrates impaired saccades.
4. **CBD — clinical features.** A strikingly **asymmetrical akinetic-rigid syndrome** with limb **dystonia, myoclonus, cortical sensory loss, ideomotor apraxia** and the **alien (foreign) hand phenomenon**. MRI shows asymmetrical fronto-parietal atrophy contralateral to the affected limb.
5. **Differentiation from other causes of parkinsonism in old age.** Lewy body dementia — dementia within a year of parkinsonism, hallucinations, neuroleptic sensitivity. Multiple system atrophy — early severe dysautonomia with cerebellar or pyramidal signs. Vascular parkinsonism — lower-body predominance, multilacunar state, pseudobulbar palsy, stepwise worsening. NPH — magnetic gait with ventriculomegaly.
6. **Management is symptomatic; no disease-modifying therapy exists.** Trial levodopa (response usually poor or transient); amantadine may help. **Botulinum toxin** for limb dystonia, blepharospasm and sialorrhoea. Priorities are **falls prevention**, physiotherapy, weighted walkers, prism glasses, speech and swallow therapy, PEG feeding for aspiration, and **early advance care planning**. Avoid antipsychotics. Median survival is about **6–8 years**; death is usually from aspiration pneumonia.

Latest Update – 1 Point

7. **Tau-directed therapy has reached phase 3 in PSP (2024–2026).** Two agents have advanced to phase 3 — **NIO752**, an intrathecal **antisense oligonucleotide against the tau gene MAPT**, and **LM11A-31**, a p75 neurotrophin-receptor modulator. The NIH-funded **PSP Platform Trial** (UCSF, from 2025) is testing LM11A-31, the anti-tau vaccine AADvac1 and AZP2006 concurrently, and **tau-PET (^{18}F-PI-2620)** plus fluid biomarkers are being validated for early diagnosis. **No disease-modifying drug is yet approved** — management remains supportive.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Falls first, tremor never, levodopa fails** — think PSP."
- "**Asymmetry, apraxia and the alien hand** — think corticobasal degeneration."
- "PSP: **axial rigidity with vertical supranuclear gaze palsy and midbrain atrophy (hummingbird sign)**."
- **Skeleton:** Both tauopathies, levodopa-unresponsive → PSP features → PSP imaging → CBD features → Differential table → Symptomatic management → Tau trials.

Question 15. Motor Neuron Disease — Presentation, Evaluation and Treatment 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and classification.** Progressive degeneration of **upper and lower motor neurons**. Variants: **amyotrophic lateral sclerosis** (commonest, UMN + LMN), **progressive bulbar palsy**, **progressive muscular atrophy** (pure LMN) and **primary lateral sclerosis** (pure UMN). About 90% are sporadic; familial forms involve **C9orf72, SOD1, TARDBP (TDP-43) and FUS**. The neuropathological hallmark of most cases is cytoplasmic **TDP-43 inclusions**.
2. **Presentation.** Painless, progressive, **asymmetrical weakness with wasting, fasciculations and cramps**, with **brisk reflexes in a wasted limb** (the mixed UMN–LMN signature). **Bulbar onset** — dysarthria, dysphagia, tongue wasting and fasciculation, nasal regurgitation — is commoner in older adults and carries a worse prognosis. There is **no sensory loss and no sphincter or extraocular involvement**.
3. **Cognitive and behavioural change** occurs in up to half of patients; **10–15% develop frank frontotemporal dementia** (ALS–FTSD revised criteria). The **ECAS** is the validated screen for motor-impaired patients. The frontotemporal syndrome is associated with **poor survival** and heavy caregiver burden.
4. **Evaluation.** Diagnosis is clinical plus electrophysiological, using the **El Escorial / revised Awaji criteria**. **EMG** shows active and chronic denervation in at least three of four regions (bulbar, cervical, thoracic, lumbosacral). MRI brain and whole spine excludes structural mimics; **CSF and serum neurofilament** serve as diagnostic and prognostic biomarkers.
5. **Exclude the treatable mimics** — a key examination point, since **many MND-mimic disorders are eminently treatable**: cervical spondylotic myelopathy, **multifocal motor neuropathy with conduction block**, myasthenia gravis, inclusion body myositis, Kennedy's disease, thyrotoxicosis and vitamin B12 deficiency.
6. **Treatment. Riluzole** (anti-glutamatergic, acts on Na^+/K^+ currents) is the only established oral disease-modifying drug — it prolongs survival by a median of about **3 months** and raised one-year survival from 49% to 58%; monitor liver enzymes. **Non-invasive ventilation prolongs survival and quality of life**; **PEG feeding** is offered for dysphagia and weight loss. Symptom control: glycopyrrolate/amitriptyline or botulinum toxin for sialorrhoea, baclofen for spasticity, quinine for cramps. **Multidisciplinary clinic care independently improves survival**, and early palliative care with advance directives is essential.

Latest Update – 1 Point

7. **Tofersen — the first gene-targeted therapy in ALS.** Tofersen is an **intrathecal antisense oligonucleotide** that reduces SOD1 protein synthesis, approved for **SOD1-mutation ALS** (about 2% of cases) under accelerated approval based on reduction of plasma neurofilament light chain. Long-term VALOR and open-label extension data (**JAMA Neurology 2026**) showed slowed functional decline and prolonged survival with **early initiation**. The **EAN 2024 ALS guideline** accordingly recommends **genetic testing for all patients with ALS**, alongside riluzole, early NIV and multidisciplinary care.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Mixed upper and lower motor neuron signs in the same limb, with no sensory loss**, is MND until proved otherwise."
- "Riluzole and non-invasive ventilation are the only two interventions that prolong survival."
- "Always exclude the treatable mimics — especially **cervical myelopathy and multifocal motor neuropathy**."
- **Skeleton:** Definition/variants → Presentation → Cognitive overlap → EMG/El Escorial → Mimics → Riluzole/NIV/PEG/MDT → Tofersen + EAN 2024.

Question 16. Restless Legs Syndrome 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and diagnostic criteria (IRLSSG — all five essential; mnemonic URGE).** (i) **Urge to move the legs**, usually with unpleasant crawling or creeping sensations; (ii) begins or worsens at **Rest**; (iii) partially or completely **Relieved by movement**; (iv) worse in the **Evening or night**; (v) not solely explained by another condition (leg cramps, positional discomfort, neuropathy, akathisia, arthritis).
2. **Classification and mechanism. Primary** — idiopathic, often familial (BTBD9, MEIS1), earlier onset. **Secondary** — **iron deficiency, chronic kidney disease and dialysis, diabetes and peripheral neuropathy, Parkinson's disease, rheumatoid arthritis** and pregnancy. The core pathophysiology is **brain iron deficiency with dopaminergic dysfunction**.
3. **Aggravating drugs — a high-yield geriatric point. Antihistamines** (including sedating antiemetics), **metoclopramide and prochlorperazine**, antipsychotics, **SSRIs, SNRIs, mirtazapine and tricyclics**, and lithium; plus **caffeine, alcohol and nicotine**. **Always review the drug chart before starting new treatment.**
4. **Consequences in the elderly.** Sleep-onset insomnia and non-restorative sleep, daytime fatigue, depression, and **nocturnal wandering with falls and confusion**. It is commonly misdiagnosed as anxiety, akathisia, nocturnal cramps or agitation in dementia, and it worsens the burden of coexisting cardiovascular disease.
5. **Investigations.** The diagnosis is **clinical**. Measure **serum ferritin and transferrin saturation** (morning, fasting sample), renal function, blood glucose and TSH. **Periodic limb movements of sleep** accompany RLS in about 80% of patients; polysomnography is needed only if the diagnosis is uncertain or obstructive sleep apnoea is suspected.
6. **Treatment.** Treat the cause and **withdraw offending drugs**. Non-pharmacological: sleep hygiene, moderate regular exercise, leg massage, avoidance of caffeine, alcohol and nicotine. **Iron replacement** if iron stores are low. Drugs: **alpha-2-delta ligands — gabapentin, gabapentin enacarbil, pregabalin** (sedation, dizziness, ataxia, ankle oedema; reduce dose in renal impairment); **dopamine agonists** (pramipexole, ropinirole) which cause **augmentation, rebound and impulse-control disorders**; and low-dose opioids for refractory disease.

Latest Update – 1 Point

7. **AASM Clinical Practice Guideline, J Clin Sleep Med 2025 — a paradigm shift. Dopamine agonists are no longer recommended as first-line therapy** because long-term harm from **augmentation** outweighs short-term benefit. **Alpha-2-delta ligands (gabapentin, gabapentin enacarbil, pregabalin) and iron therapy (oral ferrous sulfate or intravenous iron) are now first line**, targeting **serum ferritin >100 ng/mL and transferrin saturation >20%**. Extended-release oxycodone/opioids and **bilateral high-frequency peroneal nerve stimulation** are conditionally recommended additional options.

Current Practice Update

Item	Position
Textbook	Dopamine agonists (pramipexole, ropinirole) are first-line drug therapy for moderate-to-severe RLS; iron replacement only if ferritin is frankly low.
Current recommendation	AASM 2025: alpha-2-delta ligands and iron are first line; dopamine agonists are demoted because of augmentation in 50–70% of long-term users. Ferritin target is **>100 ng/mL**, not merely "normal".
Exam approach	Write the classical treatment ladder, then state: "The AASM 2025 guideline has replaced dopamine agonists with alpha-2-delta ligands and iron as first-line therapy because of augmentation."

Examiner's Tip — Verbatim Mark-Earning Lines

- "RLS is a **clinical diagnosis based on the five IRLSSG criteria** — urge, rest, relief, evening, and exclusion of mimics."
- "**Augmentation** — earlier onset, greater intensity and spread to the arms — is the defining long-term complication of dopamine agonists."
- "In an older patient with RLS, the **drug chart is the first investigation**."
- **Skeleton:** URGE criteria → Primary vs secondary → Drug triggers → Geriatric consequences → Ferritin/TSAT → Treatment ladder → AASM 2025.

Question 17. Benign Paroxysmal Positional Vertigo — Diagnosis and Epley Manoeuvre

7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and mechanism.** BPPV is the **commonest cause of recurrent vertigo in older adults** — brief episodic vertigo provoked by a change in head position relative to gravity, caused by **displaced otoconia from the utricular macula entering a semicircular canal**. **Canalolithiasis** (free-floating debris) is commoner than **cupulolithiasis** (debris adherent to the cupula). The **posterior canal is involved in 85–90%**, the horizontal canal in 5–15%, and the anterior canal rarely.
2. **Clinical features.** Sudden spinning vertigo lasting **less than one minute**, triggered by turning over in bed, lying down, sitting up, bending forward or looking up ("top-shelf vertigo"), with nausea and residual unsteadiness between attacks. **There is no hearing loss, tinnitus or neurological deficit.** In older people it more often presents as **falls, unsteadiness and fear of falling** than as classical rotatory vertigo.
3. **Diagnosis — the Dix–Hallpike manoeuvre** (posterior canal). The patient sits upright, the head is rotated **45° towards the ear being tested**, and the patient is laid rapidly supine with the head extended **20–30° below the horizontal**. A positive test shows, after a **latency of 1–5 seconds**, **up-beating torsional (geotropic) nystagmus lasting less than 60 seconds**, which **reverses on sitting up** and **fatigues on repetition**. The **supine roll (Pagnini–McClure) test** diagnoses horizontal-canal BPPV.
4. **Red flags for central positional vertigo.** Nystagmus with **no latency, no fatigability**, that is **purely vertical or down-beating** or direction-changing; disproportionate truncal ataxia; other brainstem or cerebellar signs; new headache; or vertigo unresponsive to repositioning. **These require urgent MRI to exclude posterior fossa stroke or tumour.**
5. **The Epley (canalith repositioning) manoeuvre — four steps, each held about 30 seconds or until nystagmus stops.** (a) Dix–Hallpike position with the head turned 45° to the affected side; (b) rotate the head **90° to the opposite side** while supine; (c) roll the patient onto that shoulder and turn the head a further 90° so the **nose points to the floor**; (d) sit the patient upright with the chin tucked. **Success is 80–90% in one or two sessions.** Alternatives: **Semont liberatory manoeuvre**; **Lempert barbecue roll** for horizontal canal; **Brandt–Daroff exercises** for home use.
6. **Precautions and drug therapy in the elderly.** Before repositioning, check for **cervical spondylosis, severe kyphosis, vertebrobasilar insufficiency, carotid disease, retinal detachment or recent neck surgery**, and modify with a shoulder roll and reduced neck extension. **Vestibular sedatives — betahistine, prochlorperazine, cinnarizine — do not treat BPPV**; they delay central compensation and cause drowsiness, falls and drug-induced parkinsonism, so they should not be continued beyond 24–48 hours. Recurrence occurs in 15–50%.

Latest Update – 1 Point

7. **Vitamin D supplementation reduces BPPV recurrence.** Randomised and meta-analytic evidence from 2024–2025 — including a randomised controlled trial in older adults (*Otolaryngol Head Neck Surg* 2025), a placebo-controlled RCT (*Laryngoscope Investig Otolaryngol* 2024) and a systematic review (*Nutrients* 2024) — shows that **vitamin D supplementation significantly lowers the recurrence rate of BPPV in patients with serum 25(OH)D below 20 ng/mL**. Recognised recurrence risk factors are advanced age, female sex, hypertension, diabetes, hyperlipidaemia, **osteoporosis and vitamin D deficiency**. Therefore **check vitamin D in recurrent BPPV and replace it** — a cheap intervention that simultaneously addresses osteoporosis and falls risk.

Current Practice Update

Item	Position
Textbook	BPPV is treated with repositioning manoeuvres; recurrence is accepted and simply re-treated.
Current recommendation	Add **secondary prevention**: measure serum 25(OH)D in recurrent BPPV and supplement if deficient, which significantly reduces recurrence.
Exam approach	Close the answer with: "In recurrent BPPV, correct vitamin D deficiency — recent RCT evidence shows a significant reduction in recurrence."

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Latency, torsional up-beating nystagmus, duration <60 seconds, reversal and fatigability** — the five features of a positive Dix–Hallpike test."
- "BPPV is **diagnosed by a manoeuvre and treated by a manoeuvre, not by a drug**."
- "In the elderly, BPPV presents as **falls, not as vertigo**."
- **Skeleton:** Definition/canalolithiasis → Symptoms → Dix–Hallpike → Central red flags → Epley in four steps → Precautions and why vestibular sedatives are wrong → Vitamin D.

Question 18. Myasthenia Gravis in the Older Adult 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** An **antibody-mediated disorder of the neuromuscular junction** in which antibodies against the postsynaptic **nicotinic acetylcholine receptor (AChR, ~85%)**, or against **MuSK** or **LRP4**, impair neuromuscular transmission. **Late-onset MG (>50 years) is increasing in incidence**, shows a male predominance, is usually AChR-antibody positive, and is associated with thymoma in 10–15%.
2. **Clinical features. Fatigable, fluctuating weakness** that worsens through the day and with repeated use. Ocular onset in more than half — **ptosis and diplopia**; bulbar features (dysphagia, nasal regurgitation, nasal speech, jaw fatigue on chewing); proximal limb and neck-extensor weakness ("dropped head"); and respiratory muscle weakness. **Reflexes are normal and there is no sensory loss.**
3. **Geriatric pitfall — MG is under-diagnosed in the elderly.** It is mislabelled as stroke, bulbar palsy, motor neuron disease, myopathy or simply "old age". Older patients present more often with **bulbar and respiratory involvement**. **Consider MG in any older person with ptosis, diplopia, dysphagia or unexplained fatigable weakness**, because it is a highly treatable disease.
4. **Diagnosis. Serum AChR antibody** first; test **MuSK antibody** if negative. **Repetitive nerve stimulation** shows a decremental response of more than 10%; **single-fibre EMG** is the most sensitive test. The **ice-pack test** and the sleep test are safe bedside tests for ptosis and are preferred to edrophonium in older people. **CT/MRI thorax is mandatory to exclude thymoma.** Screen for associated thyroid and other autoimmune disease.
5. **Treatment. Pyridostigmine** for symptomatic relief (cholinergic side effects — colic, diarrhoea, bradycardia, secretions). **Prednisolone** is the mainstay immunotherapy — **start low and increase slowly** to avoid the early steroid-induced deterioration. Steroid-sparing agents: **azathioprine** (check TPMT), mycophenolate, methotrexate. **Thymectomy** is indicated for thymoma at any age; in non-thymomatous MG it is usually reserved for generalised, AChR-positive patients under 50–60 years, and benefit appears only after 6–12 months.
6. **Crisis, precautions and prognosis. Myasthenic crisis** (weakness needing ventilation) is precipitated by infection, surgery or too-rapid reduction of immunotherapy; the rarer **cholinergic crisis** follows excessive anticholinesterase — if in doubt, ventilate and stop the anticholinesterase. Treat with **IVIG or plasma exchange** plus aggressive treatment of infection. **Avoid aminoglycosides, macrolides, fluoroquinolones, beta-blockers, magnesium, procainamide and iodinated contrast.** Prognosis is good — **more than 90% achieve remission or substantial improvement**.

Latest Update – 1 Point

7. **Targeted biologics have transformed refractory generalised MG.** Two classes are now available: **complement C5 inhibitors** — eculizumab, ravulizumab and zilucoplan (meningococcal vaccination is mandatory) — and **FcRn blockers** that accelerate IgG catabolism — efgartigimod, rozanolixizumab, and **nipocalimab, approved by the FDA in April 2025 and the European Commission in December 2025** for AChR- or MuSK-antibody-positive generalised MG. These give rapid, steroid-sparing IgG reduction (about 70% fall) and are particularly relevant in older adults who tolerate long-term corticosteroids poorly.

Current Practice Update

Item	Position
Textbook	Refractory MG is managed with escalating conventional immunosuppression, IVIG/plasma exchange, and eculizumab as the sole biologic option.
Current recommendation	A defined biologic pathway now exists: C5 inhibitors (eculizumab, ravulizumab, zilucoplan) and FcRn blockers (efgartigimod, rozanolixizumab, nipocalimab) for AChR/MuSK-positive generalised MG.
Exam approach	Finish the treatment paragraph with one line: "In refractory disease, complement C5 inhibitors and FcRn blockers are now established steroid-sparing options."

Examiner's Tip — Verbatim Mark-Earning Lines

- "MG incidence **rises with age but is under-diagnosed in the elderly**, where it is mistaken for stroke or MND."
- "**Fatigable ptosis, diplopia and bulbar weakness with normal reflexes and no sensory loss.**"
- "Single-fibre EMG is the most sensitive test; the **ice-pack test** is the safest bedside test in old age."
- **Skeleton:** Definition/antibodies → Fatigability → Geriatric under-diagnosis → Diagnosis + thymoma imaging → Pyridostigmine/steroids/thymectomy → Crisis and drugs to avoid → Biologics.

Question 19. Subacute Combined Degeneration of the Cord 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** A **vitamin B12 (cobalamin) deficiency myelopathy** causing symmetrical demyelination of the **dorsal (posterior) columns and lateral corticospinal tracts**, chiefly in the cervical and upper thoracic cord. It is frequently combined with a **peripheral neuropathy**, and occasionally with optic atrophy and dementia — hence "combined".
2. **Causes in the elderly. Pernicious anaemia** (autoimmune atrophic gastritis), **food-cobalamin malabsorption from atrophic gastritis** (the commonest cause in old age), gastrectomy or bariatric surgery, ileal resection or Crohn's disease, **chronic metformin and proton-pump inhibitor use**, strict vegetarian or vegan diet (highly relevant in India), tropical sprue and nitrous oxide exposure.
3. **Clinical features.** Symmetrical distal **paraesthesiae and numbness** first, then **sensory ataxia with a positive Romberg sign** and loss of vibration and joint-position sense. The classical examination finding is a **spastic paraparesis with extensor plantar responses but absent ankle jerks** — pyramidal signs coexisting with an abolished reflex because of the accompanying neuropathy. Lhermitte's phenomenon may occur.
4. **Systemic and neuropsychiatric features.** Macrocytic **megaloblastic anaemia**, glossitis, angular stomatitis and skin hyperpigmentation; and "**megaloblastic madness**" — irritability, depression, psychosis and reversible dementia. Critically, **neurological disease can occur with a normal haemoglobin and a normal MCV**, so a normal blood count never excludes SCD.
5. **Investigations.** Serum B12 (low or low-normal). If equivocal, measure **serum methylmalonic acid and plasma homocysteine** — **both are raised in B12 deficiency; only homocysteine is raised in folate deficiency**. Anti-intrinsic-factor and anti-parietal-cell antibodies for pernicious anaemia. Peripheral smear shows macro-ovalocytes and **hypersegmented neutrophils**. MRI spine shows T2 hyperintensity of the posterior columns — the **"inverted V" or rabbit-ear sign**.
6. **Treatment.** Parenteral **hydroxocobalamin or cyanocobalamin 1000 µg intramuscularly on alternate days for 1–2 weeks, then weekly until no further improvement, then monthly for life**. **Never give folic acid alone** — it corrects the anaemia but precipitates or worsens the myelopathy. Monitor **serum potassium** during early recovery (hypokalaemia) and co-supplement iron. Recovery takes months and is **often incomplete if treatment is delayed beyond 6–12 months**, so treat on suspicion.

Latest Update – 1 Point

7. **NICE guideline NG239 — Vitamin B12 deficiency in over-16s (March 2024).** Where serum B12 is equivocal, use **plasma homocysteine or serum methylmalonic acid as the initial confirmatory test**; take all diagnostic samples **before** starting replacement. Crucially, **do not delay B12 replacement while awaiting results** in anyone with suspected megaloblastic anaemia or neurological symptoms, **especially subacute combined degeneration of the cord**. Lifelong intramuscular replacement is advised after total gastrectomy, complete terminal ileal resection, or when autoimmune gastritis is the cause.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Extensor plantars with absent ankle jerks** — the classical sign of subacute combined degeneration."
- "Neurological damage may occur **before, and without,** any haematological abnormality."
- "**Never give folate before B12** — it precipitates or worsens the myelopathy."
- "MMA *and* homocysteine raised = B12; homocysteine alone = folate."
- **Skeleton:** Definition/tracts → Causes → Signs (Romberg, extensor plantars, absent ankle jerks) → Haematological/psychiatric → MMA + MRI → B12 regimen and the folate trap → NICE NG239.

Question 20. Peripheral Neuropathy in Older Adults — Aetiology, Clinical Features, Investigations and Management 15 MARKS • ASKED ×2

Answer

Textbook Core – 10 Points

1. **Definition and classification.** A disorder of peripheral nerves, classified by **fibre type** (sensory, motor, autonomic, mixed), **distribution** (mononeuropathy, mononeuritis multiplex, polyneuropathy, radiculopathy, plexopathy), **pathology** (axonal versus demyelinating) and **time course** (acute, subacute, chronic). Prevalence rises steeply with age — around **8–15% of people over 55**.

2. **Aetiology — mnemonic DANG THERAPIST. D**iabetes; **A**lcohol; **N**utritional (B12, thiamine, folate, vitamin E, copper); **G**uillain–Barré syndrome; **T**oxins and drugs; **H**ereditary (Charcot–Marie–Tooth); **E**ndocrine and metabolic (hypothyroidism, uraemia, hepatic failure); **R**heumatological and vasculitic; **A**myloidosis; **P**araneoplastic; **I**nfections (leprosy, HIV, hepatitis C, Lyme); **S**arcoidosis; **T**umour and paraproteinaemia (MGUS, myeloma, POEMS). **In India, diabetes and leprosy lead; in older adults, diabetes, B12 deficiency, alcohol, CKD, hypothyroidism, paraproteinaemia and drugs account for most cases.**

3. **Drug causes to review at every consultation. Isoniazid** (always co-prescribe pyridoxine), **metronidazole, nitrofurantoin, phenytoin, amiodarone, colchicine, statins, linezolid, dapsone, chloroquine, thalidomide**, and chemotherapy — **vincristine, cisplatin, oxaliplatin, taxanes and bortezomib**. Also **excess pyridoxine** (a sensory ataxic neuropathy), and **long-term metformin and proton-pump inhibitors** acting through B12 depletion.

4. **Clinical features. Sensory** — symmetrical distal **"glove-and-stocking" numbness, tingling, burning and allodynia**, ascending over months to years. **Motor** — distal weakness and wasting, foot drop with a high-stepping gait, and **loss of ankle jerks**. **Autonomic** — postural hypotension, gastroparesis, diarrhoea or constipation, bladder dysfunction, erectile dysfunction and impaired sweating. **Trophic** — dry skin, foot deformity, **painless ulcers and Charcot joints**.

5. **Why neuropathy matters in geriatrics.** It is a major cause of **falls, fractures, gait instability and loss of independence**; sensory loss leads to **unnoticed foot ulceration and amputation**; autonomic involvement causes syncope; and neuropathic pain destroys sleep and mood. Importantly, **ankle jerks and vibration sense decline physiologically with age**, so isolated minor abnormalities must be interpreted with care and not over-investigated.

6. **A structured approach — five questions.** (i) **What is the distribution?** symmetrical distal, multifocal (mononeuritis multiplex) or proximal. (ii) **Which fibres are involved?** small fibre — pain and autonomic features with normal reflexes; large fibre — loss of vibration, proprioception and reflexes. (iii) **Axonal or demyelinating?** (iv) **What is the time course?** acute onset suggests **Guillain–Barré syndrome, vasculitis, porphyria or a toxin**. (v) **Is there a systemic clue?** weight loss, rash, organomegaly or a monoclonal band.

7. **First-line investigations. Fasting and postprandial glucose and HbA1c**, with an **oral glucose tolerance test if these are normal** — impaired glucose tolerance alone causes small-fibre neuropathy; **serum vitamin B12, with methylmalonic acid or homocysteine if borderline**; TSH; renal and liver function; full blood count and **ESR**; and **serum protein electrophoresis with immunofixation**, which is essential in older adults to detect a paraproteinaemia. Add HIV and hepatitis serology where indicated.

8. **Second-line and specialist investigations. Nerve conduction studies and EMG** confirm the diagnosis, localise the lesion and separate axonal from demyelinating pathology. A **demyelinating** pattern should prompt consideration of **CIDP — a treatable cause** (CSF shows albuminocytological dissociation). Further directed tests: ANA, ANCA and cryoglobulins; anti-MAG and anti-ganglioside antibodies; skeletal survey; **skin biopsy for intraepidermal nerve fibre density** in small-fibre neuropathy; genetic testing; and **sural nerve biopsy**, reserved for suspected vasculitis, amyloidosis or leprosy.

9. **Treatment of the cause. Glycaemic control** — tight but not aggressive, since hypoglycaemia is more dangerous than modest hyperglycaemia in the elderly; **vitamin B12 replacement**; alcohol cessation with thiamine; thyroid replacement; dialysis or transplantation for uraemia; **multidrug therapy for leprosy**; **immunotherapy (corticosteroids, IVIG, plasma exchange) for CIDP, Guillain–Barré syndrome and vasculitic neuropathy**; treatment of an underlying malignancy or paraproteinaemia; and **withdrawal of the offending drug**.

10. **Symptomatic and supportive management.** For **neuropathic pain**, first-line agents are **amitriptyline or nortriptyline, duloxetine, gabapentin and pregabalin**; second line, topical **capsaicin 8% patch** and **lidocaine 5% plaster**; **avoid opioids for chronic neuropathic pain**. Non-pharmacological care is equally important: **daily foot inspection, protective well-fitting footwear, podiatry and callus/ulcer care**, physiotherapy with strength and balance training, an **ankle-foot orthosis for foot drop**, walking aids, home hazard assessment and structured **falls prevention**, vitamin D and bone protection, and treatment of coexisting depression and insomnia.

Latest Updates – 2 Points

11. **AAN practice guideline on painful diabetic neuropathy (2022, reaffirmed through 2023–2025).** Four drug classes have **comparable efficacy** — **tricyclic antidepressants, SNRIs (duloxetine, venlafaxine), gabapentinoids, and sodium-channel blockers (lamotrigine, lacosamide, oxcarbazepine)** — so the choice should be driven by comorbidity and adverse-effect profile rather than a fixed ladder. Critically, **opioids, including tramadol, should NOT be offered for painful diabetic neuropathy**. In older adults this pushes

practice towards **duloxetine or a reduced-dose gabapentinoid** and away from amitriptyline, which appears on the **AGS Beers Criteria 2023**.

12. **Two shifts in disease-modifying thinking (2023–2025).** (i) **Glycaemic control alone is insufficient in type 2 diabetes** — the components of the metabolic syndrome (obesity, hypertriglyceridaemia, hypertension) are now recognised as **independent, modifiable drivers of neuropathy**, so lifestyle and lipid management form part of neuropathy treatment, not merely of cardiovascular prevention. (ii) **Hereditary transthyretin amyloid polyneuropathy (ATTRv)** — which classically presents in older adults as a **painful small-fibre and autonomic neuropathy with cardiomyopathy and carpal tunnel syndrome** — is now treatable with **RNA-silencing agents (patisiran, vutrisiran) and the stabiliser tafamidis**. Amyloid neuropathy must therefore be actively sought rather than assumed untreatable.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Distribution, fibre type, axonal or demyelinating, time course, systemic clue** — the five questions that structure any neuropathy answer."
- "**A demyelinating pattern on nerve conduction studies means look for CIDP — a treatable neuropathy.**"
- "Serum protein electrophoresis is **mandatory in any older patient with an unexplained neuropathy**."
- "In the elderly, the outcome that matters is not the pain score but **the ulcer, the fall and the fracture**."

Converting this to the 7-Mark Version (6 textbook points + 1 update)

- This question has been asked at both 15 and 7 marks. For **7 marks**, compress the ten points into six: **(1)** definition and classification (fibre type, distribution, axonal vs demyelinating, course; 8–15% over 55); **(2)** common causes — diabetes commonest, then B12 deficiency, alcohol, CKD, hypothyroidism, paraproteinaemia, drugs, and **leprosy in India**; **(3)** clinical features — glove-and-stocking sensory loss, absent ankle jerks, autonomic features, painless ulcers and Charcot joints; **(4)** geriatric significance — falls, fractures, ulceration and amputation, plus the physiological age-related loss of ankle jerks and vibration sense; **(5)** investigations — glucose/HbA1c with OGTT, B12 with MMA, TSH, renal and liver function, ESR, **serum protein electrophoresis (mandatory)**, then NCS/EMG with CIDP considered if demyelinating; **(6)** management — treat the cause, neuropathic-pain agents avoiding opioids, and foot care with falls prevention.
- Retain the same latest update (AAN painful diabetic neuropathy guideline plus ATTRv amyloid neuropathy) as the seventh point.
- Points **6 (the five-question approach)** and **8 (second-line and specialist investigations)** are the ones to sacrifice first — they carry the least marks per line in a short answer.

Question 21. Temporal Arteritis and its Neurological Complications 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** Temporal (giant cell) arteritis is a **granulomatous large- and medium-vessel vasculitis** affecting the extracranial branches of the carotid artery, occurring **almost exclusively above the age of 50** (peak 70–80 years). It is the commonest primary systemic vasculitis of old age and is closely associated with **polymyalgia rheumatica**.
2. **Clinical features. New-onset persistent unilateral temporal headache**, **scalp tenderness** (pain on combing the hair or resting the head on a pillow), **jaw claudication — the most specific symptom**, and a **tender, thickened, nodular or pulseless temporal artery**. Constitutional features include **fever of unknown origin**, weight loss, anorexia and malaise, with pain and morning stiffness of the shoulder and hip girdles if PMR coexists.
3. **Neuro-ophthalmic complications — the core of the answer. Sudden, painless, irreversible monocular visual loss** from **anterior ischaemic optic neuropathy** (commonest), central retinal artery occlusion, or preceding **amaurosis fugax**; and **diplopia** from ocular motor palsy. If untreated, **the second eye is affected in 25–50% within 1–2 weeks**. Other neurological complications: **transient ischaemic attack and stroke (characteristically vertebrobasilar)**, scalp and tongue necrosis, occipital neuropathy, and rarely mononeuritis multiplex, depression and dementia.
4. **Investigations. Raised ESR** (often >50 mm/h, classically >75 mm/h) and **CRP**, with normochromic normocytic anaemia, thrombocytosis and raised alkaline phosphatase. **Temporal artery biopsy** of a 1–2 cm segment, ideally within 1–2 weeks of starting steroids, shows granulomatous panarteritis with giant cells and fragmentation of the internal elastic lamina — but **skip lesions cause false negatives, so a negative biopsy does not exclude the diagnosis**. Colour Doppler ultrasound shows the **"halo sign"**; PET-CT or MR angiography detects large-vessel and aortic involvement.
5. **Treatment — a medical emergency. Start corticosteroids immediately on clinical suspicion; never wait for the biopsy.** Without visual symptoms: **prednisolone 40–60 mg/day**. With visual loss or amaurosis: **intravenous methylprednisolone 500–1000 mg/day for 3 days**, then oral prednisolone. Add **low-dose aspirin** and a proton-pump inhibitor. Taper slowly over **12–24 months**, guided by symptoms and CRP rather than ESR alone.
6. **Steroid toxicity and steroid-sparing therapy.** Older patients are highly vulnerable to **osteoporosis and fragility fracture, diabetes, hypertension, cataract, glaucoma, infection, proximal myopathy and delirium**. Start **calcium, vitamin D and a bisphosphonate from day one**, and monitor blood pressure and glucose. **Tocilizumab** (IL-6 receptor blocker) is the established steroid-sparing agent for relapsing or refractory disease; methotrexate is an alternative. A late complication is **thoracic aortic aneurysm**, requiring long-term surveillance.

Latest Update – 1 Point

7. **Upadacitinib — the first oral JAK inhibitor approved for giant cell arteritis** (European Commission April 2025; FDA 29 April 2025), at **15 mg once daily with a corticosteroid taper**. Approval was based on the phase 3 **SELECT-GCA trial (n=428)**, in which **46.4% achieved sustained remission from week 12 to week 52 with a 26-week steroid taper, versus 29.0% on placebo with a 52-week taper (p=0.002)**; sustained complete remission was 37.1% versus 16.1%. It provides an oral steroid-sparing alternative to tocilizumab — **particularly relevant in older patients at high risk of glucocorticoid toxicity**.

Current Practice Update

Item	Position
Textbook	High-dose corticosteroids are the treatment; methotrexate is used as a steroid-sparing agent in relapsing disease.
Current recommendation	Steroids remain the emergency treatment, but **tocilizumab** and now **upadacitinib 15 mg once daily** are approved steroid-sparing agents that increase sustained remission and shorten steroid exposure.
Exam approach	Write "steroids immediately, biopsy later", then close with: "Tocilizumab and upadacitinib (SELECT-GCA, 2025) are now the recognised steroid-sparing options."

Examiner's Tip — Verbatim Mark-Earning Lines

- "Giant cell arteritis is a **medical emergency — steroids first, biopsy afterwards**; delay costs the sight of the second eye."
- "**Jaw claudication is the most specific symptom; visual loss is the most feared complication.**"
- "A **negative temporal artery biopsy does not exclude GCA** because of skip lesions."
- "Any older patient with new headache and an **ESR above 50 mm/h** has GCA until proved otherwise."
- **Skeleton:** Definition/PMR link → Headache, scalp tenderness, jaw claudication → Visual and neurological complications → ESR/CRP/biopsy/halo sign → Steroid regimen → Steroid toxicity and bone protection → Upadacitinib.

Question 22. Trigeminal Neuralgia 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition and classification (ICHD-3).** Recurrent **unilateral, brief, electric shock-like facial pain**, abrupt in onset and termination, confined to one or more divisions of the trigeminal nerve and triggered by innocuous stimuli. Three categories: **classical** (neurovascular compression, usually by the superior cerebellar artery) in 80–90%; **secondary** (multiple sclerosis, cerebellopontine angle tumour, skull-base lesion, stroke); and **idiopathic**.
2. **Clinical features.** Paroxysms lasting from a fraction of a second to **2 minutes**, affecting **V2 and V3 most often and V1 least**, right more than left, and **almost never crossing the midline**. **Trigger zones around the nasolabial fold and chin** — pain provoked by chewing, talking, brushing the teeth, shaving, washing the face or cold wind. There is a refractory period after an attack, and remissions may last months. Some patients have superimposed continuous background pain ("type 2").
3. **Red flags suggesting secondary trigeminal neuralgia.** Age below 40, **bilateral pain**, **sensory loss in the trigeminal territory, an absent corneal reflex**, other cranial nerve palsies, deafness, and **failure to respond to carbamazepine**. These mandate detailed imaging.
4. **Investigations and differential diagnosis. MRI brain with dedicated high-resolution trigeminal sequences** (3D FIESTA/CISS with MR angiography) should be performed in all patients to demonstrate neurovascular compression and exclude a secondary cause; **trigeminal reflex (blink reflex) testing** is an alternative where MRI is unavailable. Differentials: **dental pain, temporomandibular joint dysfunction, giant cell arteritis, post-herpetic neuralgia, cluster headache, glossopharyngeal neuralgia and sinusitis**.
5. **Medical management. Carbamazepine is the drug of choice (Level A evidence)** — start **100 mg twice daily and titrate to 600–1200 mg/day**; **70–80% obtain initial relief**. **Oxcarbazepine (Level B)** is equally effective with better tolerability and fewer drug interactions. Second-line and add-on agents: **lamotrigine, baclofen, gabapentin and pregabalin**. Note that **more than half of initial responders lose their response over 5–10 years**.
6. **Geriatric precautions and surgical options.** Carbamazepine in older adults causes **hyponatraemia (SIADH), ataxia, falls, drowsiness, diplopia, bradycardia and AV block, leucopenia and aplastic anaemia, and rash including Stevens–Johnson syndrome** (test **HLA-B*1502** in Asian patients); it is a potent CYP450 inducer, reducing levels of warfarin, DOACs, statins and other antiepileptics — **monitor sodium, full blood count and liver function**. For drug-refractory pain: **microvascular decompression** gives the best long-term relief (about 70–80% pain-free at 10 years) but needs posterior fossa craniotomy, so frailty must be assessed; **percutaneous procedures** (radiofrequency thermocoagulation, balloon compression, glycerol rhizolysis) and **Gamma Knife stereotactic radiosurgery** are preferred in frail or high-risk elderly patients.

Latest Update – 1 Point

7. **Botulinum toxin type A for refractory trigeminal neuralgia.** An updated systematic review with meta-analysis (*Clin J Pain*, 2024) and a comprehensive review of 35 studies (*Toxins*, 2024) confirm that **subcutaneous or submucosal BTX-A significantly reduces VAS pain scores and attack frequency in patients refractory to, or intolerant of, medical and surgical therapy**, with **transient facial asymmetry** as the main adverse effect. A 2026 umbrella review positions BTX-A as an **adjunctive third-line option for focal peripheral neuropathic pain** — a useful, low-risk choice in frail older patients unsuitable for craniotomy.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Carbamazepine is both the drug of choice and a diagnostic test** — failure to respond suggests a secondary cause."
- "**Sensory loss or bilateral pain means it is not classical trigeminal neuralgia** — image the patient."
- "In the elderly, the commonest reason to abandon carbamazepine is **hyponatraemia and ataxia with falls**."
- "Microvascular decompression gives the best durability; **percutaneous and radiosurgical options suit the frail**."
- **Skeleton:** ICHD-3 definition and three types → Paroxysms and triggers → Red flags → MRI and differentials → Carbamazepine/oxcarbazepine → Geriatric toxicity and surgery → Botulinum toxin A.

Question 23. Cluster Headache 7 MARKS • ASKED ×2

Answer

Textbook Core – 6 Points

1. **Definition (ICHD-3).** A **trigeminal autonomic cephalalgia** characterised by attacks of severe, strictly **unilateral orbital, supraorbital and/or temporal pain lasting 15–180 minutes**, occurring from once every other day to **eight times a day**, accompanied by ipsilateral cranial autonomic features and/or a sense of restlessness or agitation.
2. **Classification and epidemiology.** Male predominance of about 3:1; onset usually between 20 and 40 years, but it can begin in old age. **Episodic cluster headache (80–90%)** — bouts lasting weeks to months separated by remissions of at least 3 months; **chronic cluster headache (10–20%)** — no remission, or remissions shorter than 3 months within a year.
3. **Clinical features.** The pain is **excruciating, boring or stabbing and retro-orbital**, with striking **circadian and circannual periodicity** — attacks wake the patient 1–2 hours after falling asleep and recur at the same time each day ("alarm-clock headache"), with bouts recurring in the same season each year. Ipsilateral autonomic features: **lacrimation, conjunctival injection, nasal congestion or rhinorrhoea, eyelid oedema, forehead and facial sweating, and miosis with ptosis (partial Horner's syndrome)**. Unlike migraine, the patient is **restless and pacing, not lying still**. Alcohol reliably triggers attacks during a bout but not during remission.
4. **Differential diagnosis.** Migraine; other trigeminal autonomic cephalalgias — **paroxysmal hemicrania** (shorter, more frequent, and **absolutely responsive to indomethacin**) and **SUNCT/SUNA** (attacks lasting seconds); trigeminal neuralgia; acute angle-closure glaucoma; **giant cell arteritis**; sinusitis; and **secondary cluster-like headache** from a pituitary lesion or carotid dissection. **A first presentation over the age of 50, or any abnormal neurological sign, mandates MRI brain with pituitary views.**
5. **Acute (abortive) treatment. High-flow 100% oxygen at 12–15 L/min through a non-rebreathing mask for 15–20 minutes** aborts about 70% of attacks (avoid in severe COPD with carbon dioxide retention), and **subcutaneous sumatriptan 6 mg** (fastest acting; maximum two doses in 24 hours) or **intranasal zolmitriptan 5 mg**. Oral triptans and simple analgesics act far too slowly to be useful. **Triptans are contraindicated in uncontrolled hypertension, ischaemic heart disease, previous stroke and peripheral vascular disease** — a major limitation in older patients, for whom **oxygen becomes the treatment of choice**.
6. **Preventive treatment. Verapamil is first line** (240–960 mg/day in divided doses); an **ECG must be done before starting and before every dose increase** because of bradycardia and heart block — critically important in older patients. Give **transitional therapy** with a short tapering course of oral prednisolone, or a **greater occipital nerve block**, to break the bout while verapamil is titrated. Alternatives: lithium (especially for the chronic form), topiramate and melatonin. For refractory chronic disease: occipital nerve stimulation or sphenopalatine ganglion stimulation.

Latest Update – 1 Point

7. **Galcanezumab — the only agent specifically approved for the prevention of episodic cluster headache.** A monoclonal antibody against **calcitonin gene-related peptide (CGRP)**, given as **300 mg subcutaneously at the onset of a bout and repeated monthly through the cluster period**; it **failed to show benefit in chronic cluster headache**. **Real-world data and an expert consensus published in 2024** (*Journal of Headache and Pain*) support its use as an add-on when verapamil is ineffective, not tolerated, or contraindicated — precisely the situation in older patients with conduction disease, in whom high-dose verapamil is hazardous. This sits alongside the American Headache Society 2024 position statement establishing CGRP-targeting therapies as a first-line option in migraine prevention.

Converting this to the 6-Mark Version (5 textbook points + 1 update)

- **Omit point 4 (differential diagnosis)** and retain points 1, 2, 3, 5 and 6 plus the latest update — giving exactly **6 points**.
- Carry the one indispensable line from point 4 into point 1 instead: "**A first presentation after the age of 50 requires MRI brain with pituitary views to exclude secondary cluster-like headache.**"
- Keep the numbers — **15–180 minutes, up to 8 attacks a day, oxygen 12–15 L/min, sumatriptan 6 mg SC, verapamil 240–960 mg** — whichever version is asked.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**The migraine patient lies still in a dark room; the cluster patient paces the floor.**"
- "**Oxygen and subcutaneous sumatriptan abort; verapamil prevents; steroids bridge.**"
- "**ECG before every verapamil dose increase** — the doses used in cluster headache are far higher than cardiological doses."
- "An **indomethacin trial** should be given to exclude paroxysmal hemicrania before labelling any TAC as cluster headache."

Question 24. Tension Headache 6 MARKS

Answer

Textbook Core – 5 Points

1. **Definition (ICHD-3).** The commonest primary headache disorder. Pain is **bilateral, pressing or tightening (non-pulsating), of mild to moderate intensity, lasting 30 minutes to 7 days, and NOT aggravated by routine physical activity**. There is **no nausea or vomiting**; photophobia *or* phonophobia may be present, but not both. The classic description is a **"tight band" around the head**.
2. **Classification. Infrequent episodic** (fewer than 1 day per month), **frequent episodic** (1–14 days per month) and **chronic** (15 or more days per month for over 3 months). Chronic tension-type headache very commonly coexists with, and is perpetuated by, **medication-overuse headache**.
3. **Contributing factors.** Psychological stress, **anxiety and depression**, sleep disturbance and obstructive sleep apnoea, **pericranial muscle tenderness (the hallmark physical sign)**, cervical spondylosis and poor posture, eye strain, and caffeine or analgesic overuse. In older adults the dominant contributors are **cervical degenerative disease, depression and analgesic overuse**.
4. **Red flags mandating investigation in an older patient. Any new or changed headache after the age of 50**, thunderclap onset, progressive or positional headache, systemic features (fever, weight loss), **scalp tenderness or jaw claudication — check ESR and CRP for giant cell arteritis**, focal neurological signs, papilloedema, immunosuppression or malignancy, and **headache in an anticoagulated patient (subdural haematoma)**. In their absence, no imaging is required.
5. **Management. Non-pharmacological measures come first**: reassurance, a headache diary, sleep hygiene, regular meals, stress management, relaxation training, cognitive behavioural therapy, physiotherapy, posture correction and regular exercise. **Acute** — paracetamol, or an NSAID used cautiously in the elderly because of gastrointestinal, renal and cardiovascular risk; **limit acute analgesic use to fewer than 15 days a month to prevent medication-overuse headache**; **avoid opioids and butalbital combinations entirely**. **Preventive** for frequent or chronic forms — **amitriptyline is first line** starting at 10 mg at night, but it is anticholinergic, sedating, orthostatic and arrhythmogenic in older people; nortriptyline, mirtazapine or venlafaxine are alternatives.

Latest Update – 1 Point

6. **Current guidance and evidence syntheses (2023–2025)** place **non-pharmacological therapy at the centre of tension-type headache management**, with the strongest evidence for **cognitive behavioural therapy, relaxation training and supervised exercise or physiotherapy**. This matters especially in older adults, because **amitriptyline appears on the AGS Beers Criteria 2023** as a drug to avoid in older people (anticholinergic burden, sedation, orthostatic hypotension and falls). The second key message is the active identification and **withdrawal of medication-overuse headache**, which is a common, reversible and frequently missed cause of what is labelled "chronic tension headache" in this population.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Bilateral, pressing, mild to moderate, not worsened by activity, no vomiting** — the four-part ICHD-3 definition."
- "**Any new headache after 50 is not tension headache until giant cell arteritis and a space-occupying lesion have been excluded.**"
- "**Amitriptyline is first-line prophylaxis but is on the Beers list** — use the lowest dose, or choose nortriptyline."
- "Ask about analgesic frequency — **medication-overuse headache is the commonest reversible cause of chronic daily headache**."

Question 25. Hypoxic-Ischaemic Encephalopathy — Causes, Clinical Manifestations, Diagnosis and Management 15 MARKS

Answer

Textbook Core – 10 Points

1. **Definition.** Diffuse brain injury caused by a **global reduction in oxygen delivery (hypoxia) and/or cerebral blood flow (ischaemia)**, most often after cardiac arrest. The injury is **biphasic**: **primary ischaemic injury** during the arrest, followed by **secondary reperfusion injury** after return of spontaneous circulation — and it is the secondary phase that is modifiable.
2. **Causes. Cardiac arrest is the commonest**. Others: respiratory arrest and severe hypoxaemia (COPD exacerbation, drowning, choking, strangulation, hanging), profound or prolonged shock and haemorrhage, **carbon monoxide and cyanide poisoning**, severe anaemia, status asthmaticus, anaesthetic and airway mishaps, and prolonged status epilepticus.
3. **Pathophysiology and selective vulnerability.** Energy failure → **glutamate excitotoxicity** → calcium influx → free-radical generation, mitochondrial dysfunction and apoptosis. Certain neurons are selectively vulnerable: **the hippocampal CA1 sector, cerebellar Purkinje cells, cortical layers 3, 5 and 6, and the basal ganglia**. Prolonged hypotension additionally causes **watershed (border-zone) infarction**.
4. **Clinical spectrum.** Outcomes range from full recovery through **persistent coma, vegetative state (unresponsive wakefulness syndrome), minimally conscious state, and brain death**. Milder injury leaves an **amnestic (Korsakoff-like) syndrome from hippocampal damage**, cortical blindness with denial (**Anton's syndrome**), the watershed **"man-in-a-barrel"** pattern of proximal arm weakness with preserved distal function, and post-hypoxic parkinsonism or dystonia.
5. **Post-hypoxic myoclonus.** Two distinct forms. **Acute myoclonic status** within 24 hours of arrest is a poor prognostic sign but **is no longer regarded as uniformly fatal** and must not alone justify withdrawal of treatment. **Lance–Adams syndrome** is a delayed **action myoclonus** appearing days to weeks later in a patient who has regained consciousness; it responds to clonazepam, valproate, levetiracetam or piracetam.
6. **Delayed post-hypoxic leukoencephalopathy.** An apparent recovery followed by relapse after **2–4 weeks**, with cognitive decline, parkinsonism and akinetic mutism, and diffuse white matter change on MRI — classically after **carbon monoxide poisoning**, but also after opioid overdose and prolonged hypoxia.
7. **Clinical assessment. Serial neurological examination is central**: GCS or FOUR score, **pupillary and corneal reflexes**, oculocephalic and oculovestibular responses, motor response to a standardised painful stimulus, breathing pattern, and the presence of myoclonus. **Confounders must be excluded before any conclusion is drawn** — residual sedatives (propofol, opioids, neuromuscular blockers), hypothermia, metabolic and electrolyte derangement, unrecognised seizures, and organ failure.
8. **Investigations. EEG** — malignant patterns are burst-suppression, a suppressed background and status epilepticus, whereas a **continuous reactive background is favourable**. **Somatosensory evoked potentials** — **bilaterally absent N20 responses indicate a very poor prognosis**. **Serum neuron-specific enolase (NSE)** and neurofilament light chain. **CT brain** — loss of grey–white differentiation, effaced sulci and the "pseudo-subarachnoid haemorrhage" sign. **MRI with DWI at 2–7 days is the most sensitive imaging test.**
9. **Management — prevent secondary injury.** Treat the underlying cause (coronary angiography and PCI where indicated). Maintain **MAP ≥65–80 mmHg**; **avoid both hypoxaemia and hyperoxaemia**; maintain normocapnia; keep **normoglycaemia while strictly avoiding hypoglycaemia**; **prevent fever aggressively**; treat seizures (levetiracetam or valproate) while avoiding deep prolonged sedation that will later confound prognostication; correct electrolytes; and provide standard critical-care supportive measures.
10. **Prognostication and geriatric/ethical issues.** Prognostication must be **multimodal and delayed to at least 72 hours after normothermia and after sedation has cleared**; **no single test may be used alone**. Markers of poor outcome: absent pupillary and corneal reflexes at ≥72 hours, bilaterally absent N20 SSEPs, a malignant EEG, myoclonic status, very high NSE, and diffuse injury on CT or MRI. In older adults, discuss **goals of care, advance directives and surrogate decision-making early**. Because **withdrawal of life-sustaining therapy is the commonest mode of death**, premature pessimism creates a **self-fulfilling prophecy** and must be avoided.

Latest Updates – 2 Points

11. **ERC/ESICM 2025 Post-Resuscitation Care Guidelines (adopting the 2024 ILCOR recommendations).** The goal is now **active fever prevention with a target temperature at or below 37.5 °C**, rather than routine therapeutic hypothermia at 33 °C — following the TTM2 and HYPERION trials. Temperature control should be maintained for **36–72 hours** using devices with feedback-controlled temperature monitoring, and **routine prehospital cooling with cold intravenous fluid is not recommended**. Neuroprognostication should be **multimodal and delayed**, with a **repeat brain CT at 72–96 hours** if the first scan showed no hypoxic-ischaemic change, and MRI ideally at **2–7 days**.

12. **AHA Post-Cardiac Arrest Care Guideline (*Circulation*, 2025).** The neuroprognostication section has been expanded to include **predictors of favourable outcome**, not only of poor outcome, and **serum neurofilament light chain (NfL) has been added alongside NSE as a biomarker** — when used **in combination with other prognostic tests**, high NSE or NfL within 72 hours supports a prediction of unfavourable neurological outcome. Temperature control should be maintained for **at least 36 hours** in patients who remain unresponsive to verbal commands after ROSC, and CT plus echocardiography are reasonable after ROSC to establish the cause of arrest and detect resuscitation complications.

Current Practice Update

Item	Position
Textbook	Therapeutic hypothermia to 32–34 °C for 12–24 hours is recommended for comatose survivors of cardiac arrest.
Current recommendation	ERC/ESICM 2025 and AHA 2025: the aim is **fever prevention with a target ≤37.5 °C**, maintained 36–72 hours; deep hypothermia at 33 °C is no longer routine (TTM2, HYPERION). **No prehospital cold-fluid cooling.**
Exam approach	State: "Targeted temperature management has shifted from therapeutic hypothermia at 33 °C to **active fever prevention at or below 37.5 °C** for 36–72 hours."

Examiner's Tip — Verbatim Mark-Earning Lines

- "The injury is **biphasic — primary ischaemia and secondary reperfusion injury**; only the second is modifiable."
- "**Hippocampal CA1, cerebellar Purkinje cells and the basal ganglia** are the selectively vulnerable regions."
- "**Prognostication must be multimodal and never before 72 hours** off sedation and at normothermia."
- "Withdrawal of life-sustaining therapy is the commonest mode of death — **beware the self-fulfilling prophecy**."
- **Skeleton:** Definition/biphasic → Causes → Selective vulnerability → Clinical spectrum → Myoclonus → Delayed leukoencephalopathy → Examination → EEG/SSEP/NSE/MRI → Prevent secondary injury → Prognostication + ethics → 2 updates.

Question 26. Post-Acute Management of Traumatic Brain Injury 7 MARKS

Answer

Textbook Core – 6 Points

1. **Scope and geriatric context.** The post-acute phase begins once the patient is medically and neurosurgically stable, and covers **rehabilitation, prevention of secondary complications, and management of long-term sequelae**. In older adults, TBI is usually caused by **falls**, is frequently complicated by antiplatelet or anticoagulant use, and carries **higher mortality and worse functional outcome for any given injury severity**.
2. **Structured multidisciplinary rehabilitation.** Refer early to a team comprising a rehabilitation physician, physiotherapist, occupational therapist, speech and language therapist, **neuropsychologist**, dietitian and social worker. Set goal-directed, individualised targets and measure progress with **GOS-E, FIM or Barthel Index** and formal cognitive testing. **Early, intensive, specialist inpatient rehabilitation produces better functional outcomes** than generic ward care.
3. **Cognitive rehabilitation.** Measure the **duration of post-traumatic amnesia** (a key prognostic marker) with the GOAT or Westmead scale. Deficits in **attention, memory, processing speed and executive function** are managed with compensatory strategies, memory aids and diaries, environmental structuring and errorless learning. Formal screening is essential in older adults, in whom these deficits are easily mislabelled as dementia.
4. **Neurobehavioural and psychiatric sequelae.** Agitation and aggression, apathy, disinhibition, emotional lability, **depression (up to 50%)**, anxiety, post-traumatic stress, disturbed sleep–wake cycle and fatigue. Manage behaviour **non-pharmacologically first** — routine, environmental modification, identifying triggers. Use SSRIs for depression; **avoid typical antipsychotics and benzodiazepines, which impair motor and cognitive recovery**. Methylphenidate or amantadine may improve arousal and attention in selected patients.
5. **Medical complications to anticipate. Post-traumatic seizures** — prophylaxis only for the first 7 days; longer-term antiseizure medication (preferably levetiracetam) only if seizures actually occur. **Post-traumatic hydrocephalus** — suspect when recovery plateaus or reverses; image and consider shunting. Also spasticity and contractures, heterotopic ossification, **dysphagia and aspiration**, malnutrition, bladder and bowel dysfunction, pressure ulcers, venous thromboembolism, chronic pain and post-traumatic headache, **post-traumatic hypopituitarism** (growth hormone, thyroid, cortisol and gonadal deficiency — commonly missed), and **chronic subdural haematoma appearing weeks later**.
6. **Long-term, social and geriatric issues.** Assess **mental capacity** and undertake advance care planning; give explicit **driving cessation and return-to-activity advice**; train and support caregivers and arrange respite. Prevent the next injury — **falls prevention: home hazard assessment, vision and hearing, footwear, gait aids, medication review, bone health** — and decide with the cardiology team on reintroducing antithrombotics. Counsel that TBI raises the long-term risk of **dementia, epilepsy and Parkinson's disease**, and arrange disability certification and welfare access under NPHCE and the **Rights of Persons with Disabilities Act 2016**.

Latest Update – 1 Point

7. **Contemporary guidance and evidence syntheses (2023–2025)** add three practice points. (i) **Blood biomarkers GFAP and UCH-L1** (available as an FDA-cleared point-of-care assay) assist triage and prognostication after TBI and reduce unnecessary CT scanning — useful in frail patients in whom repeated imaging is undesirable. (ii) **Systematic screening for post-traumatic hypopituitarism at 3–6 and 12 months** is recommended, since untreated hypopituitarism mimics and worsens post-concussive fatigue, apathy and cognitive slowing. (iii) **Age alone must not be used to withhold or limit rehabilitation** — outcome data consistently show that older TBI survivors achieve meaningful functional gains when given adequate rehabilitation intensity.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Seizure prophylaxis is for 7 days only** — it prevents early, not late, post-traumatic seizures."
- "When recovery **plateaus or reverses, think post-traumatic hydrocephalus or chronic subdural haematoma**."
- "**Screen for hypopituitarism** — it is the most commonly missed treatable cause of poor recovery after TBI."
- "**Avoid antipsychotics and benzodiazepines**; they slow motor and cognitive recovery."

Question 27. Wernicke Encephalopathy 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** An **acute, potentially reversible neuropsychiatric emergency caused by thiamine (vitamin B1) deficiency**, with lesions in the **mammillary bodies, medial thalami, periaqueductal grey matter and the floor of the fourth ventricle**. If untreated, it progresses to the largely irreversible **Korsakoff syndrome** — together, the Wernicke–Korsakoff syndrome.
2. **Causes in the elderly.** Chronic alcoholism is the classical cause, but in older adults the **non-alcoholic causes dominate and are routinely overlooked**: malnutrition and starvation, prolonged vomiting, **bariatric surgery and gastrectomy**, malignancy and chemotherapy, dialysis, **prolonged parenteral nutrition without vitamin supplementation**, severe systemic illness and sepsis, thyrotoxicosis, and critically — **administration of glucose to a thiamine-deplete patient**.
3. **Classical triad. Confusion, ophthalmoplegia and ataxia**. However, the **complete triad is present in only about 10–16% of cases**, so waiting for it is a diagnostic error. Ocular signs: **horizontal nystagmus, bilateral lateral rectus palsy and conjugate gaze palsy**; the ataxia is predominantly truncal and affects gait. In older adults it frequently presents simply as **unexplained delirium, apathy or "failure to thrive"**.
4. **Caine criteria — the practical bedside rule.** Diagnose (and treat) if **any TWO** of the following four are present: (i) **dietary deficiency**, (ii) **oculomotor abnormality**, (iii) **cerebellar dysfunction**, (iv) **either altered mental state or mild memory impairment**. This substantially increases sensitivity over the classical triad and should be quoted in the answer.
5. **Investigations. The diagnosis is clinical and treatment must never await results.** Serum thiamine or erythrocyte transketolase activity may be sent, but **take the sample before giving thiamine**. **MRI** (about 53% sensitive, 93% specific) shows **symmetrical T2/FLAIR hyperintensity of the medial thalami, periaqueductal grey, mammillary bodies and tectal plate**. Also check **magnesium** (an essential cofactor — thiamine will not work while hypomagnesaemia persists), sodium, glucose, liver function and vitamin B12.
6. **Treatment. Give parenteral thiamine BEFORE any glucose load**. Standard regimen: **thiamine 500 mg IV three times daily for 2–3 days**, then **250 mg IV/IM daily for 3–5 days**, then oral 100 mg daily long term. **Correct magnesium**, give the remaining B-complex vitamins, treat the underlying cause and provide nutritional rehabilitation. Ocular signs improve within hours to days and ataxia over weeks, but **confusion and memory often do not recover — about 80% of survivors develop Korsakoff syndrome** with anterograde amnesia and confabulation.

Latest Update – 1 Point

7. **Reviews and practice guidance published 2023–2025** converge on three messages. First, the **low-dose oral or 100 mg intramuscular thiamine still given in many hospitals is inadequate** for suspected Wernicke encephalopathy — **high-dose parenteral thiamine (500 mg IV three times daily) is the standard**, and prophylactic parenteral thiamine (200–300 mg daily) should be given to any at-risk patient before glucose or refeeding. Second, there is growing emphasis on **non-alcoholic Wernicke encephalopathy in older patients** — after bariatric surgery, prolonged vomiting, chemotherapy and prolonged ICU stay — which is where most missed cases now occur. Third, **magnesium must be corrected concurrently**, or thiamine replacement fails.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Never give glucose before thiamine** in a malnourished or alcoholic patient — it can precipitate Wernicke encephalopathy."
- "**The complete triad occurs in only 10–16%** — use the Caine criteria (any two of four) and treat on suspicion."
- "Wernicke encephalopathy is a **clinical diagnosis and a therapeutic emergency**; a normal MRI does not exclude it."
- "**Correct magnesium** — thiamine cannot work without it."

Question 28. CSF Findings in Pyogenic, Tuberculous, Fungal and Carcinomatous Meningitis

7 MARKS

Answer

Textbook Core – 6 Points

1. **Normal CSF and pre-requisites.** Opening pressure **8–18 cm H_2O**; clear and colourless; **0–5 lymphocytes/mm³**; protein **15–45 mg/dL**; glucose **45–80 mg/dL, or at least 60% of a simultaneous blood glucose** — **always send a paired blood sugar, or the CSF glucose cannot be interpreted**. Contraindications to lumbar puncture: raised intracranial pressure with focal signs or papilloedema, coagulopathy or anticoagulation, and local sepsis. **CT brain before LP** in any older, immunocompromised, seizing or focally abnormal patient.
2. **The comparison table — the core of the answer.** See table below.
3. **Pyogenic (bacterial) meningitis. Turbid** fluid at high pressure; **neutrophilic pleocytosis, typically 1000–5000/mm³**; protein 100–500 mg/dL; **glucose markedly reduced (<40% of blood glucose)**; **raised CSF lactate (>3.5 mmol/L)**; Gram stain positive in 60–90% before antibiotics; culture and multiplex PCR. **Partially treated meningitis** shifts towards a lymphocytic picture with a less dramatic fall in glucose, and is a common diagnostic trap.
4. **Tuberculous meningitis.** Clear or ground-glass fluid at high pressure, forming a **cobweb (spider-web) clot on standing**; **lymphocytic pleocytosis of 100–500/mm³** (neutrophils may predominate in the first few days); **protein markedly raised, 100–500 mg/dL, and may exceed 1 g/dL with spinal block (Froin's syndrome)**; **glucose low**; **adenosine deaminase raised**. AFB smear has a low yield; **Xpert MTB/RIF Ultra is the recommended rapid test**; culture takes weeks.
5. **Fungal (especially cryptococcal) meningitis.** Clear fluid, often at a **very high opening pressure requiring therapeutic drainage**; **lymphocytic pleocytosis of 20–500/mm³**, which may be minimal in the profoundly immunosuppressed; protein raised; **glucose low**; **India ink positive in about 50–70%**; and **CSF cryptococcal antigen (CrAg) is the test of choice with sensitivity above 95%**. Fungal culture confirms.
6. **Carcinomatous (neoplastic/leptomeningeal) meningitis.** Clear or xanthochromic; **mononuclear pleocytosis, usually modest (<100/mm³)**; **protein raised**; and **glucose low (hypoglycorrhachia) — making it the great mimic of tuberculous meningitis**. Diagnosis rests on **CSF cytology from repeated large-volume samples** (a single sample is only about 50% sensitive; three samples approach 90%), flow cytometry for haematological malignancy, and **contrast MRI of the whole neuraxis** showing leptomeningeal enhancement.

Table 1 — Comparative CSF Findings

Parameter	Pyogenic	Tuberculous	Fungal	Carcinomatous
Appearance	Turbid / purulent	Clear, ground-glass; **cobweb clot**	Clear	Clear or xanthochromic
Pressure	Raised	Raised	**Very high**	Normal or raised
Cell count	1000–5000/mm³	100–500/mm³	20–500/mm³	Usually <100/mm³
Cell type	**Neutrophils**	Lymphocytes	Lymphocytes	Lymphocytes + **malignant cells**
Protein	100–500 mg/dL	**100–500, may exceed 1 g/dL**	Raised	Raised
Glucose	**Markedly low**	Low	Low	**Low**
Key test	Gram stain, culture, lactate	**Xpert MTB/RIF Ultra**, ADA	**CrAg**, India ink	**Cytology ×3**, flow cytometry
Onset	Hours	Weeks	Weeks	Weeks–months

Table 2 — Contrast with Viral and Normal CSF

Parameter	Viral meningitis	Normal
Cells	10–500/mm³, lymphocytic	0–5 lymphocytes/mm³
Protein	Normal or mildly raised (<100 mg/dL)	15–45 mg/dL
Glucose	**NORMAL** — the key discriminator	45–80 mg/dL (≥60% of blood)

Latest Update – 1 Point

7. **Two diagnostic and therapeutic changes with direct Indian relevance.** (i) **WHO now recommends Xpert MTB/RIF Ultra as the initial diagnostic test on CSF for suspected tuberculous meningitis**, in preference to smear microscopy and culture, and India's **NTEP has scaled up Ultra and Truenat testing** accordingly. (ii) For cryptococcal disease, WHO guidance (2022, implemented through 2023–2025) recommends the **CrAg lateral flow assay as the preferred rapid test** and a **single high-dose liposomal amphotericin B (10 mg/kg) plus**

flucytosine and fluconazole induction regimen, based on the **AMBITION-cm** trial — markedly less toxic and more feasible than 7–14 days of conventional amphotericin in resource-limited settings.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Low CSF glucose in a lymphocytic meningitis means TB, fungus or malignancy — never a virus.**"
- "**Always send a simultaneous blood glucose**; the CSF glucose is meaningless without it."
- "**Carcinomatous meningitis is the great mimic of tuberculous meningitis** — send cytology on three large-volume samples."
- "**Partially treated pyogenic meningitis** looks lymphocytic — ask about prior antibiotics."

Question 29. Serotonin Syndrome 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** A **predictable, dose-related toxic state caused by excess serotonergic activity** at central and peripheral 5-HT receptors, chiefly **5-HT$_{2A}$**. It is **not idiosyncratic** — it follows starting or increasing a serotonergic drug, or more commonly **adding a second serotonergic agent**. Onset is rapid: **within 6–24 hours** in most cases.
2. **Causative drugs.** SSRIs, SNRIs, **tricyclics**, **MAO inhibitors — including linezolid and methylene blue**, trazodone, mirtazapine, **tramadol, fentanyl, pethidine and dextromethorphan**, triptans, ondansetron and metoclopramide, lithium, valproate, **St John's wort**, amphetamines, and enzyme inhibitors that raise SSRI levels. In geriatric practice the two classic culprits are **an SSRI plus tramadol** and **an SSRI plus linezolid**.
3. **Clinical triad.** (i) **Neuromuscular hyperactivity** — **clonus (spontaneous, inducible and ocular), hyperreflexia, tremor and rigidity, all more marked in the LOWER limbs**; (ii) **autonomic instability** — hyperthermia, tachycardia, hypertension, diaphoresis, **mydriasis**, flushing, and **diarrhoea with hyperactive bowel sounds**; (iii) **altered mental state** — agitation, anxiety, restlessness and confusion.
4. **Diagnosis — Hunter Serotonin Toxicity Criteria.** In a patient on a serotonergic agent, the diagnosis is made if **any one** of the following is present: **spontaneous clonus; inducible clonus with agitation or diaphoresis; ocular clonus with agitation or diaphoresis; tremor with hyperreflexia; or hypertonia with temperature above 38 °C plus ocular or inducible clonus** — **sensitivity 84%, specificity 97%**. There is no confirmatory laboratory test; investigations (CK, renal function, electrolytes, coagulation, ABG, ECG) are for complications and mimics.
5. **Differential diagnosis. Neuroleptic malignant syndrome** — slower onset over days, **lead-pipe rigidity greater in the upper body, bradyreflexia, normal pupils**, dopamine antagonist exposure; **anticholinergic toxicity** — **dry skin, absent bowel sounds, normal reflexes**; malignant hyperthermia (anaesthetic exposure); sympathomimetic toxicity; meningitis or encephalitis; thyroid storm; and alcohol or benzodiazepine withdrawal.
6. **Management. Stop all serotonergic drugs immediately** — this alone resolves most cases within 24 hours. Supportive care is the mainstay: IV fluids, cardiac monitoring, and **benzodiazepines (diazepam or lorazepam) for agitation, tremor and rigidity**, which also lower temperature. Use **active external cooling** for hyperthermia and **avoid antipyretics — the fever is muscular, not hypothalamic**. Control blood pressure with short-acting agents (esmolol, nitroprusside); **avoid bromocriptine, dantrolene and physical restraints**. For severe or refractory cases give **cyproheptadine, a 5-HT$_{2A}$ antagonist — 12 mg orally, then 2 mg every 2 hours**. Temperature above 41.1 °C requires intubation, sedation and **non-depolarising neuromuscular paralysis**.

Latest Update – 1 Point

7. **Prevention has become the focus, not new antidotes.** The **AGS Beers Criteria 2023** specifically flags the combination of an **SSRI or SNRI with tramadol** as a drug–drug interaction to avoid in older adults — both for serotonin toxicity and for the compounded risks of **hyponatraemia, falls and fracture**. **Linezolid**, a reversible monoamine oxidase inhibitor, now carries an explicit requirement for a formal serotonergic-drug review before prescription, an issue that arises frequently when treating MRSA or VRE infections in older inpatients already on an antidepressant. Electronic interaction alerts and structured deprescribing, rather than pharmacological rescue, are the current practice emphasis.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Clonus is to serotonin syndrome what lead-pipe rigidity is to neuroleptic malignant syndrome.**"
- "**Rapid onset, lower-limb predominance, hyperreflexia, mydriasis and diarrhoea** — serotonin syndrome."
- "**Do not give antipyretics** — the hyperthermia is generated by muscle activity, not by the hypothalamic set point."
- "The commonest cause in geriatric practice is **an SSRI plus tramadol**."

Question 30. Neuroleptic Malignant Syndrome 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** A rare, life-threatening **idiosyncratic reaction to dopamine (D_2) receptor blockade**, or to abrupt withdrawal of dopaminergic therapy, characterised by hyperthermia, rigidity, autonomic instability and altered consciousness. Onset is **subacute, over 1–3 days**, and most cases occur **within the first two weeks** of starting or increasing the drug. Mortality has fallen to about **5–10%** with early recognition.
2. **Causes. Typical antipsychotics — haloperidol is the classic culprit**; atypical antipsychotics (risperidone, olanzapine, quetiapine), often with milder rigidity; and the frequently forgotten **antiemetics — metoclopramide, prochlorperazine, promethazine and domperidone**. Also **abrupt withdrawal of levodopa or a dopamine agonist in Parkinson's disease** (the parkinsonism–hyperpyrexia syndrome). Risk factors: dehydration, agitation, high or rapidly escalated dose, parenteral or depot administration, male sex, a previous episode, and pre-existing extrapyramidal disease.
3. **Clinical tetrad.** (i) **Severe generalised "lead-pipe" rigidity** with tremor and dysphagia; (ii) **hyperthermia above 38 °C, often exceeding 40 °C**; (iii) **autonomic instability** — labile blood pressure, tachycardia, tachypnoea, profuse diaphoresis, urinary incontinence; (iv) **altered mental state** ranging from agitated confusion to stupor and coma. Crucially, **reflexes are normal or reduced and there is no clonus** — the key discriminator from serotonin syndrome.
4. **Investigations. Markedly raised creatine kinase — often above 1000 IU/L and sometimes above 10,000** — reflecting rhabdomyolysis; leucocytosis; raised LDH and transaminases; **low serum iron**; metabolic acidosis; deranged renal function with myoglobinuria; and disseminated intravascular coagulation in severe cases. Exclude mimics with CT or MRI brain, lumbar puncture, blood and urine cultures, thyroid function and toxicology. **The diagnosis remains clinical** (DSM-5 criteria).
5. **Differential diagnosis. Serotonin syndrome** (rapid onset, clonus, hyperreflexia, lower-limb predominance, diarrhoea, mydriasis); **malignant hyperthermia** (anaesthetic exposure); **malignant catatonia** (may be clinically indistinguishable); anticholinergic delirium; CNS infection; heat stroke; thyroid storm; tetanus; status epilepticus; and in older patients, **drug-induced parkinsonism complicated by an intercurrent infection**.
6. **Management. Stop the offending antipsychotic immediately — or restart the withdrawn dopaminergic drug** — and transfer to intensive care. Supportive care dominates: **aggressive intravenous fluids to prevent acute kidney injury from rhabdomyolysis**, active cooling, correction of electrolytes, VTE and aspiration prophylaxis, and **benzodiazepines (lorazepam)** for agitation and for mild cases. For moderate to severe disease: **bromocriptine 2.5–5 mg 8-hourly** (or amantadine) to restore dopaminergic tone, and **dantrolene 1–2.5 mg/kg IV** for severe rigidity and hyperthermia. **Electroconvulsive therapy** is used for refractory cases and when malignant catatonia cannot be excluded. Recovery takes 7–14 days; if an antipsychotic is later essential, **wait at least 2 weeks and restart with a low dose of a low-potency or atypical agent**.

Latest Update – 1 Point

7. **Prevention is the dominant geriatric message, reinforced by the AGS Beers Criteria 2023.** Antipsychotics should be **avoided for the behavioural and psychological symptoms of dementia** unless non-pharmacological measures have failed and the patient poses a danger to self or others, because of the **boxed warning of increased mortality and stroke**, together with falls, aspiration and NMS. Recent reviews (2023–2025) additionally emphasise that **NMS from atypical antipsychotics is increasingly common and often presents atypically in older adults — with lower fever and less prominent rigidity**. The practical corollary: **a raised creatine kinase in a rigid, confused older patient on any antipsychotic or antiemetic should trigger the diagnosis**, rather than waiting for the classical tetrad.

Table — Serotonin Syndrome versus Neuroleptic Malignant Syndrome

Feature	Serotonin syndrome	Neuroleptic malignant syndrome
Drug	Serotonergic agent (SSRI, tramadol, linezolid)	Dopamine antagonist, or dopaminergic withdrawal
Onset	**Hours (<24 h)**	**Days (1–3 days)**
Reflexes	**Hyperreflexia and clonus**	**Normal or reduced; no clonus**
Rigidity	Lower limbs > upper limbs	Generalised **"lead-pipe"**, upper body prominent
Pupils	**Mydriasis**	Normal
Bowel sounds	**Hyperactive, diarrhoea**	Normal or reduced
Resolution	Within 24 hours of stopping the drug	7–14 days
Specific drug	**Cyproheptadine**	**Bromocriptine ± dantrolene**

Question 31. Rhabdomyolysis 7 MARKS

Answer

Textbook Core – 6 Points

1. **Definition.** A syndrome of **skeletal muscle necrosis with release of intracellular contents — myoglobin, creatine kinase, potassium, phosphate and urate — into the circulation**. It is diagnosed by a **creatine kinase more than five times the upper limit of normal (usually >1000 IU/L)**, and a **CK above 5000 IU/L** marks significant risk of acute kidney injury.
2. **Causes in older adults. The "long lie" after an unwitnessed fall is the single most important cause in geriatric practice**, along with prolonged immobility and pressure necrosis. Others: **drugs — statins, especially when combined with fibrates, amiodarone, macrolides, azoles, ciclosporin or colchicine**; alcohol; antipsychotics via NMS; **infection and sepsis**; **hypokalaemia, hypophosphataemia and hyponatraemia**; hypothyroidism; diabetic ketoacidosis and hyperosmolar state; **heat stroke**; seizures and status epilepticus; trauma and crush injury; compartment syndrome; and inflammatory myopathies.
3. **Clinical features.** The classical triad of **myalgia, weakness and dark "cola-coloured" urine is present in fewer than 10%** of cases; muscles may be swollen and tender. In older patients the presentation is typically **non-specific — a fall, confusion, immobility or being "off legs"** — so the diagnosis depends on **actively checking the CK** rather than waiting for classical features. Examine for pressure sores and dependent oedema.
4. **Investigations. Serum CK** — rises within 12 hours, peaks at 24–72 hours and falls over 3–5 days. **Urine dipstick positive for blood but with NO red cells on microscopy** — this mismatch indicates myoglobinuria and is the classic examination point. Also serum and urine myoglobin; **potassium, calcium, phosphate, urate and bicarbonate**; urea and creatinine; liver enzymes (a raised AST/ALT of muscle origin); coagulation screen for DIC; **ECG for hyperkalaemia**; and a search for the underlying cause.
5. **Complications. Acute kidney injury in 10–50%** — the mechanism is renal vasoconstriction, direct myoglobin tubular toxicity and **intratubular cast obstruction**, all worsened by hypovolaemia and acidic urine. **Hyperkalaemia with life-threatening arrhythmia** is the immediate danger. There is **early hypocalcaemia** (calcium deposits in damaged muscle) followed by **late rebound hypercalcaemia** — so calcium should NOT be given unless there is symptomatic hypocalcaemia or hyperkalaemic ECG change. Also hyperphosphataemia, hyperuricaemia, metabolic acidosis, **compartment syndrome** and DIC.
6. **Management. Early, aggressive intravenous fluid resuscitation is the single most important intervention.** Start isotonic saline as soon as possible — initially **1–1.5 L/hour**, then titrated to a **urine output of 200–300 mL/hour** — while monitoring carefully for fluid overload in older patients with heart failure or chronic kidney disease. Stop the causative drug; treat hyperkalaemia; correct the precipitating cause; monitor for compartment syndrome and refer for fasciotomy if it develops; and use **renal replacement therapy** for refractory hyperkalaemia, severe acidosis, uraemia or fluid overload. **Urinary alkalinisation with bicarbonate and the use of mannitol are NOT routinely recommended** — the evidence is weak and both carry risk (hypocalcaemia, volume overload).

Latest Update – 1 Point

7. **Contemporary reviews and guidance (2023–2025)** reaffirm that **volume resuscitation alone — without bicarbonate or mannitol — is the standard of care**, and place new emphasis on **early risk stratification using the McMahon score**, which combines age, sex, initial creatinine, calcium, phosphate, bicarbonate, CK and cause to identify patients likely to need renal replacement therapy, allowing earlier escalation. The corresponding **geriatric preventive message** is equally examinable: **falls prevention, personal alarm systems and a rapid response to the "long lie"**, together with a **statin interaction review** (particularly with fibrates, macrolides, azoles and amiodarone) at every medication reconciliation.

Examiner's Tip — Verbatim Mark-Earning Lines

- "**Urine positive for blood on dipstick with no red cells on microscopy is myoglobinuria until proved otherwise.**"
- "**Fluids, fluids and more fluids** — and neither bicarbonate nor mannitol."
- "**Early hypocalcaemia, late hypercalcaemia** — do not correct the calcium unless the patient is symptomatic."
- "In geriatrics, rhabdomyolysis is the **metabolic consequence of the long lie** — check the CK in every patient found on the floor."

Appendix — Rapid Revision Grid

Consolidated from both source volumes. Where a fact appears in more than one answer it is listed once here.

A. Examinable Numbers

Topic	Number to reproduce
Epilepsy in the elderly	Incidence >100/1,00,000/yr after 65; cerebrovascular cause 30–50%; EEG sensitivity 26–38%; ~80% seizure-free on low-dose monotherapy
Complex partial seizure	Duration 30 s–3 min; post-ictal confusion 5–30 min; temporal lobectomy seizure-free in ~2/3 of selected cases
Status epilepticus	Lorazepam 0.1 mg/kg; levetiracetam 60 mg/kg; fosphenytoin 20 PE/kg; valproate 40 mg/kg
TIA	ABCD² ≥4 = high risk; stroke risk ~5% at 7 days, 10% at 90 days; DAPT 21 days; DWI lesion in up to 1/3
Lacunar stroke	Infarct <15–20 mm; ~25% of ischaemic strokes; SPS3 systolic target <130 mmHg
Subarachnoid haemorrhage	85% aneurysmal; CT sensitivity >95% within 6 h; LP after 12 h; nimodipine 60 mg 4-hourly × 21 days; vasospasm days 4–14; mortality 30–40%
Carotid disease	Symptomatic 70–99% → CEA, ARR ~16%, NNT ~6, within 2 weeks; risk thresholds <6% symptomatic, <3% asymptomatic
Hypoxic-ischaemic encephalopathy	Prognosticate at ≥72 h off sedation, normothermic; temperature target ≤37.5 °C for 36–72 h; MRI at 2–7 days
Traumatic brain injury	Seizure prophylaxis 7 days only; depression up to 50%; screen pituitary at 3–6 and 12 months
Wernicke encephalopathy	Complete triad in only 10–16%; Caine criteria = any 2 of 4; thiamine 500 mg IV tds × 2–3 days; ~80% progress to Korsakoff
Cluster headache	Attacks 15–180 min, up to 8/day; O_2 12–15 L/min effective in ~70%; sumatriptan 6 mg SC; verapamil 240–960 mg/day; galcanezumab 300 mg
Tension headache	Chronic = ≥15 days/month for >3 months; limit analgesics to <15 days/month; amitriptyline from 10 mg nocte
Peripheral neuropathy	Prevalence 8–15% over age 55
CSF	Normal: 0–5 cells, protein 15–45 mg/dL, glucose ≥60% of blood; pyogenic 1000–5000 neutrophils; TB 100–500 lymphocytes; CSF lactate >3.5 mmol/L in bacterial
Serotonin syndrome	Onset <24 h; Hunter criteria sensitivity 84%, specificity 97%; cyproheptadine 12 mg then 2 mg 2-hourly
Neuroleptic malignant syndrome	Onset 1–3 days; mortality 5–10%; CK often >1000 IU/L; bromocriptine 2.5–5 mg tds; dantrolene 1–2.5 mg/kg; wait ≥2 weeks before rechallenge
Rhabdomyolysis	CK >5× ULN (>1000 IU/L); AKI risk above 5000 IU/L; AKI in 10–50%; fluids 1–1.5 L/h, urine output 200–300 mL/h
NPH	Evans index >0.3; shunt success ~80%; gait 81–86%, bladder 70%, cognition 40–44%; serious adverse events 11%
PSP / CBD	Falls within first year; median survival 6–8 years; midbrain “hummingbird sign”
MND	Riluzole prolongs survival ~3 months; 1-year survival 58% vs 49%; FTD in 10–15%; SOD1 ~2% of ALS
Myasthenia gravis	AChR antibody in ~85%; thymoma 10–15%; RNS decrement >10%; >90% remission or major improvement
SCD of cord	B12 1000 µg IM alternate days × 1–2 weeks → weekly → monthly lifelong; recovery poor if delayed >6–12 months
RLS	Ferritin target >100 ng/mL, transferrin saturation >20%; augmentation in 50–70% of long-term dopamine agonist users; PLMS in ~80%
BPPV	Posterior canal 85–90%; nystagmus latency 1–5 s, duration <60 s; Epley success 80–90%; recurrence 15–50%; vitamin D threshold <20 ng/mL
Subdural haematoma	Acute <3 days / subacute 3 days–3 weeks / chronic >3 weeks; recurrence 10–30%; anticoagulation restart ~4 weeks
Stroke reperfusion	Alteplase 0.9 mg/kg (max 90 mg); tenecteplase 0.25 mg/kg (max 25 mg); sICH 2–6%; thrombectomy NNT ~2.6; BP limits 185/110 pre-lysis, 180/105 post-lysis
Post-stroke depression	Affects ~one-third of survivors; peaks 3–6 months; continue antidepressant ≥6 months after remission
Giant cell arteritis	ESR often >50 (classically >75) mm/h; prednisolone 40–60 mg/day; IV methylprednisolone 500–1000

	mg × 3 days; second eye involved in 25–50% within 1–2 weeks; taper 12–24 months
Trigeminal neuralgia	Pain <2 minutes; classical type 80–90%; carbamazepine 600–1200 mg/day, 70–80% initial response; MVD ~70–80% pain-free at 10 years

B. Named Trials, Guidelines and Regulatory Decisions (2023–2026)

Trial / Guideline	One-line message
ILAE Elderly Task Force (Epilepsia 2023)	Lamotrigine, levetiracetam and lacosamide first line in older adults; gabapentin last resort.
ELUCID (2025)	Late-onset unexplained epilepsy is a marker of future dementia and stroke, not just of seizures.
SANAD II	Levetiracetam was neither superior nor cost-effective versus lamotrigine in focal epilepsy.
Cenobamate	High seizure-freedom rates in drug-resistant focal epilepsy; slow 12-week titration to avoid DRESS.
ANNEXA-I (NEJM 2024)	Andexanet improved haemostasis (67.0% vs 53.1%) but doubled thrombotic events (10.3% vs 5.6%); no mortality benefit.
INSPIRES (NEJM 2023)	Clopidogrel + aspirin up to 72 h reduces 90-day stroke after minor stroke or high-risk TIA.
CHANCE / POINT	DAPT for 21 days within 24 h after high-risk TIA or minor stroke.
SPS3	After lacunar stroke: systolic <130 mmHg helps; long-term DAPT causes harm.
AHA/ASA 2023 aSAH Guideline	Secure the aneurysm within 24 h; early enteral nimodipine; **prophylactic hypervolaemia is harmful**; no routine statin or magnesium.
CREST	Stenting carries higher periprocedural stroke than endarterectomy, especially over age 70.
CREST-2 (NEJM 2025)	Asymptomatic ≥70% stenosis: stenting 2.8% vs 6.0% (p=0.02); **endarterectomy no better than intensive medical therapy** (3.7% vs 5.3%).
AHA/ASA 2026 AIS Guideline	Tenecteplase Class 1; thrombolyse disabling deficits regardless of NIHSS; thrombectomy ASPECTS 3–10 and up to 24 h; thrombectomy for basilar occlusion.
ERC/ESICM 2025 Post-Resuscitation	Fever prevention at ≤37.5 °C for 36–72 h replaces hypothermia at 33 °C; no prehospital cold fluids.
AHA Post-Cardiac Arrest 2025 (Circulation)	NfL added alongside NSE for neuroprognostication; temperature control ≥36 h; predictors of *favourable* outcome now included.
Galcanezumab (consensus 2024)	Only approved preventive for **episodic** cluster headache; failed in chronic cluster headache.
AAN Painful Diabetic Neuropathy Guideline	TCAs, SNRIs, gabapentinoids and sodium-channel blockers are equally effective; **do not offer opioids or tramadol**.
AMBITION-cm / WHO	Single high-dose liposomal amphotericin B 10 mg/kg + flucytosine + fluconazole for cryptococcal meningitis; CrAg is the preferred rapid test.
WHO / NTEP	Xpert MTB/RIF Ultra is the initial CSF test for suspected tuberculous meningitis.
AGS Beers Criteria 2023	Avoid SSRI + tramadol; avoid antipsychotics for BPSD; amitriptyline is potentially inappropriate in older adults.
PENS (NEJM 2025)	First placebo-controlled trial of shunting in iNPH — improves gait and balance, not cognition or continence.
NIO752 / LM11A-31; PSP Platform Trial	Tau-directed therapies in phase 3 for PSP; none yet approved.
VALOR + OLE (JAMA Neurol 2026); **EAN 2024**	Tofersen slows decline and prolongs survival in SOD1-ALS; genetic testing now recommended for all ALS.
Nipocalimab (FDA Apr 2025, EC Dec 2025)	FcRn blocker for AChR/MuSK-positive generalised MG; joins efgartigimod, rozanolixizumab and the C5 inhibitors.
NICE NG239 (Mar 2024)	MMA or homocysteine as confirmatory test for B12 deficiency; never delay replacement when SCD is suspected.
AASM RLS Guideline (JCSM 2025)	Alpha-2-delta ligands and iron are first line; dopamine agonists demoted because of augmentation.
Vitamin D RCTs (2024–2025)	Vitamin D supplementation reduces BPPV recurrence when 25(OH)D <20 ng/mL.
EMBOLISE, STEM, MAGIC-MT (NEJM, 20 Nov 2024)	Middle meningeal artery embolisation reduces recurrence of chronic subdural haematoma.
AHA/ASA 2026 AIS Guideline	Tenecteplase Class 1; thrombolysis 4.5–9 h with mismatch; thrombectomy ASPECTS 3–10 and up to 24 h.
VA/DoD Stroke Rehab 2024; FOCUS/AFFINITY/EFFECTS IPD meta-	Do not use antidepressants to *prevent* post-stroke depression; fluoxetine increases falls, fractures and seizures.

analysis (Int J Stroke 2024)	
SELECT-GCA (upadacitinib, 2025)	Sustained remission 46.4% vs 29.0%; first oral JAK inhibitor approved for giant cell arteritis.
BTX-A meta-analysis (Clin J Pain 2024)	Botulinum toxin A reduces pain and attack frequency in refractory trigeminal neuralgia.

C. Drug or Intervention of Choice — One Line Each

Condition	Drug / intervention of choice
New-onset focal epilepsy in the elderly	Levetiracetam or lamotrigine (avoid enzyme inducers)
Status epilepticus	IV lorazepam, then IV levetiracetam / fosphenytoin / valproate
Seizure in a patient on an anticoagulant and a statin	Levetiracetam (no CYP450 interaction; IV form available)
Drug-resistant focal epilepsy	Cenobamate, or referral for pre-surgical evaluation
High-risk TIA / minor stroke (non-cardioembolic)	Aspirin + clopidogrel for 21 days, then single agent
TIA with atrial fibrillation	DOAC anticoagulation — not antiplatelet therapy
Lacunar stroke	Single antiplatelet + high-intensity statin + systolic BP <130 mmHg
Aneurysmal subarachnoid haemorrhage	Endovascular coiling within 24 h + oral nimodipine 21 days
Symptomatic carotid stenosis 70–99%	Carotid endarterectomy within 2 weeks
Asymptomatic carotid stenosis	Intensive medical therapy (CREST-2)
Wallenberg syndrome	Stroke unit care + nil by mouth and formal swallow assessment
Comatose survivor of cardiac arrest	Temperature control ≤37.5 °C for 36–72 h + delayed multimodal prognostication
Suspected Wernicke encephalopathy	IV thiamine 500 mg tds, given before any glucose
Acute cluster headache attack	High-flow oxygen 12–15 L/min (or subcutaneous sumatriptan 6 mg)
Cluster headache prevention	Verapamil (galcanezumab for episodic cluster if verapamil fails)
Chronic tension-type headache	CBT and exercise first; amitriptyline (or nortriptyline) as preventive
Painful diabetic neuropathy in the elderly	Duloxetine or a reduced-dose gabapentinoid — never an opioid
Tuberculous meningitis	Xpert MTB/RIF Ultra on CSF + ATT with adjunctive corticosteroids
Cryptococcal meningitis	Single-dose liposomal amphotericin B 10 mg/kg + flucytosine + fluconazole
Serotonin syndrome	Stop the drug + benzodiazepines (cyproheptadine if severe)
Neuroleptic malignant syndrome	Stop the drug + fluids + bromocriptine ± dantrolene
Rhabdomyolysis	Aggressive isotonic saline — no bicarbonate, no mannitol
Normal pressure hydrocephalus	Ventriculoperitoneal shunt after a positive tap test or lumbar drainage
PSP / CBD	No disease-modifying drug — trial of levodopa, botulinum toxin for dystonia, falls prevention
Motor neuron disease	Riluzole + non-invasive ventilation (tofersen if SOD1 mutation)
Myasthenia gravis	Pyridostigmine + prednisolone (azathioprine as steroid-sparing); IVIG or plasma exchange in crisis
Subacute combined degeneration	Parenteral vitamin B12 — never folate first
Restless legs syndrome	Iron replacement + alpha-2-delta ligand (gabapentin or pregabalin)
BPPV	Epley canalith repositioning manoeuvre — not vestibular sedatives
Chronic subdural haematoma	Burr-hole drainage with drain ± middle meningeal artery embolisation
Acute ischaemic stroke <4.5 h	Tenecteplase or alteplase; thrombectomy for large-vessel occlusion
Post-stroke depression	SSRI (escitalopram or sertraline) — avoid tricyclics
Central post-stroke pain	Amitriptyline or pregabalin — not simple analgesics
Giant cell arteritis	Immediate high-dose corticosteroid (IV methylprednisolone if visual loss) + aspirin + bone protection
Trigeminal neuralgia	Carbamazepine (oxcarbazepine if poorly tolerated)

Format Reminder for the Examination Hall

- **20 marks = 17 points** (14 + 3) • **15 marks = 12 points** (10 + 2) • **7 marks = 7 points** (6 + 1) • **6 marks = 6 points** (5 + 1). Do not pad beyond the count.
- Bold or box the keywords the examiner scans for: definition, diagnostic criterion, cut-off value, first-line drug, drug of choice, dangerous complication.
- **One named trial with a year and a number**, correctly quoted, outscores three vague sentences.
- Where textbook and current practice differ — dopamine agonists in RLS, triple-H therapy in SAH, surgery for asymptomatic carotid stenosis, targeted temperature management, prophylactic antidepressants after stroke, enzyme-inducing antiseizure drugs — **say so explicitly in one line**. Examiners reward it.

Questions 21–28

Strict mark-wise format observed throughout

7-mark answer = **6 textbook points + 1 latest update = exactly 7 points** 15-mark answer = **10 textbook points + 2 latest updates = exactly 12 points**

Primary source: *Pathy's Principles and Practice of Geriatric Medicine, 6th edition · Kane's Essentials of Clinical Geriatrics* **Supplemented with:** guidelines and evidence 2023 – present, with Indian clinical and policy context

Prepared for: Sudarsan — MD Geriatric Medicine, Postgraduate Examination Revision

QUESTION 21

What are the behavioural and psychological symptoms of dementia? Describe their types, etiology, investigations and line of management, including the modes of action, indications and side effect profile of the drugs used.

RECURRING TOPIC — ASKED 3 TIMES. Appears both as a 15-mark essay and as a 7-mark note. **Both versions are given below**, followed by extra recall scaffolding.

15-Mark Answer

Textbook Core — 10 Points

1. Definition. Neuropsychiatric symptoms (NPSs), also called **behavioural and psychological symptoms of dementia (BPSD)**, are **signs and symptoms of disturbed perception, thought content, mood or behaviour** occurring in a person with dementia. They may appear **before, during or after** the diagnosis and may be the **earliest sign of incipient cognitive decline**.

2. Epidemiology. 90–98% of people with dementia develop at least one NPS over the disease course. NPSs occur in **all dementia types and all stages**. In AD the commonest is **apathy**, followed by **depression, aggression, anxiety, sleep disturbance, irritability, appetite disturbance, motor problems, delusions, disinhibition, hallucinations and euphoria**.

3. Types — five clusters. (i) Psychosis — delusions (commonly theft, infidelity, misidentification, phantom boarder) and hallucinations; **(ii) Affective** — depression, anxiety, apathy, elation; **(iii) Hyperactive/agitation** — aggression, restlessness, pacing, wandering, disinhibition, screaming; **(iv) Vegetative** — sleep–wake reversal, sundowning, appetite and eating change, hyperorality; **(v) Care-related** — rejection of care, resistance to bathing and dressing.

4. Aetiology — patient factors. Neurodegeneration with cholinergic, serotonergic and frontal–subcortical circuit disruption, plus **acute medical issues — pain, infection (urinary, respiratory), constipation, urinary retention, dehydration, drug change, poor sleep and sensory impairment**. **Pain is a common and frequently missed cause of agitation**, and sometimes a trial of scheduled analgesia is the only way to prove it.

5. Aetiology — caregiver and environmental factors. Unmet needs (hunger, boredom, toileting, need for company), **pre-existing personality and psychiatric illness**, **caregiver factors** (communication style, unrealistic expectations, countertherapeutic approach) and **environmental factors** (clutter, poor lighting, over- or under-stimulation, unfamiliar surroundings, lack of routine).

6. Investigations. Exclude delirium first using the **Confusion Assessment Method (CAM)** — acute onset and fluctuating course, plus inattention, plus disorganised thinking or altered consciousness. Then: **urinalysis and culture, complete blood count, blood glucose, blood urea, electrolytes (sodium, potassium in mEq/L), calcium (mg/dL), liver function tests, TSH (μIU/mL), vitamin B12 (pg/mL), oxygen saturation, ECG (QTc before any antipsychotic), chest radiograph if indicated, and a full medication review**. **Pain assessment** using observational tools (PAINAD, Abbey) in non-verbal patients, and imaging only if focal signs, head injury or rapid change.

7. Symptom assessment tools. Neuropsychiatric Inventory (NPI, NPI-Q, NPI-C) for the symptom profile; **Cohen-Mansfield Agitation Inventory (CMAI)** for agitation; **Cornell Scale for Depression in Dementia (CSDD)** for mood.

8. Management — the DICE framework. Describe the behaviour and its context and triggers; **Investigate** modifiable patient, caregiver and environmental causes; **Create** a plan built on **five strategies — caregiver education, effective communication, meaningful activity, task simplification with structured routine, and a safe simplified environment**; **Evaluate** effectiveness, caregiver distress and unintended effects, and **consider dose reduction or withdrawal of any psychotropic used**.

9. Non-pharmacological management is first line. Family and paid caregiver interventions have the strongest evidence and a greater effect size (0.34) than antipsychotics for behavioural symptoms. Efficacy is best in **mild and moderate stages**. **Music therapy, exercise and tailored activity** work best embedded within caregiver-directed programmes. **Training and supervising paid caregivers in communication or person-centred care skills is effective for severe agitation, immediately and up to six months afterward.**

10. Pharmacological principles. Drugs are reserved for **three "medication as first-line" scenarios — major depression, psychosis, or aggression with risk of harm to self or others** — and for acute safety crises. **International Delphi consensus** endorses an escalating approach: identify causes → caregiver training, environmental adaptation, person-centred care and tailored activities → then **citalopram and analgesia before antipsychotics**; but for **psychosis specifically, risperidone is prioritised**. **Valproate and carbamazepine are ineffective and harmful; benzodiazepines are for crises only; cholinesterase inhibitors and memantine do not help NPS in AD but do help in DLB and PDD.**

Drug Table — Mode of Action, Indications and Side Effects

Drug	Mode of action	Indication in BPSD	Key adverse effects
Risperidone	D2 and 5-HT2A antagonist	**Best evidence for short-term (6–12 wk) agitation and aggression**; licensed in EU/Canada for severe aggression	**Stroke, increased mortality**, extrapyramidal symptoms, hyperprolactinaemia, sedation, falls
Olanzapine	Multi-receptor (D2, 5-HT2, H1, M1) antagonist	Agitation, psychosis	Sedation, **anticholinergic and metabolic effects**, weight gain, hyperglycaemia, stroke, mortality
Quetiapine	D2/5-HT2A antagonist, low D2 affinity	**Agent of choice with clozapine in DLB and PDD** psychosis	Sedation, postural hypotension, falls; least extrapyramidal risk
Aripiprazole	D2 partial agonist, 5-HT1A partial agonist	Agitation, psychosis	Akathisia, sedation, stroke, mortality
Haloperidol	Potent D2 antagonist	**Avoid in dementia**; delirium only, lowest effective dose	**Severe extrapyramidal effects; catastrophic neuroleptic sensitivity in DLB**; QTc prolongation
Citalopram	SSRI	**Agitation** (CitAD trial, target 30 mg), anxiety, irritability	**QTc prolongation and cognitive decline at 30 mg**; hyponatraemia (SIADH), falls, GI upset
Sertraline	SSRI	**Major depression in dementia** (DIADS)	Hyponatraemia, GI upset, bleeding risk with NSAIDs, tremor
Trazodone	Serotonin antagonist and reuptake inhibitor	**Night-time agitation and sleep disturbance**; stabilises circadian rhythm	**Sedation**, postural hypotension, falls, rarely priapism
Lorazepam / oxazepam	GABA-A positive allosteric modulator	**Crisis use only**, short- to intermediate-acting preferred	Sedation, falls, **paradoxical agitation, respiratory depression, worsened cognition, dependence**
Cholinesterase inhibitors	Inhibit acetylcholinesterase, raising synaptic acetylcholine	**Not for NPS in AD**; effective for psychiatric and cognitive symptoms in **DLB and PDD**	Nausea, vomiting, diarrhoea, **bradycardia and syncope**, weight loss; **worsens tremor** in PD
Memantine	**Uncompetitive, voltage-dependent, low-affinity NMDA receptor antagonist**	Moderate–severe AD cognition; **cognitive and global benefit in DLB but no psychiatric benefit**	Dizziness, headache, confusion; **case reports of worsening delusions and hallucinations in DLB**
Pimavanserin	Selective **5-HT2A inverse agonist**, no dopaminergic action	**Parkinson's disease psychosis only**	QTc prolongation, peripheral oedema, confusion

Latest Updates (2023–Present)

11. Agitation in AD now has two licensed drugs. Brexpiprazole (Rexulti) — a **serotonin–dopamine activity modulator (D2 and 5-HT1A partial agonist, 5-HT2A antagonist)** — received **FDA approval in May 2023**, the first approval for any neuropsychiatric symptom of dementia, showing about **31% reduction in agitation versus placebo (CMAI effect size ~0.35)**, with benefit on CGI-S significant only at 3 mg. It retains the **class boxed warning for increased mortality in elderly patients with dementia-related psychosis**, plus akathisia, somnolence and weight gain.

12. The first non-antipsychotic option has arrived. Dextromethorphan–bupropion (AXS-05, Auvelity) was FDA-approved in 2026 for agitation in AD dementia: **dextromethorphan is an NMDA receptor antagonist and sigma-1 agonist**, while **bupropion inhibits CYP2D6** to sustain dextromethorphan levels. **ADVANCE-1** showed CMAI improvement versus placebo at week 5; **ACCORD-2** showed **delayed relapse (HR 0.276) and reduced relapse (8.4% vs 28.6%)** over 26 weeks. It carries a **boxed warning for suicidal thoughts and behaviours** and is contraindicated in **seizure disorder, eating disorders, recent alcohol or benzodiazepine withdrawal, and with MAOIs**.

7-Mark Answer

Textbook Core — 6 Points

1. BPSD/NPS = disturbed perception, thought content, mood or behaviour in dementia; **90–98%** of patients develop at least one, across **all dementia types and stages**; **apathy is commonest in AD**, followed by depression and aggression.

2. Five symptom clusters: psychosis (delusions, hallucinations), **affective** (depression, anxiety, apathy), **hyperactive/agitation** (aggression, wandering, disinhibition), **vegetative** (sleep reversal, sundowning, eating change) and **care-related** (rejection of care).

3. Aetiology is multifactorial: neurodegeneration; **acute medical triggers — pain, infection, constipation, retention, dehydration, drug change, poor sleep, sensory loss**; unmet needs; caregiver communication and expectations; and environmental over- or under-stimulation.

4. Investigations: rule out delirium with the CAM, then urinalysis and culture, CBC, **glucose, urea, electrolytes (mEq/L), calcium (mg/dL)**, LFT, **TSH (μIU/mL)**, **B12 (pg/mL)**, oxygen saturation, **ECG for QTc before any antipsychotic**, medication review, and observational pain assessment (PAINAD, Abbey). Quantify with **NPI, CMAI and Cornell Scale**.

5. Non-pharmacological measures are first line and follow the **DICE approach (Describe, Investigate, Create, Evaluate)**, with **caregiver education, communication training, meaningful activity, task simplification with routine, and a safe simplified environment**. **Caregiver interventions (effect size 0.34) outperform antipsychotics.**

6. Drugs are reserved for major depression, psychosis, or aggression risking harm. Risperidone has the best short-term evidence for agitation (stroke and mortality risk); **quetiapine or clozapine** in DLB/PDD; **citalopram** helps agitation but causes **QTc prolongation and cognitive decline at 30 mg**; **trazodone** for night-time agitation; **benzodiazepines for crises only**; **valproate and carbamazepine are ineffective**; **ChEIs and memantine do not help NPS in AD** but do in DLB and PDD.

Latest Update — 1 Point

7. Two drugs are now formally licensed for agitation in AD dementia: **brexpiprazole (FDA 2023)**, a serotonin–dopamine activity modulator with an effect size of about 0.35 and a boxed mortality warning; and **dextromethorphan–bupropion (AXS-05, FDA 2026)** — **NMDA antagonist plus sigma-1 agonist with CYP2D6 inhibition** — the **first non-antipsychotic** option, which delayed relapse in **ACCORD-2 (HR 0.276)**.

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Licensed drugs for agitation	**None approved**; all off-label except pimavanserin in PD psychosis	**Brexpiprazole (2023)** and **dextromethorphan–bupropion (2026)** approved	State the textbook position first, then add both approvals as the update
First-line management	Non-pharmacological, caregiver-directed	**Unchanged and reinforced** — DICE, person-centred care, tailored activity, music therapy	Always open the management section with non-pharmacological measures
SSRIs for agitation	CitAD positive at 30 mg with QTc and cognitive cost	**S-CitAD (escitalopram, 2024) negative** — SSRI role remains uncertain	Quote both trials to show balance

Extra Recall Box — Recurring Topic

Mnemonic for the reversible triggers to check before prescribing: "PINCH ME" **P**ain · **I**nfection · **N**utrition and dehydration · **C**onstipation · **H**ydration/**H**ypoxia · **M**edication · **E**nvironment

Numerical anchors: NPS in **90–98%** · caregiver intervention effect size **0.34** · risperidone efficacy window **6–12 weeks** · brexpiprazole effect size **~0.35** · ACCORD-2 relapse **8.4% vs 28.6%**

Named trials to quote: DIADS and DIADS-2 (sertraline) · **HTA-SADD** (sertraline vs mirtazapine) · **CitAD** and **S-CitAD** (citalopram, escitalopram) · **WHELD** (person-centred care) · **ADVANCE-1 and ACCORD-2** (AXS-05) · **HARMONY** (pimavanserin)

Examiner traps: 1. Reaching for an antipsychotic before excluding **pain, infection, constipation and retention**. 2. Forgetting that **delirium must be excluded first** — the CAM takes two minutes. 3. Prescribing **haloperidol in DLB** — potentially catastrophic neuroleptic sensitivity. 4. Claiming ChEIs help behaviour in AD — **they do not**; they help in DLB and PDD. 5. Omitting the **ECG/QTc** before citalopram or an antipsychotic. 6. Continuing psychotropics indefinitely — **the "E" of DICE demands a withdrawal trial**.

15-second answer skeleton: Define → 90–98% prevalence → five clusters → aetiology in three domains (patient, caregiver, environment) → exclude delirium and PINCH ME triggers with named investigations → **DICE** and caregiver-directed non-pharmacological care first → drugs only for depression, psychosis or dangerous aggression, with the mode-of-action/indication/side-effect table → the two new licensed agents → Indian context (family caregiving, DMHP, unregulated antipsychotic access).

Exam One-Liners

- **90–98%** of people with dementia develop at least one NPS.
- **Apathy is the commonest NPS in AD.**
- **DICE = Describe, Investigate, Create, Evaluate.**
- Caregiver interventions **(effect size 0.34) beat antipsychotics**.
- **Risperidone** = best short-term evidence; **quetiapine/clozapine** in DLB.
- **Citalopram 30 mg** = agitation benefit at the cost of **QTc prolongation and cognitive decline**.
- **Valproate and carbamazepine are ineffective and harmful.**
- **ChEIs and memantine help NPS in DLB/PDD, not in AD.**
- Memantine = **uncompetitive NMDA antagonist**; may worsen hallucinations in DLB.
- New licences: **brexpiprazole 2023, dextromethorphan–bupropion 2026**.

QUESTION 22

Non-pharmacological management of behavioural disturbances in dementia.

RECURRING TOPIC — ASKED 3 TIMES as a 7-mark note. Extra recall scaffolding is given after the answer.
Pivot from Question 21: Question 21 covers the whole BPSD syndrome including drugs. This answer is pivoted entirely to **the non-drug evidence base and its practical delivery**, and should not repeat the pharmacology.

7-Mark Answer

Textbook Core — 6 Points

1. Rationale and evidence. Non-pharmacological measures are **first-line for all behavioural disturbance in dementia**. A meta-analysis of **23 randomised trials in nearly 3300 community-dwelling patient–caregiver dyads** confirmed that caregiver-directed interventions **significantly reduce behavioural symptoms with an effect size of 0.34 — greater than that of antipsychotics for behavioural symptoms and of cholinesterase inhibitors for memory**. Efficacy is best in **mild and moderate stages**, when cognition and communication are better preserved.

2. The DICE framework. Describe the behaviour, its context and its triggers with the caregiver; **I**nvestigate modifiable causes across patient, caregiver and environmental domains; **C**reate a collaborative plan; **E**valuate whether the target symptom improved, caregiver distress fell and no unintended effects occurred. DICE was designed for **any health professional working within a team**.

3. The five caregiver-training strategies with the strongest evidence base. Train caregivers to **(i) use problem-solving skills to manage NPS; (ii) increase activity for the person with dementia; (iii) enhance communication within the dyad; (iv) reduce environmental complexity; and (v) simplify tasks for the person with dementia** — supplemented by **establishing structured routines and ensuring safety**.

4. Interventions targeting the person with dementia. Music therapy, aromatherapy, exercise, tailored activity programmes, reminiscence and multisensory stimulation. Individual approaches work best **embedded within tailored-activity programmes** rather than delivered alone. **Bright light therapy with good sleep hygiene is first-line for circadian rhythm disorder**, for which there is no evidence for drug treatment.

5. Interventions targeting professional caregivers. In nursing homes, **training and supervising paid caregivers in communication or person-centred care skills is effective for symptomatic and severe agitation, immediately and up to six months afterward**. A **systematic review and meta-analysis of 11 randomised trials** showed psychosocial interventions in nursing homes **reduced psychotropic drug prescribing**, using three intervention classes — **staff training on psychotropic prescribing and NPS management, consultation with external experts for complex NPS, and person-centred psychosocial interventions**.

6. Interventions targeting the environment. Address **over- or under-stimulation, safety problems, lack of activity and structure, and absence of established routine**; add **architectural modification improving secure access to the outdoors and helping navigation** of the home or institution. Because strategies are used in combination, **no single approach can be identified as preferred — a combination of environmental adjustments yields the behavioural change**, and individual environmental studies remain too small and disparate for firm conclusions.

Latest Update — 1 Point

7. International Delphi expert consensus now formally places **caregiver training, environmental adaptation, person-centred care and tailored activities ahead of any pharmacological approach** for overall NPS and agitation, and identifies **DICE and music therapy as the two most promising non-pharmacological approaches**. This is reinforced by **person-centred care packages such as WHELD** and by **Cochrane reviews of music-based interventions (2022–2025)** showing consistent modest benefit on agitation and depressive symptoms **with no drug-related harm** — while **digital and telehealth delivery of caregiver skills training** (web-based psychoeducation, telecoaching, multicomponent platforms) has been shown feasible and effective, greatly widening access in resource-limited settings including India.

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Position in the treatment ladder	First-line, but no formal consensus ranking	**Delphi consensus formally ranks non-drug measures ahead of drugs**; DICE and music therapy top the list	Say “first-line by expert consensus, not merely by default”
Delivery mode	Face-to-face caregiver programmes	**Digital and telehealth delivery** validated — critical for India’s dispersed families	Add one line on telehealth to modernise the answer
Environmental interventions	Too small and disparate to draw conclusions	Position largely unchanged; **combination approaches** remain the recommendation	Do not overclaim environmental evidence

Extra Recall Box — Recurring Topic

Mnemonic for the five caregiver-training targets: “PACES” Problem-solving skills · **A**ctivity increased for the patient · **C**ommunication enhanced within the dyad · **E**nvironmental complexity reduced · **S**implified tasks

Numerical anchors: caregiver intervention meta-analysis — **23 trials, ~3300 dyads, effect size 0.34** · nursing-home psychosocial meta-analysis — **11 trials, reduced psychotropic prescribing** · paid-caregiver training benefit sustained **up to 6 months**

Named entities: DICE (Kales, Gitlin and Lyketsos, BMJ 2015) · **Brodaty and Arasaratnam meta-analysis** · **WHELD** · **Cochrane music-based interventions**

Examiner traps: 1. Listing activities without the **framework** — DICE is what earns the structure marks. 2. Forgetting that the intervention target is often **the caregiver, not the patient**. 3. Claiming strong evidence for **environmental modification alone** — the textbook explicitly says the studies are too small and disparate. 4. Omitting the **nursing-home/paid-caregiver** limb of the evidence. 5. Missing **bright light therapy and sleep hygiene** as first-line for circadian disturbance.

15-second answer skeleton: State first-line status with the effect size 0.34 → **DICE** → five caregiver-training targets (**PACES**) → patient-directed therapies (music, exercise, tailored activity, bright light) → professional caregiver training reduces psychotropic prescribing → environmental modification in combination → Delphi consensus and digital delivery → Indian application through family caregivers, ARDSI and DMHP.

Exam One-Liners

- Caregiver-directed interventions: **effect size 0.34, greater than antipsychotics**.
- **DICE = Describe, Investigate, Create, Evaluate.**

- Five training targets: **problem-solving, activity, communication, reduced complexity, simplified tasks**.
- Best efficacy in **mild and moderate** stages.
- Paid-caregiver **person-centred care training works for severe agitation, sustained to 6 months**.
- Nursing-home psychosocial interventions **reduce psychotropic prescribing**.
- **Bright light therapy + sleep hygiene** = first-line for circadian rhythm disorder.
- **Environmental interventions work in combination**, not singly.
- **DICE and music therapy** are the two consensus-endorsed approaches.

QUESTION 23

How will you address caregiver stress in dementia?

7-Mark Answer

Textbook Core — 6 Points

1. Recognise the scale and the domains of impact. Caregiving affects the carer's **physical health, mental health, financial well-being, social support and spiritual well-being**. Caregivers of people with dementia are particularly vulnerable, and **caregiver counselling and support is listed among the evidence-based preventive interventions in geriatric psychiatry, with the specific outcome of preventing caregiver depression**.

2. Screen and quantify the burden. Use validated instruments: the **Zarit Burden Interview (22 items, with validated 3-item and shortened versions and translations into many languages)**; the **Caregiver Self-Assessment Questionnaire (CSAQ)**, an 18-item American Medical Association tool **also validated as a screen for depression**; the **Rapid Screen for Caregiver Burden (7 items)**; and the **Caregiver Well-Being Scale**. **These tools allow a quick assessment of needs and stress levels so that appropriate referrals can be made.**

3. Psychoeducation and skills training. The largest body of evidence supports **psychoeducational programmes that teach problem-solving techniques for behavioural problems**, including **cognitive behavioural family intervention**, structured behaviour-management programmes, and **combined education and support programmes supplemented by follow-up telephone support**. In one three-country randomised trial, **five sessions of counselling plus ad hoc telephone support combined with cholinesterase inhibitor therapy in the patient reduced caregiver depression from moderate to lower levels**.

4. Mindfulness, yoga and meditation. Mindfulness-Based Stress Reduction (MBSR) — formal practice (mindful movement, body scan, sitting meditation) plus informal practice in everyday life — improves psychological well-being in healthy and clinical populations. A **twice-weekly online mindfulness intervention reduced caregiver burden and improved quality of life**, and **yoga and compassion-meditation programmes improved quality of life and self-compassion in family caregivers of people with Alzheimer's disease**.

5. Support groups and respite. Support groups are of two types: **time-limited groups training caregivers in care delivery and role management**, and **ongoing forums for sharing experience and mutual support**, the latter providing lasting social support and social activity. Caregivers generally evaluate them positively, but **not all are comfortable meeting others, and substitute care arrangements may be needed to allow the caregiver to attend**. **Respite and adult day care** are core components of multidimensional caregiver programmes, and **adult day programmes reduce the risk of accelerated cognitive decline associated with nursing home placement**.

6. Treat the dyad, not the patient alone, and respect culture. Interventions have traditionally focused on one party rather than **the dyad of caregiver and care recipient**, and new strategies must support **both**. Caregiving practices vary across cultures: in **traditional Asian cultures the family is expected to care for elders at home, and suggesting a care facility may be perceived as abandonment and is culturally insensitive** — directly relevant to Indian practice. Other proven measures include **family intervention to delay institutionalisation** and **exercise plus behavioural management to reduce disability in the person with dementia**, both of which reduce the demands placed on the caregiver.

Latest Update — 1 Point

7. Digital and telehealth caregiver support has been validated and is the most scalable answer for India. Randomised and systematic-review evidence (2024–2026) for **web-based psychoeducation, telecoaching, multicomponent online platforms and telehealth-adapted caregiver skills training** shows reductions in burden and depression comparable to face-to-face delivery. Indian-specific work is now available: **LASI-DAD (2025)** provides the first nationally representative data on dementia caregiving in India, analysing **4196 informants** and demonstrating that the care recipient's cognitive impairment measurably worsens caregiver **stress, mental health and positive affect**; and a **coproduced digital media caregiver intervention developed at NIMHANS (CTRI-registered)** has established feasibility and acceptability for Indian family caregivers.

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Delivery of caregiver support	Face-to-face programmes, telephone follow-up noted as promising	**Digital, web-based and telehealth delivery validated** as effective and scalable	Mention telephone support from the textbook, then extend to digital platforms
Indian evidence	Cultural discussion, largely Western data	**LASI-DAD (2025)** — first nationally representative Indian caregiving data	Quote LASI-DAD to anchor the Indian angle
Target of intervention	Caregiver-focused	**Dyadic interventions** supporting caregiver and care recipient together	Use the word "dyad" — it is the current framing

Practical Indian Framework to Quote

- **Assess:** Zarit Burden Interview (Hindi and regional-language versions validated) at every dementia review
- **Educate:** diagnosis, expected course, behavioural management, safety, driving, finances, advance planning
- **Support: ARDSI** chapters — caregiver training, memory clinics, day care and support groups
- **Relieve:** respite through day care, planned short-stay admission, shared family rotas
- **Refer: District Mental Health Programme** for caregiver depression; **NPHCE** geriatric clinics; **Elder Line 14567**
- **Protect: Maintenance and Welfare of Parents and Senior Citizens Act, 2007** where caregiving has broken down; **AB-PMJAY / Ayushman Vay Vandana Card** for those 70+; **Rashtriya Vayoshri Yojana** for assistive devices
- **Anticipate:** screen the caregiver's **own** blood pressure, glycaemia, sleep and mood — the caregiver is frequently an older adult too

Exam One-Liners

- Screen with the **Zarit Burden Interview**; **CSAQ (18 items) also screens for depression**; **Rapid Screen for Caregiver Burden = 7 items**.
- **Caregiver counselling and support prevents caregiver depression** — an evidence-based preventive intervention.
- Five sessions of counselling plus telephone support **reduced caregiver depression** in a three-country RCT.
- **MBSR, yoga and compassion meditation** improve caregiver quality of life.
- **Adult day programmes reduce accelerated cognitive decline** linked to nursing home placement.
- **Family intervention delays institutionalisation.**
- Treat the **dyad**, not the caregiver alone.
- In Asian cultures, **suggesting a care facility may be read as abandonment** — counsel with cultural sensitivity.
- **LASI-DAD (2025)**: first nationally representative Indian dementia caregiving data, **4196 informants**.

QUESTION 24

What are the innovations you would suggest to ease caregiver burden?

Pivot from Question 23: Question 23 asks how you would *address* caregiver stress with established interventions. This answer is pivoted to **innovation and service design** — technology, new models of delivery, workforce and policy — and should not simply repeat the psychoeducation and support-group list.

7-Mark Answer

Textbook Core — 6 Points

1. Information and communication technology as a delivery channel. The textbook already identifies that **the use of telephone support highlights the potential of alternative modes of delivery to enhance or replace face-to-face interventions**, and reviews **the impact of information and communication technology on family carers of older people and professionals**. Innovation therefore begins by **moving proven interventions onto remote platforms** rather than inventing new content — **telephone, video, app and web-based delivery of psychoeducation, counselling and behaviour-management training**.

2. Online and remote psychological interventions. A **twice-weekly mindfulness intervention delivered online was correlated with a decrease in caregiver burden and an increase in quality of life** — direct textbook support for remote delivery of stress-reduction programmes, extendable to **online yoga and compassion meditation**, which improved quality of life and self-compassion in caregivers of people with Alzheimer's disease.

3. Telemedicine and telepsychiatry for the care recipient. Telemedicine prevents psychiatric admissions from long-term care homes, and **geriatric telepsychiatry has a role in long-term care psychiatry, in the assessment and management of dementias in primary care, in geriatric emergencies in the emergency department, and in managing depression in primary care through collaborative care**. Every avoided admission or avoided journey is caregiver burden removed.

4. Ambient and assistive technology in the home. Context-aware computing and context-awareness — technology that senses the situation and responds — together with **design and technology for older people** and **assistive devices**, reduce supervision demand. Practical applications are **wandering alerts and GPS location, fall detection, medication reminders and automated dispensers, stove and door sensors, and video check-in**. **Security must be built in**, since these systems carry recognised risks of **denial of service and identity theft**.

5. Restructured services and new models of care. Community-based, multidisciplinary geriatric mental health treatment teams are the ideal model of community psychiatry service delivery, supported by **hospital-based consultation-liaison services**, **care home liaison services** and **memory clinics** giving **informed discussion of diagnosis and prognosis with arrangements for ongoing review, support and management**. **Adult day programmes reduce the risk of accelerated cognitive decline associated with nursing home placement**, and **respite and adult day care** are core components of multidimensional caregiver programmes.

6. Reduce demand at source and fund the workforce. Burden falls when the patient's condition is better managed: **exercise plus behavioural management reduces disability in people with dementia**; **comprehensive nutritional treatment prevents weight loss**; **family intervention delays institutionalisation**; and **DICE training for family and professional caregivers manages agitation and aggression without psychotropic drugs**. Structurally, **more funding and new payment models are needed to train health professionals, primary care providers and family caregivers in assessing and managing NPS**, and **primary care providers should be reimbursed for time spent on approaches like DICE and given better access to backup specialist services**.

Latest Update — 1 Point

7. Digital caregiver platforms have moved from pilot to evidence. Randomised trials and systematic reviews (2024–2026) of **home-based digital interventions — web psychoeducation, telecoaching, digital cognitive training, assistive technology and multicomponent platforms** — show reductions in caregiver burden and depression, with dedicated platforms (**GamePlan4Care, TeleCARE**) tested in randomised designs, and **nature-based and community respite models** under formal evaluation. For India specifically, a **coproduced digital media caregiver resource developed at NIMHANS and registered with CTRI** has demonstrated feasibility and acceptability for Indian family caregivers — the model most likely to scale, given that **India has one of the world's fastest-growing dementia populations, over 90% of care is family-provided, and formal respite and long-term care infrastructure is scarce**.

Innovations Grid — Ready-Made Answer Structure

Level	Innovation	Burden relieved
Technology	App and web psychoeducation, telecoaching, online MBSR, video support groups	Access, isolation, travel time
Home	GPS/wandering alerts, fall detection, automated pill dispensers, door and stove sensors, video check-in	Supervision load, night-time vigilance
Clinical service	Memory clinic with case manager, telepsychiatry, care home liaison, single point of contact	Fragmented care, repeated hospital visits
Respite	Adult day care, planned short-stay respite, community and nature-based respite programmes	Physical exhaustion, loss of employment
Workforce	DICE training for family and paid caregivers; reimbursement for caregiver-facing time	Behavioural crises, antipsychotic prescribing
Peer	Dementia-friendly communities, self-help and peer-caregiver networks, employer flexibility	Social isolation, financial strain
Policy (India)	NPHCE geriatric clinics, DMHP linkage, Elder Line 14567, Ayushman Vay Vandana Card (70+), Rashtriya Vayoshri Yojana, ARDSI day care	Cost, legal insecurity, unmet need

Exam One-Liners

- Start with **ICT delivery of proven interventions** — do not invent new content.
- **Online mindfulness reduced caregiver burden and improved quality of life.**
- **Telemedicine prevents psychiatric admissions from long-term care homes.**
- **Context-aware computing** and assistive technology reduce supervision demand — but carry **DoS and identity-theft risks**.
- **Adult day programmes reduce accelerated cognitive decline** linked to nursing home placement.
- **Family intervention delays institutionalisation**; **exercise plus behavioural management reduces disability**.
- **DICE training manages agitation without psychotropics.**
- Structural need: **funding, training and reimbursement for caregiver-facing time**.
- India: **>90% family-provided care**, scarce respite — **digital and community models are the realistic innovation**.

QUESTION 25

What are the reversible dementias? How would you investigate and treat them?

RECURRING TOPIC — ASKED 3 TIMES as a 7-mark note. Extra recall scaffolding follows the answer.

7-Mark Answer

Textbook Core — 6 Points

1. Definition and scale. Dementia is grouped into **reversible or partially reversible** and **non-reversible** types. **Reversible dementia accounts for probably less than 4% of cases**, but **concurrent medical conditions causing mild cognitive disturbance are much commoner and are potentially treatable**; identifying them **avoids unnecessary disability and misdiagnosis**. Crucially, **finding a reversible cause does not guarantee that the dementia will improve once the cause is treated**.

2. The causes. Drugs (anticholinergics and antihistamines, analgesics including narcotics and NSAIDs, anticonvulsants, antihypertensives, antiparkinsonian agents, digoxin, antiarrhythmics, H2 blockers, antianxiety drugs, antidepressants, antipsychotics, sedative-hypnotics, muscle relaxants, steroids, alcohol); **psychiatric — depression ("depressive pseudodementia")**; **metabolic and endocrine** (hypothyroidism, hyperparathyroidism, hyponatraemia, hypercalcaemia, hepatic and renal failure); **nutritional** (**vitamin B12**, folate, thiamine — Wernicke–Korsakoff, pellagra); **neoplasms**; **trauma — chronic subdural haematoma**; **toxins** (alcohol, heavy metals, organic poisons); **infections** (HIV and opportunistic infection, neurosyphilis, tuberculous meningitis); **autoimmune** (CNS vasculitis, temporal arteritis, SLE, multiple sclerosis); and **other — normal-pressure hydrocephalus**.

3. Clinical evaluation. These disorders are detected by careful history, physical examination and selected laboratory studies. Take a **complete drug history including over-the-counter agents**, maintain a **high index of suspicion for excessive alcohol intake** (easily missed, and a cause of dementia, delirium, depression and falls), and screen for depression. **Pointers to**

depressive pseudodementia are **prominent complaints of memory loss, patchy and inconsistent cognitive deficits, and frequent "don't know" answers**.

4. Laboratory investigation. Complete blood count, glucose, blood urea nitrogen, electrolytes (sodium and potassium in mEq/L), calcium and phosphorus (mg/dL), liver function tests, thyroid-stimulating hormone (μIU/mL), vitamin B12 (pg/mL), serological test for syphilis if suspected, and HIV antibodies if suspected. These blood tests are **directed at finding common comorbidities rather than at identifying the cause of the underlying dementia**.

5. Imaging and neuropsychology. CT or MRI of the head should be done in **dementia of recent onset with no other clinical finding to explain it, and in those with focal neurological signs or symptoms**, to exclude **subdural haematoma, tumour and normal-pressure hydrocephalus**. **CT and MRI are roughly equivalent for detecting most remediable structural lesions**; MRI shows more lesions in multi-infarct dementia but also white-matter changes of uncertain significance. **Neuropsychological testing** is particularly useful for **differentiating depression from dementia** and where mental-status score and functional status are discordant.

6. Treatment. Discontinue whenever feasible every drug known to impair cognition, especially strong anticholinergics. **Treat depression energetically** — an SSRI such as **citalopram or sertraline**, or the NaSSA **mirtazapine**, all with minimal cognitive side effects; where doubt persists, **a careful trial of an antidepressant is justified** both diagnostically and therapeutically. **Correct B12 deficiency, hypothyroidism, hyponatraemia and hypercalcaemia; refer normal-pressure hydrocephalus for shunt assessment and chronic subdural haematoma for neurosurgery; treat neurosyphilis, HIV and tuberculous meningitis specifically; and control vascular risk factors, especially hypertension**, which may favourably influence the course of both degenerative and vascular cognitive impairment. Note that **thyroid hormone and vitamin B12 replacement may be important for general health but have not been shown to reverse cognitive deficits**, and that **older patients with reversible cognitive impairment during depression are at high risk of later dementia and need close follow-up**.

Latest Update — 1 Point

7. Shunting for idiopathic normal-pressure hydrocephalus now has randomised, placebo-controlled proof. The **PENS trial (NEJM, 2025)** randomised **99 patients across 17 centres** to open versus placebo (closed) shunt valve settings: **gait velocity improved by 0.21 m/s more with an open shunt (95% CI 0.12–0.31; p<0.001)**, with **80% versus 24% achieving meaningful improvement**, better balance and fewer falls — but **no significant improvement in cognition or continence at 3 months**. Alongside this, **antibody-mediated autoimmune encephalitis (LGI1, CASPR2, NMDAR, GAD65)** is now an established, immunotherapy-responsive cause of subacute cognitive decline, to be suspected with **rapid progression over weeks to months, seizures, hyponatraemia, movement disorder or psychiatric prominence**.

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
NPH shunting	Surgery, with risk–benefit carefully assessed; efficacy debated	**PENS (2025)** — randomised proof of gait benefit; cognition and continence do not reliably improve	Quote the numbers and the nuance
Autoimmune causes	CNS vasculitis, SLE, MS	**Antibody-mediated encephalitis** a distinct, treatable category	Add autoantibody panel to the workup for rapid decline
B12 and thyroid replacement	Not shown to reverse cognitive deficits	**Unchanged** — treat for general health, not expecting cognitive reversal	State this explicitly; it is a marking point

Extra Recall Box — Recurring Topic

Mnemonic — "DEMENTIA": Drugs and **D**epression · **E**motional/**E**ndocrine · **M**etabolic · **E**yes and **E**ars (sensory deprivation) · **N**utritional and **N**PH · **T**umour and **T**rauma (subdural) · **I**nfection and **I**nflammatory · **A**lcohol and toxins

Numerical anchors: reversible dementia **<4%** · depression coexists in **>1/3** of dementia outpatients · rapidly progressive dementia = decline within **12 months** · **PENS: 0.21 m/s gait gain; 80% vs 24%**

Examiner traps: 1. Overstating frequency — it is **<4%**. 2. Claiming B12 or thyroid replacement reverses dementia — **it has not been shown to**. 3. Forgetting that **drugs are the commonest single reversible contributor**. 4. Omitting **NPH and chronic subdural haematoma** — both surgically treatable. 5. Diagnosing dementia while delirium is present — **the diagnosis must await treatment of all reversible causes of delirium**.

15-second answer skeleton: Define and state <4% → causes by system (drugs, depression, metabolic/endocrine, nutritional, structural, infective, autoimmune, NPH) → history, drug review, alcohol history, depression screen → named blood panel plus CT/MRI → treat each specifically, deprescribe first → caveat that reversal is not guaranteed → PENS and autoimmune encephalitis as the update → Indian angle (**B12 deficiency, hypothyroidism, neurosyphilis, HIV, TB meningitis are all commoner here**).

Exam One-Liners

- **<4%** of dementias are truly reversible.
- **Finding the cause does not guarantee reversal.**
- **Drugs first** — anticholinergics are the commonest culprit.
- Depressive pseudodementia: **prominent memory complaints, patchy deficits, "don't know" answers**.
- Panel: **CBC, glucose, urea, electrolytes, calcium/phosphorus, LFT, TSH, B12, VDRL and HIV if suspected + CT/MRI**.
- Blood tests find **comorbidities, not the cause of the dementia**.
- **CT and MRI are equivalent** for remediable structural lesions.
- Structural causes: **subdural haematoma, tumour, NPH**.
- **PENS 2025**: shunting improves **gait**, not cognition or continence.

QUESTION 26

Mild cognitive impairment — evaluation, treatment and outcome.

RECURRING TOPIC — ASKED TWICE as a 7-mark note. Extra recall scaffolding follows the answer.
Pivot: the emphasis here is on **evaluation, treatment and outcome** rather than on the full biomarker classification — the criteria are stated compactly and the weight is placed on the clinical workup, management and prognosis.

7-Mark Answer

Textbook Core — 6 Points

1. Definition and criteria. MCI is **(i) a subjective disorder of memory and/or other cognitive domains, (ii) objective impairment of memory and/or other cognitive domains, and (iii) no significant impact on activities of daily living** — so patients **do not meet criteria for dementia**. The **NIA-AA core clinical criteria** are **concern about a change in cognition** (from patient, informant or clinician), **impairment in one or more cognitive domains greater than expected for age and education**, **preservation of independence in functional abilities** (mild difficulty with complex tasks is allowed, with minimal aids), and **not demented**. **No thresholds are defined** for the degree of impairment. The DSM-5 equivalent is **mild neurocognitive disorder**.

2. Clinical evaluation. History from **both patient and an informant**, focused on **the impact on usual activities, lifestyle, the history of the cognitive disorder, and above all whether functional decline has occurred** — the point that separates MCI from dementia. **Old age alone does not cause cognitive impairment severe enough to render a person dysfunctional**, so decline must not be dismissed as ageing.

3. Cognitive and functional testing. A **standardised mental status test** plus **neuropsychological testing**, which is especially useful when the mental status score is normal but function or behaviour has changed (high baseline intelligence) or the score is low without functional deficit (low educational level), and for **differentiating depression from dementia**. Function is documented with **Lawton IADL and basic ADL scales**; mood with the **Geriatric Depression Scale**.

4. Exclude the treatable — the same three questions used for any confusional presentation. (i) Has the onset been acute (hours to days)? (ii) Are there physical factors — medical illness, sensory deprivation, drugs? (iii) Are psychological factors — depression, psychosis — contributing? Investigate with **complete blood count, glucose, blood urea, electrolytes (mEq/L), calcium and phosphorus (mg/dL), liver function tests, TSH (μIU/mL), vitamin B12 (pg/mL), syphilis and HIV serology if suspected**, and **CT or MRI head** where indicated. MCI is **heterogeneous** and may be due to **AD, other neurodegenerative disease, depression, vascular lesions or traumatic brain injury**.

5. Biomarkers where available. NIA-AA research criteria stratify by **amyloid markers (CSF Aβ42, amyloid PET)** and **neuronal injury markers (CSF total tau and p-tau, MRI atrophy, FDG-PET/SPECT hypometabolism)**: **"high likelihood" MCI due to AD = both positive; "intermediate likelihood" = one positive with the other untested; "unlikely due to AD" = both negative**. The **IWG criteria for prodromal AD** require **abnormal CSF Aβ1-42 and tau or an abnormal amyloid PET (IWG-2)**. **Most countries, including India, lack national guidelines on biomarker use**, which limits harmonisation.

6. Treatment. No intervention has classically been shown to prevent progression to dementia, and **cholinesterase inhibitors are not licensed for MCI**. Management therefore centres on: **an informed discussion of diagnosis and prognosis with arrangements for ongoing review and support**; **treating contributory conditions** — depression with **citalopram, sertraline or mirtazapine** (minimal cognitive side effects), hypothyroidism, B12 deficiency, sleep apnoea and alcohol excess; **withdrawing anticholinergic and other cognition-impairing drugs**; **controlling vascular risk factors, especially hypertension, which may favourably influence the course of both degenerative and vascular cognitive impairment**; and **physical activity and multicomponent exercise**, the intervention with the most promising evidence (**FINGER** positive for multidomain intervention; **MAPT** largely negative). Add **cognitive training, driving and safety assessment, and advance planning**.

Latest Update — 1 Point

7. MCI due to AD has become a treatable, biomarker-defined diagnosis. Lecanemab (FDA full approval July 2023, CLARITY-AD) and **donanemab (FDA approval July 2024, TRAILBLAZER-ALZ 2)** are licensed specifically for **MCI due to AD or mild AD dementia with confirmed amyloid pathology**, requiring **APOE genotyping and serial MRI for amyloid-related imaging abnormalities (ARIA)**, with the **EMA restricting use to non-APOE ε4 homozygotes**. Confirmation of amyloid is now possible by blood: the **FDA cleared the Lumipulse G pTau217/Aβ1-42 plasma ratio in May 2025** for symptomatic adults aged 55 and over, and the **Alzheimer's Association Clinical Practice Guideline (2025)** endorses blood biomarkers in patients with objective cognitive impairment including MCI — as a **triaging test at ≥90% sensitivity and ≥75% specificity**, or **as a substitute for amyloid PET or CSF at ≥90% for both**. **US POINTER (2025)** confirmed benefit from structured multidomain lifestyle intervention in at-risk older adults.

Outcome — Learn These Numbers

Outcome	Figure
Prevalence of cognitive impairment without dementia, age 71+	**Just over 20%**
Annual conversion of MCI/CIND to dementia	**15–20% per year**
Remainder	A proportion **remain stable**, and some **revert to normal** — especially where depression, drugs or sleep disorder were contributory
Biomarker effect	**Biomarker-positive MCI converts far faster**; biomarker-negative MCI often remains stable
Depression-related cognitive impairment	Older patients with reversible cognitive impairment during depression are at **high risk of dementia within a few years** — follow closely

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Treatment	"No intervention has been shown to prevent progression"	**Anti-amyloid antibodies licensed at the MCI stage** — slowing, not prevention	State the textbook line, then add the caveat that slowing ≠ prevention
Amyloid confirmation	PET or CSF, limited availability	**FDA-cleared plasma p-tau217/Aβ42 ratio (2025)**	This is the single most quotable update
Lifestyle intervention	FINGER positive, MAPT largely negative	**US POINTER (2025) positive**	Quote all three trials for balance

Extra Recall Box — Recurring Topic

Mnemonic for the four core criteria — "CIPN": Concern about cognition · **I**mpairment objectively demonstrated · **P**reserved independence in function · **N**ot demented

Numerical anchors: >20% of those 71+ have CIND · **15–20%** annual conversion · biomarker thresholds **≥90/≥75** for triage, **≥90/≥90** to replace PET or CSF

Examiner traps: 1. Saying MCI has **defined cognitive thresholds** — it does not. 2. Saying **ChEIs are indicated** — they are not licensed for MCI. 3. Forgetting that MCI can **revert to normal**, especially with depression or drugs. 4. Failing to exclude depression, drugs, B12 deficiency and thyroid disease before labelling MCI. 5. Missing the functional criterion — **any significant ADL impairment makes it dementia, not MCI**.

15-second answer skeleton: Define with the three components → four NIA-AA core criteria (**CIPN**) → evaluation: informant history, cognitive and functional testing, the three screening questions, named blood panel and imaging → biomarkers and likelihood tiers → treatment: no licensed drug classically, treat contributors, deprescribe, control vascular risk, exercise and multidomain lifestyle → outcome: **20% prevalence, 15–20% annual conversion, some revert** → anti-amyloid antibodies and plasma p-tau217 as the update.

Exam One-Liners

- MCI = **subjective complaint + objective impairment + preserved ADLs + not demented**.
- **No thresholds are specified** for the degree of impairment.
- **Just over 20%** of people aged 71+ have cognitive impairment without dementia.
- **15–20% convert to dementia per year.**
- **ChEIs are not licensed for MCI.**
- **Exercise and multidomain intervention** carry the best evidence (**FINGER**, **US POINTER**).
- **Anti-amyloid antibodies are licensed at the MCI stage** when amyloid is confirmed.
- **Plasma p-tau217/Aβ42 ratio FDA-cleared (2025)** for symptomatic adults 55+.
- Reversible cognitive impairment during depression → **high risk of later dementia**.

QUESTION 27

Vascular dementia.

7-Mark Answer

Textbook Core — 6 Points

1. Definition and concept. Vascular dementia (VaD) is **dementia resulting from cerebrovascular disease**, having evolved from the older concept of **arteriosclerotic dementia**. The current and preferred umbrella term is **vascular cognitive impairment (VCI)**, which spans the full spectrum from **vascular MCI (Va-MCI) to VaD**, and includes **mixed vascular and AD pathology**. **About 5% of people over 65 have VCI**, and **in patients under 74 VCI may be the single most common cause of cognitive impairment**. The inclusion of **VCI-no dementia** emphasises the **preventable nature of VCI and the importance of early diagnosis**; the asymptomatic susceptible host with risk factors is termed the **"brain at risk"**.

2. Classification — seven subtypes. Multi-infarct (cortical) dementia from large cortical infarcts; **small-vessel (subcortical) dementia** from lacunes and white or deep grey matter lesions; **strategic infarct dementia** from a unilateral or bilateral infarct in a strategic area; **hypoperfusion dementia**; **haemorrhagic dementia**; **Alzheimer's disease with cerebrovascular disease**

(mixed); and **hereditary dementia** such as **CADASIL, due to NOTCH3 mutation on chromosome 19**. **Subcortical ischaemic vascular disease (SIVD)** — the **lacunar state and Binswanger's disease** — is the commonest subtype (**82.2% small-vessel versus 25.9% large-vessel** in one study).

3. Clinical features by vessel size. Large-vessel disease produces cortical infarcts in strategic locations giving a **cortical dementia** — **frontal lobe** (aphasia, apraxia, disinhibition, apathy), **hippocampus and basal forebrain** (amnesia), **gyrus angularis** (construction problems), **parietal lobe** (alexia, agraphia). **Small-vessel disease** affects **thalamus, caudate nucleus and internal capsule**, disrupting **frontal–subcortical or thalamocortical circuits** to give a **subcortical dementia** — **executive dysfunction, attention deficit, apathy and personality change** with **comparatively milder memory deficit** and slowed processing speed. **"Lower-half parkinsonism"** produces **hesitation, marche à petit pas and diminished step height**, and **the triad of dementia, urinary incontinence and gait disturbance is more often produced by small-vessel VaD than by normal-pressure hydrocephalus**.

4. Course. Classically **abrupt onset with stepwise deterioration and a fluctuating course with plateaus**, but in practice **60% have a slow, less abrupt onset and 80% show slow progression** with or without stepwise decline — so a gradual course does not exclude VaD.

5. Diagnosis. NINDS-AIREN criteria for probable VaD require **(i) dementia; (ii) cerebrovascular disease — focal neurological signs consistent with stroke plus neuroimaging evidence of clinically relevant vascular lesions; and (iii) a temporal relationship — onset of dementia within three months of a recognised stroke, abrupt deterioration, or fluctuating/stepwise progression**. Supportive clinical features are **early gait disturbance, unsteadiness with frequent unprovoked falls, early urinary frequency and urgency unexplained by urological disease, pseudobulbar palsy, and personality and mood change with abulia, depression, emotional incontinence, psychomotor retardation and abnormal executive function**. Imaging severity criteria include **white matter lesions affecting more than 25% of white matter**. These criteria **exclude about 90% of AD but have only modest sensitivity (50–70%)** and **misclassify mixed dementia as VaD (54% for ADDTC, 29% for NINDS-AIREN)**. MRI shows **basal ganglionic and thalamic hyperintense foci, thromboembolic infarcts, confluent white matter and irregular periventricular hyperintensities (leukoencephalopathy)**; **SPECT shows multiple focal deficits**; and **cerebral microbleed number independently predicts cognitive impairment and dementia severity**.

6. Management — four-pronged. (i) Symptomatic treatment for cognition: three donepezil and two galantamine studies show **modest improvement of about two points on the VADAS-Cog**, with inconsistent effects on activities of daily living, behaviour and global function; two memantine studies show **modest cognitive benefit but no global benefit**. **There is no recommendation to prescribe cholinesterase inhibitors for pure VaD, but they should be used in mixed dementia once both AD and vascular components are demonstrated. (ii) Management of neuropsychiatric disturbance — depression is common with stroke and SIVD and is eminently treatable, so an antidepressant course is justified where suspected**. **(iii) Stroke prevention** — control of vascular risk factors, especially **hypertension**, remains **the most effective strategy**; **aspirin's effect on cognition and prognosis remains unclear**, and **antithrombotics should be used with caution when lobar microbleeds are seen on MRI** because of amyloid angiopathy. **Neither pravastatin (PROSPER) nor atorvastatin (LEADe) improved cognition. (iv) Management of stroke-related disability** — spasticity, parkinsonism and incontinence; **levodopa can help apraxic gait in SIVD** when the vascular burden lies in the basal ganglia or substantia nigra. **Physical activity and multicomponent exercise combining aerobic and strength training** have the most promising preventive evidence.

Latest Update — 1 Point

7. The field has moved from "vascular dementia" to biologically and clinically harmonised vascular cognitive impairment. The **VASCOG statement** and the harmonised **VICCCS** criteria have superseded NINDS-AIREN and ADDTC, aligning with **DSM-5 major and mild vascular neurocognitive disorder**, and **STRIVE-2 (2023)** standardised the neuroimaging reporting of small-vessel disease (**lacunes, white matter hyperintensities, perivascular spaces, microbleeds, cortical superficial siderosis, incidental infarcts**). Therapeutically, **intensive blood pressure lowering remains the only intervention with randomised evidence for cognitive benefit** — **SPRINT MIND** reduced incident MCI and the combined MCI-plus-dementia outcome, and its extended follow-up supports sustained benefit — reinforced by the **Lancet Commission 2024**, which added **high midlife LDL cholesterol (population attributable fraction 7%)** to hypertension, diabetes, smoking, obesity and physical inactivity among the modifiable determinants of vascular brain injury.

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Nomenclature	Vascular dementia; NINDS-AIREN and ADDTC criteria	**Vascular cognitive impairment (VCI)**; **VASCOG/VICCCS** criteria aligned to DSM-5	Use VCI as the umbrella term and NINDS-AIREN for the operational criteria
Imaging reporting	Descriptive leukoencephalopathy and infarcts	**STRIVE-2 (2023)** standardised small-vessel disease terminology	Name the six STRIVE features
Prevention	Vascular risk factor control, no randomised cognitive endpoint quoted	**SPRINT MIND** — intensive BP lowering reduced incident MCI	Best single trial to quote for VaD prevention
Symptomatic drugs	ChEIs not recommended for pure VaD; use in mixed dementia	**Unchanged**	State plainly; it is a common marking point

Exam One-Liners

- **VCI** is the preferred umbrella term; **~5% of those over 65** have VCI; **under 74 it may be the commonest cause of cognitive impairment**.
- **Seven subtypes**; **SIVD (lacunar state and Binswanger's) is commonest**.
- **CADASIL = NOTCH3 mutation, chromosome 19.**
- **Large vessel → cortical dementia; small vessel → subcortical dementia.**

- NINDS-AIREN needs **dementia + cerebrovascular disease + temporal relationship (within 3 months of stroke, abrupt deterioration, or stepwise course)**.
- White matter lesions must affect **>25% of white matter**.
- Criteria **exclude 90% of AD but have only 50–70% sensitivity** for VaD.
- **60% have slow onset, 80% slow progression** — stepwise decline is not obligatory.
- **The gait–incontinence–dementia triad is commoner in small-vessel VaD than in NPH.**
- **ChEIs are not recommended in pure VaD**; use in **mixed dementia**; benefit ≈ **2 points on VADAS-Cog**.
- **PROSPER and LEADe negative** for statins and cognition; **SPRINT MIND positive** for intensive BP lowering.
- **Levodopa may help apraxic gait** in SIVD.

QUESTION 28

Differentiating features of delirium, depression and dementia.

7-Mark Answer

Textbook Core — 6 Points

1. The three screening questions. Any older person presenting with confusion should be assessed with three questions that separate the three D's: **(i) Has the onset of abnormalities been acute — over a few hours or a few days?** (delirium); **(ii) Are there physical factors — medical illness, sensory deprivation, drugs — that may contribute?** (delirium or reversible dementia); **(iii) Are psychological factors — depression and/or psychosis — contributing to or complicating the impairment?** (depression). **These questions focus on identifying treatable conditions which, when diagnosed and treated, might result in substantially improved cognitive function.**

2. Delirium. An **acute or subacute alteration in mental status**, with **prevalence of about 15% on admission in hospitalised geriatric patients and incidence up to one-third**; it may **persist for days or weeks** and so is common in post-acute care. Key features are **disturbance of consciousness**, **change in cognition not better accounted for by dementia**, **development over hours to days with fluctuation through the day**, and **evidence of a causative medical condition, substance intoxication, side effect or withdrawal**. **The disturbances of consciousness and attention, with sudden onset and fluctuating cognitive status, are the major features that distinguish delirium from other causes of impaired cognitive function.** There is **difficulty sustaining attention, sensory misperception (illusions), fragmented or disordered stream of thought, psychomotor disturbance (restlessness, picking at bedclothes, or sluggishness and drowsiness) and emotional disturbance**; **neurological signs other than asterixis are uncommon**.

3. Dementia. A **clinical syndrome of sustained loss of intellectual function and memory sufficient to cause dysfunction in daily living**, with **a gradually progressing course over months to years** and **no disturbance of consciousness**. **Loss of functional ability due to impaired cognition is the feature that distinguishes dementia from MCI.**

4. Depression ("depressive pseudodementia"). Refers to patients with **reversible or partially reversible impairment of cognitive function caused by depression**. **Depression may coexist with dementia in more than one-third of outpatients with dementia and in an even greater proportion in nursing homes**, and the relationship is complex: **many patients with early dementia become depressed, and depression may be diagnosed in many patients before they become demented**. Helpful clinical characteristics are **prominent complaints of memory loss, patchy and inconsistent cognitive deficits on examination, and frequent "don't know" answers**.

5. Tools and testing. Delirium is screened with the **Confusion Assessment Method (CAM)**, which requires **acute onset and fluctuating course, AND inattention, AND either disorganised thinking OR altered level of consciousness**; **inattention is tested by months of the year backward, days of the week backward, or digit span backward**, and **disorganised thinking by orientation to time and place and observation of illogical flow of ideas**. Depression is quantified with the **Geriatric Depression Scale**, or the **Cornell Scale for Depression in Dementia** where dementia coexists. **Detailed neuropsychological testing, performed by someone skilled in these tools, is helpful in differentiating depression and dementia**, and **where uncertainty persists after full assessment, a careful trial of an antidepressant is justified** to facilitate diagnosis and improve function and quality of life.

6. Why the distinction matters, and the pitfalls. Differentiating delirium from dementia is important because the latter is not immediately life-threatening, and inappropriately labelling a delirious patient as demented may delay diagnosis of serious and treatable underlying medical conditions. It is not possible to diagnose dementia while delirium is present in a patient with previously normal or unknown cognitive function — **the diagnosis of dementia must await treatment of all potentially reversible causes of delirium**. Conversely, **attributing symptoms common in dementia — disorientation, agitation — to the dementia itself leads to under-diagnosis of delirium and to missing a serious underlying illness**. The practical strategy when both are possible is to **focus on the core diagnostic symptoms of abnormal attention and awareness and altered level of consciousness or alertness, rather than on the behavioural symptoms** — especially useful when no reliable informant is available. **Sundowning** — increased confusion at night, especially in pre-existing dementia — is probably related to **sensory deprivation in unfamiliar surroundings**, and such patients **may actually meet the criteria for delirium**.

Latest Update — 1 Point

7. Delirium superimposed on dementia (DSD) is now a defined clinical entity in its own right, present in a large proportion of hospitalised people with dementia and associated with **prolonged length of stay, accelerated long-term cognitive decline and poor outcomes**. Detection has been simplified by **ultra-brief validated tools — the 4AT, the 3D-CAM, the brief CAM (bCAM) and the Ultra-Brief 2-item screener** — which are practical at the bedside and in emergency departments; the **NICE delirium guidance (updated 2023)** and Indian practice both favour the **4AT** because it requires no special training and can be completed in under two minutes even in an uncooperative patient. Alongside this, the **"depression–dementia continuum"** is now better characterised: **late-life depression with cognitive impairment carries a substantially raised risk of subsequent dementia**, so such patients require **structured cognitive follow-up rather than reassurance**, and **plasma p-tau217** can help distinguish depression-related cognitive impairment from underlying Alzheimer pathology in specialist settings.

Master Differentiation Table

Feature	Delirium	Dementia	Depression
Onset	**Acute — hours to days**	**Insidious — months to years**	Subacute — weeks to months, often datable
Course	**Fluctuating through the day**, worse at night	Slowly progressive, stable through the day	Diurnal variation, typically **worse in the morning**
Consciousness	**Reduced clarity of awareness — the defining feature**	**Clear until terminal stages**	Clear
Attention	**Impaired — cardinal feature**	Normal early, impaired late	Poor concentration but attention preserved on testing
Orientation	Impaired, fluctuating	Impaired as disease advances	Usually intact
Memory complaint	Not volunteered	**Concealed or minimised**; informant reports it	**Prominently complained of**
Cognitive deficits	Global, fluctuating	Consistent, progressive	**Patchy and inconsistent**
Answers on testing	Wrong, inconsistent, distractible	**Near-miss or confabulated** answers, effortful	**Frequent "don't know"**, poor effort
Psychomotor activity	**Hyperactive, hypoactive or mixed**; picking at bedclothes	Usually normal until late	**Retardation** or agitation
Perception	**Illusions and hallucinations common** (visual)	Hallucinations late (early in DLB)	Uncommon; mood-congruent if psychotic
Thought	**Fragmented, disordered, illogical**	Impoverished	Themes of guilt, worthlessness, hopelessness
Sleep–wake cycle	**Markedly disrupted, reversed**	Fragmented, sundowning	**Early morning waking**
Neurological signs	**Uncommon except asterixis**	Late focal or extrapyramidal signs	Absent
Reversibility	**Usually reversible** if the cause is treated	Largely irreversible (<4% reversible)	**Reversible with treatment**
Screening tool	**CAM, 4AT, 3D-CAM**	MMSE, MoCA, informant history	**GDS, Cornell Scale**

Current Practice Update

Area	Textbook	Current recommendation	Exam approach
Delirium screening	CAM (4 criteria)	**4AT and 3D-CAM** for ultra-brief bedside and emergency use	Name CAM first, then the 4AT as the practical update
Delirium with dementia	Recognised as difficult	**DSD is a defined entity** with worse outcomes; focus on **attention and level of consciousness**, not behaviour	Use the phrase "delirium superimposed on dementia"
Depression with cognitive impairment	High risk of later dementia; follow closely	**Confirmed**; **plasma p-tau217** can identify underlying AD pathology	Mention structured follow-up, not reassurance

Exam One-Liners

- The three discriminators: **onset, attention and level of consciousness**.
- **Delirium: acute, fluctuating, inattentive, clouded consciousness.**
- **Dementia: insidious, progressive, clear consciousness.**
- **Depression: prominent memory complaints, patchy deficits, "don't know" answers.**
- Delirium prevalence **~15% on admission**, incidence **up to one-third**.
- **CAM = acute onset and fluctuation + inattention + (disorganised thinking OR altered consciousness).**
- **Neurological signs other than asterixis are uncommon in delirium.**
- **You cannot diagnose dementia while delirium is present.**
- Depression coexists with dementia in **over one-third** of outpatients.
- **Sundowning patients may actually meet criteria for delirium.**
- When both are possible, judge by **attention and alertness, not by behaviour**.

CONSOLIDATED NIGHT-BEFORE MASTER SHEET

Questions 21–28 on One Page

#	Topic	Marks	The single fact most likely to earn the mark
21	BPSD — types, aetiology, investigation, management, drugs	15 + 7	**90–98%** develop at least one NPS; **DICE**; **brexpiprazole 2023 and dextromethorphan–bupropion 2026** now licensed for agitation
22	Non-pharmacological management of behavioural disturbance	7	Caregiver-directed interventions: **23 trials, ~3300 dyads, effect size 0.34 — greater than antipsychotics**
23	Addressing caregiver stress	7	**Zarit Burden Interview**; caregiver counselling **prevents caregiver depression**; treat the **dyad**
24	Innovations to ease caregiver burden	7	**ICT delivery of proven interventions**; **telemedicine prevents psychiatric admissions from LTC homes**
25	Reversible dementias	7	**<4% truly reversible**; **treatment does not guarantee reversal**; **PENS 2025 — gait improves, cognition does not**
26	Mild cognitive impairment	7	**>20% of those 71+ have CIND**; **15–20% convert per year**; **anti-amyloid antibodies now licensed at MCI stage**
27	Vascular dementia	7	**VCI is the umbrella term**; **ChEIs not recommended for pure VaD, use in mixed**; **SPRINT MIND** for prevention
28	Delirium vs depression vs dementia	7	Judge by **onset, attention and level of consciousness**; **you cannot diagnose dementia during delirium**

The Twelve Numbers to Carry Into the Hall

Fact	Number
Dementia patients developing at least one NPS	**90–98%**
Caregiver intervention effect size on behavioural symptoms	**0.34**
Brexpiprazole CMAI effect size	**~0.35**
AXS-05 relapse rate versus placebo (ACCORD-2)	**8.4% vs 28.6%**
Truly reversible dementias	**<4%**
Depression coexisting with dementia in outpatients	**>1/3**
Cognitive impairment without dementia, age 71+	**>20%**
MCI annual conversion to dementia	**15–20%**
VCI prevalence over age 65	**~5%**
White matter lesion threshold, NINDS-AIREN	**>25% of white matter**
Delirium prevalence on admission / incidence in hospital	**~15% / up to one-third**
PENS trial gait velocity gain (iNPH shunting)	**0.21 m/s; 80% vs 24% improved**

Indian Policy Sentences to Drop Into Any of These Answers

- **LASI-DAD:** dementia prevalence **7.4%** in adults 60+, about **8.8 million cases**, projected **16.9 million by 2036**; caregiving data from **4196 informants (2025)** confirm measurable caregiver stress and mental-health impact
- **Over 90% of dementia care in India is family-provided**, with scarce respite and long-term care infrastructure — the case for **digital and community-based caregiver support**
- **NPHCE** — Regional Geriatric Centres, district geriatric units and CHC/PHC geriatric clinics: the platform for cognitive and caregiver screening
- **National and District Mental Health Programme** — the practical route for BPSD management and caregiver depression
- **AB-PMJAY and the Ayushman Vay Vandana Card** — cover for all citizens aged 70 and above regardless of income
- **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** — legal remedy where caregiving breaks down
- **Rights of Persons with Disabilities Act, 2016** — disability certification including chronic neurological conditions and mental illness
- **Rashtriya Vayoshri Yojana / AVYAY** — assistive devices and senior citizen welfare

- **Elder Line 14567** — national toll-free helpline
- **ARDSI** — caregiver training, day care, support groups, Dementia India reports
- **WHO ICOPE (2nd edition)** — cognitive decline as one of the six domains of intrinsic capacity screened in primary care

End of compilation — Questions 21 to 28.

Parkinsonism, Movement Disorders & the Ageing Brain

MD Geriatric Medicine — Strict Mark-Wise Answers (Q53–Q60)

Primary sources: Pathy's Principles and Practice of Geriatric Medicine (6th ed.) and Essentials of Clinical Geriatrics (7th ed.)
Latest updates from guidelines and peer-reviewed evidence to August 2026 | Indian context integrated

Contents

53.	**15 marks**	Motor and non-motor symptoms of Parkinson's disease; treatment modalities and side effect profile, with special reference to the geriatric population RECURS
54.	**7 marks**	Principles of therapy in a 65-year-old with newly diagnosed PD, predominant rigidity and minimal tremor
55.	**7 marks**	Levodopa RECURS
56.	**7 marks**	Drug-induced parkinsonism
57.	**15 marks**	Multiple system atrophy — clinical features, types, diagnosis, prognosis and treatment RECURS
58.	**7 marks**	Essential tremor RECURS
59.	**7 marks**	Movement disorders in the elderly
60.	**15 marks**	Ageing changes in the central nervous system including the brain, and the degenerative diseases of the brain

Format used in this compilation

- **15-mark essay = exactly 12 points** — 10 textbook core points (1–10) plus 2 latest updates (11–12).
- **7-mark note = exactly 7 points** — 6 textbook core points (1–6) plus 1 latest update (point 7).
- Tables, algorithms and panels are **revision aids, not extra points** — they compress content you would otherwise write as prose.
- A **Current Practice Update** appears only where the textbook meaningfully differs from current recommendations.
- Topics flagged RECURS carry a green **Extra Points to Remember** panel.

Q53. Enumerate the motor and non-motor symptoms of Parkinson's disease. What treatment modalities are available and what is the side effect profile of the drugs used, with special reference to the geriatric population? RECURS

15-Mark Answer | 10 Textbook Points + 2 Latest Updates = 12 Points

Source: Pathy's 6th ed., Chapter 53 (Tables 53.3, 53.4); Essentials of Clinical Geriatrics 7th ed., Chapter 10 (Table 10-6).

Textbook Core — 10 Points

1. **Definition.** Parkinson's disease is the **second most common neurodegenerative disease**, caused by **loss of substantia nigra neurons with striatal dopamine depletion** and **α-synuclein Lewy bodies**. Prevalence is **about 1% over age 65**.
2. **Cardinal motor symptoms. Bradykinesia** (obligatory), **4–6 Hz rest tremor**, **rigidity** and **postural instability**. Onset is **asymmetric or unilateral** and becomes bilateral as the disease progresses.
3. **Other motor symptoms.** Difficulty in moving, writing and walking; **flexed posture of limbs and trunk**; **reduced step length and height with reduced arm swing**; **falls**; expressionless face; freezing; dysarthria and dysphagia in advanced disease.
4. **Non-motor — neuropsychiatric and cognitive. Bradyphrenia** (slowness of mental function); **depression in about 50%**; anxiety, mainly **generalised anxiety disorder and obsessive–compulsive disorder**; visual hallucinations and delusions; **PD-related dementia only after several years** — cognitive impairment is **never a sign of early PD**.
5. **Non-motor — autonomic.** Dominated by **orthostatic hypotension** (fall of **20 mmHg systolic or 10 mmHg diastolic within three minutes of standing**, often worsened by antiparkinsonian drugs) and **constipation in about 50%**. Also sweating, drooling, sexual dysfunction, urinary frequency, urgency and dysuria, and **delayed gastric emptying in at least 70%**.
6. **Non-motor — other. Hyposmia**, insomnia, REM sleep behaviour disorder, pain and fatigue. In advanced disease, insomnia, pain, sweats, dysphagia, dysarthria, drooling and urinary dysfunction cluster together.
7. **Levodopa — the mainstay in the elderly.** It is the **main and often the only treatment for PD in older people**, given with a peripheral decarboxylase inhibitor as **Madopar** (levodopa + benserazide) or **Sinemet** (carbidopa + levodopa). Effective for **tremor, bradykinesia and rigidity**. Start low, increase very gradually; usual early control on **300–600 mg/day** in 3–4 doses **30 minutes before meals**; dispersible form for **early-morning akinesia**.
8. **Side effect profile of levodopa.** Nausea, vomiting, anorexia, **orthostatic hypotension**; sedation, nightmares, vivid dreams, **hallucinations, delusions and delirium** (dose-related, especially in the old); and after several years **motor fluctuations** (delayed on, wearing-off, on–off) with **dyskinesias** — chorea, athetosis and dystonia.
9. **Other drug classes and their geriatric restrictions. Dopamine agonists are not used in older people with PD** and **anticholinergics are never used**. COMT inhibitors, amantadine and MAO-B inhibitors are adjuncts (see table).

10. **Non-drug modalities and non-motor treatment. Bilateral deep brain stimulation of the STN or GPi** for cognitively intact patients with refractory motor complications; **rehabilitation started early and timed to the peak effect of levodopa**; speech therapy for dysarthria, drooling and swallowing; home support, caregiver education and psychological support. Non-motor symptoms are treated only **after adjusting levodopa** — venlafaxine for depression, clozapine or pimavanserin for psychosis, rivastigmine for dementia and apathy, droxidopa or midodrine for orthostatic hypotension, macrogol for constipation, domperidone for nausea.

Side Effect Profile of Antiparkinsonian Drugs (revision table)

Drug	Dose	Side effects	Geriatric comment
Carbidopa–levodopa	300–600 mg/day levodopa, 3–4 doses	Nausea, vomiting, orthostatic hypotension, dyskinesia, vivid dreams, hallucinations, delirium	**Drug of choice; start low, go slow**
Dopamine agonists (pramipexole 0.5–1.5 mg tid, ropinirole 3–8 mg tid, bromocriptine)	As listed	Hallucinations, somnolence, nausea, orthostatic hypotension, syncope, behavioural change, impulse-control disorder	**Not used in older people with PD**
Anticholinergics (trihexyphenidyl 2–20 mg/day, benztropine)	As listed	Dry mouth, constipation, urinary retention, blurred vision, glaucoma exacerbation, tachycardia, **confusion and delirium**	**Never used in the elderly**
Amantadine	100–300 mg/day; 200–400 mg/day for dyskinesia	**Delirium**, hallucinations, livedo reticularis, ankle oedema	**Renally excreted — reduce dose in renal impairment**
Selegiline / Rasagiline	10 mg/day / 1 mg/day	Selegiline: nausea, confusion, agitation, insomnia. Rasagiline: balance difficulty, anorexia, weight loss, depressive symptoms	Rasagiline needs **no dietary restriction**
Entacapone / Tolcapone	200 mg with each levodopa dose / 100–200 mg tid	Nausea, dyskinesia, orthostatic hypotension, **diarrhoea**; tolcapone — **liver dysfunction**	Useful for motor fluctuations in the old
Clozapine (for psychosis)	12.5 mg start → 25–50 mg	**Neutropenia**, sedation, hypotension	**Stop permanently if neutrophils <1500/mm^3**

Latest Updates — 2 Points

11. **New levodopa delivery systems (2024–25). Crexont** (extended-release carbidopa/levodopa capsules) was FDA-approved in **August 2024**, **Vyalev** (foslevodopa/foscarbidopa) — the **first 24-hour continuous subcutaneous infusion** — in **October 2024**, and **Onapgo** (subcutaneous apomorphine infusion) in **February 2025**. **Tavapadon**, a novel **D1/D5 partial agonist**, gave an extra **1.1 hours of daily "on" time** in Phase 3 TEMPO-3 and is under FDA review.
12. **Adaptive deep brain stimulation (February 2025).** The FDA approved Medtronic **BrainSense Adaptive DBS** on the basis of the **ADAPT-PD** randomised crossover trial — the first closed-loop system, which titrates stimulation in real time to sensed **beta-band local field potentials** for patients with motor fluctuations. Contemporary data also show DBS outcomes in patients **over 70 are comparable to younger patients**, so age alone is no longer a contraindication.

Current Practice Update

Aspect	Textbook	Current recommendation
DBS in the elderly	"Not currently used in elderly people with PD"	**Age alone is not a bar**; adaptive closed-loop DBS approved February 2025
Levodopa safety	Nausea, hypotension, neuropsychiatric effects, motor complications	Add **vitamin B6 deficiency and seizures** — FDA label warning for all carbidopa/levodopa products, **March 2026**
Neuroprotection	MAO-B inhibitors "proposed for neuroprotective effects"	No disease-modifying agent exists; **Exenatide-PD3 was negative** (Lancet 2025). MAO-B inhibitors are used for **symptomatic benefit only**

Exam approach: state the textbook position first, then add the current position in one sentence — examiners reward awareness of the change, not contradiction of the textbook.

Extra Points to Remember — this topic recurs

- **Enumeration mnemonic for non-motor symptoms — "SAD CUPS":** **S**leep (insomnia, RBD), **A**utonomic (orthostatic hypotension, constipation, bladder, sexual), **D**epression and anxiety; **C**ognitive (bradyphrenia, dementia), **U**rinary, **P**ain and fatigue, **S**mell loss.
- **The single highest-yield sentence in this answer:** "Levodopa does not improve non-motor symptoms, posture or gait."
- **Two drugs to name as contraindicated: metoclopramide** (use domperidone instead) and **typical neuroleptics**.
- If the question weights "geriatric population", spend two of your ten points on the **two prohibitions** (agonists, anticholinergics) and on **orthostatic hypotension monitoring at every visit** — that is what distinguishes a geriatrics answer from a neurology answer.

Examiner's Tip — lines that earn marks

- The word "enumerate" means the examiner wants **lists** — write motor and non-motor symptoms as two clearly headed lists before you begin treatment.
- Give the three numbers: **depression ~50%, constipation ~50%, delayed gastric emptying ≥70%**.
- Reproduce the side effect table — a drug-by-drug table converts directly into marks and saves writing time.
- Close with: "**In the elderly, levodopa is the main and often the only treatment; dopamine agonists are not used and anticholinergics are never used.**"

Q54. What are the principles of therapy and treatment in a 65-year-old patient recently diagnosed with Parkinson's disease who has predominant rigidity and minimal tremor?

7-Mark Answer | 6 Textbook Points + 1 Latest Update = 7 Points

Source: Pathy's 6th ed., Chapter 53 (Tables 53.2, 53.3, 53.4; Box 53.1); Essentials of Clinical Geriatrics 7th ed.

Textbook Core — 6 Points

1. **Confirm the diagnosis before treating.** Apply the **Queen Square Brain Bank criteria**. An **akinetic-rigid presentation with minimal tremor** must prompt exclusion of other causes of extrapyramidal syndrome, which account for **20–40% of late-onset parkinsonism** — drug-induced parkinsonism (take an exhaustive neuroleptic history), vascular parkinsonism, PSP, MSA and normal pressure hydrocephalus. **Ioflupane SPECT** is normal in drug-induced parkinsonism and abnormal in PD.
2. **Levodopa is the drug of choice.** It is **effective in tremor, bradykinesia and rigidity**, and is the **main and often the only treatment for PD in the elderly**. Give it as **Madopar or Sinemet** with a peripheral decarboxylase inhibitor. Since rigidity and bradykinesia dominate here, levodopa targets exactly the symptoms present.
3. **Start low and titrate slowly.** Begin at a low dose and increase **very gradually** until adequate effect; most patients are controlled in the first years on **300–600 mg/day** in **3–4 divided doses given 30 minutes before meals**. A good response supports the diagnosis; a **negative response to large doses is an exclusion criterion for PD**.
4. **Avoid the two prohibited classes. Anticholinergics are never used in older people with PD** — and are in any case indicated for tremor, which is minimal in this patient. **Dopamine agonists are not used in older people** because adverse effects are numerous and can be severe.
5. **Anticipate and monitor adverse effects.** Warn about nausea (treat with **domperidone**, never metoclopramide), and check for **orthostatic hypotension at every visit** — a fall of 20 mmHg systolic or 10 mmHg diastolic within three minutes, frequently worsened by antiparkinsonian drugs. Watch for sedation, vivid dreams and hallucinations. Counsel that **motor fluctuations and dyskinesia appear after several years**.
6. **Start non-pharmacological therapy at once and think as a geriatrician. Functional rehabilitation should be started early as it helps preserve motor function**, with sessions **timed to the peak effect of levodopa**, combining joint flexibility, walking, posture, balance and turning exercises against the flexed attitude. Add **combined aerobic, strengthening, balance and stretching exercise**. Screen for non-motor symptoms (depression, constipation), review polypharmacy for dopamine-blocking drugs, assess falls risk, and provide **patient and caregiver education and psychological support**.

Latest Update — 1 Point

7. **Levodopa should be started early at the lowest effective dose, not withheld.** No agent has proven disease modification — the Phase 3 **Exenatide-PD3** trial (*Lancet* 2025) showed **no slowing of progression**, and MAO-B inhibitors are no longer claimed to be neuroprotective. Contemporary evidence confirms levodopa is **not toxic to nigral neurons** and that delaying it does not alter disease course, so "saving levodopa for later" is obsolete — particularly in a 65-year-old with disabling rigidity. Newer formulations (**Crexont**, August 2024) are available if wearing-off develops later.

Current Practice Update

Aspect	Textbook	Current recommendation
Timing of levodopa	Implicit — first-line in the elderly	**Explicitly start early at lowest effective dose**; no benefit from delaying
Neuroprotection	Selegiline/rasagiline "proposed for neuroprotective effects in early PD"	Prescribed for **symptomatic benefit only**; no proven disease modification

Examiner's Tip — lines that earn marks

- The examiner has deliberately written "**predominant rigidity and minimal tremor**" — your first point must show you recognise this as a **red flag for atypical parkinsonism**, not just a variant of PD.
- Second, use it to justify **not** prescribing an anticholinergic: "anticholinergics are used for tremor, which is minimal here, and are never used in the elderly."
- Write the dose precisely: "**levodopa–carbidopa started low and titrated to 300–600 mg/day of levodopa in 3–4 doses, 30 minutes before meals.**"
- End on the geriatric note: **early rehabilitation timed to peak levodopa effect, falls assessment, and caregiver education.**

Q55. Levodopa RECURS

7-Mark Answer | 6 Textbook Points + 1 Latest Update = 7 Points

Source: Pathy's 6th ed., Chapters 53 and 30; Essentials of Clinical Geriatrics 7th ed.

Textbook Core — 6 Points

1. **Mechanism.** Levodopa is the **precursor of dopamine** and, unlike dopamine, **crosses the blood-brain barrier**. It is combined with a **peripheral dopa-decarboxylase inhibitor** to lessen systemic effects — **Madopar** (levodopa + benserazide) and **Sinemet** (carbidopa + levodopa).
2. **Indication.** It is the **main and often the only treatment for Parkinson's disease in the elderly**, and is **effective in tremor, bradykinesia and rigidity**. Critically, it **does not improve non-motor symptoms, posture or gait**.
3. **Dose and administration. Start at low doses and increase very gradually.** Most patients are controlled in the first years on **300–600 mg/day**, given **three or four times daily, 30 minutes before meals**. The **dispersible form** reaches peak plasma concentration faster and is used for **early-morning akinesia**.
4. **Adverse effects. Peripheral** — nausea, vomiting, anorexia and hypotension. **Neuropsychiatric** — sedation, nightmares, vivid dreams, hallucinations, delusions and delirium, all **dose-related** and common in older patients.
5. **Long-term complications.** After several years, **motor fluctuations** appear — delayed effect of levodopa, wearing-off between doses, and the **on–off phenomenon** — together with **involuntary movements: chorea, athetosis and dystonia**. These require **revision of the timing of administration**. **Gastric emptying is delayed in at least 70%** of patients, and levodopa retained in the stomach is metabolised to dopamine and lost, causing erratic absorption that itself contributes to the on–off phenomenon.
6. **Diagnostic role.** In the **levodopa challenge**, a fasting patient is given **150–250 mg with a decarboxylase inhibitor** and tremor, rigidity and akinesia are assessed **every 30 minutes for two to three hours**. This indicates **dopaminergic responsiveness and is not a formal diagnostic test**. An **excellent 70–100% response sustained for five years or more** is a supportive criterion for PD; a **negative response to large doses is an exclusion criterion**.

Latest Update — 1 Point

7. **New formulations and a new safety warning. Crexont** (extended-release carbidopa/levodopa capsules) was FDA-approved in **August 2024** for wearing-off, and **Vyalev** (foslevodopa/foscarbidopa) in **October 2024** as the **first 24-hour continuous subcutaneous infusion**, which bypasses the gastrointestinal tract and solves the erratic gastric absorption problem **without surgery**. In **March 2026 the FDA required a new label warning for all carbidopa/levodopa products regarding vitamin B6 deficiency and seizures**.

Extra Points to Remember — this topic recurs

- **Drugs that must not be combined: metoclopramide is contraindicated** in parkinsonian patients because of its striatal dopamine receptor effects — use **domperidone**, which does not cross the blood–brain barrier (with ECG monitoring for QT prolongation).
- **Protein interaction:** dietary protein competes with levodopa for absorption — this is the reason for pre-meal dosing, and in Indian practice a high-protein evening meal (dal, paneer, milk) can blunt the last dose of the day.
- **Never stop levodopa abruptly** — abrupt withdrawal can precipitate a **neuroleptic malignant-like syndrome** with rigidity, fever and raised creatine kinase. This matters when a patient is kept nil by mouth perioperatively; use a dispersible preparation via nasogastric tube or a rotigotine patch instead.
- **Drugs that prolong or modify levodopa action:** COMT inhibitors (entacapone, tolcapone), the fixed combination **Stalevo**, and **amantadine 200–400 mg/day** for peak-dose dyskinesia.
- **The one-line definition to open with:** "Levodopa is the metabolic precursor of dopamine which, unlike dopamine, crosses the blood–brain barrier, and is given with a peripheral decarboxylase inhibitor."

Examiner's Tip — lines that earn marks

- Structure a drug note as **Mechanism → Indication → Dose → Adverse effects → Long-term complications → Precautions** — exactly six points.
- Quote the numbers: **300–600 mg/day; 3–4 doses; 30 minutes before meals; challenge 150–250 mg; ≥70% delayed gastric emptying.**
- Do not forget the negative: "**Levodopa does not improve non-motor symptoms, posture or gait.**"

Q56. Drug-induced parkinsonism

7-Mark Answer | 6 Textbook Points + 1 Latest Update = 7 Points

Source: Pathy's 6th ed., Chapters 53 (Table 53.2) and 54 (Tables 54.3, 54.4); Essentials of Clinical Geriatrics 7th ed., Chapters 10 and 14.

Textbook Core — 6 Points

1. **Definition and importance.** Drug-induced parkinsonism is an extrapyramidal syndrome defined by **exposure to neuroleptics or other drugs before the onset of parkinsonism**. It is listed among the causes **frequently observed as very late-onset parkinsonism**, and **many elderly patients, especially in long-term care institutions, have undiagnosed but treatable drug-induced parkinsonism** resulting from the extrapyramidal side effects of antipsychotics.
2. **Causative drugs. Antipsychotics** — haloperidol, fluphenazine, olanzapine; **antiemetics** — metoclopramide and prochlorperazine; and other agents implicated in drug-induced movement disorders including **calcium channel blockers, lithium, valproate, carbamazepine, phenytoin, amiodarone, antidepressants and antihistamines**.
3. **Clinical features. Dyskinesia is frequent and tremor is absent** — the reverse of idiopathic PD. The picture is usually more symmetrical, and **ioflupane (DaTSCAN) SPECT shows a normal pattern**, which distinguishes it from PD and other degenerative parkinsonian syndromes.
4. **Course after withdrawal.** When the offending drug is stopped, signs often alleviate but **very slowly, over periods as long as several weeks or months**. In **about 20% of patients some extrapyramidal signs persist**, which suggests these people had **PD or another neurodegenerative parkinsonism precipitated (unmasked) by the drug challenge**. **Tardive dyskinesia is often permanent** in many patients even after stopping the drug.
5. **Management.** There is **no satisfactory treatment** for drug-induced parkinsonism — **stopping the responsible drug is the best option**, and in elderly patients this is often possible. If severe psychosis demands treatment, **switch from a classical neuroleptic to a low-dose atypical antipsychotic**. **Anticholinergic drugs, used in younger psychiatric patients on neuroleptics, must be avoided in the elderly** because they often induce delirium and other adverse effects. For established tardive dyskinesia, options are slow down-titration of the offending agent, switching to **clozapine or quetiapine**, and specific pharmacotherapy with **valbenazine or deutetrabenazine**.
6. **Prevention. Prevention of drug-induced parkinsonism is a crucial issue in geriatric care** and is achieved by **avoiding the prescription of neuroleptics in elderly patients, especially those with dementia — a condition for which they are ineffective** for behavioural complications. Untreated parkinsonian patients eventually become immobile and develop **flexion contractures, pressure sores, malnutrition and aspiration pneumonia**.

Latest Update — 1 Point

7. **Deprescribing is now formalised.** The **AGS Beers Criteria 2023 update** (*JAGS* 2023) lists **antipsychotics and metoclopramide as potentially inappropriate medications in older adults**, with antipsychotics carrying a boxed warning for **increased mortality in dementia**, and specifically advises avoiding metoclopramide unless for gastroparesis and limiting it to under 12 weeks. Where signs persist after withdrawal, current practice adds **DaTSCAN** and, in research settings, **α-synuclein seed amplification assay** to identify the subgroup in whom the drug has unmasked underlying Parkinson's disease.

Current Practice Update

Aspect	Textbook	Current recommendation
Prevention	"Avoid prescribing neuroleptics in elderly patients, especially those with dementia"	Formalised in the **AGS Beers Criteria 2023**; antipsychotics and metoclopramide are explicitly potentially inappropriate in older adults
Persisting signs after withdrawal	20% persist, "suggests underlying neurodegeneration"	Confirm with **DaTSCAN**; α-synuclein SAA can identify unmasked PD in research settings

Examiner's Tip — lines that earn marks

- Two contrasts win marks: "**dyskinesia is frequent and tremor is absent**" and "**ioflupane SPECT is normal, unlike in PD**."
- Quote the two figures: recovery takes **weeks to months**, and **about 20% have persisting signs** indicating unmasked neurodegenerative disease.
- State the prohibition explicitly: "**anticholinergics should be avoided in the elderly because they often induce delirium**" — this is a common trap, since anticholinergics are standard in younger psychiatric patients.
- Close with the geriatric public-health line: "**Prevention is a crucial issue in geriatric care — avoid neuroleptics in older people with dementia, in whom they are ineffective.**"

Q57. Multiple system atrophy — clinical features, types, diagnosis, prognosis and treatment RECURS

15-Mark Answer | 10 Textbook Points + 2 Latest Updates = 12 Points

*Source: Pathy's 6th ed., Chapter 32 (Hypotension) and Chapter 53 (Table 53.2). Note: Pathy's covers MSA only briefly; the detailed MDS classification, MRI signs and prognostic figures are **not covered adequately in the uploaded textbook** and are supplied from current evidence, clearly separated below.*

Textbook Core — 10 Points

1. **Definition.** Multiple system atrophy is a **sporadic, progressive, adult-onset disorder characterised by autonomic dysfunction, parkinsonism and ataxia in any combination**.
2. **Types (textbook nomenclature).** Subtypes include **striatonigral degeneration** (parkinsonian predominant), **sporadic olivopontocerebellar atrophy** (cerebellar predominant) and **Shy–Drager syndrome** (autonomic predominant).
3. **Autonomic features and their timing — the key diagnostic clue. Orthostatic hypotension, impotence, urinary incontinence or retention is typically seen before the onset of motor symptoms, or within two years after the onset of motor symptoms.** Table 53.2 emphasises **severe dysautonomia early in the course of parkinsonism** — orthostatic hypotension, urinary disorder, sexual dysfunction and gastrointestinal symptoms.
4. **Motor features. Parkinsonism with a poor or unsustained motor response to levodopa therapy** — this poor levodopa response is the single most useful clinical discriminator from idiopathic PD.
5. **Additional neurological signs.** There may be **cerebellar or corticospinal (pyramidal) signs on physical examination**. In Table 53.2 the syndrome is defined by severe dysautonomia **plus a pyramidal or cerebellar syndrome**.
6. **Orthostatic hypotension — definition and measurement.** A fall in **systolic BP of 20 mmHg or diastolic BP of 10 mmHg within three minutes of standing**. **Delayed orthostatic hypotension** occurs after six minutes, and some patients require **standing for 10 minutes** before the fall appears. **Asymptomatic orthostatic hypotension is more common than the symptomatic form**, and even when asymptomatic it predicts falls, cerebrovascular and cardiovascular disease and all-cause mortality.
7. **Context among neurogenic causes of orthostatic hypotension.** The commonest neurogenic causes are **pure autonomic failure (PAF), Parkinson's disease with autonomic failure, and MSA**. PAF is idiopathic and sporadic with widespread autonomic failure and **reduced supine plasma noradrenaline**; **some PAF patients later manifest MSA**. In all three there is **decreased sympathetic and parasympathetic innervation of cardiac and extra-cardiac autonomic receptors**. Orthostatic hypotension affects **30–40% of PD patients**, against a pooled prevalence of **22% in community-dwelling older adults**.
8. **Epidemiology and place among the Parkinson-plus syndromes.** MSA is listed among the causes **very rarely observed as very late-onset parkinsonism** — important, because in a very old patient with parkinsonism, drug-induced, vascular, PSP and Lewy body causes are far more likely.
9. **Diagnosis.** Diagnosis is **clinical**, resting on the triad of **early severe dysautonomia + levodopa-unresponsive parkinsonism + cerebellar or pyramidal signs**. Response to levodopa can be tested formally by the **levodopa challenge** (150–250 mg fasting, assessed every 30 minutes for two to three hours). Ioflupane SPECT is abnormal but **does not separate MSA from PD**. The differential includes **PSP, corticobasal degeneration, dementia with Lewy bodies, vascular parkinsonism and normal pressure hydrocephalus**.
10. **Treatment — symptomatic only.** Give an **adequate trial of levodopa** although the response is poor or unsustained. Treat **orthostatic hypotension** with **droxidopa, midodrine, fludrocortisone and elastic venous compression**, together with physical manoeuvres that reduce postural hypotension, adequate salt and fluid, head-up tilt at night, and **withdrawal of drugs that worsen orthostasis** — alpha blockers, nitrates, diuretics, calcium channel blockers, tricyclics and antiparkinsonian drugs. Manage bladder dysfunction (solifenacin has low brain penetration; catheterisation for retention), constipation, drooling with botulinum toxin, and dysphagia and dysarthria with **speech and swallow therapy**. Provide falls prevention, rehabilitation and caregiver support. **Deep brain stimulation is not indicated.**

Latest Updates — 2 Points

11. **MDS 2022 diagnostic criteria and imaging biomarkers.** The **Movement Disorder Society criteria for MSA** (Wenning et al., *Mov Disord* 2022) replaced the 2008 consensus and define **four levels of certainty — neuropathologically established, clinically established, clinically probable, and the research category of**

possible prodromal MSA. Nomenclature is now **MSA-P (parkinsonian) and MSA-C (cerebellar)**. MRI markers are formally incorporated: the **"hot cross bun" sign** in the pons (seen in around **75% of MSA-C**) and the **hyperintense putaminal rim** with putaminal atrophy in MSA-P. Brain-bank validation confirmed better early sensitivity, and a 2026 registry re-evaluation found the 2022 criteria gave **94% specificity for clinically established MSA** versus 71% for clinically probable.

12. **Prognosis and biomarkers.** Prevalence is about **3.4–4.9 per 100,000**, with mean onset near **55–60 years**; **median survival from symptom onset is 6–10 years** (natural-history cohorts report 8.9–9.8 years), and **severe symptomatic autonomic failure at diagnosis and early dysphagia predict shorter survival**. **α-Synuclein seed amplification assay** in CSF and skin, and **fibrillar phosphorylated α-synuclein in Schwann cells** as an MSA-specific hallmark, are emerging diagnostic tools, and **neurofilament light chain (NfL)** is elevated in MSA and predicts mortality (*Lancet Neurology* 2024; *npj Parkinson's Disease* 2026). There is still **no disease-modifying therapy**; agents such as TEV-56286 are in Phase 2.

Current Practice Update

Aspect	Textbook	Current recommendation
Classification	Striatonigral degeneration, sporadic olivopontocerebellar atrophy, Shy–Drager syndrome	**MSA-P and MSA-C**; the eponym Shy–Drager is obsolete because all MSA has dysautonomia
Diagnostic criteria	Clinical description only	**MDS 2022 criteria** with four certainty levels, including **possible prodromal MSA**
Imaging	Not specified for MSA	**Hot cross bun sign** (pons, MSA-C) and **putaminal rim sign** with putaminal atrophy (MSA-P) are formal supportive features
Biomarkers	Reduced supine noradrenaline in PAF	Add **α-synuclein SAA (CSF/skin)**, Schwann-cell phospho-α-synuclein and **NfL**
Prognosis	Not stated	**Median survival 6–10 years**; worse with early severe autonomic failure and dysphagia

Exam approach: write the textbook triad and subtypes first, then add "current MDS 2022 criteria classify MSA as MSA-P and MSA-C with four levels of diagnostic certainty" — one sentence secures the update mark.

Extra Points to Remember — this topic recurs

- **The defining timing rule to quote:** "Orthostatic hypotension, impotence and urinary symptoms appear **before, or within two years of**, the onset of motor symptoms." This is what separates MSA from PD, where autonomic failure appears late.
- **Red flags for MSA in a parkinsonian patient (mnemonic "RAPID"):** **R**apid progression; **A**utonomic failure early and severe; **P**yramidal or cerebellar signs; **I**nspiratory stridor and disproportionate antecollis; **D**ysphagia and dysarthria early, with poor levodopa response.
- **Two clinical signs examiners like: nocturnal inspiratory stridor** (from vocal cord abductor paralysis — a cause of sudden death, may need CPAP or tracheostomy) and **disproportionate antecollis**.
- **Supine hypertension is the therapeutic trap:** most MSA patients with orthostatic hypotension also have supine hypertension. Never give midodrine or fludrocortisone within a few hours of lying down; raise the head of the bed by 30–40° and avoid daytime recumbency.
- **Non-pharmacological measures first for orthostatic hypotension:** physical counter-manoeuvres (leg crossing, squatting, tensing), abdominal binder and compression stockings, small frequent meals to limit postprandial hypotension, adequate salt and 2–2.5 L fluid, and slow rising.
- **Neuropathology one-liner:** MSA is an **α-synucleinopathy** characterised by **glial cytoplasmic inclusions (Papp-Lantos bodies) in oligodendrocytes**, in contrast to the neuronal Lewy bodies of PD.

Examiner's Tip — lines that earn marks

- Open with the textbook definition verbatim: "**a sporadic, progressive, adult-onset disorder characterised by autonomic dysfunction, parkinsonism and ataxia in any combination.**"
- Give the orthostatic hypotension definition with numbers — **20 mmHg systolic or 10 mmHg diastolic within three minutes** — and mention **delayed orthostatic hypotension after six minutes**, which most candidates omit.
- Answer the four parts of the question in order, with clear headings: **Clinical features → Types → Diagnosis → Prognosis → Treatment**. The question names them, so the examiner is marking against them.
- Name the two MRI signs: **hot cross bun sign** and **putaminal rim sign**.
- Prognosis must have a number: **median survival 6–10 years**, worse with early severe autonomic failure.

Q58. Essential tremor RECURS

7-Mark Answer | 6 Textbook Points + 1 Latest Update = 7 Points

Source: Pathy's 6th ed., Chapter 54 (Tables 54.3, 54.4) and Chapter 53.

Textbook Core — 6 Points

1. **Definition and epidemiology.** Essential tremor is the **most common tremor disorder and the most common movement disorder**, with prevalence **up to 3% in the general population and up to 5% in adults over 60**, rising to as high as **21.7% in adults over 95**.
2. **Pathophysiology.** Tremor arises from dysfunction in networks involving the **inferior olive, cerebellum, thalamus, basal ganglia and cortex**. The **basal ganglia network triggers the onset** of tremor while the **cerebellar network — predominantly affected in essential tremor — modulates its amplitude**.
3. **Clinical presentation.** A **bilateral action-induced (postural and kinetic) tremor** of the upper limbs, which may involve **head and voice**. It may be asymmetric but is **usually not unilateral**. An **intention tremor and a kinetic tremor of greater amplitude than the postural tremor** make ET more likely; **rest tremor is not typical** and suggests parkinsonism. A **family history of tremor** is common; **ethanol may improve** and **caffeine and smoking may worsen** the tremor.
4. **Differential diagnosis. Parkinsonian tremor** (rest tremor with rigidity, bradykinesia, postural instability, hypomimia); **dystonic tremor** (isolated head tremor, unilateral tremor, abnormal posturing or thumb flexion, torticollis, geste antagoniste, arrhythmic and directional head tremor); **cerebellar tremor** (intention tremor with dysmetria, scanning speech, truncal ataxia); **functional tremor** (variability, distractibility, entrainment, suggestibility); **drug-induced tremor** — caffeine, ethanol, nicotine, beta-agonists, tricyclics, lithium, SSRIs, neuroleptics, valproate, amiodarone, ciclosporin, tacrolimus, metoclopramide; and **hyperthyroidism, orthostatic tremor and late-onset Wilson's disease**. The **spiral test** is a useful bedside discriminator — ET spirals have **one clear axis**, dystonic tremor spirals have **multiple or no clear axes**.
5. **Investigation.** In most elderly patients **no further workup is required**, as clinical assessment is sufficient. **Liver function tests and thyroid studies** can at times be helpful; **EMG is very beneficial for orthostatic tremor**; **DaTSCAN is normal in essential tremor** and abnormal in parkinsonism; MRI with and without contrast is indicated if cerebellar tremor is suspected. **Misdiagnosis is frequent** and leads to inadequate therapy.
6. **Treatment.** There is **no curative therapy, and the indication for symptomatic therapy depends solely on the functional and social impairment the patient experiences**. **First line: propranolol and primidone**, which give a **30–70% reduction in tremor amplitude** but frequently have to be discontinued for side effects — **bradycardia with propranolol; nausea, dizziness and drowsiness with primidone**. **Second line: topiramate, gabapentin and benzodiazepines. Surgery** — deep brain stimulation of the **ventral intermediate (Vim) nucleus of the thalamus**, gamma knife surgery or **focused ultrasound thalamotomy** — gives greater amplitude reduction but is reserved for **severe medication-refractory tremor**.

Latest Update — 1 Point

7. **Staged bilateral MR-guided focused ultrasound thalamotomy is now approved.** The FDA approved **staged bilateral MRgFUS thalamotomy** for essential tremor, with the **second side treated at least nine months after the first**; the pivotal open-label trial was published by Kaplitt and colleagues in ***JAMA Neurology* 2024**. A 2025 *Movement Disorders* analysis found efficacy **comparable to bilateral DBS**, with two target "sweet spots" (dorsal Vim–Vop border and ventral Vim/posterior subthalamic area), while prospective series confirm **gait and balance impairment as the principal adverse effects** — a significant consideration for falls risk in older patients.

Extra Points to Remember — this topic recurs

- **Modern classification:** the MDS consensus uses **two axes** (clinical characteristics and aetiology) and defines "**essential tremor plus**" — isolated tremor with additional soft signs such as mild dystonic posturing, impaired tandem gait or questionable rest tremor. Pathy's uses the phrase "ET or ET plus" without defining it.
- **Practical prescribing in the elderly:** propranolol is contraindicated in asthma, COPD, bradycardia and decompensated heart failure and may mask hypoglycaemia in diabetes; **primidone is preferred in these patients**, started at 12.5–25 mg at night to avoid the notorious acute first-dose reaction of nausea, vertigo and ataxia.
- **Why the distinction from PD matters:** misdiagnosing ET as PD leads to years of unnecessary levodopa; misdiagnosing PD as ET delays effective treatment. **DaTSCAN settles it** — normal in ET.
- **Indian context:** propranolol and primidone are inexpensive and universally available; MRgFUS exists in only a handful of Indian tertiary centres and is largely out-of-pocket, so **DBS and stereotactic thalamotomy remain the practical surgical options**. Check **serum ceruloplasmin, 24-hour urinary copper and slit-lamp examination** in any atypical or younger tremor, as Wilson's disease is relatively more common in India.
- **The sentence that defines the geriatric approach:** "Treat the disability, not the tremor amplitude."

Examiner's Tip — lines that earn marks

- Open with the epidemiology triple: **3% general population, 5% over 60, 21.7% over 95.**
- The one-line contrast: "**rest tremor in Parkinson's disease, action tremor in essential tremor; DaTSCAN is abnormal in the former and normal in the latter.**"
- Name the **spiral test** — a bedside test always scores.
- Quote the treatment principle verbatim and give the **30–70% amplitude reduction** figure for propranolol and primidone.

Q59. Movement disorders in the elderly

7-Mark Answer | 6 Textbook Points + 1 Latest Update = 7 Points

Source: Pathy's 6th ed., Chapter 54 (Tables 54.1–54.4) and Chapters 44 and 53.

Textbook Core — 6 Points

1. **Classification. The most common movement disorders in the elderly are the parkinsonian syndromes.** The non-parkinsonian movement disorders affecting older people are **myoclonus, tremor, dystonia, tardive dyskinesia, chorea, functional movement disorders, and restless legs syndrome with periodic limb movements** during sleep and while awake.
2. **Phenomenology (Table 54.1). Myoclonus** — sudden brief muscle jerks (positive) or sudden cessation of muscle activity (negative), "lightning brief", irregular and non-stereotyped. **Tremor** — rhythmic oscillation around a body part. **Dystonia** — sustained or intermittent contractions causing abnormal movements or postures. **Chorea** — irregular movements flitting from one body part to another with a dance-like appearance. **Tardive dyskinesia** — stereotyped masticatory movements with lip and tongue protrusion. **Restless legs syndrome** — an urge to move relieved by walking or stretching.
3. **Commonest conditions and age relationship. Essential tremor** is the most common, affecting up to **5% of adults over 60** and up to **21.7% over 95**. Parkinsonism prevalence also rises with age, and **mild extrapyramidal signs, ageing-related tremor and paratonia (gegenhalten)** may be found in healthy older people as part of neurological ageing.
4. **Drug-induced movement disorders are a major geriatric issue** because of polypharmacy (Table 54.3): **myoclonus** — gabapentin, pregabalin, phenytoin, valproate, penicillins, cephalosporins, quinolones, SSRIs, lithium, opioids, amiodarone; **tremor** — SSRIs, tricyclics, lithium, beta-agonists, valproate, amiodarone, ciclosporin, tacrolimus, metoclopramide; **dystonia and tardive dyskinesia** — haloperidol, olanzapine, metoclopramide, prochlorperazine, phenytoin, carbamazepine; **chorea** — levodopa, dopamine agonists, neuroleptics, phenytoin, lamotrigine, lithium, oestrogens; **restless legs** — olanzapine, quetiapine, mirtazapine, topiramate. **The medication list must be scrutinised in every case and offending drugs stopped where possible.**
5. **Diagnosis.** Most are **clinical diagnoses** based on history and examination. Investigations are selective: metabolic and liver profile and thyroid studies; **brain and spine imaging**, particularly where symptoms are focal or cerebellar signs are present; **CSF studies** in inflammatory conditions; **EEG and EMG** to classify myoclonus; **EMG for orthostatic tremor**; and **DaTSCAN** to separate parkinsonism from essential tremor.
6. **Treatment (Table 54.4). Reverse the cause first** — stop the offending drug, correct metabolic derangement. **Myoclonus** — valproate, piracetam or levetiracetam for cortical myoclonus; botulinum toxin or GABAergic drugs for segmental and peripheral myoclonus. **Tremor** — propranolol and primidone, then topiramate, gabapentin or benzodiazepines, with DBS, gamma knife or focused ultrasound for refractory cases. **Dystonia** — physiotherapy, botulinum toxin injections, anticholinergic and GABAergic drugs, tetrabenazine for tardive dystonia, DBS for refractory cases. **Tardive dyskinesia** — slow down-titration of the offending agent, switch to clozapine or quetiapine, and **valbenazine or deutetrabenazine**. **Chorea** — tetrabenazine, deutetrabenazine or valbenazine, or neuroleptics. **Restless legs syndrome** — iron replacement if indicated, then **α2δ ligands (gabapentin, pregabalin) or dopaminergic drugs** first line and opioids second line. **Functional movement disorders** — convey the diagnosis as a genuine neurological condition with potential for recovery, with physiotherapy for motor retraining, CBT and treatment of comorbid anxiety and depression.

Latest Update — 1 Point

7. **Restless legs syndrome — a complete reversal of first-line therapy.** The **AASM clinical practice guideline (Winkelman et al., *Journal of Clinical Sleep Medicine*, January 2025)** now gives a **strong recommendation for α2δ ligands — gabapentin, gabapentin enacarbil and pregabalin — and for intravenous ferric carboxymaltose**, while **dopamine agonists have been moved to "conditional against" and are no longer recommended as initial therapy** because of **augmentation**, which affects roughly **7–10% of patients per year**. Cabergoline carries a strong recommendation against use at any dose. Iron should be assessed in every patient, with **serum ferritin targets above 75–100 µg/L and transferrin saturation above 20%**, regardless of haemoglobin. This is a complete inversion of the 2012 guideline and is directly relevant to older patients, in whom augmentation and impulse-control disorders are especially damaging.

Current Practice Update

Aspect	Textbook	Current recommendation
First-line therapy for restless legs syndrome	"α2δ ligands and dopaminergic medications" — both offered; dopamine agonists officially approved and widely used	**Gabapentinoids and IV ferric carboxymaltose are first line; dopamine agonists are recommended against** (AASM 2025)
Rationale	Augmentation noted — 76% of dopaminergic-treated patients need dose increase or develop augmentation	Same rationale, now translated into a formal **strong recommendation against** dopamine agonists

Exam approach: state the textbook option pair, then add "the 2025 AASM guideline now recommends gabapentinoids and IV iron first line and advises against dopamine agonists because of augmentation."

Examiner's Tip — lines that earn marks

- Open with the classification sentence: "**The most common movement disorders in the elderly are the parkinsonian syndromes**," then list the non-parkinsonian six.
- Define each phenomenologically in **one line each** — the examiner is testing whether you can describe an abnormal movement precisely.
- Devote a full point to **drug-induced movement disorders**; in a geriatrics paper this is the highest-yield element of the answer.
- Use the mnemonic **URGE** for restless legs syndrome: **U**rge to move the legs, worse at **R**est, **G**ets better with movement, occurs in the **E**vening or night.

Q60. Describe the ageing changes in the central nervous system including the brain, and the degenerative diseases of the brain

15-Mark Answer | 10 Textbook Points + 2 Latest Updates = 12 Points

Source: Pathy's 6th ed., Chapter 2 (Physiology of ageing), Chapter 6 (Ageing of the brain, Table 6.2) and Chapter 44 (Neurological signs of ageing, Table 44.1); Essentials of Clinical Geriatrics 7th ed., Chapter 6 (Table 6-7).

Textbook Core — 10 Points

1. **Cellular changes.** With age **some neurons are lost and others shrink**, and neurons attempt to compensate by **dendritic proliferation**. Support structures such as **neuroglia increase**. Unlike other systems, **new neurons cannot grow to replace lost neurons**, but the sheer number of CNS neurons means losses are not recognised until a threshold is crossed. **Lipofuscin accumulates** in nerve cells.
2. **Structural and volume changes.** Imaging shows **selective, not generalised, atrophy**. Global brain atrophy increases from **0.2% per year at ages 30–50 to 0.3–0.5% per year at ages 70–80**. **Grey matter loss is greater in frontal and parietal than in temporal and occipital cortices**, while **temporal lobe and hippocampal volumes decline continuously with accelerating loss after age 70**.
3. **Regional neuronal loss.** There is **relative preservation of cortical and hippocampal neuronal populations**, but **subcortical structures — the basal forebrain, locus ceruleus and substantia nigra — do show neuronal loss**. Plasticity persists through **dendritic sprouting**, though this compensatory ability declines with age.
4. **Mechanisms of brain ageing. Mitochondrial dysfunction** with oxidative damage to mitochondrial DNA; **oxidative damage** from increased reactive oxygen species and reduced antioxidant defence; **loss of proteostasis** with impaired autophagic and proteasomal degradation; **dysregulation of calcium homeostasis** causing calcium-mediated excitotoxicity; **impaired adaptive stress responses** (reduced BDNF and NGF signalling); **neuroinflammation** from microglia and astrocytes; **impaired DNA repair**; **impaired neurogenesis** in the subventricular zone and hippocampal dentate gyrus; and **dysregulated energy metabolism** with neuronal insulin resistance.
5. **Neurotransmitter and network changes. Impaired inhibitory GABA signalling** causes excitatory imbalance, hyperexcitability and excitotoxicity, and **dysregulation of acetylcholine, dopamine and serotonin** is linked with neurodegeneration and impaired brain function. There is a **progressive reduction of synaptic plasticity with ageing**, similar to that seen in Alzheimer-like and Parkinson-like conditions, underlying cognitive and motor impairment.
6. **Neuropathology of the normal ageing brain.** Both **neurofibrillary pathology (tangles and neuropil threads)** and **senile neuritic plaques** — the hallmarks of the Alzheimer brain — are found in **cognitively normal older individuals**. Neurofibrillary pathology follows a **stereotyped hierarchical pattern, appearing first in the transentorhinal cortex** (Braak staging), and spread to hippocampal and association cortex parallels the appearance of cognitive decline. **Senile plaques have a broader, more variable distribution, and a significant burden may coexist with normal cognition.** Similarly, **α-synuclein-immunopositive Lewy bodies and Lewy neurites** are found in ageing but asymptomatic brains.
7. **Vascular changes.** Vascular change becomes more frequent in the ageing brain, manifested as **leukoaraiosis — small-vessel ischaemic change in white matter — and silent infarcts**, possibly related to **elevated blood pressure and cholesterol in midlife**. Age-related vascular changes also reduce cerebral perfusion and impair endothelial function.
8. **Cognitive ageing.** Typical cognitive ageing involves losses in **processing speed, cognitive flexibility, and the efficiency of working memory and sustained attention**, so it takes longer or more trials to learn new information. **Vocabulary, access to remotely learned information including semantic networks, and retention of well-encoded new information are spared** — therefore **impairment in these latter domains is a sensitive indicator of pathology rather than physiology**. Memory decline in healthy ageing is largely secondary to reduced processing speed.
9. **Clinical signs of the ageing nervous system (Tables 6.2 and 44.1). Sensory** — impaired distal vibration sense (about one-third of healthy people over 60), reduced pain perception and joint position sense. **Reflexes — loss of ankle jerks in almost one-third of healthy people by age 80** while knee, biceps and triceps jerks are maintained, and emergence of **primitive reflexes** (palmomental, snout, sustained glabellar, grasp). **Cranial nerves** — diminished olfaction after 60, presbyopia, senile miosis, **reduced upward conjugate gaze and convergence**, increased saccadic latency, presbycusis. **Motor** — loss of muscle bulk and strength, **mild increase in tone with paratonia (gegenhalten)**, mild parkinsonism, ageing-related tremor. **Gait, posture and balance** — reduced walking speed and stride length, reduced tandem ability, stooped posture, reduced ability to stand on one leg with increased postural sway.

10. **Degenerative diseases of the brain (Essentials Table 6-7). Degenerative CNS diseases** — Alzheimer's disease, dementia associated with Lewy bodies, Parkinson's disease, Pick disease (frontotemporal degeneration), Huntington's disease and progressive supranuclear palsy. **Vascular dementias** — multi-infarct dementia, Binswanger disease, arteritis, and anoxic damage. **Traumatic** — craniocerebral injury including dementia pugilistica. **Infective** — HIV-associated dementia, opportunistic infections, Creutzfeldt–Jakob disease, progressive multifocal leukoencephalopathy, post-encephalitic dementia. Alzheimer's disease affects **6–8% of those over 65** with prevalence **doubling every five years**, reaching nearly **30% over 85**. **The crucial clinical principle is that neurodegenerative conditions share pathophysiological processes, neuropathological modifications and phenotypic manifestations with the physiological ageing process**, so the key skill is to juxtapose the signs of ageing against those of incipient neurological disease.

Ageing versus disease — the discriminating features

Domain	Normal ageing	Suggests disease
Memory	Slower learning; retrieval helped by cueing; preserved semantic and well-encoded memory	Impaired **recognition** and loss of well-encoded information; no benefit from cueing
Gait	Reduced speed and stride length; stooped posture	Freezing, festination, early falls, wide-based ataxia, step-wise decline
Tone	Mild increase; paratonia	True lead-pipe rigidity with bradykinesia
Reflexes	Absent ankle jerks; primitive reflexes	Loss of knee, biceps or triceps jerks; extensor plantars
Eye movements	Reduced **upgaze** and convergence	Reduced **downgaze** — suggests progressive supranuclear palsy
Function	Instrumental and basic ADLs preserved	Loss of independence in ADLs

Latest Updates — 2 Points

11. **Neurodegenerative disease is now defined biologically, not clinically.** The **2024 revised Alzheimer's Association criteria** (Jack et al., *Alzheimer's & Dementia* 2024) define Alzheimer's disease by **core biomarkers of amyloid and tau — including blood-based p-tau217** — rather than by syndrome, and **anti-amyloid monoclonal antibodies (lecanemab, donanemab)** are now approved for early symptomatic disease. In parallel, the **NSD-ISS and SynNeurGe frameworks** (*Lancet Neurology* 2024) redefine Parkinson's disease and dementia with Lewy bodies as **neuronal α-synuclein disease** using **α-synuclein seed amplification assay**. The practical consequence is that the boundary between "brain ageing" and "early degenerative disease" is increasingly drawn by **biomarkers rather than symptoms**.
12. **Much of late-life cognitive decline is preventable.** The **2024 Lancet Commission on dementia prevention, intervention and care** identified **14 modifiable risk factors accounting for about 45% of dementia cases worldwide**, adding **untreated vision loss and high LDL cholesterol** to the previous twelve (low education, hearing loss, hypertension, smoking, obesity, depression, physical inactivity, diabetes, excess alcohol, traumatic brain injury, air pollution, social isolation). This reframes the ageing brain as a **modifiable** rather than purely degenerative target, and is highly relevant to India, where hypertension, diabetes, low education, hearing loss, cataract-related visual impairment and air pollution are all highly prevalent.

Current Practice Update

Aspect	Textbook	Current recommendation
Diagnosis of degenerative disease	Clinical syndromes with pathology confirmed at autopsy	**Biomarker-based biological definitions** — plasma p-tau217 for Alzheimer's, α-synuclein SAA for synucleinopathies
Treatment of Alzheimer's disease	Cholinesterase inhibitors and memantine (symptomatic)	**Anti-amyloid antibodies (lecanemab, donanemab)** for early symptomatic disease with confirmed amyloid, with ARIA monitoring; not yet routine in India
Prevention	Risk factors mentioned in passing	**14 modifiable risk factors, ~45% of dementia potentially preventable** (Lancet Commission 2024)

Examiner's Tip — lines that earn marks

- The question has **two halves** — allocate roughly seven points to ageing changes and three to degenerative diseases, and head them separately.
- Give the atrophy numbers: "**0.2% per year at 30–50, rising to 0.3–0.5% per year at 70–80**."
- The sentence that shows genuine understanding: "**Plaques and tangles occur in cognitively normal older people; a significant plaque burden may be associated with normal cognition.**"
- Reproduce the ageing-versus-disease table — it directly answers the unstated question the examiner is really asking.
- Two reflex facts always score: **one-third of healthy people over 60 have impaired distal vibration sense, and almost one-third have lost ankle jerks by 80, while knee and upper limb jerks are maintained.**
- Close with the Chapter 44 principle: "**The key skill is to juxtapose the signs of ageing with those of incipient neurological disease.**"

Rapid Revision Grid — Q53 to Q60

Numbers to memorise

- **Parkinson's disease:** prevalence ~1% over 65; levodopa 300–600 mg/day, 3–4 doses, 30 min pre-meal; challenge dose 150–250 mg; rest tremor 4–6 Hz; depression ~50%; constipation ~50%; delayed gastric emptying ≥70%; orthostatic hypotension in 30–40% of PD patients.
- **Orthostatic hypotension:** ≥20 mmHg systolic or ≥10 mmHg diastolic within 3 minutes; delayed form after 6 minutes; pooled prevalence 22% in community-dwelling older adults, 23.9% in long-term care.
- **Drug-induced parkinsonism:** recovery over weeks to months; ~20% have persisting signs; DaTSCAN normal.
- **Multiple system atrophy:** prevalence 3.4–4.9/100,000; autonomic features before or within 2 years of motor onset; median survival 6–10 years; hot cross bun sign in ~75% of MSA-C.
- **Essential tremor:** 3% general population, 5% over 60, 21.7% over 95; propranolol and primidone reduce amplitude by 30–70%; MRgFUS second side at ≥9 months.
- **Restless legs syndrome:** augmentation 7–10% per year on dopamine agonists; ferritin target >75–100 µg/L, transferrin saturation >20%.
- **Ageing brain:** atrophy 0.2%/year at 30–50 → 0.3–0.5%/year at 70–80; impaired distal vibration sense in one-third over 60; ankle jerks lost in one-third by 80; Alzheimer's 6–8% over 65, ~30% over 85, prevalence doubling every 5 years.
- **Clozapine:** discontinue permanently if neutrophils <1500/mm^3.

APPENDIX — CONSOLIDATED NIGHT-BEFORE MASTER SHEETS			

HOW THIS COMPENDIUM IS ORGANISED

This volume consolidates three separate question sets into a single continuously numbered sequence and regroups them by subject rather than by the order in which they were originally set. **All 29 questions are distinct.** Several address the same organ system or disease from different angles — four separate urinary questions, four tropical febrile illnesses, two metabolic bone questions — and these have been placed adjacent to one another and cross-referenced rather than merged, because each asks something the others do not. Where content genuinely overlaps (giant cell arteritis, vaccination, stewardship, the metabolic bone laboratory table), the fuller treatment is kept in one place and signposted from the others; the map below shows where to look.

Topic overlap map — questions to revise together

Theme running across several questions	Questions to read together
Bacteriuria, catheters and urinary infection	**Q16** asymptomatic bacteriuria · **Q17** CAUTI · **Q18** pyelonephritis · **Q19** recurrent UTI. Q16 sets the rule ("no symptom, no culture, no cure") that the other three depend on.
Giant cell arteritis	**Q21** polymyalgia rheumatica (the association, 16–21%) · **Q22** systemic vasculitides (full GCA work-up and treatment) · **Q1** fever of unknown origin (GCA is the commonest identifiable cause in over-65s).
Vaccination	**Q10** is the consolidated schedule; disease-specific detail sits in **Q7** zoster (RZV), **Q8** COVID-19, **Q9** influenza (high-dose/adjuvanted).
Antimicrobial stewardship	**Q4** is the framework; applied in **Q3** procalcitonin-guided stopping, **Q16** not treating bacteriuria, **Q17** catheter bundles, **Q20** *C. difficile*, **Q18–19** resistance-driven empirical choice.
Acute undifferentiated febrile illness in India	**Q12** dengue and leptospirosis · **Q13** chikungunya · **Q14** scrub typhus · **Q15** cerebral malaria · **Q2** septic shock (all five can present as shock).
Inflammatory arthritis of later life	**Q21** PMR · **Q23** late-onset RA · **Q24** psoriatic arthropathy · **Q25** Sjögren's · **Q13** post-chikungunya arthritis. The three-way PMR / LORA / YORA table in Q23 is the discriminator.
Metabolic bone laboratory differential	**Q26** osteoporosis and **Q27** Paget's share the calcium / phosphate / alkaline phosphatase / PTH table reproduced in Q27.
Corticosteroid-sparing therapy	**Q21** sarilumab in PMR · **Q22** tocilizumab and upadacitinib in GCA, avacopan in AAV · **Q24** IL-17/IL-23 inhibitors · **Q23** and **Q29** the harms that make steroid-sparing necessary.
Drugs to avoid in older adults	**Q29** is the systematic answer (Beers, STOPP/START, anticholinergic burden); specific instances appear in **Q7** amitriptyline, **Q24** JAK inhibitors and NSAIDs, **Q19** nitrofurantoin, **Q4** fluoroquinolones.

CONVENTIONS USED THROUGHOUT

Every answer follows the same four-block architecture: **Textbook Core** (6 points for a 7-mark note, 10 for a 15-mark essay), **Latest Update** (1 point for 7 marks, 2 for 15 marks, all from 2023 onwards and cited inline), a **Current Practice Update** table wherever the textbook position and current evidence genuinely diverge, and **Exam One-Liners** for rapid recall. Questions flagged RECURRING or ASKED ×n carry additional scaffolding — a mnemonic anchor, numerical anchors, named examiner traps, a 15-second answer skeleton and an extra recall box. Where a 7-mark note is also examinable at 15 marks, a boxed **expansion note** lists exactly what further content to add. Topics not adequately covered by the two primary textbooks are explicitly flagged at the head of the answer, with the textbook fragments that do exist quoted and marked, and guideline-derived content kept separate. All clinical and laboratory values use **Indian conventional units**.

PART I

Infection in Old Age — Principles, Diagnosis and Stewardship

The cross-cutting material: how infection presents differently in older adults, how to work up prolonged fever, how to recognise and resuscitate septic shock, the role of biomarkers, and the stewardship framework that governs every antibiotic decision in the rest of this book.

Question 1. Fever of unknown origin — definition, evaluation and management of prolonged fever in the elderly 15 MARKS

ANSWER

Textbook Core – 10 Points

1. **Classical definition.** Petersdorf and Beeson (1961), modified by Durack and Street (1991): a temperature **>38.3 °C (101 °F) on several occasions**, of **more than 3 weeks' duration**, remaining **undiagnosed after appropriate investigation** — three days of inpatient work-up, three outpatient visits, or one week of intelligent and invasive ambulatory investigation.
2. **The four categories (Durack and Street). Classic** FUO; **nosocomial** FUO (onset in hospital, not incubating on admission); **neutropenic / immune-deficient** FUO (neutrophils <500/mm³); and **HIV-associated** FUO. Each has a different differential and a different work-up — say which you are addressing.
3. **Why the definition must be adapted in old age.** Kane's: the **febrile response may be blunted or absent** in older people with bacterial infection, baseline body temperature is lower, and nursing-home residents may fail to show a diurnal rise. Fever in a long-term care resident is therefore redefined as **a single oral temperature above 37.8 °C (100 °F), repeated oral temperatures above 37.2 °C (99 °F), or a rise of more than 1.1 °C (2 °F) above the patient's baseline**. Applying the 38.3 °C threshold to a frail older patient will miss disease. **A poor febrile response is itself a negative prognostic factor.**
4. **The causes are distributed differently in the elderly — the key examinable fact.** Approximate shares in over-65s: **infection 25–35%**, **connective tissue and inflammatory disease 25–30%** (far higher than in the young, and **giant cell arteritis with polymyalgia rheumatica is the single commonest identifiable cause**), **malignancy 15–20%**, **miscellaneous including drug fever 10%**, and **undiagnosed 10–20%** (lower than in the young). The governing principle is that **FUO in an older person is usually an atypical presentation of a common disease, not a rare disease**.
5. **Infective causes to hunt for. Tuberculosis**, especially **miliary and extrapulmonary** — Kane's rule: "suspect tuberculosis when a patient is inexplicably failing". **Infective endocarditis** — nearly **50% of cases occur in older adults**, on degenerative valves and prostheses, and blood cultures may be negative if antibiotics were given. Also **intra-abdominal, hepatobiliary and pelvic abscess**, **complicated urinary infection and prostatic abscess**, **vertebral osteomyelitis and discitis**, **infected prosthetic joints and devices**, dental and sinus sepsis, and — in India — **enteric fever, brucellosis, melioidosis, kala-azar, scrub typhus and malaria**.
6. **Non-infective causes. Inflammatory**: giant cell arteritis and polymyalgia rheumatica, adult-onset Still's disease, rheumatoid arthritis, ANCA-associated vasculitis, polyarteritis nodosa, sarcoidosis. **Malignant**: **lymphoma is commonest**, then renal cell carcinoma, hepatocellular carcinoma, myelodysplastic syndrome, leukaemia, atrial myxoma and metastatic disease. **Miscellaneous**: **drug fever** — very common with polypharmacy (antibiotics, allopurinol, anticonvulsants, antiarrhythmics, heparin); **venous thromboembolism**; subacute thyroiditis and apathetic thyrotoxicosis; gout and pseudogout; resolving haematoma; adrenal insufficiency; and factitious fever.
7. **Step 1 — history and repeated examination.** The highest-yield "investigation" is a **meticulous, repeated daily physical examination**. Take a full **drug history including over-the-counter and AYUSH preparations and every recently started agent**, plus travel, animal and rural exposure, dental work, prosthetic implants, prior TB, transfusions and immunosuppression. On examination, look specifically at: **temporal arteries**, a **new or changing murmur**, all lymph node groups, liver and spleen, skin, nails and splinter haemorrhages, joints, thyroid, prostate and pelvis, rectum, fundi (Roth spots) and every prosthesis or device site.
8. **Step 2 — first-line investigations.** CBC with differential and **peripheral blood film**, **ESR and CRP**, renal and liver function, electrolytes, LDH, creatine kinase, urinalysis and urine culture, **three sets of blood cultures taken off antibiotics**, chest radiograph, sputum for AFB and **GeneXpert**, HIV test, TSH, ANA and rheumatoid factor, serum and urine protein electrophoresis, and — in India — a **blood film and rapid test for malaria** plus dengue and scrub typhus serology in season.
9. **Step 3 — second-line and targeted investigations. CT of chest, abdomen and pelvis**; **echocardiography** (transthoracic, then transoesophageal if endocarditis is suspected); ultrasound of abdomen and of any tender area; **temporal artery ultrasound or biopsy in anyone over 50 with an ESR above 50**; **bone marrow aspiration and trephine biopsy with culture** (high yield for miliary TB, lymphoma and myelodysplasia); and **FDG-PET/CT**. Then **tissue is the answer** — lymph node, liver or bone biopsy sent for histology, culture and TB PCR; lumbar puncture if there are any CNS features; joint aspiration if any joint is involved.
10. **Management principles. Avoid empirical "blind" antibiotics.** They obscure cultures, cause *C. difficile* and resistance, and are themselves a common cause of drug fever. Empirical therapy is justified only for **haemodynamic instability or sepsis, neutropenia, or a strong suspicion of a dangerous treatable condition**. **The great**

exception is giant cell arteritis — start high-dose corticosteroids immediately on suspicion, without waiting for the biopsy, to prevent blindness. A trial of anti-tuberculous therapy may be justified in a high-burden setting when miliary TB is strongly suspected and the patient is deteriorating, but only after a determined attempt at tissue diagnosis. **Stop or substitute every non-essential drug** — drug fever settles within 48–72 hours. Throughout, provide geriatric care in parallel: hydration and nutrition, delirium and pressure-injury prevention, early mobilisation, medication review, and an explicit discussion of goals of care. **Knowing when to stop investigating a very frail patient, and to observe instead, is itself a legitimate management decision** — a specific diagnosis is eventually reached in 70–90% of older patients, and undiagnosed FUO that settles spontaneously has a good prognosis.

Latest Updates (2023 – present)

11. **FDG-PET/CT is now the recommended second-line imaging modality in FUO**, with a diagnostic yield of roughly **50–60%** and the highest utility when CRP or ESR are raised. Current EANM/SNMMI and European guidance place it **before invasive biopsy** in the algorithm, and it is particularly valuable in older adults because it detects **large-vessel vasculitis, occult lymphoma and vertebral osteomyelitis** — the three commonest occult causes in this age group — and it directs the biopsy when one is needed.
12. **Molecular diagnostics and a reframed terminology. Metagenomic next-generation sequencing of plasma cell-free DNA** and targeted NGS can now identify pathogens in **culture-negative endocarditis** and deep-seated infection, though cost and false-positive signals limit routine use. Separately, current practice increasingly uses the term **"inflammation of unknown origin" (IUO)** for the raised-CRP, no-fever presentation — an important reframing for geriatrics, because many older patients with occult giant cell arteritis, lymphoma or endocarditis **never mount a fever at all** and would be missed by a temperature-based definition.

Current Practice Update

Item	Textbook / classical position	Current recommendation	Exam approach
Fever threshold	>38.3 °C for >3 weeks	In frail/LTC older adults, use the lower thresholds (single oral >37.8 °C, repeated >37.2 °C, or a rise of 1.1 °C)	Give the classical definition, then the geriatric modification
Imaging sequence	CT then invasive biopsy	**FDG-PET/CT before biopsy**; use it to direct the biopsy	Name PET/CT and its ~50–60% yield
Empirical antibiotics	Common practice	**Avoid** unless septic, neutropenic or a specific strong suspicion	State the exception for GCA steroids
Terminology	Fever of unknown origin	Add **inflammation of unknown origin (IUO)** for afebrile raised-CRP presentations	A high-value closing line for a geriatrics paper

Exam One-Liners

- Classical definition — **>38.3 °C, >3 weeks, undiagnosed after appropriate work-up**.
- Four categories — **classic, nosocomial, neutropenic, HIV-associated**.
- Commonest identifiable cause in over-65s — **giant cell arteritis / PMR**.
- Commonest malignancy — **lymphoma**; commonest infection — **tuberculosis**.
- Highest-yield "test" — **repeated physical examination and the drug chart**.
- Best single imaging test — **FDG-PET/CT**.
- The one condition to treat empirically — **giant cell arteritis**.
- Undiagnosed FUO that settles spontaneously — **good prognosis**.

Question 2. Types of shock; aetiopathogenesis, diagnosis and treatment of septic shock

15 MARKS ASKED ×2

ANSWER

Textbook Core – 10 Points

1. **Definition of shock.** Acute circulatory failure causing **inadequate tissue oxygen delivery relative to demand**, leading to cellular dysoxia, anaerobic metabolism, lactate accumulation and progressive organ dysfunction. **Hypotension is a late sign** — compensated shock with a normal blood pressure but raised lactate is common, and in a chronically hypertensive older patient a "normal" pressure may already represent profound shock. Clinically: tachycardia, tachypnoea, cool or mottled peripheries, prolonged capillary refill, oliguria and altered mentation.
2. **The four types of shock.**

Type	Causes	Cardiac output	SVR	Filling pressures (CVP/PCWP)
Hypovolaemic	Haemorrhage, GI losses, burns, dehydration — the elderly are highly susceptible (reduced total body water, blunted thirst, diuretics)	Low	High	Low
Cardiogenic	Myocardial infarction, arrhythmia, acute valvular failure, myocarditis, cardiomyopathy, drug toxicity	Low	High	High
Obstructive	Massive pulmonary embolism, tension pneumothorax, cardiac tamponade, severe pulmonary hypertension	Low	High	High
Distributive	**Septic** (commonest), anaphylactic, neurogenic, adrenal crisis, acute liver failure	**High** (or normal)	**Low**	Low or normal

   Mixed patterns are the rule in older patients — septic shock with a hypovolaemic and a cardiogenic component is the commonest single combination.
3. **Definitions of sepsis and septic shock (Sepsis-3, 2016). Sepsis = life-threatening organ dysfunction caused by a dysregulated host response to infection**, operationalised as an acute rise in the **SOFA score of 2 or more points**. **Septic shock** = sepsis with **persisting hypotension requiring vasopressors to maintain a MAP ≥65 mmHg AND a serum lactate >2 mmol/L despite adequate volume resuscitation** — a subset with **hospital mortality exceeding 40%**. **qSOFA** (respiratory rate ≥22, altered mentation, systolic BP ≤100 mmHg) is a bedside *prompt*, not a diagnostic tool; NEWS2 performs better for screening.
4. **Aetiology in the older adult.** Commonest sources: **respiratory (pneumonia), urinary, intra-abdominal, skin and soft tissue including pressure injury, and device-related**. Kane's makes the key microbiological point that **Gram-negative bacilli increase in frequency in every infection category in older adults** — *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter* and *Pseudomonas* — alongside *S. pneumoniae*, *S. aureus*, *Enterococcus*, *Listeria* and *Candida*. Predisposing factors: immunosenescence, malnutrition, diabetes, indwelling devices, institutionalisation, and recent hospitalisation or antibiotics (which raise the risk of multidrug-resistant organisms).
5. **Pathogenesis — six linked mechanisms.** Pathogen-associated molecular patterns bind pattern-recognition (Toll-like) receptors → NF-κB activation → a cytokine storm of **TNF-α, IL-1 and IL-6**, producing: **(i) vasodilatation** through inducible nitric oxide synthase and loss of vascular tone — the distributive component; **(ii) endothelial injury with glycocalyx shedding** → capillary leak, interstitial oedema and **relative hypovolaemia**; **(iii) immunothrombosis** — tissue factor expression, microvascular thrombi and, at the extreme, DIC; **(iv) septic cardiomyopathy** — direct cytokine-mediated myocardial depression; **(v) mitochondrial dysfunction and cytopathic hypoxia**, so cells cannot use the oxygen that is delivered; and **(vi) a later immunoparalysis phase** with lymphocyte apoptosis and monocyte deactivation, which explains secondary infection and the late deaths that are so characteristic of older survivors.
6. **Presentation in the elderly — atypical and easily missed.** Kane's: **fever may be blunted or absent**, and the **absence of leucocytosis does not exclude bacterial infection**; **hypothermia in an older patient should promptly be treated as sepsis unless proven otherwise**. **Delirium, falls, functional decline, incontinence, anorexia and unexplained tachypnoea** may be the only features. Kane's list of the signs that should raise suspicion of infection in a long-term care resident — decline in functional status, increasing confusion, incontinence, falling, deteriorating mobility, reduced food intake, or failure to cooperate with staff — is worth reproducing verbatim.
7. **Diagnosis and investigations. At least two sets of blood cultures before antibiotics** where this does not delay them, plus site-directed cultures (urine, sputum, wound, CSF, drain fluid). **Serum lactate, repeated** to guide resuscitation. CBC, renal and liver function, coagulation screen with fibrinogen and D-dimer, arterial blood gas, glucose, **procalcitonin** and CRP, ECG and troponin, chest radiograph, and focused ultrasound or CT to identify the source. **Echocardiography** to assess cardiac function and volume status. Calculate the **SOFA score** and document a **Clinical Frailty Scale** score.
8. **Treatment — the first hour.** Oxygen to target saturation; obtain cultures and lactate; **broad-spectrum intravenous antibiotics within 1 hour** for septic shock, chosen from the **local antibiogram** and covering Gram-

negatives; **fluid resuscitation with at least 30 mL/kg of balanced crystalloid over the first 3 hours**; and **vasopressors if hypotension persists**. **Critical geriatric modification:** in an older patient with heart failure, valvular disease or chronic kidney disease, give fluid in **250–500 mL aliquots with reassessment after each** rather than an unmonitored bolus — over-resuscitation causes pulmonary oedema and is a common iatrogenic death. **Source control within 6–12 hours** is non-negotiable: drain the abscess, remove the infected line or urinary catheter, debride the necrotic tissue, decompress the obstructed urinary tract.

9. **Vasopressors and adjunctive therapy. Noradrenaline is first-line**, and may be started peripherally to avoid delay while central access is obtained. **Add vasopressin** when the noradrenaline requirement is escalating (usually around 0.25–0.5 µg/kg/min) rather than escalating noradrenaline indefinitely; **add adrenaline** if the MAP remains inadequate. Use **dobutamine or adrenaline** for septic cardiomyopathy with persistent hypoperfusion despite adequate filling. Give **intravenous hydrocortisone 200 mg/day** for shock requiring ongoing vasopressors. Supportive care: lung-protective ventilation if ARDS develops, VTE prophylaxis, stress-ulcer prophylaxis, glucose target **140–180 mg/dL**, early enteral nutrition, renal replacement therapy for the usual indications, and **daily antibiotic review with de-escalation** as cultures return.
10. **Geriatric-specific management and outcome.** Age is an independent predictor of mortality, and survivors face a **"post-sepsis syndrome"** of long-term functional and cognitive decline, sarcopenia, readmission and late death — so recovery, not just survival, is the outcome that matters. Therefore: **renal dose-adjust every drug** and monitor aminoglycoside and vancomycin levels; avoid nephrotoxins; screen for and prevent **delirium**; mobilise early and start rehabilitation in the ICU; prevent pressure injury; attend to nutrition; and hold an **early, explicit discussion of goals of care and ceilings of treatment** with the patient and family — **frailty and comorbidity, not chronological age, should inform escalation decisions**.

Latest Updates (2023 – present)

11. The **Surviving Sepsis Campaign 2026 international guidelines** confirm crystalloids as first-line fluid, **balanced crystalloids in preference to 0.9% saline**, **at least 30 mL/kg in the first 3 hours with frequent ongoing reassessment** to avoid both under- and over-resuscitation, and **crystalloids alone rather than routine supplemental albumin**. Noradrenaline remains first-line with vasopressin added on escalation. Two changes are directly geriatric: an **initial MAP target of 60–65 mmHg rather than a higher target in adults aged 65 and over** (permissive hypotension, from the 65 trial), and the suggestion to use **capillary refill time as an adjunct to lactate** for guiding resuscitation — a bedside measure available in any Indian hospital.
12. **Antibiotic timing has been formally stratified rather than made universally one-hour.** Current guidance recommends antimicrobials **within 1 hour for definite septic shock or high-probability sepsis**, but permits **up to 3 hours where sepsis is only possible and there is no shock**, allowing rapid assessment for a non-infectious mimic. This matters most in older adults, in whom pulmonary embolism, myocardial infarction, gastrointestinal bleeding, adrenal crisis, drug reactions and hypothermia routinely mimic sepsis. Counterbalancing this, the stewardship agenda now emphasises **de-escalation and procalcitonin-guided discontinuation** to shorten courses.

MNEMONIC ANCHOR

Types of shock = **"HCOD"** — **H**ypovolaemic · **C**ardiogenic · **O**bstructive · **D**istributive.
The septic shock bundle = **"CLAF-V-S"** — **C**ultures · **L**actate · **A**ntibiotics within 1 hour · **F**luids (balanced crystalloid) · **V**asopressor (noradrenaline) · **S**ource control.

NUMERICAL ANCHORS

Sepsis-3: SOFA rise **≥2** · septic shock MAP **<65 mmHg on vasopressors** + lactate **>2 mmol/L** · mortality **>40%** · qSOFA: RR ≥22, altered mentation, SBP ≤100 · fluids **30 mL/kg in 3 hours** (aliquots of 250–500 mL in the elderly) · antibiotics **<1 hour** in shock, up to 3 hours without shock · source control **6–12 hours** · vasopressin added at noradrenaline **0.25–0.5 µg/kg/min** · hydrocortisone **200 mg/day** · glucose **140–180 mg/dL** · MAP target **60–65 mmHg if ≥65 years**.

NAMED EXAMINER TRAPS

(a) Hypothermia in an older patient is sepsis until proved otherwise — and carries a worse prognosis than fever. **(b)** A "normal" blood pressure in a chronic hypertensive may be shock — ask what the patient's usual pressure is. **(c) qSOFA is a prompt, not a diagnostic criterion**, and it performs poorly in the elderly because altered mentation is so common. **(d)** Do **not** give an unmonitored 30 mL/kg bolus to a frail patient with heart failure — aliquot and reassess. **(e) No antibiotic can substitute for source control** — the infected catheter or undrained abscess will defeat any regimen. **(f)** Absence of leucocytosis does not exclude bacterial infection. **(g)** Steroids are for **vasopressor-dependent shock**, not for sepsis without shock.

15-SECOND ANSWER SKELETON

Define shock and note that hypotension is late → the four types in a table with CO/SVR/filling pressures → Sepsis-3 definitions of sepsis and septic shock with the numbers → aetiology and the Gram-negative shift in the elderly → the six pathogenic mechanisms → atypical presentation (hypothermia, delirium, falls) → investigations including lactate, cultures, SOFA, frailty score → the first-hour bundle with the geriatric fluid modification → source control → noradrenaline → vasopressin → adrenaline → hydrocortisone → post-sepsis syndrome and goals of care → close with SSC 2026 (balanced crystalloid, MAP 60–65 in ≥65s, stratified antibiotic timing).

EXTRA RECALL BOX — THE INDIAN ANGLE AND THE MIMICS

Indian context. Empirical therapy must follow the **local hospital antibiogram**, not a textbook: carbapenem-resistant *Klebsiella* and *Acinetobacter* and ESBL *E. coli* are widespread, and *Candida auris* has emerged as a nosocomial bloodstream pathogen. **NAP-AMR 2.0 (2025–2029)** makes infection prevention and stewardship programmes mandatory in every facility. In an Indian older adult with fever and shock, always also consider **severe falciparum malaria, scrub typhus, leptospirosis, dengue and disseminated tuberculosis** — all of which can present exactly as septic shock and several of which have specific, life-saving treatment.

The mimics that must be excluded before committing to "sepsis": pulmonary embolism, myocardial infarction and cardiogenic shock, gastrointestinal haemorrhage, acute adrenal insufficiency, thyroid storm and myxoedema coma, anaphylaxis, drug reactions including neuroleptic malignant and serotonin syndromes, pancreatitis, mesenteric ischaemia, and heat stroke.

Exam One-Liners

- Four types — **hypovolaemic, cardiogenic, obstructive, distributive**.
- Distributive shock alone has a **high cardiac output with low SVR**.
- Sepsis-3 — **life-threatening organ dysfunction from a dysregulated host response**; SOFA rise ≥2.
- Septic shock — **vasopressor-dependent MAP <65 plus lactate >2**; mortality >40%.
- First-line vasopressor — **noradrenaline**; second — **vasopressin**.
- Fluid of choice — **balanced crystalloid**.
- MAP target in adults ≥65 years — **60–65 mmHg**.
- Steroid — **hydrocortisone 200 mg/day for vasopressor-dependent shock**.
- The intervention no drug replaces — **source control**.

Question 3. Procalcitonin 7 MARKS

ANSWER

Textbook Core – 6 Points

1. **What it is.** A **116-amino-acid precursor peptide of calcitonin**, encoded by the **CALC-1 gene**. In health it is produced only by thyroid C cells and is completely cleaved to calcitonin, so circulating levels are negligible (**<0.05 ng/mL**). During **bacterial infection**, bacterial endotoxin and the cytokines IL-1β, TNF-α and IL-6 induce **ubiquitous extrathyroidal CALC-1 expression** in liver, lung, kidney, intestine and adipose tissue, releasing large amounts of **intact, uncleaved procalcitonin** into the blood.
2. **Kinetics — why it is more useful than CRP.** It **rises within 2–4 hours**, **peaks at 12–24 hours**, has a half-life of about **22–35 hours**, and **falls rapidly once the infection is controlled**. CRP by contrast peaks only at 48 hours and falls slowly. This makes procalcitonin usable for **early decisions and for serial trend interpretation**.
3. **The discriminating principle.** Procalcitonin synthesis is **suppressed by interferon-γ**, which is released in viral infection — so **it stays low in viral illness and rises in bacterial illness**. This is the single concept the examiner wants. It is therefore more **specific for bacterial infection** than CRP, ESR or the white cell count, and its magnitude correlates with the extent of infection and with organ dysfunction, giving it prognostic value.
4. **Interpretation thresholds.** In suspected lower respiratory tract infection: **<0.1 ng/mL** — antibiotics strongly discouraged; **0.1–0.25** — discouraged; **0.25–0.5** — encouraged; **>0.5 ng/mL** — strongly encouraged. In the critically ill, **>2 ng/mL** suggests a high probability of severe sepsis or septic shock, and **>10 ng/mL** suggests overwhelming bacterial sepsis with organ failure. For monitoring, **failure of the level to fall by 80%, or to below 0.5 ng/mL, by day 4** predicts a poor outcome.
5. **Clinical uses. (i) Antimicrobial stewardship** — procalcitonin-guided algorithms reduce antibiotic initiation and duration in lower respiratory tract infection and in ICU sepsis without increasing mortality. **(ii) Differential diagnosis** — helping separate bacterial pneumonia or bacteraemia from a COPD exacerbation, decompensated heart failure, viral illness or a non-infective inflammatory state. **(iii) Prognostication and monitoring** of response to treatment. **(iv) Particular value in the older adult**, in whom fever, leucocytosis and symptoms are all unreliable, and in whom CRP and ESR are often non-specifically raised by comorbidity.
6. **Limitations — the marks are here. False positives**: major surgery and trauma, burns, cardiac arrest and resuscitation, prolonged cardiogenic shock, severe pancreatitis, malaria, heat stroke, **medullary thyroid carcinoma and small-cell lung cancer**, **end-stage renal disease and dialysis**, and treatment with anti-thymocyte globulin or OKT3. **False negatives**: very early presentation (<6 hours), and **localised or walled-off infection** — abscess, empyema, **infective endocarditis**, osteomyelitis and septic arthritis — as well as intracellular and atypical organisms. It must therefore **never be used alone** to start or stop antibiotics; it supplements, but does not replace, clinical judgement and culture.

Latest Update (2023 – present)

7. Recent randomised evidence — including the **ADAPT-Sepsis** and **PRONTO** trials and the **NICE 2023 diagnostics guidance** — has clarified exactly where procalcitonin adds value. It **safely shortens antibiotic duration** in ICU sepsis and in suspected lower respiratory tract infection, but it **does not reduce mortality** and does **not** reliably reduce antibiotic *initiation* in the emergency department. Current guidance therefore supports its use for **guiding discontinuation and de-escalation rather than for deciding whether to start**. In Indian public hospitals, where cost limits routine availability, this is the rational deployment — reserve it for **de-escalation decisions in the ICU** rather than as a screening test.

Exam One-Liners

- Nature — **precursor of calcitonin**, CALC-1 gene, normally <0.05 ng/mL.
- Rises in **2–4 h**, peaks at **12–24 h**, half-life **~24 h**.
- Key principle — **suppressed by interferon-γ, so low in viral infection**.
- Antibiotic threshold in LRTI — **>0.5 ng/mL strongly encourages**, **<0.1 strongly discourages**.
- Classic false positives — **surgery, trauma, burns, dialysis, medullary thyroid carcinoma**.
- Classic false negatives — **endocarditis, abscess, empyema, osteomyelitis**.
- Best proven role — **shortening antibiotic duration**, not starting antibiotics.

Question 4. Infection control and antimicrobial stewardship in hospitals 7 MARKS

ANSWER

Textbook Core — 6 Points

1. **Definitions and why they matter in geriatrics. Infection prevention and control (IPC)** is the set of measures that prevent transmission of pathogens within healthcare settings. **Antimicrobial stewardship (AMS)** is a coordinated programme to optimise the **choice, dose, route and duration** of antimicrobials so as to improve outcomes, reduce toxicity and cost, and limit resistance. Older inpatients are the highest-risk group because of **atypical presentation** (fever and leucocytosis may be absent), high device use, prolonged stay and heavy antibiotic exposure.
2. **Core IPC measures. Hand hygiene (WHO 5 moments) is the single most effective intervention**; **standard precautions** plus **transmission-based precautions** (contact, droplet, airborne); appropriate PPE; environmental cleaning and disinfection; safe injection and sharps practice; **isolation or cohorting** of MDRO carriers and *C. difficile*; biomedical waste management; and **device care bundles** for CAUTI, CLABSI, ventilator-associated pneumonia and surgical site infection.
3. **Surveillance.** Continuous surveillance of **device-associated infection rates**, construction of a **hospital antibiogram** to guide empirical therapy, outbreak detection, and MDRO screening. In India, the **ICMR Antimicrobial Resistance Surveillance Network (AMRSN)** and NCDC's HAI surveillance network provide national resistance data.
4. **Core elements of an AMS programme (CDC / ICMR). Leadership commitment** (budget and staff); **accountability** — a named physician lead; **pharmacy expertise**; **action** — formulary restriction and pre-authorisation, **prospective audit and feedback**, an **antibiotic timeout at 48–72 hours**, de-escalation on culture results, **IV-to-oral switch** and defined duration limits; **tracking** (DDD per 100 bed-days, days of therapy); **reporting**; and **education**.
5. **Practical prescribing rules.** Send cultures **before** the first antibiotic dose; choose empirical therapy from the **local antibiogram**, not from memory; apply the **WHO AWaRe classification** — **Access** preferred, **Watch** restricted, **Reserve** for last-line use; use the **shortest effective duration**; and **adjust every dose for renal function**, with therapeutic drug monitoring mandatory for **aminoglycosides and vancomycin** in older adults.
6. **Geriatric-specific stewardship issues.** Do not treat **asymptomatic bacteriuria** or colonisation; avoid **fluoroquinolones** where possible (delirium, tendon rupture, QT prolongation, aortic aneurysm, *C. difficile* — flagged in the Beers criteria); watch for antibiotic-related **drug interactions** (warfarin, statins, antiarrhythmics); recognise antibiotics as a leading precipitant of ***C. difficile* infection** and of delirium; and remember that **vaccination** (influenza, pneumococcal, COVID-19, herpes zoster) is itself a stewardship intervention because it prevents antibiotic-requiring illness.

Latest Update (2023 – present)

7. India launched the **National Action Plan on Antimicrobial Resistance 2.0 (NAP-AMR 2.0, 2025–2029)** on **18 November 2025**, during World AMR Awareness Week. Key changes from NAP-AMR 1.0 (2017–21): **IPC programmes are now mandatory in all healthcare facilities**; **environmental surveillance of antibiotic residues** in wastewater from hospitals, farms and pharmaceutical units is mandatory; the **ICMR AMRSN is being expanded** with genomic surveillance; and **governance is elevated to a standalone pillar**, with 20+ ministries required to submit time-bound, budgeted action plans. It follows the **One Health** approach and is aligned with the **UNGA 2024 political declaration target of a 10% reduction in AMR-related deaths by 2030**.

If this appears as a 15-mark question, add: the burden of AMR (Lancet GRAM: 1.27 million deaths directly attributable globally in 2019; ~2.97 lakh AMR-attributable deaths in India); Indian resistance patterns (carbapenem-resistant *Klebsiella* and *Acinetobacter*, ESBL *E. coli*, *Candida auris*); a full CAUTI/CLABSI/VAP bundle; the Schedule H1 regulation of antibiotic sales; NABH accreditation requirements for hospital infection control committees; AMS outcome metrics and reported Indian results (reduction in ceftriaxone and piperacillin-tazobactam DDDs after AMSP introduction); and barriers to AMS in Indian secondary-care hospitals.

Exam One-Liners

- Single most effective IPC measure — **hand hygiene**.
- AWaRe — **Access, Watch, Reserve**.
- Stewardship intervention with best evidence — **prospective audit and feedback**.
- Antibiotic timeout — **48–72 hours**.
- Indian surveillance network — **ICMR AMRSN**.
- Current national policy — **NAP-AMR 2.0 (2025–2029)**.

PART II

Tuberculosis

Programmatic management and drug-resistant disease, followed by the molecular diagnostic that underpins it.

Question 5. DOTS; treatment, dose and regimens of MDR and XDR tuberculosis; drug-resistant TB

7 MARKS ASKED ×4

ANSWER

Textbook Core – 6 Points

1. **Definitions of drug resistance (WHO 2021 revision). Mono-resistant** — resistance to one first-line drug. **Poly-resistant** — resistance to more than one first-line drug other than to isoniazid and rifampicin together. **MDR-TB** — resistance to at least **isoniazid AND rifampicin**. **RR-TB** — rifampicin resistance with or without other resistance; managed exactly as MDR-TB. **Pre-XDR-TB** — MDR/RR-TB plus resistance to **any fluoroquinolone**. **XDR-TB** — MDR/RR-TB plus fluoroquinolone resistance plus resistance to **at least one Group A drug (bedaquiline or linezolid)**.
2. **DOTS — the five components.** (i) **Sustained political and financial commitment**; (ii) **case detection by quality-assured bacteriology**; (iii) **standardised short-course chemotherapy given under direct observation with patient support**; (iv) an **uninterrupted, quality-assured drug supply and management system**; and (v) **standardised recording, reporting, monitoring and impact measurement**. **DOTS-Plus** extended the framework to programmatic management of drug-resistant TB. In India, RNTCP became the **National TB Elimination Programme (NTEP)** in 2020, with the **Ni-kshay** digital notification portal, **Ni-kshay Poshan Yojana** direct-benefit nutritional support (raised to **₹1000 per month in 2024**), the **Pradhan Mantri TB Mukt Bharat Abhiyaan** with **Ni-kshay Mitra** community adoption, and a national elimination target ahead of the global 2030 goal.
3. **Drug-susceptible TB (for contrast). 2HRZE / 4HR** — two months of isoniazid, rifampicin, pyrazinamide and ethambutol, then four months of isoniazid and rifampicin, given **daily as weight-band fixed-dose combinations** (NTEP moved from thrice-weekly to daily dosing in 2017). Doses: **H 5 mg/kg, R 10 mg/kg, Z 25 mg/kg, E 15 mg/kg**, with **pyridoxine 10 mg daily** — essential in older adults to prevent isoniazid neuropathy.
4. **Current MDR/RR-TB regimens — the core of the answer.**

Regimen	Composition	Use
BPaLM — 6 months (preferred)	**B**edaquiline + **Pa**retomanid + **L**inezolid 600 mg + **M**oxifloxacin	MDR/RR-TB, age ≥14 y. Drop moxifloxacin → **BPaL** if fluoroquinolone-resistant (pre-XDR). **Not** for pregnancy/breastfeeding (no pretomanid safety data)
BDLLfxC — 6 months	**B**edaquiline + **D**elamanid + **L**inezolid 600 mg + **L**evo**flox**acin + **C**lofazimine	Alternative 6-month regimen; usable in **pregnancy, breastfeeding and children**. Becomes **BDLC** if fluoroquinolone-resistant. Requires no prior exposure >1 month to bedaquiline, delamanid or linezolid
9-month all-oral	Bedaquiline-containing (BPaLM or BDLLfxZ)	**Fluoroquinolone-susceptible only** — must not be used in pre-XDR-TB
Longer individualised 18–20 months	Built from Groups A → B → C	When short regimens are unsuitable, and **mandatory for CNS, osteoarticular and disseminated multi-organ TB** — all short regimens are contraindicated in these

5. **Drug groups and key doses. Group A (include all three)** — levofloxacin or moxifloxacin, **bedaquiline**, **linezolid**. **Group B (add both)** — clofazimine, cycloserine or terizidone. **Group C (add to complete)** — ethambutol, delamanid, pyrazinamide, imipenem-cilastatin or meropenem, amikacin, ethionamide, para-aminosalicylic acid. Doses to quote: **bedaquiline 400 mg daily for 2 weeks then 200 mg three times a week for 22 weeks**; **pretomanid 200 mg daily**; **linezolid 600 mg daily**; **moxifloxacin 400 mg daily**; **levofloxacin 750–1000 mg daily**; **delamanid 100 mg twice daily**; **clofazimine 100 mg daily**.
6. **Monitoring and geriatric considerations.** Monthly **sputum smear and culture** for conversion; monthly weight; baseline and serial **ECG for QT interval** (bedaquiline, moxifloxacin, clofazimine and delamanid all prolong QT — correct potassium and magnesium first); **monthly CBC, vision and peripheral nerve assessment for linezolid** (myelosuppression, optic and peripheral neuropathy — the commonest reason for dose reduction to 300 mg or interruption); liver and renal function; TSH (ethionamide, PAS); psychiatric review (cycloserine — psychosis, depression, seizures); and audiometry if an aminoglycoside is unavoidable — **injectable aminoglycosides should be avoided altogether in older adults** because of ototoxicity and nephrotoxicity. In the elderly also: **dose-adjust for the age-related fall in GFR**, review interactions with cardiac and psychotropic drugs, screen for and treat diabetes and malnutrition, and provide family-supported or video-observed treatment rather than daily clinic attendance.

Latest Update (2023 – present)

7. The **WHO Consolidated Guidelines on Tuberculosis, Module 4 (2025 update)** now prioritise **all-oral 6-month**

regimens — BPaLM and BDLLfxC — as the standard of care for MDR/RR-TB, with 9-month all-oral regimens reserved for fluoroquinolone-susceptible disease, and **CNS, osteoarticular and disseminated TB listed as contraindications to all short regimens**. Uptake has accelerated sharply: **34,256 people worldwide started a 6-month regimen in 2024, up from 5,653 in 2023**, across 97 countries. WHO also **strongly recommended 6 months of levofloxacin (6-Lfx) as preventive treatment for household contacts of MDR/RR-TB** in September 2024. India, which carries about **27% of the global rifampicin-resistant TB burden**, has rolled out BPaLM nationally under NTEP, with pooled Indian real-world **treatment success of about 89.7%**, the main toxicities being linezolid-related **anaemia (13.4%)** and **peripheral neuropathy (8.7%)**.

MNEMONIC ANCHOR

Group A = "B-L-Q" — **B**edaquiline, **L**inezolid, **Q**uinolone (all three always included).
Group B = "2 C's" — **C**lofazimine, **C**ycloserine.
Regimens = "6 – 6 – 9 – 18" — BPaLM 6 months · BDLLfxC 6 months · all-oral 9 months (FQ-sensitive only) · longer individualised 18–20 months.

NUMERICAL ANCHORS

DOTS has **5 components** · drug-susceptible regimen **2HRZE/4HR** · bedaquiline **400 mg × 2 weeks → 200 mg thrice weekly × 22 weeks** · linezolid **600 mg daily** · pretomanid **200 mg daily** · moxifloxacin **400 mg daily** · delamanid **100 mg BD** · clofazimine **100 mg daily** · Ni-kshay Poshan Yojana **₹1000/month** · India ≈ **27%** of global RR-TB · Indian BPaLM success **≈90%** · 6-Lfx preventive therapy for MDR contacts.

NAMED EXAMINER TRAPS

(a) RR-TB is managed as MDR-TB — rifampicin resistance alone is enough. **(b)** The **2021 XDR definition changed** — it is no longer "second-line injectable resistance" but **resistance to a Group A drug (bedaquiline or linezolid)**. **(c)** The **9-month regimen is only for fluoroquinolone-susceptible disease** — using it in pre-XDR is a serious error. **(d) Short regimens are contraindicated in CNS, osteoarticular and disseminated TB. (e) Avoid injectable aminoglycosides in older adults. (f)** Always add **pyridoxine** with isoniazid in the elderly. **(g)** Get a **baseline ECG** before starting — three of the four drugs in BPaLM prolong QT.

15-SECOND ANSWER SKELETON

Definitions of resistance (mono → poly → MDR → RR → pre-XDR → XDR with the 2021 change) → the 5 components of DOTS and the Indian NTEP framework → drug-susceptible regimen for contrast → the four current regimens in a table → Groups A/B/C with doses → monitoring (culture, ECG, CBC, vision, nerves) and geriatric caveats → WHO 2025 Module 4 and the Indian BPaLM roll-out.

EXTRA RECALL BOX — TB IN THE OLDER ADULT (THIS IS WHAT MAKES IT A GERIATRICS ANSWER)

Kane's makes three points that must appear: **(i)** older people of all groups are **especially at risk**, having lived through a period of higher TB incidence, having probably never received isoniazid preventive therapy, and having predisposing factors — physiological change, malnutrition and underlying disease — that lead to **reactivation**; they are also at increased risk of **primary infection**, particularly in long-term care facilities. **(ii) TB screening programmes should be implemented in long-term care facilities**, with isoniazid 300 mg/day for 9–12 months for skin-test converters who have an abnormal chest film, diabetes, end-stage renal disease, haematological malignancy, steroid or immunosuppressive therapy, or malnutrition. **(iii)** The single most quotable line: **"A useful rule in geriatric care is to suspect tuberculosis when a patient is inexplicably failing."** Add that **tuberculin skin testing may be falsely negative because of anergy** in older people, so an IGRA or a two-step test is preferred.

Exam One-Liners

- MDR-TB — resistance to **isoniazid + rifampicin**.
- Pre-XDR — MDR/RR + **fluoroquinolone** resistance.
- XDR (2021) — pre-XDR + resistance to **bedaquiline or linezolid**.
- Preferred regimen — **BPaLM for 6 months**; drop the M if FQ-resistant.
- Regimen usable in pregnancy — **BDLLfxC**.
- Group A drugs — **quinolone, bedaquiline, linezolid**.
- Commonest limiting toxicity — **linezolid** (marrow, optic and peripheral nerve).
- Mandatory baseline test — **ECG for QT**.
- MDR contact prophylaxis — **6 months levofloxacin**.

Question 6. GeneXpert test 7 MARKS

ANSWER

Source note: Not covered in the uploaded textbooks; content is from WHO consolidated guidelines on rapid diagnostics and Indian NTEP policy, and is presented as current evidence.

Textbook Core – 6 Points

1. **What it is. Xpert MTB/RIF** is an automated, **cartridge-based, closed-system, real-time PCR** (nucleic acid amplification test) run on the GeneXpert platform. In a single step it **simultaneously detects *Mycobacterium tuberculosis* complex DNA and rifampicin resistance**, the latter by using five molecular beacon probes to detect mutations in the **81-base-pair "hot-spot" (core) region of the *rpoB* gene**, which harbours >95% of rifampicin-resistance mutations. **Result in about 2 hours**, with minimal training and biosafety requirements — hence its Indian programme name, **CBNAAT** (cartridge-based nucleic acid amplification test).
2. **Xpert MTB/RIF Ultra.** The improved-generation assay adds two **multi-copy amplification targets (IS6110 and IS1081)**, a larger reaction chamber and **melting-curve analysis** for rifampicin resistance. This lowers the limit of detection from about **114 to 16 colony-forming units/mL**, giving markedly better sensitivity in **smear-negative, paucibacillary, HIV-associated, paediatric and extrapulmonary disease**. Ultra reports an additional semi-quantitative **"trace"** category, which is treated as positive in high-risk groups but may require clinical correlation elsewhere.
3. **Performance.** Against culture, pooled **sensitivity ≈85% and specificity ≈98%** for pulmonary TB; sensitivity is about **98% in smear-positive but only ≈67% in smear-negative** disease (Ultra improves this). For **rifampicin resistance, sensitivity ≈95% and specificity ≈98%**. It therefore vastly outperforms Ziehl–Neelsen smear microscopy, which needs about 10,000 bacilli/mL.
4. **Indications.** WHO recommends Xpert MTB/RIF or Ultra as the **initial diagnostic test in all people with signs or symptoms of TB**, replacing smear microscopy. It is particularly indicated in **presumptive MDR-TB, HIV-associated TB, paediatric TB, and extrapulmonary specimens** — and it is the **preferred initial test on cerebrospinal fluid for TB meningitis** (where a rapid answer changes outcome), as well as on lymph node aspirate, pleural and other body fluids, gastric aspirate and tissue.
5. **Limitations — the marks are here.** It **cannot distinguish live from dead bacilli**, so it must **never be used for treatment monitoring or as a test of cure** (remains positive for months). It **does not detect isoniazid or fluoroquinolone resistance** — that needs a line probe assay, Xpert MTB/XDR or sequencing. **False rifampicin resistance** can arise from silent or borderline *rpoB* mutations, so a positive result in a low-prevalence setting should be confirmed by a second method. Sensitivity is **lower in pleural fluid and in paucibacillary extrapulmonary disease**, so a negative result never excludes TB. Practical constraints: stable electricity, ambient temperature control, annual module calibration, and cartridge cost.
6. **Indian context.** Under NTEP, **universal drug susceptibility testing** mandates a rapid molecular test with rifampicin resistance detection for **every** diagnosed TB patient, and CBNAAT machines have been placed down to district and sub-district level. India also uses the indigenous **Truenat MTB / MTB Plus and MTB-RIF Dx** — a chip-based, battery-operated, portable real-time PCR system (Molbio, Goa), **WHO-endorsed in 2020**, which can be deployed at primary health centre level without air conditioning and has brought molecular diagnosis to peripheral settings.

Latest Update (2023 – present)

7. The WHO rapid-diagnostics menu has broadened well beyond Xpert alone: **targeted next-generation sequencing (tNGS) directly on sputum** was recommended in 2023 for comprehensive drug-resistance profiling in one test; **low-complexity automated assays (Xpert MTB/XDR)** now detect **isoniazid, fluoroquinolone, ethionamide and amikacin resistance** as a reflex test after a positive Xpert MTB/RIF; and **computer-aided detection (CAD) software on digital chest radiographs** is recommended for TB triage in people aged 15 and over. **Tongue-swab sampling** with Xpert Ultra — which removes the need for sputum production, a real advantage in frail and cognitively impaired older adults — is under active evaluation for programmatic use.

Exam One-Liners

- Principle — **cartridge-based real-time PCR**; target the **81-bp *rpoB* hot-spot**.
- Detects — **M. tuberculosis complex + rifampicin resistance**, in **2 hours**.
- Ultra adds — **IS6110 and IS1081**; limit of detection **16 CFU/mL**; reports **"trace"**.
- Best extrapulmonary use — **CSF in TB meningitis**.
- Never use for — **treatment monitoring or test of cure**.
- Does not detect — **isoniazid or fluoroquinolone resistance**.
- Indian portable alternative — **Truenat**.

PART III

Viral and Vaccine-Preventable Infection

The four vaccine-preventable illnesses that dominate morbidity in older adults, followed by the consolidated immunisation schedule and a high-consequence viral haemorrhagic fever.

Question 7. Herpes zoster and post-herpetic neuralgia 15 MARKS RECURRING

ANSWER

Textbook Core — 10 Points

1. **Definition.** Herpes zoster (shingles) is **reactivation of latent varicella-zoster virus (VZV)** from the **dorsal root ganglion**, where it lies dormant after childhood chickenpox. Reactivation occurs because of **immunosenescence**. **Post-herpetic neuralgia (PHN)** is severe shooting, burning or stabbing pain persisting **beyond 3 months** after the rash.
2. **Epidemiology and risk.** Incidence rises considerably after **age 50**, with a **50% lifetime risk by 85 years**. Incidence is **11.8 per 1000 per year in those over 60** versus 1.2–3.4 per 1000 per year at all ages. **Increasing age is the strongest risk factor for PHN**; others are severe rash, severe acute pain and prodromal pain.
3. **Clinical features.** A **prodrome of neuropathic pain** — intense burning or aching in the dermatome — precedes the rash. Then a **unilateral, dermatomal cluster of vesicles on an erythematous base**, which **crusts over in 7–10 days**, after which the patient is no longer contagious.
4. **Important clinical variants. Herpes zoster ophthalmicus** (V1 division; **Hutchinson's sign** = vesicles on the nose tip indicating nasociliary involvement — urgent ophthalmology referral); **Ramsay Hunt syndrome** (facial palsy with vesicles in the ear canal); **disseminated zoster** in the immunosuppressed.
5. **Complications. PHN is the commonest.** Also **zoster encephalitis** — most common in advanced age, immunosuppression and disseminated cutaneous zoster; **contralateral hemiplegia** occurring weeks after zoster ophthalmicus (VZV granulomatous arteritis) accounts for up to **one-third** of CNS zoster; post-herpetic itch; secondary bacterial infection; myelitis; ocular complications.
6. **Diagnosis.** Usually **clinical**. **VZV DNA PCR** from vesicle fluid confirms. In suspected CNS disease, CSF shows **lymphocytic pleocytosis with raised protein** (also seen in up to 40% of zoster patients *without* CNS involvement); **CSF VZV PCR specificity >95%, sensitivity 80–95%**; viral culture is rarely helpful.
7. **Antiviral therapy.** Start ideally **within 72 hours** of symptom onset for maximum effect. **Aciclovir 800 mg five times daily**, or **valaciclovir 1 g three times daily**, or famciclovir — for **7 days**. Early therapy prevents new vesicles and reduces pain intensity and duration, viral shedding and **PHN incidence**. **Reduce dose for renal impairment** — GFR falls ~30% with normal ageing. IV aciclovir 30 mg/kg/day in divided doses for CNS disease.
8. **Acute pain management.** Paracetamol and, where safe, an NSAID; **moderate-to-severe pain may require opioids**. Corticosteroids or gabapentin may be added if pain persists — but **corticosteroids have NOT been shown to reduce the incidence of PHN in the elderly**.
9. **Treatment of established PHN.** Approved options: **topical 5% lidocaine patch, gabapentin and pregabalin**. **Nortriptyline** and opioids are also of benefit; **combination therapy** is often necessary. Avoid **amitriptyline** in older adults — strongly anticholinergic (dry mouth, retention, constipation, delirium, tachycardia, blurred vision, falls). Gabapentinoids need renal dose reduction and cause sedation and ataxia.
10. **Prevention (textbook position). Zostavax**, a **live attenuated** vaccine, is recommended for immunocompetent adults **≥60 years** (permitted from 50). It reduces the incidence of **herpes zoster by 51%** and of **PHN by 66%**, and also reduces ophthalmic zoster and zoster hospitalisations.

Latest Updates (2023 – present)

11. **Recombinant zoster vaccine (RZV, Shingrix) has replaced the live vaccine.** Two IM doses 2–6 months apart, efficacy **>90%**, now the **preferred vaccine from age 50** and — because it is **non-live** — the only zoster vaccine usable in the **immunocompromised**. Live Zostavax was discontinued in the USA (2020) and many other countries.
12. **Zoster vaccination and dementia risk.** *Nature* 2025 (Eyting et al., Wales natural experiment) found roughly a **20% relative reduction in dementia** over 7 years after zoster vaccination; *Nature Medicine* 2024 (Taquet et al.) showed RZV was associated with lower dementia risk than the live vaccine — **17% more diagnosis-free time (≈164 extra days)**. Large cohort data (Kaiser Permanente, Medicare) are concordant. This is now a strong additional argument for offering RZV to all older adults.

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
Vaccine	Live attenuated Zostavax, age ≥60	Recombinant RZV, 2 doses, age ≥50, including immunocompromised	Quote Zostavax figures (51% / 66%), then name RZV as the current standard
Steroids	May be added if pain persists	Do not use to prevent PHN; use only for selected acute severe pain	State explicitly that steroids do not prevent PHN

PHN first-line drug	Lidocaine patch, gabapentin, TCA	Gabapentinoid or lidocaine patch first; TCAs avoided in frail elderly (Beers)	Name the drug and the geriatric caveat together
Wider benefit	Not discussed	Zoster vaccination associated with reduced dementia incidence	Use as the closing "latest update" line

MNEMONIC ANCHOR

"72 – 7 – 3" → antiviral within **72 hours** · give for **7 days** · call it **PHN after 3 months**.

NUMERICAL ANCHORS

50% lifetime risk by age 85 · incidence 11.8/1000/yr over 60 · crusting at 7–10 days · antiviral window 72 h · aciclovir 800 mg × 5/day · valaciclovir 1 g TDS · PHN threshold 3 months · Zostavax ↓HZ 51%, ↓PHN 66% · RZV efficacy >90% · dementia risk ↓ ~20%.

NAMED EXAMINER TRAPS

(a) PHN is defined at **3 months**, not 1 month. **(b)** Corticosteroids do **not** reduce PHN incidence. **(c)** RZV is **non-live** — therefore safe in immunosuppression, unlike Zostavax. **(d) Hutchinson's sign** means nasociliary involvement — same-day ophthalmology. **(e)** Do not start amitriptyline in a frail older adult for PHN. **(f)** Vesicles are infectious until crusted — isolate from non-immune contacts and pregnant staff.

15-SECOND ANSWER SKELETON

Define (VZV reactivation, dorsal root ganglion, immunosenescence) → epidemiology (50% by 85) → prodromal pain then dermatomal vesicles → variants (ophthalmicus, Ramsay Hunt) → complications (PHN, encephalitis, contralateral hemiplegia) → PCR → antiviral <72 h × 7 days, renal dose → acute pain ladder → PHN: gabapentinoid / lidocaine patch / nortriptyline → prevention with RZV → dementia signal.

EXTRA RECALL BOX

Zoster ophthalmicus followed weeks later by contralateral hemiplegia = VZV granulomatous arteritis — a classic viva question; angiography shows unilateral arteritis or thrombosis and CT/MR shows infarction. **Zoster sine herpete** = dermatomal pain with no rash, diagnosed by PCR/serology. **Zoster is a marker of immunosuppression** — in an older Indian patient, consider undiagnosed diabetes, malignancy, HIV and steroid use.

Exam One-Liners

- Site of latency — **dorsal root ganglion**.
- Antiviral window — **72 hours**.
- Drug of choice — **aciclovir / valaciclovir**, renally dose-adjusted.
- PHN definition — pain **>3 months** after rash.
- PHN drugs — **gabapentin, pregabalin, lidocaine 5% patch, nortriptyline**.
- Vaccine of choice today — **recombinant zoster vaccine, 2 doses, ≥50 years**.
- Most feared eye sign — **Hutchinson's sign**.

Question 8. COVID-19 in the older adult — presentation and management 7 MARKS

ANSWER

Textbook Core — 6 Points

1. **Why older adults are the highest-risk group. Immunosenescence and inflammaging**, multimorbidity, reduced pulmonary and cardiac reserve, and **frailty** make **age the single strongest predictor of severe disease and death**. Residents of long-term care facilities are at particular risk because of close cohabitation and shared staff. The great majority of COVID-19 hospitalisations occur in those **≥65 years**, with the highest rates over 75.
2. **Atypical presentation. Delirium or acute confusion may be the sole presenting feature.** Also falls, functional decline, anorexia, generalised weakness, unexplained tachypnoea and **"silent hypoxia"** — significant desaturation without breathlessness. **Fever may be absent** because of the blunted febrile response of ageing; anosmia is reported less often than in younger patients.
3. **Assessment. Pulse oximetry** is essential (target SpO_2 94–98%, or 88–92% if at risk of hypercapnia); respiratory rate; CBC (lymphopenia), CRP, renal and liver function, blood glucose, D-dimer, ECG and chest imaging; **RT-PCR or rapid antigen test**. Document a **Clinical Frailty Scale** score and comorbidity — used **alongside, never instead of**, clinical assessment when making escalation decisions. Screen for delirium with the **4AT**.
4. **Mild-to-moderate disease in a high-risk older adult.** Start an antiviral **within 5 days of symptom onset**. **Nirmatrelvir/ritonavir** is first line — dose-reduce if eGFR 30–60 mL/min, **avoid if eGFR <30**, and check for **CYP3A4 interactions**, which are the major geriatric pitfall (statins, calcium-channel blockers, amiodarone, DOACs, tacrolimus, some antipsychotics — many need temporary suspension or dose reduction). Alternatives: **remdesivir** (3-day IV course) or **molnupiravir**.
5. **Severe disease (hypoxia).** Controlled oxygen, awake proning if tolerated, **dexamethasone 6 mg daily for up to 10 days** (only if hypoxic), plus **tocilizumab or baricitinib** in rapidly progressive inflammatory disease; escalate to HFNO/NIV/ventilation according to agreed goals of care. Give **LMWH thromboprophylaxis** unless contraindicated. Antibiotics only when bacterial co-infection is genuinely suspected. Monitor for hyperglycaemia and steroid-induced delirium.
6. **The geriatric care bundle. Delirium prevention** (reorientation, hearing aids and spectacles, hydration, early mobilisation, sleep hygiene, minimising sedatives and restraints); nutrition and swallow assessment; **pressure-ulcer prevention**; medication review; **early rehabilitation** for deconditioning and post-COVID functional decline; and explicit **advance care planning and goals-of-care discussion** with the patient and family. Prevention: **updated COVID-19, influenza and pneumococcal vaccination**, ventilation, and IPC in long-term care.

Latest Update (2023 – present)

7. The **2025 IDSA guideline update** continues to **strongly recommend nirmatrelvir/ritonavir** for high-risk adults with mild-to-moderate COVID-19. However, the **PANORAMIC and CanTreatCOVID platform trials (NEJM 2026)**, conducted in a largely **vaccinated** higher-risk community population, found **faster symptom recovery but no significant reduction in hospitalisation or death** — so the absolute benefit is now understood to be greatest in the **unvaccinated, immunocompromised and oldest-old**. CDC 2025–2026 guidance recommends COVID-19 vaccination for adults **≥65 years through individual-based (shared clinical) decision-making**, and CDC MMWR 2026 data show only about **31% of eligible outpatients ≥65 years receive an antiviral within 7 days** — under-treatment, not over-treatment, is the current practice gap.

If this appears as a 15-mark question, add: pathophysiology (ACE2, cytokine response, endothelial injury, immunothrombosis); a severity classification table (mild / moderate / severe / critical with SpO_2 and respiratory rate cut-offs); the Indian Ministry of Health clinical management protocol and its home-isolation criteria; specific management of long COVID / post-COVID syndrome in older adults (fatigue, breathlessness, cognitive impairment, deconditioning, and the role of pulmonary rehabilitation); the ethical framework for triage and ceilings of care in frail older adults; and lessons for outbreak management in Indian old-age homes.

Exam One-Liners

- Commonest atypical presentation — **delirium**.
- Most dangerous missed sign — **silent hypoxia**.
- Antiviral window — **within 5 days**.
- Biggest practical problem with nirmatrelvir/ritonavir — **CYP3A4 drug interactions**.
- Steroids — only if **hypoxic**; dexamethasone 6 mg × up to 10 days.
- Frailty score — used **with**, not instead of, clinical judgement.

Question 9. Prevention and management of influenza 7 MARKS

ANSWER

Textbook Core – 6 Points

1. **Why it matters in older adults.** Influenza A and B cause annual epidemics, and **the great majority of influenza deaths occur in those aged over 65** — through **primary viral pneumonia**, **secondary bacterial pneumonia** (*S. pneumoniae*, *S. aureus*, *H. influenzae*), and **decompensation of heart failure, COPD, diabetes and cerebrovascular disease**. The risk of **myocardial infarction and stroke rises sharply in the week following influenza**. Long-term care facilities are the classic setting for explosive outbreaks with high mortality.
2. **Presentation in the elderly.** Frequently **atypical**: fever may be absent or low-grade, and the illness may present as **delirium, functional decline, falls, anorexia, generalised weakness or an exacerbation of a chronic disease** rather than the classical abrupt fever, myalgia, headache and dry cough. Kane's directs that **at the onset of a suspected respiratory viral outbreak in a facility, a nasopharyngeal wash or swab should be obtained for virus isolation and rapid diagnostic testing for influenza A and other common viruses**.
3. **Diagnosis. RT-PCR (or a multiplex respiratory panel) on a nasopharyngeal swab is the test of choice** — sensitive, specific, and able to distinguish influenza A from B and to subtype. **Rapid antigen tests are quick but insensitive**, so a negative result during an outbreak does not exclude influenza and should not delay treatment. Add pulse oximetry, chest radiograph if hypoxic or if pneumonia is suspected, and CBC, renal function and CRP.
4. **Vaccination — the cornerstone. Annual inactivated influenza vaccine for everyone aged 65 and over**, for **residents and staff** of long-term care facilities, and for household contacts. Kane's records that over ten seasons, influenza vaccination in community-dwelling older people was associated with a **hazard ratio of 0.75 for hospitalisation for pneumonia or influenza and 0.52 for death**. Because immunosenescence blunts the antibody response, **high-dose, adjuvanted or recombinant formulations are preferentially recommended over standard-dose vaccine from age 65**. The **live attenuated (nasal) vaccine is contraindicated in older adults**. Timing in India: before the monsoon in most of the country, with a second winter peak in the north; the Southern Hemisphere formulation is generally appropriate.
5. **Antiviral treatment.** Start **as early as possible and within 48 hours of symptom onset** for maximum benefit — but **treat any hospitalised, severe or high-risk patient regardless of how long symptoms have been present**. **Oseltamivir 75 mg twice daily for 5 days** is first-line, and the frequently missed geriatric point is that the dose must be **reduced to 30 mg twice daily if creatinine clearance is 30–60 mL/min**, with further reduction below that. Alternatives: **inhaled zanamivir** (avoid in asthma and COPD), intravenous **peramivir**, and **baloxavir marboxil** as a single oral dose. Add antibiotics only where bacterial co-infection is genuinely suspected. Use paracetamol for fever; **avoid aspirin**.
6. **Outbreak control in long-term care.** Kane's protocol: give **oseltamivir or zanamivir within 24–48 hours of an outbreak of suspected influenza**, to **residents and staff**, and continue **throughout the outbreak** — in practice, oseltamivir 75 mg once daily as chemoprophylaxis for at least 14 days and until 7 days after the last case. Alongside this: **annual vaccination of residents and staff**, isolation and cohorting of cases, restriction of new admissions and visitors, exclusion of symptomatic staff from work, hand hygiene, droplet precautions with masks, and environmental cleaning.

Latest Update (2023 – present)

7. Current WHO and national guidance now emphasise **co-administration of influenza vaccine with COVID-19 and RSV vaccines at the same visit** for older adults, since separate visits reduce uptake; and **ACIP preferentially recommends the high-dose, adjuvanted or recombinant influenza vaccine for all adults aged 65 and over** rather than standard-dose. The Indian problem is structural: **influenza vaccine is not part of the Universal Immunisation Programme** and is available only through the private sector or selected state initiatives, so out-of-pocket cost and lack of physician recommendation are the main barriers. The strongest practical levers in Indian practice are therefore **vaccinating healthcare workers and long-term care staff**, and **opportunistic vaccination at every comprehensive geriatric assessment**.

Exam One-Liners

- Most influenza deaths occur in those **over 65**.
- Test of choice — **RT-PCR on nasopharyngeal swab**.
- Vaccine of choice from 65 — **high-dose, adjuvanted or recombinant**; live nasal vaccine contraindicated.
- Kane's vaccination figures — **HR 0.75 for hospitalisation, 0.52 for death**.
- Antiviral — **oseltamivir 75 mg BD × 5 days**; **30 mg BD if CrCl 30–60**.
- Treat within **48 hours**, but treat any hospitalised or severe case regardless of timing.
- Outbreak in a facility — **chemoprophylaxis for residents and staff within 24–48 hours**.

Question 10. Vaccinations in elderly patients 7 MARKS

ANSWER

Textbook Core – 6 Points

1. **Rationale. Immunosenescence** — thymic involution, reduction in naive T cells, impaired B-cell affinity maturation and class switching — together with **inflammaging**, both increases susceptibility to infection and **blunts the response to vaccines**, which is why older adults need higher-potency formulations. Vaccine-preventable infection in older adults causes hospitalisation, delirium, functional decline and death, and drives a large share of antibiotic use, so **vaccination is also an antimicrobial stewardship intervention**. Vaccination status should be recorded and reviewed at **every comprehensive geriatric assessment**.
2. **Influenza. Annually for everyone aged 65 and over**, and for **residents and staff of long-term care facilities**. **High-dose, adjuvanted or recombinant formulations are preferred over standard-dose** from age 65. The **live attenuated nasal vaccine is contraindicated** in this group.
3. **Pneumococcal.** A single dose of a **pneumococcal conjugate vaccine — PCV20 or PCV21 — for all PCV-naïve adults**. If **PCV15** is used it must be followed by **PPSV23 at least one year later** (or after 8 weeks if the patient is immunocompromised, or has a cerebrospinal fluid leak or a cochlear implant). Pathy's states that all adults aged 65 and over should be vaccinated, and that adults with **asplenia, CSF leak, cochlear implants or immunosuppressing conditions** should also be vaccinated regardless of age.
4. **Herpes zoster. Two doses of the recombinant zoster vaccine (RZV, Shingrix), 2–6 months apart, from age 50**, including in the **immunocompromised** — it is non-live, with efficacy above **90%**. It has replaced the live Zostavax, which was recommended from age 60 and reduced herpes zoster by **51%** and post-herpetic neuralgia by **66%**.
5. **Tetanus, diphtheria and pertussis. Td booster every 10 years**, and every 5 years for a tetanus-prone wound, with **one dose given as Tdap** to cover pertussis, since pertussis immunity wanes. Kane's makes the important point that **many older people never received primary vaccination** and therefore require **tetanus toxoid plus 250–500 units of tetanus immune globulin**, with the series completed by a second injection at 4–6 weeks and a third at 6–12 months.
6. **COVID-19, RSV and situational vaccines.** An **updated COVID-19 vaccine for adults aged 65 and over**, now through individual/shared clinical decision-making. **RSV vaccine — a single dose for all adults aged 75 and over, and for those aged 50–74 with high-risk conditions, frailty, or residence in a long-term care facility**; it is currently a **one-time dose, not annual**. Situational: **hepatitis B** in diabetes and dialysis; **rabies** post-exposure prophylaxis; **typhoid, hepatitis A and yellow fever** for travel; and **meningococcal vaccine for Hajj and Umrah pilgrims** — a common and examinable Indian indication. **Live vaccines are contraindicated in significant immunosuppression.**

Latest Update (2023 – present)

7. Three changes dominate current adult immunisation practice. **(i)** ACIP **lowered the age-based pneumococcal conjugate recommendation from 65 to 50 years** (October 2024, effective January 2025), and added **PCV21 (CAPVAXIVE)** alongside PCV20, PCV21 offering broader serotype coverage and superior immunogenicity for 10 of its 11 unique serotypes. **(ii)** ACIP **lowered the risk-based RSV vaccination age from 60 to 50 years** (April 2025), retaining the universal recommendation at 75. **(iii)** COVID-19 vaccination for those aged 65 and over moved from a universal recommendation to **individual-based (shared clinical) decision-making** for the 2025–26 season. In addition, evidence that **recombinant zoster vaccination is associated with roughly a 20% lower incidence of dementia** (*Nature*, 2025) provides a powerful further argument for uptake in this population.

Quick-Reference Schedule

Vaccine	Who and when	Key points
Influenza	Annually, all ≥65; LTC residents and staff	**High-dose / adjuvanted / recombinant** preferred; live nasal contraindicated
Pneumococcal	Single PCV20 or PCV21 from age 50 if PCV-naïve	If PCV15 used → **PPSV23 after ≥1 year** (8 weeks if immunocompromised)
Herpes zoster	**RZV × 2 doses**, 2–6 months apart, from age 50	Non-live → safe in immunosuppression; efficacy >90%
Td / Tdap	Booster every 10 years; one dose as Tdap	Every 5 years for tetanus-prone wounds; many elderly never primed
COVID-19	Updated vaccine, ≥65 years	Now **shared clinical decision-making** (2025–26)
RSV	All ≥75; ages 50–74 if high risk or frail or in LTC	**One-time dose**, not annual

INDIAN CONTEXT — WHAT TO WRITE FOR THE INDIAN EXAMINER

India has **no national adult immunisation programme**: the Universal Immunisation Programme covers children and pregnant women only, so influenza, pneumococcal, zoster and RSV vaccines are almost entirely **out-of-pocket in the private sector**. The **Association of Physicians of India (API) and Geriatric Society of India** have issued adult immunisation recommendations, and **NPHCE** geriatric clinics are the natural delivery platform. Practical answer points: prioritise **influenza and pneumococcal** as the two with the strongest cost-benefit case; **vaccinate caregivers and long-term care staff**; use **every hospital contact opportunistically**; counsel on cost transparently; and remember that **tetanus toxoid coverage is genuinely poor in older rural Indians**, making tetanus-prone wound management a real and examinable issue.

Exam One-Liners

- Underlying reason for altered schedules — **immunosenescence**.
- Influenza — **annual, high-dose/adjuvanted/recombinant from 65**.
- Pneumococcal — **single PCV20 or PCV21 from age 50**.
- Zoster — **2 doses of recombinant vaccine from age 50**, safe in immunosuppression.
- RSV — **all ≥75; 50–74 if high risk**; one-time dose.
- Contraindicated in immunosuppression — **all live vaccines**.
- India — **no adult immunisation programme**; delivery through NPHCE geriatric clinics.

Question 11. Ebola virus — clinical features, spread, treatment and prevention 7 MARKS

ANSWER

Source note: Not covered in the uploaded textbooks; content is from WHO and current outbreak-response literature.

Textbook Core – 6 Points

1. **Aetiology.** Ebolavirus is an enveloped, single-stranded, negative-sense RNA **filovirus** (family Filoviridae). Six species are recognised, four of which cause human disease: ***Zaire ebolavirus*** — much the most virulent, with case fatality of **25–90%** — *Sudan*, *Bundibugyo* and *Taï Forest* ebolavirus. The natural reservoir is believed to be **fruit bats**, with index cases arising from contact with infected bats or non-human primates (bushmeat). **Incubation 2–21 days.**
2. **Spread.** Human-to-human transmission is by **direct contact with blood or body fluids** — vomit, stool, urine, saliva, sweat, semen, breast milk — of a **symptomatic** or **dead** person, entering through broken skin or mucous membranes, or through contact with contaminated surfaces, linen and needles. **It is not airborne.** The classic outbreak amplifiers are **traditional burial practices** involving washing of the body, and **nosocomial transmission to healthcare workers** where PPE is inadequate. Critically, the virus **persists in immune-privileged sites — semen for 18 months or more**, ocular fluid, CNS and breast milk — causing sexual transmission, late relapse, and new outbreaks seeded from survivors.
3. **Clinical features.** Abrupt onset of **fever, profound weakness, myalgia, headache and sore throat** (the "dry" phase), followed at days 3–10 by the **"wet" phase — high-volume vomiting and profuse watery diarrhoea** causing massive fluid and electrolyte loss, hypovolaemic shock, acute kidney injury and hepatitis. **Haemorrhage occurs in only about 20%** (petechiae, mucosal and gastrointestinal bleeding) — **death at days 6–16 is usually from hypovolaemic and septic shock with severe electrolyte derangement, not from bleeding**, which is the point examiners look for. Late features: encephalopathy, seizures, DIC and multi-organ failure. Survivors develop **post-Ebola syndrome** — arthralgia, **uveitis which may cause blindness**, hearing loss and cognitive difficulty.
4. **Diagnosis. RT-PCR on whole blood is the confirmatory test**; it may be **negative in the first 3 days**, so a symptomatic patient must be retested at 72 hours. Antigen-detection rapid tests are used for triage, and ELISA detects IgM and IgG. Supportive findings: early leucopenia then neutrophilia, **thrombocytopenia**, markedly **raised transaminases with AST greater than ALT**, rising creatinine, and profound **hypokalaemia and hyponatraemia**. All specimens are **category A infectious substances** requiring high-level biosafety handling and specialised transport. In an endemic region the differential includes **malaria — test every patient** — typhoid, Lassa fever, meningococcaemia and dengue.
5. **Treatment.** The foundation, which by itself substantially reduces mortality, is **aggressive supportive care**: high-volume oral and intravenous **fluid and electrolyte replacement** with particular attention to **potassium, magnesium and calcium**, antiemetics, nutritional support, analgesia, correction of hypoglycaemia, and **empirical antimalarials and antibiotics** for co-infection, with organ support as needed. **Specific therapy for *Zaire ebolavirus*:** two monoclonal antibody products are approved on the basis of the **PALM trial — Inmazeb (atoltivimab/maftivimab/odesivimab)** and **Ebanga (ansuvimab)** — both of which substantially reduced mortality compared with ZMapp and remdesivir. **No approved therapy exists for Sudan virus disease.**
6. **Prevention. Isolation with strict barrier nursing** and full PPE, dedicated staff and equipment, safe injection practice and safe waste disposal; **contact tracing with 21-day monitoring**; **safe and dignified burials**; community engagement; and avoidance of bushmeat. **Vaccines against *Zaire ebolavirus*: rVSV-ZEBOV-GP (Ervebo)**, a single-dose live vaccine, WHO-prequalified and used in **ring vaccination** of contacts, contacts-of-contacts and healthcare workers; and the two-dose **Ad26.ZEBOV / MVA-BN-Filo (Zabdeno / Mvabea)** regimen for preventive use. **Survivors must use condoms and undergo semen testing until two negative PCR results.**

Latest Update (2023 – present)

7. Outbreak response has become dramatically faster and now follows a standard template. In the **2025 Democratic Republic of Congo (Kasai) outbreak of *Zaire ebolavirus***, declared in September 2025 and declared over in December 2025, **ring vaccination with Ervebo and treatment with the licensed monoclonals were deployed within days of declaration** — the fastest response yet achieved, and one now formalised in WHO's outbreak playbook alongside pre-positioned vaccine stockpiles. For **Sudan virus disease**, against which neither the licensed vaccine nor the licensed monoclonal antibodies are effective, candidate vaccines are held in a **"trial-ready" stockpile** so that randomised ring-vaccination trials can be launched within days, as was done in **Uganda's 2022 and 2025 outbreaks**.

Exam One-Liners

- Family — **filovirus**; reservoir — **fruit bats**; incubation **2–21 days**.
- Transmission — **direct contact with body fluids of a symptomatic or dead person; not airborne**.
- Commonest cause of death — **hypovolaemic shock from vomiting and diarrhoea**, not haemorrhage.
- Confirmatory test — **RT-PCR on blood**; may be negative in the first 3 days.
- Approved drugs (Zaire only) — **Inmazeb and Ebanga**.
- Vaccines — **Ervebo (single dose, ring vaccination)** and **Zabdeno/Mvabea**.
- Persistence site of greatest public health importance — **semen**.

PART IV

Tropical and Vector-Borne Infection

The seasonal Indian febrile illnesses. Each is a distinct question, but all share the same geriatric trap — atypical presentation with a blunted febrile response and a narrow margin between under- and over-resuscitation.

Question 12. Leptospirosis and dengue in the older adult 7 MARKS

ANSWER

Source note: Dengue and leptospirosis are **not covered adequately in the uploaded textbooks**. The geriatric principles below (blunted febrile response, atypical presentation, narrowed homeostatic reserve, the need to consider drug and renal factors) are taken from Pathy's and Kane's; the disease-specific content is drawn from current national and international guidance and is clearly separated.

Textbook Core — 6 Points

1. **Why these matter in the elderly (textbook principle).** Both are **monsoon-season febrile illnesses** that are highly prevalent in India. Older adults have **higher morbidity and mortality** because the **febrile response is blunted or absent**, symptoms are under-reported, coexisting disease masks acute infection, and **acute unexplained functional deterioration or confusion** may be the only presenting feature. **Absence of fever or leucocytosis does not exclude serious infection.**
2. **Dengue — clinical.** WHO classification: **dengue without warning signs**; **dengue with warning signs** (abdominal pain or tenderness, persistent vomiting, clinical fluid accumulation, mucosal bleeding, lethargy or restlessness, liver enlargement >2 cm, rising haematocrit with rapidly falling platelets); and **severe dengue** (shock, severe bleeding, severe organ impairment). Older adults **less often** show the classical rash and retro-orbital pain and **more often** present with **"expanded dengue syndrome"** — encephalopathy, myocarditis, acute kidney injury, hepatitis and decompensation of existing heart failure or diabetes.
3. **Dengue — diagnosis. NS1 antigen** (days 1–5), **IgM ELISA** (after day 5), RT-PCR where available; serial **CBC** (thrombocytopenia with rising haematocrit), liver and renal function, ECG. **Geriatric pitfall:** baseline anaemia, chronic kidney disease and diuretic therapy make **haematocrit an unreliable marker of plasma leakage** — a "normal" haematocrit may already represent significant haemoconcentration.
4. **Dengue — management. No antiviral exists**; treatment is careful fluid replacement. Use **weight-based crystalloids titrated to haematocrit, urine output and haemodynamics**, with **far tighter monitoring in the elderly** because the window between hypovolaemia and **iatrogenic fluid overload / pulmonary oedema** is very narrow. **Paracetamol only** — **avoid NSAIDs and aspirin** (bleeding and acute kidney injury). Platelet transfusion only for **clinically significant bleeding**, never for a platelet number alone. **Withhold antiplatelets and anticoagulants during the thrombocytopenic phase** and restart deliberately — a key geriatric decision.
5. **Leptospirosis — clinical.** Zoonosis from **rodent urine and floodwater**; risk in farmers, paddy workers and those wading through contaminated water — heavily represented in older rural and coastal populations (Kerala, Tamil Nadu, Gujarat, Andaman). Classically **biphasic**: a septicaemic phase (abrupt fever, **severe myalgia especially of the calves**, **conjunctival suffusion**, headache) followed by an immune phase. Severe forms: **Weil's disease** (jaundice + acute kidney injury + haemorrhage), **pulmonary haemorrhage syndrome** (highest mortality), myocarditis and aseptic meningitis.
6. **Leptospirosis — diagnosis and treatment. Microscopic agglutination test (MAT)** is the reference standard; **IgM ELISA / rapid tests** for early diagnosis; blood culture in the first week and urine culture in the second; PCR. **Mild disease — doxycycline 100 mg twice daily for 7 days**. **Severe disease — IV penicillin G or ceftriaxone 1–2 g daily.** Watch for the **Jarisch–Herxheimer reaction**. Supportive care is decisive: **early dialysis for AKI improves survival**, and ventilatory support for pulmonary haemorrhage.

Latest Update (2023 – present)

7. **India's first dengue vaccine was approved on 21 July 2026**: the DCGI granted marketing authorisation to **TAK-003 (Qdenga)**, a live-attenuated tetravalent vaccine given as **two doses three months apart, without pre-vaccination screening** — but licensed only for ages **4–60 years**, so it **does not currently cover the older adult population**, in whom **vector control, early recognition and meticulous fluid management remain the only strategy**. (TAK-003 was WHO-prequalified in May 2024; 7-year TIDES data show ~84% efficacy against hospitalised dengue. India's indigenous single-dose candidate **DengiAll** — ICMR/Panacea Biotec — is in Phase 3.) For leptospirosis, current NCVBDC/ICMR practice supports **presumptive doxycycline for acute undifferentiated febrile illness during monsoon in endemic districts**, and **doxycycline 200 mg weekly chemoprophylaxis** for high-risk post-flood exposure, as used in Kerala's post-flood outbreak response.

If this appears as a 15-mark question, add: a comparison table of dengue vs leptospirosis vs scrub typhus vs malaria in acute undifferentiated febrile illness (a favourite Indian examiner question — conjunctival suffusion and calf tenderness for lepto, eschar and doxycycline response for scrub typhus, thrombocytopenia with haemoconcentration for dengue); the dengue fluid algorithm by group A/B/C; criteria for ICU admission; the Faine's criteria for leptospirosis; complications of both in patients on RAAS blockers, diuretics, metformin and anticoagulants; and the role of the National Centre for Vector Borne Diseases Control (NCVBDC) programme.

Exam One-Liners

- Dengue in the elderly — more **expanded dengue syndrome**, less classical rash.
- Most dangerous dengue error in the elderly — **fluid overload**.
- Never give in dengue — **NSAIDs and aspirin**.
- Leptospirosis triad — **fever + calf myalgia + conjunctival suffusion**.
- Weil's disease — **jaundice + AKI + haemorrhage**.
- Drug of choice — **doxycycline** (mild), **penicillin G / ceftriaxone** (severe).
- Dengue vaccine in India — **TAK-003, ages 4–60 only**.

Question 13. Chikungunya — clinical presentation, differential diagnosis, laboratory tests and management 7 MARKS

ANSWER

Source note: Not covered in the uploaded textbooks. The geriatric principles (blunted febrile response, atypical presentation, narrowed reserve) are from Pathy's and Kane's; disease-specific content is from WHO, NCVBDC and current literature.

Textbook Core – 6 Points

1. **Aetiology.** Chikungunya virus is an **alphavirus (family Togaviridae)**, transmitted by the daytime-biting ***Aedes aegypti*** **and** ***Aedes albopictus*** mosquitoes. **Incubation 3–7 days** (range 1–12). The name is Makonde for "that which bends up", describing the stooped posture caused by joint pain. It is endemic and epidemic in India, with recurrent **post-monsoon outbreaks**, and a major global resurgence occurred in 2024–25.
2. **Acute clinical presentation.** Abrupt **high fever** with **severe, symmetrical, incapacitating polyarthralgia and arthritis** of the small joints of hands and wrists, ankles and feet; a maculopapular rash on the trunk and limbs in about half; headache, myalgia, conjunctivitis and profound fatigue. **In older adults, atypical and severe forms are far more common — encephalitis and encephalopathy, myocarditis, hepatitis, acute kidney injury, Guillain–Barré syndrome, bullous skin lesions**, and decompensation of pre-existing diabetes, heart failure and chronic kidney disease. **Advanced age is the principal risk factor for severe disease and death**: in the 2024–25 La Réunion outbreak, older adults accounted for almost half of all hospitalisations and nearly two-thirds of severe cases with organ failure.
3. **The chronic phase — the defining problem in geriatrics. Persistent or relapsing inflammatory arthralgia and arthritis lasting months to years occurs in up to 40–50% of patients**, and is commoner and more severe with increasing age. It closely resembles **seronegative rheumatoid arthritis**, and it is a major cause of lasting disability, immobility, deconditioning, depression and loss of independence — often more damaging to an older person than the acute illness.
4. **Differential diagnosis. Dengue** (thrombocytopenia, haemoconcentration, bleeding and shock; the arthralgia is less severe and does not persist) — **co-infection is common, and when in doubt manage as dengue, which is the more dangerous**; **Zika** (milder, prominent rash and conjunctivitis); **scrub typhus** (eschar, rapid response to doxycycline); **leptospirosis** (conjunctival suffusion, calf tenderness, jaundice with acute kidney injury); **malaria** and **enteric fever**. For the **chronic arthritis**, the differential becomes **elderly-onset rheumatoid arthritis, polymyalgia rheumatica, reactive arthritis and crystal arthropathy**.
5. **Laboratory tests — timing determines the test. RT-PCR is the test of choice in the first 5–7 days** (the viraemic phase); **IgM ELISA (MAC-ELISA) from about day 5 onwards**, with IgG appearing later and paired sera showing a four-fold rise. Supportive findings: **lymphopenia is characteristic** (in contrast to the thrombocytopenia of dengue), with mild thrombocytopenia, raised transaminases and raised CRP. **Always test simultaneously for dengue (NS1 antigen and IgM).** In the chronic phase, rheumatoid factor and anti-CCP are typically **negative**, which helps separate it from elderly-onset rheumatoid arthritis.
6. **Management. Entirely supportive — there is no specific antiviral.** Rest, adequate fluids and **paracetamol for fever and pain**. **Avoid NSAIDs and aspirin until dengue has been excluded** (risk of bleeding and acute kidney injury), and thereafter use them only with great caution in older adults. For **inflammatory arthritis persisting beyond three months**: a short course of **corticosteroids**, and in refractory cases **hydroxychloroquine or methotrexate** under rheumatology supervision. **Physiotherapy and graded exercise are essential** to prevent contractures, deconditioning and functional decline. Prevention is **vector control** — source reduction of domestic water containers, mosquito nets, repellents and full-sleeved clothing — remembering that ***Aedes*** **bites during the day**, so night-time bed nets alone are inadequate.

Latest Update (2023 – present)

7. Two chikungunya vaccines are now licensed: **IXCHIQ (VLA1553)**, a **live-attenuated** vaccine approved in 2023, and **VIMKUNYA**, a **virus-like-particle (non-live)** vaccine approved in 2025. Following reports of serious adverse events — including encephalitis and deaths — in vaccinees aged 62 to 89 years, the **US FDA suspended the Ixchiq licence in August 2025** and several countries restricted its use above age 60–65; the **EMA's PRAC concluded in July 2025 that the overall benefit–risk balance remained favourable and lifted the contraindication in those aged ≥65**, with updated product information. Because it is non-live, the **VLP vaccine (Vimkunya) is currently the preferred option in older adults**, and early post-authorisation data support its safety in over-65s. **Neither vaccine is yet available in India**, where **vector control and early supportive care remain the only strategy**.

Exam One-Liners

- Virus and vector — **alphavirus**, spread by ***Aedes*****, which bites by day**.
- Hallmark — **severe symmetrical polyarthralgia with stooped posture**.
- Blood picture — **lymphopenia** (dengue gives thrombocytopenia).
- Test in first 5 days — **RT-PCR**; after day 5 — **IgM ELISA**.
- Never give before excluding dengue — **NSAIDs and aspirin**.
- Chronic arthritis in up to **40–50%**; treat with steroids ± hydroxychloroquine/methotrexate.
- Preferred vaccine in older adults — **the non-live VLP vaccine**.

Question 14. Scrub typhus 7 MARKS

ANSWER

Source note: Not covered in the uploaded textbooks; content is drawn from current Indian and international literature and clearly separated from the geriatric principles taken from Pathy's and Kane's.

Textbook Core – 6 Points

1. **Aetiology and epidemiology.** ***Orientia tsutsugamushi***, an obligate intracellular Gram-negative bacterium, transmitted by the bite of the **larval stage (chigger) of trombiculid mites** (*Leptotrombidium* species) — which are both the vector and the reservoir. Endemic across the **"tsutsugamushi triangle"** of South and South-East Asia and the Pacific. India carries a very large burden, with **post-monsoon (August–November) outbreaks** in the sub-Himalayan belt, the north-east, Tamil Nadu, Kerala, Karnataka and Odisha, and it is **one of the commonest identifiable causes of acute undifferentiated febrile illness in India**.
2. **Clinical features.** Incubation **6–21 days**; then abrupt **fever with rigors, severe headache, myalgia** and a maculopapular rash. The pathognomonic sign is the **eschar** — a painless, black, necrotic, cigarette-burn-like lesion with an erythematous halo — which is found in only about **20–50% of Indian patients** and characteristically lies in **hidden, moist, covered sites**: axilla, groin, inframammary fold, perineum, waistline and behind the ears. **It must be actively hunted for by fully undressing and examining the patient**, which is the single highest-yield bedside act in this disease. Also **generalised lymphadenopathy and hepatosplenomegaly**.
3. **Complications — why it kills older adults. ARDS is the commonest severe complication**; also **acute kidney injury, myocarditis, meningoencephalitis, hepatitis with jaundice, septic shock, multi-organ dysfunction, haemophagocytic lymphohistiocytosis** and sensorineural hearing loss. **Older age, delayed treatment, jaundice, hypoalbuminaemia and ARDS predict death.** Untreated mortality reaches 30–70%, but falls to **under 5% with prompt doxycycline** — which is why empirical treatment matters so much.
4. **Investigations. IgM ELISA is the most widely used and practical confirmatory test in India**, becoming positive from about day 5–7. The **Weil–Felix (OX-K agglutination) test** is cheap and still used in peripheral settings but is **insensitive and non-specific**. The **indirect immunofluorescence assay (IFA) is the reference standard**. **PCR from eschar tissue or whole blood** is the most useful test in the **first week**, before antibodies appear. Supportive findings: **thrombocytopenia, raised transaminases, hypoalbuminaemia, raised CRP**, a normal or raised white cell count, and bilateral infiltrates on chest radiograph.
5. **Treatment. Doxycycline 100 mg twice daily for 7 days is the drug of choice**, and **defervescence within 48 hours is characteristic and supports the diagnosis**. Alternatives: **azithromycin 500 mg daily for 3–5 days** (preferred in pregnancy, in doxycycline intolerance and where resistance is suspected), with **intravenous doxycycline or azithromycin in severe disease**; chloramphenicol and rifampicin are further options. Supportive care for ARDS, acute kidney injury and shock determines outcome in severe cases. In older adults, doxycycline is safe and does not need renal adjustment, but must be taken **upright with water to avoid oesophagitis**, and it **interacts with warfarin** (raises INR) and is chelated by antacids, calcium and iron.
6. **Prevention, and the geriatric presentation. There is no vaccine.** Prevention is avoidance of chigger-infested scrub and long grass, protective and **permethrin-treated clothing**, DEET repellent, and clearing vegetation around dwellings. The geriatric point to make: in older adults the illness frequently presents **non-specifically — delirium, functional decline, falls, or unexplained ARDS or acute kidney injury without a recognised fever**. Therefore, **in the post-monsoon season in India, scrub typhus should be actively considered in any older patient with acute undifferentiated febrile illness or unexplained deterioration, an eschar hunted for, and empirical doxycycline started while awaiting serology**.

Latest Update (2023 – present)

7. The landmark Indian randomised controlled trial by **Varghese and colleagues (*New England Journal of Medicine*, 2023)** compared intravenous doxycycline, azithromycin, and the combination in **severe scrub typhus with organ dysfunction**, and showed that **combination intravenous doxycycline plus azithromycin was superior to either drug alone**, reducing the composite endpoint of death at day 7, persistent organ complications and persistent fever. **Combination therapy is now the preferred regimen for severe scrub typhus**, while oral doxycycline monotherapy remains standard for uncomplicated disease. **Empirical doxycycline for acute undifferentiated febrile illness during the post-monsoon season in endemic Indian districts** continues to be recommended practice.

Exam One-Liners

- Organism and vector — ***Orientia tsutsugamushi***, transmitted by the **chigger (larval trombiculid mite)**.
- Pathognomonic sign — **eschar**, present in only 20–50%, in **hidden moist sites**.
- Commonest severe complication — **ARDS**.
- Practical confirmatory test in India — **IgM ELISA**; reference standard — **IFA**; first week — **PCR**.
- Drug of choice — **doxycycline 100 mg BD × 7 days**; response within **48 hours**.
- Severe disease — **IV doxycycline PLUS azithromycin** (NEJM 2023).
- Prevention — **no vaccine**; permethrin-treated clothing and vegetation clearance.

Question 15. Cerebral malaria 6 MARKS

ANSWER

Textbook Core – 5 Points

1. **Definition.** A diffuse, potentially reversible **encephalopathy complicating *Plasmodium falciparum* infection**, defined strictly as **unrousable coma (Glasgow Coma Scale ≤11 in adults; Blantyre ≤2 in children) persisting for more than 30 minutes after a seizure**, in the presence of **asexual parasitaemia**, with **no other identifiable cause of coma**. It is the commonest lethal complication of falciparum malaria, with mortality of **15–20% even with optimal treatment**, and 10–20% of survivors have persistent neurological sequelae. It is rarely reported with *P. knowlesi* and *P. vivax*.
2. **Pathogenesis.** Parasitised red cells express **PfEMP-1** on their surface and **cytoadhere** to endothelial receptors — **ICAM-1, EPCR and CD36** — in cerebral microvessels, producing **sequestration and rosetting**. The result is **microvascular obstruction**, endothelial activation, cytokine release (particularly TNF-α), **blood–brain barrier breakdown**, cerebral oedema and reduced cerebral perfusion. Contributing systemically: **lactic acidosis, hypoglycaemia** and severe anaemia.
3. **Clinical features.** Fever, headache and progressive **impairment of consciousness to coma**; **generalised or focal seizures**; **symmetrical upper motor neurone signs** with decerebrate or decorticate posturing; and **malarial retinopathy** — retinal whitening, vessel discolouration, retinal haemorrhages and papilloedema, which is **the most specific bedside sign** and should be sought on fundoscopy. Characteristically there is **no meningism and no focal lateralising deficit**. Look for the other features of severe malaria: severe anaemia, jaundice, acute kidney injury, ARDS, hypoglycaemia, shock, spontaneous bleeding and DIC. **Older adults have a substantially higher risk of renal failure, pulmonary oedema and death.**
4. **Diagnosis. Peripheral blood smear** — thick film for detection, thin film for species identification and parasite counting (hyperparasitaemia >2–5% indicates severe malaria); repeat 12-hourly if initially negative. **Rapid diagnostic tests** detect HRP-2 (*P. falciparum*) and pLDH, but HRP-2 can remain positive for weeks after treatment. PCR where available. Essential adjuncts: **blood glucose — hypoglycaemia must be excluded and corrected in every case**, lactate, CBC, renal and liver function, coagulation screen and blood cultures. **Lumbar puncture is needed to exclude bacterial meningitis** unless contraindicated — in cerebral malaria the CSF is essentially normal or shows only a minimally raised protein. CT or MRI to exclude an alternative cause of coma.
5. **Treatment. Intravenous artesunate is the drug of choice — 2.4 mg/kg at 0, 12 and 24 hours, then once daily** — and is superior to quinine, having reduced mortality by about **35% in adults in the SEAQUAMAT trial**. Give parenteral therapy for at least 24 hours, then switch to a **full 3-day course of oral artemisinin-based combination therapy** once the patient can swallow. Supportive care is what determines survival: **correct hypoglycaemia with 25% dextrose**, treat seizures with a benzodiazepine followed by a maintenance anticonvulsant, maintain careful fluid balance avoiding both under-filling and pulmonary oedema, provide ventilation and dialysis as required, nurse the unconscious patient appropriately, and treat concurrent bacterial sepsis (common). **Do NOT give prophylactic phenobarbitone (it increased mortality), dexamethasone, routine mannitol, heparin or adrenaline** — all are ineffective or harmful. Watch for **post-artesunate delayed haemolysis** at 1–3 weeks, and check the haemoglobin at follow-up.

Latest Update (2023 – present)

6. The **WHO Guidelines for Malaria (2024–2025 updates)** reaffirm **intravenous artesunate for a minimum of 24 hours** as first-line treatment for all severe malaria, followed by a complete ACT course, and recommend **pre-referral rectal artesunate** where parenteral treatment cannot be started immediately — directly relevant to rural India. India's **National Framework for Malaria Elimination** and the NCVBDC national drug policy follow the same. The important current concern is that **artemisinin partial resistance (*Kelch13* mutations)**, long established in the Greater Mekong subregion, is now **confirmed in East Africa**, which makes a **full ACT course after parenteral therapy and follow-up parasite clearance monitoring mandatory** rather than optional.

Exam One-Liners

- Definition — **unrousable coma >30 min after a seizure with falciparum parasitaemia and no other cause**.
- Key adhesion molecule — **PfEMP-1**; receptors ICAM-1, EPCR, CD36.
- Most specific bedside sign — **malarial retinopathy**.
- Must exclude and correct in every case — **hypoglycaemia**.
- Drug of choice — **IV artesunate 2.4 mg/kg at 0, 12, 24 h then daily**.
- Never give — **steroids, prophylactic phenobarbitone, heparin, routine mannitol**.
- Late complication to check for — **post-artesunate delayed haemolysis**.

PART V

Urinary and Gastrointestinal Infection

Four separate urinary questions that are frequently confused with one another, arranged deliberately from colonisation through to recurrent infection, followed by antibiotic-associated colitis.

Question 16. Asymptomatic bacteriuria in the older adult 7 MARKS RECURRING

ANSWER

Textbook Core — 6 Points

1. **Definition. Significant bacteriuria without any signs or symptoms attributable to urinary infection**. Quantitatively: **≥10^5 CFU/mL** of the same organism in **two consecutive** clean-voided specimens in women, **one** specimen in men, or **≥10^2 CFU/mL** from a catheter specimen.
2. **Prevalence. Bacteriuria in older persons is common and usually asymptomatic.** Prevalence **rises with age** and roughly **parallels the prevalence of incontinence**; it is much higher in institutionalised residents and reaches essentially **100% in those with a chronic indwelling catheter**.
3. **Why it is so common in old age. Vaginal and urethral atrophy**, **obstructive uropathy** (prostatic hypertrophy in men), **"puddling" of urine related to bed rest**, incomplete bladder emptying, and **bladder catheterisation**. Prostatic hypertrophy specifically predisposes older men to urinary infection.
4. **Prognostic significance.** Although some studies suggested increased mortality, **when adjusted for age, the excess mortality is explained by the fatal diseases associated with bacteriuria, not by bacteriuria itself**. Antimicrobial therapy in hospitalised or institutionalised elderly has not been effective because of the **high rate of recurrence**. Eradicating bacteriuria does **not** improve chronic stable incontinence in nursing home residents.
5. **The core rule. In the absence of obstructive uropathy, there is no evidence to support routine antimicrobial therapy for asymptomatic bacteriuria in older persons.** Treatment causes adverse drug events, *Clostridioides difficile* infection, candidiasis and antimicrobial resistance, without benefit. **Do not send screening or surveillance urine cultures.**
6. **Recognised exceptions and cautions.** Treat before **urological procedures with anticipated mucosal bleeding** (e.g. TURP) and in pregnancy. The textbook additionally advises eradicating bacteriuria as part of the **initial assessment of new or worsening incontinence** in non-institutionalised patients. In the nursing home population, **new-onset incontinence, worsening incontinence, unexplained fever and decline in mental or functional status may be manifestations of a true urinary infection** — but other causes must be excluded first.

Latest Update (2023 – present)

7. **IDSA guidance**, reinforced by the AGS "Choosing Wisely" position and current stewardship practice, recommends **against screening for or treating asymptomatic bacteriuria in older adults — including those with delirium or falls** — provided there are **no localising urinary symptoms and no haemodynamic instability**; such patients should instead be assessed for an alternative cause and observed with hydration. **Diagnostic stewardship** — reflex culture only when the urinalysis is abnormal *and* the patient is symptomatic, and removal of "urine culture" from routine admission order sets — is now a core antimicrobial stewardship intervention and is embedded in the stewardship pillar of India's **NAP-AMR 2.0 (2025–2029)**.

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
New/worsening incontinence	Eradicate bacteriuria as part of the initial assessment	Incontinence alone is not an indication to treat; look for another cause	State the textbook position, then give the current standard as your answer
Delirium or falls with bacteriuria	May be a manifestation of infection	Do not treat if no localising urinary symptoms and haemodynamically stable; evaluate other causes	Say "delirium alone does not equal UTI"
Screening cultures	Discouraged in catheterised patients	Discouraged in all older adults — diagnostic stewardship	Extend the principle beyond catheters

MNEMONIC ANCHOR

"No SYMPTOM → No CULTURE → No CURE." And for the only true exception: **"Only cut, then treat"** — treat before urological procedures with mucosal bleeding.

NUMERICAL ANCHORS

≥10^5 CFU/mL (voided) · ≥10^2 CFU/mL (catheter) · two specimens in women, one in men · ~100% prevalence with chronic indwelling catheter · prevalence parallels that of incontinence.

NAMED EXAMINER TRAPS

(a) Pyuria is not infection — most bacteriuric elderly have pyuria. **(b) Cloudy or foul-smelling urine is not an indication to treat** — it usually reflects concentration or diet. **(c)** Do not attribute delirium to bacteriuria until other causes are excluded. **(d)** Asymptomatic **candiduria** also does not need treatment — remove the catheter instead. **(e)** The exception list is short: **urological mucosal procedures and pregnancy** (not renal transplant beyond the early period, not diabetes, not spinal cord injury).

15-SECOND ANSWER SKELETON

Define with quantitative criteria → prevalence rises with age, ~100% with catheter → why (atrophy, obstruction, puddling, catheter) → no independent effect on mortality once age-adjusted → do not screen, do not treat → exceptions (urological procedure, pregnancy) → what to do instead (look for another cause, hydrate, review drugs) → stewardship framing.

EXTRA RECALL BOX

ASB versus UTI in the frail older adult — the practical rule is that you need **bacteriuria + a genuine localising symptom** (dysuria, new urgency/frequency, suprapubic or costovertebral angle pain, new gross haematuria) **or** systemic signs with no other explanation. In a resident who is delirious and bacteriuric, the commonest true culprits are **drugs, constipation, dehydration, pain, retention and hypoxia** — not the urine. Treating ASB is one of the most frequent sources of unnecessary antibiotic use in Indian hospitals and nursing homes.

Exam One-Liners

- Definition — bacteriuria **without attributable symptoms**.
- Treat or not — **do not treat**, except before urological mucosal procedures (and in pregnancy).
- Does it increase mortality — **no**, once adjusted for age and comorbidity.
- Does treatment help incontinence — **no** (chronic stable incontinence in nursing homes).
- Key stewardship message — **do not send the culture in the first place**.

Question 17. Catheter-associated urinary tract infection (CAUTI) 7 MARKS

ANSWER

Textbook Core — 6 Points

1. **Definition and the central rule.** CAUTI is a **symptomatic** urinary infection in a patient with an indwelling urethral catheter, or within 48 hours of its removal. **All patients with chronic indwelling catheters have bacteriuria**, which is frequently **polymicrobial** and whose organisms **change frequently** — therefore **bacteriuria alone is colonisation, not CAUTI**.
2. **Pathogenesis and risk factors. Duration of catheterisation** is the single most important risk factor. Bacteria ascend extraluminally along the catheter–urethral interface or intraluminally after breaks in the drainage system, and form a protective **biofilm** that antibiotics cannot penetrate. Other risks: female sex, diabetes, poor catheter care, and catheter obstruction. Indwelling catheterisation is **still overused in acute hospitals**.
3. **Accepted indications for an indwelling catheter (Kane). Urinary retention** causing persistent overflow incontinence, symptomatic infection or renal dysfunction that cannot be corrected surgically/medically or managed by intermittent catheterisation; **skin wounds or pressure ulcers being contaminated by urine**; care of the **terminally ill or severely impaired** in whom bed and clothing changes are distressing; and **patient preference** when toileting causes excessive discomfort. Incontinence alone and staff convenience are **not** indications.
4. **Presentation in the older adult.** Often **non-specific** — fever without localising signs, **new or worsening delirium**, functional decline, falls, anorexia, suprapubic or flank pain, or new haematuria. The **febrile response may be blunted or absent**. Symptoms are non-specific, so **other sources of infection must be carefully excluded before attributing them to the urinary tract**.
5. **Diagnosis. Do not perform surveillance cultures** to guide management — all chronically catheterised patients are bacteriuric. Send urine culture **only when symptomatic**, and ideally from a **freshly replaced catheter** (biofilm on the old catheter gives misleading organisms). **Pyuria does not diagnose CAUTI** in a catheterised patient. Blood cultures if systemically unwell; ultrasound if obstruction, stones or abscess suspected.
6. **Management and prevention — key principles of catheter care.** Treat **only if symptomatic**; **replace the catheter before starting antibiotics**; give culture-directed therapy for the **shortest effective duration**. Prevention: maintain a **sterile closed gravity-drainage system** and avoid breaking it; secure the catheter to thigh or lower abdomen; wash the entry site with soap and water once daily only; **do not routinely irrigate**; **do not use prophylactic or suppressive antiseptics or antimicrobials**; treat bypassing without obstruction as bladder spasm; and **remove the catheter at the earliest opportunity**.

Latest Update (2023 – present)

7. Practice has shifted to a bundled **"avoid – remove – maintain"** model: nurse-driven removal protocols, a documented **daily catheter necessity review**, and CAUTI as a **mandatory device-associated HAI surveillance indicator**. In India this is reinforced by the **National Action Plan on Antimicrobial Resistance 2.0 (NAP-AMR 2.0, 2025–2029, launched 18 November 2025)**, which makes **infection prevention and control programmes mandatory in all healthcare facilities**. Current IDSA/SHEA guidance continues to recommend **against treating catheter-associated asymptomatic bacteriuria** and **against antibiotic prophylaxis at routine catheter change**, and favours **intermittent catheterisation or external (condom) catheters** over indwelling catheters wherever feasible.

If this appears as a 15-mark question, add: microbiology (*E. coli*, *Klebsiella*, *Proteus* — urease-splitting, struvite stones and encrustation; *Pseudomonas*, *Enterococcus*, *Candida*; rising carbapenem resistance in Indian ICUs); complications (bladder stones, periurethral abscess, epididymo-orchitis, prostatitis, bacteraemia, pyelonephritis, and squamous-cell bladder cancer with very long-term use); antibiotic duration (7 days if prompt response, 10–14 days if delayed response or bacteraemia); catheter material evidence (no clear benefit of silver-alloy or antibiotic-impregnated catheters); and a formal CAUTI prevention bundle with audit indicators.

Exam One-Liners

- All chronic catheters are bacteriuric — **treat the patient, not the culture**.
- Biggest modifiable risk factor — **duration of catheterisation**.
- Never do — **surveillance cultures, routine irrigation, prophylactic antibiotics**.
- Always do — **replace catheter before starting antibiotics**; culture from the new catheter.
- Best prevention — **do not insert it; if inserted, remove it early**.

Question 18. Clinical presentations and diagnosis of acute pyelonephritis 7 MARKS

ANSWER

Textbook Core – 6 Points

1. **Definition and organisms.** Acute bacterial infection of the **renal pelvis and parenchyma**, usually arising by **ascending spread** from the bladder and, less often, haematogenously. Urinary infection is among the commonest infections of older people, and Pathy's emphasises that its pathogenesis is **strongly related to obstructive uropathy**. ***Escherichia coli*** predominates, but Kane's table shows that in older adults ***Proteus, Klebsiella, Enterobacter, Pseudomonas*** **and** ***Enterococcus*** are much more frequent than in the young — and in India, **ESBL-producing and carbapenem-resistant organisms** are now common.
2. **Predisposing factors in the elderly. Obstructive uropathy** — benign prostatic hyperplasia in men, pelvic organ prolapse and cystocele in women; **incomplete bladder emptying with a raised post-void residual**; **catheterisation and instrumentation**; stones; **diabetes**; vaginal and urethral atrophy; immobility and bed rest with urinary stasis; neurogenic bladder; and previous urological surgery. The **age-related fall in GFR of about 30%** and reduced renal reserve mean acute kidney injury occurs readily.
3. **Classic clinical presentation. Fever with rigors, loin or flank pain, costovertebral angle tenderness, nausea and vomiting**, with or without lower urinary tract symptoms (dysuria, frequency, urgency, suprapubic discomfort). **Gram-negative bacteraemia and septic shock may develop abruptly and be life-threatening** — a point Pathy's makes explicitly.
4. **Presentation in the older adult — the examinable half of the question.** It is frequently **atypical and non-localising**. **Delirium or acute confusion, new or worsening urinary incontinence, falls, functional decline, anorexia, generalised weakness and tachypnoea** may be the only features. **Fever is blunted or absent in a substantial proportion**, and Kane's warns that **hypothermia should be treated as sepsis until proved otherwise**; **the absence of leucocytosis does not exclude bacterial infection**. Loin pain and costovertebral tenderness are often absent. The necessary counterbalance: **do not attribute delirium to the urine unless there are localising urinary symptoms or systemic sepsis with no other explanation**, because **asymptomatic bacteriuria is very common and must not be treated**.
5. **Investigations. Urinalysis** — pyuria, nitrites, leucocyte esterase, and **white cell casts, which indicate renal parenchymal involvement**. **Urine culture with sensitivity must be sent before antibiotics in every case** of pyelonephritis (unlike simple cystitis). **Blood cultures** where there is fever, rigors, sepsis or immunosuppression. Also CBC, CRP, renal function and electrolytes, blood glucose, and **serum lactate** if unwell. **Imaging is not routine** but becomes **mandatory** if there is severe sepsis, **failure to defervesce within 48–72 hours**, known stones, a single kidney, diabetes, or suspected obstruction: **ultrasound first** (hydronephrosis, stones, abscess, post-void residual), then **contrast CT**, which is the investigation of choice for **emphysematous pyelonephritis, renal and perinephric abscess, and pyonephrosis**.
6. **Complications and differential diagnosis.** Complications: **bacteraemia and septic shock, acute kidney injury, renal and perinephric abscess, emphysematous pyelonephritis** (almost exclusively in diabetics — a urological emergency requiring drainage or nephrectomy), **pyonephrosis**, **papillary necrosis**, and chronic renal scarring. Differential diagnosis in an older patient: acute cholecystitis, appendicitis, diverticulitis, basal pneumonia, herpes zoster of the flank before the rash appears, renal colic, and **vertebral osteomyelitis or discitis** — all of which can present with fever and back or flank pain.

Latest Update (2023 – present)

7. Current guidance stresses **empirical therapy driven by the local antibiogram** rather than by textbook first choices, because resistance has outrun the traditional agents: in India, **fluoroquinolones and cotrimoxazole are no longer reliable empirical choices**, and **ICMR treatment guidelines** favour intravenous **amikacin**, a **beta-lactam/beta-lactamase inhibitor such as piperacillin-tazobactam**, or a **carbapenem for severe hospital-onset disease**, with **rapid de-escalation and switch to oral therapy once the patient has been afebrile for 48 hours**. Recommended durations have **shortened**: about **7 days** for fluoroquinolone-treated and **10–14 days** for beta-lactam-treated uncomplicated pyelonephritis. Newer agents — **ceftazidime-avibactam, ceftolozane-tazobactam and cefiderocol** — are reserved for confirmed carbapenem-resistant organisms under stewardship control.

Exam One-Liners

- Classic triad — **fever with rigors, loin pain, costovertebral angle tenderness**.
- In the elderly — **delirium, falls, incontinence and functional decline may be the only features**.
- Urinary sign of parenchymal involvement — **white cell casts**.
- Always send before antibiotics — **urine culture** (and blood cultures if septic).
- Imaging indication — **no defervescence in 48–72 hours**, suspected obstruction, stones, diabetes.
- Investigation of choice for complications — **contrast CT**.
- Diabetic emergency — **emphysematous pyelonephritis**.

Question 19. Management of recurrent urinary tract infection in an older female

7 MARKS

ANSWER

Textbook Core – 6 Points

1. **Definition, and the essential first step.** Recurrent UTI is **two culture-proven episodes in 6 months, or three in 12 months**. The first management step is to **confirm that each episode really was a symptomatic, culture-proven infection**. The commonest reason an older woman carries a label of "recurrent UTI" is **repeated treatment of asymptomatic bacteriuria** — which Kane's is explicit about: **bacteriuria in older persons is common and usually asymptomatic, and in the absence of obstructive uropathy there is no evidence to support routine antimicrobial therapy**. Review the actual culture and symptom records before doing anything else.
2. **Look for and correct the reversible cause. Genitourinary syndrome of menopause** — vaginal and urethral atrophy; **incomplete bladder emptying** — measure the **post-void residual**; **pelvic organ prolapse and cystocele**; **constipation and faecal incontinence**; **inadequate fluid intake**; **diabetes with glycosuria**; **stones or obstruction**; **catheter use**; and **immobility or cognitive impairment causing difficulty in toileting**. Examine the perineum, perform a pelvic examination, and assess the functional and cognitive ability to reach and use the toilet — this last is a genuinely geriatric point that is often the actual cause.
3. **Investigations. Urine culture with sensitivity for each episode** — both to direct therapy and to track resistance; blood glucose and HbA1c; renal function; **post-void residual by bladder scan**; and **ultrasound of kidneys, ureters and bladder**. Referral for **cystoscopy and further imaging is indicated only if** there is haematuria, a suspected stone or obstruction, a suspected fistula, persistent infection with the same organism, or failure of conservative management — **routine cystoscopy in every older woman is not indicated**.
4. **Behavioural and fluid measures — first line. Increase fluid intake to about 1.5–2 L per day if current intake is below 1.5 L** (proven in a randomised trial); **timed, complete and double voiding**; treat constipation; perineal hygiene; avoid spermicides; and **avoid unnecessary catheterisation**. If there is a significant post-void residual, manage it with bladder retraining or **clean intermittent catheterisation rather than an indwelling catheter**.
5. **Vaginal oestrogen — the single most important intervention in a postmenopausal woman.** Low-dose **vaginal oestrogen cream, pessary or ring** restores the vaginal epithelium, lowers vaginal pH and re-establishes lactobacilli, significantly reducing recurrence. **Systemic absorption is negligible**, so age is not a barrier, and it can generally be used in women with a history of breast cancer after discussion with the oncologist. **Systemic hormone replacement therapy does NOT work for this indication** — a favourite examiner distinction.
6. **Antiseptic and antibiotic prophylaxis — only after the above. Methenamine hippurate 1 g twice daily** is a urinary antiseptic that is **not an antibiotic** and was shown **non-inferior to daily antibiotic prophylaxis in the ALTAR randomised trial** — it is now the preferred first prophylactic step. **Cranberry products and D-mannose** may be offered (weak evidence). If antibiotic prophylaxis is still required: **low-dose continuous prophylaxis for 3–6 months** — **nitrofurantoin 50–100 mg nightly** (**avoid if eGFR <45**, avoid prolonged use because of pulmonary fibrosis and hepatotoxicity, and note it is on the **Beers list** in renal impairment), **trimethoprim 100 mg nightly**, or **cefalexin 125–250 mg nightly** — or **post-coital prophylaxis** where episodes relate to intercourse. **Self-start standby therapy** with a culture-directed agent is useful in a reliable, cognitively intact woman. **Never perform a test-of-cure culture in an asymptomatic patient.**

Latest Update (2023 – present)

7. The **AUA/CUA/SUFU 2025 amendment** to the recurrent uncomplicated UTI guideline substantially **expanded the non-antibiotic options**: clinicians **may now offer cranberry, methenamine hippurate, and increased water intake (where intake is below 1.5 L/day)** for prophylaxis; **vaginal oestrogen remains a "should recommend" for peri- and postmenopausal women**; and a new recommendation directs clinicians to **evaluate for an alternative cause of symptoms in women whose symptoms persist after microbiological cure**. **NICE (2024)** similarly now recommends **methenamine hippurate as an alternative to daily antibiotic prophylaxis** where behavioural measures and vaginal oestrogen have not been sufficient. This shift is a direct antimicrobial stewardship gain in a population that accounts for a disproportionate share of community antibiotic prescribing.

> **THE STEPWISE ANSWER — WRITE IT AS A LADDER**
>
> **Step 1** Confirm the episodes were true symptomatic culture-proven UTIs, not treated asymptomatic bacteriuria → **Step 2** Find and correct the reversible cause (atrophy, residual urine, prolapse, constipation, diabetes, catheter, toileting ability) → **Step 3** Behavioural measures and fluid intake → **Step 4 Vaginal oestrogen** → **Step 5 Methenamine hippurate** (± cranberry, D-mannose) → **Step 6** Low-dose antibiotic or post-coital prophylaxis, or self-start standby therapy → **Step 7** Refer for cystoscopy/imaging only on specific indications.

Exam One-Liners

- Definition — **2 episodes in 6 months or 3 in 12 months**, culture-proven.
- Commonest reason for the label — **repeated treatment of asymptomatic bacteriuria**.
- Single most effective intervention — **vaginal oestrogen** (systemic HRT does not work).
- Non-antibiotic prophylaxis of choice — **methenamine hippurate 1 g BD** (ALTAR trial).
- Fluids — **increase to 1.5–2 L/day if intake is below 1.5 L**.

- Nitrofurantoin — **avoid if eGFR <45**; avoid long-term.
- Never do — **test-of-cure culture in an asymptomatic woman**.

Question 20. Diagnosis and management of *Clostridioides difficile* 7 MARKS

ANSWER

Textbook Core – 6 Points

1. **Definition and risk factors.** *Clostridioides difficile* is a **Gram-positive, spore-forming, toxin-producing anaerobe** causing **antibiotic-associated diarrhoea and pseudomembranous colitis** through disruption of the colonic microbiota and elaboration of **toxins A and B**. Risk factors: **antibiotics** — especially clindamycin, fluoroquinolones, third-generation cephalosporins, carbapenems and broad-spectrum penicillins — **age 65 and over**, hospitalisation and long-term care residence, **proton pump inhibitors**, previous infection, enteral tube feeding, abdominal surgery, chemotherapy and comorbidity. **Older adults are the highest-risk group and have the highest mortality and the highest recurrence rate.**
2. **Clinical spectrum. Asymptomatic colonisation** is common in long-term care residents — **do not test and do not treat**. **Mild-to-moderate infection**: watery diarrhoea (three or more unformed stools in 24 hours), cramping abdominal pain, low-grade fever and leucocytosis. **Severe infection**: white cell count **≥15,000/mm³** or serum creatinine **>1.5 mg/dL**. **Fulminant infection**: hypotension or shock, ileus, or **toxic megacolon** — which may present with a **paradoxical reduction in diarrhoea** as the colon becomes atonic, a dangerous trap. Kane's advises considering *C. difficile* in any long-term care resident with fever, abdominal cramps and diarrhoea with or without blood or white cells in the stool.
3. **Diagnosis. Test only unformed, diarrhoeal stool from a symptomatic patient.** Do not test formed stool, do not repeat within 7 days, and **never perform a test of cure** — the assays stay positive for weeks. Use a **two-step algorithm**: a sensitive screening test — **glutamate dehydrogenase (GDH) antigen** or a **NAAT/PCR for the toxin gene** — followed by a specific confirmatory **toxin A/B enzyme immunoassay**. GDH-positive with toxin-positive confirms infection; both negative excludes it; a **discordant NAAT-positive but toxin-negative result may represent colonisation** and needs clinical judgement. Adjuncts: CBC, creatinine, albumin, lactate; **abdominal radiograph or CT** if fulminant disease is suspected; and **flexible sigmoidoscopy showing pseudomembranes** when the diagnosis remains uncertain.
4. **General measures. Stop the precipitating antibiotic** wherever possible, or narrow it; **stop the proton pump inhibitor** if it has no indication; **avoid antimotility agents** (loperamide, opiates) in severe disease; correct fluid and electrolyte losses. Infection control: **single room with contact precautions, gloves and gowns**; **hand washing with soap and water — alcohol hand rub does not kill spores**; and environmental cleaning with a **sporicidal, chlorine-based agent**. These are the highest-yield infection-control points for a geriatrics paper.
5. **Treatment of the initial episode. Oral fidaxomicin 200 mg twice daily for 10 days is now preferred**, because it produces markedly lower recurrence; **oral vancomycin 125 mg four times daily for 10 days** is an acceptable alternative and remains the pragmatic first choice in India where cost is limiting. **Metronidazole is no longer first-line** and is reserved for mild disease where neither agent is available, or as adjunctive intravenous therapy in fulminant disease. **Fulminant infection**: **oral or nasogastric vancomycin 500 mg four times daily plus intravenous metronidazole 500 mg eight-hourly**, with **vancomycin retention enemas if there is ileus**, and **early surgical consultation** for subtotal colectomy or diverting loop ileostomy with colonic lavage.
6. **Recurrence — the dominant problem in older adults.** Recurrence occurs in **20–25% after a first episode and 40–60% after subsequent episodes**. **First recurrence**: fidaxomicin (including the extended-pulsed regimen) if vancomycin was used first, or a **tapering and pulsed vancomycin** course. **Second and later recurrences**: tapered/pulsed vancomycin, **vancomycin followed by rifaximin**, **bezlotoxumab** — a single-infusion monoclonal antibody against toxin B, used as an adjunct but with caution in heart failure — or **faecal microbiota transplantation**, which achieves cure rates above **85%**.

Latest Update (2023 – present)

7. The therapeutic landscape has changed with the approval of two **standardised live biotherapeutic microbiome products** for the prevention of recurrent infection — **faecal microbiota, live-jslm (Rebyota)**, given rectally, and **faecal microbiota spores, live-brpk (Vowst)**, given as oral capsules — which provide regulated, quality-controlled, donor-screened alternatives to conventional faecal microbiota transplantation. These followed the **2021 IDSA/SHEA focused update**, which established **fidaxomicin in preference to vancomycin** for both initial and recurrent episodes and introduced **bezlotoxumab** as an adjunct for patients with an episode in the preceding six months. A **2024 Emerging Infections Network survey** found uptake of fidaxomicin still limited by cost, so **oral vancomycin remains the realistic first-line agent in most Indian hospitals**, with fidaxomicin reserved for those at highest risk of recurrence.

Exam One-Liners

- Test only **diarrhoeal stool from a symptomatic patient**; never a test of cure.
- Algorithm — **GDH or NAAT screen, then toxin A/B EIA confirm**.
- Severe disease — **WBC ≥15,000 or creatinine >1.5 mg/dL**.
- Fulminant — **hypotension, ileus or toxic megacolon**; diarrhoea may paradoxically stop.
- First-line — **fidaxomicin 200 mg BD × 10 days**; alternative **vancomycin 125 mg QID × 10 days**.
- Metronidazole — **no longer first-line**.
- Hand hygiene — **soap and water; alcohol gel does not kill spores**.

- Multiply recurrent disease — **FMT, cure rate >85%**.

PART VI

Rheumatology and Systemic Vasculitis

The inflammatory diseases of later life, ordered so that the polymyalgia–giant cell arteritis axis is read before the wider vasculitides, and the inflammatory arthritides together.

Question 21. Polymyalgia rheumatica 7 MARKS RECURRING

ANSWER

Textbook Core — 6 Points

1. **Definition.** An inflammatory condition of older adults — essentially never below **age 50** — producing **pain and morning stiffness of the shoulder and pelvic girdles** with a systemic inflammatory response. It causes **painful muscles with proximal myopathy** and is an important, **completely reversible** cause of frailty that is **often misdiagnosed by clinicians**.
2. **Clinical features.** Bilateral, symmetrical aching of shoulders, neck and hips; **morning stiffness >45 minutes**; difficulty rising from a chair, turning in bed or combing the hair. Constitutional features — **weight loss, low-grade fever, fatigue, anorexia and depression**. Weakness is **pain-limited**, with preserved true power.
3. **Investigations. Raised ESR and CRP** (ESR often >40 mm/h) — the diagnosis is confirmed by finding an elevated ESR in the right clinical setting. Normocytic normochromic anaemia, raised alkaline phosphatase, thrombocytosis. **Normal creatine kinase** — the key discriminator from inflammatory myopathy. RF and anti-CCP negative. Ultrasound shows **subacromial–subdeltoid bursitis, biceps tenosynovitis and trochanteric bursitis**.
4. **Differential diagnosis. Elderly-onset rheumatoid arthritis**, inflammatory myopathy (polymyositis — CK raised), **hypothyroidism**, cervical spondylosis and shoulder osteoarthritis, **multiple myeloma** and occult malignancy, statin-induced myopathy, RS3PE, and other endocrine disorders of insidious onset (hyperthyroidism, hypoadrenalism).
5. **Relationship with giant cell arteritis.** There is a **close association between PMR and temporal arteritis**: about **16–21% of PMR patients develop GCA**, and 40–50% of GCA patients have PMR symptoms. **Any symptom suggesting temporal artery involvement — headache, jaw claudication, scalp tenderness or a recent change in vision — especially with a very high ESR (>75 mm/h), should prompt consideration of temporal artery biopsy. Acute treatment of temporal arteritis with high-dose steroids is needed to prevent blindness.**
6. **Treatment. Prednisolone 12.5–25 mg daily** produces a **dramatic response within 24–72 hours** — a poor response should make you doubt the diagnosis. Taper slowly over 1–2 years. **Methotrexate** is used as a **corticosteroid-sparing agent** for frequent relapses or steroid toxicity; **infliximab has NOT been shown to be beneficial and is not recommended**. Mandatory alongside steroids: **calcium, vitamin D and a bisphosphonate**, glucose and blood-pressure monitoring, gastroprotection, and a steroid alert card.

Latest Update (2023 – present)

7. The **2025/2026 EULAR recommendations for PMR and primary large-vessel vasculitis** now name **sarilumab (IL-6 receptor blocker, 200 mg subcutaneously every 2 weeks)** as the **preferred add-on for relapsing or refractory PMR**, with tocilizumab as an alternative and methotrexate retained as a cheaper option — a glucocorticoid taper as rapid as **14 weeks** is possible on sarilumab. For GCA, suspected cases must be **referred within 24 hours**, and adjunctive **tocilizumab or upadacitinib 15 mg once daily** is recommended for refractory/relapsing disease or where the risk of steroid toxicity is high (upadacitinib FDA-approved April 2025 on the **SELECT-GCA** trial: sustained remission **46% vs 29%** with placebo, with roughly halved cumulative steroid exposure).

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
Steroid-sparing agent	Methotrexate; infliximab not beneficial	Sarilumab preferred for relapsing PMR; tocilizumab alternative; methotrexate still valid	Give steroids as first-line, then cite EULAR 2025 for refractory disease
GCA treatment	High-dose steroids to prevent blindness	Steroids immediately, plus tocilizumab or upadacitinib as steroid-sparing adjunct	Never omit "start steroids before biopsy"
Referral	Consider temporal artery biopsy	Suspected GCA — specialist referral within 24 hours; ultrasound "halo sign" as first-line imaging	Frame GCA as a medical emergency

MNEMONIC ANCHOR

"PMR = Pain (girdle), Morning stiffness, Rapid steroid Response." If any one of the three is missing — **rethink the diagnosis**.

NUMERICAL ANCHORS

Age >50 always · morning stiffness >45 min · ESR often >40 mm/h (GCA suspicion if >75 mm/h) · prednisolone **12.5–25 mg/day** · response within 24–72 h · GCA in 16–21% of PMR · GCA steroid dose 40–60 mg (higher / IV if visual loss) · taper over 1–2 years · sarilumab 200 mg SC 2-weekly · upadacitinib 15 mg OD.

NAMED EXAMINER TRAPS

(a) CK is normal in PMR — a raised CK means myositis, not PMR. **(b)** Failure to respond within a week means the diagnosis is wrong — think elderly-onset RA, myeloma or malignancy. **(c) Never delay steroids awaiting temporal artery biopsy** — the biopsy stays positive for up to 2 weeks. **(d)** Start **bone protection with the very first steroid prescription**, not later. **(e)** A normal ESR does not fully exclude GCA — check CRP too. **(f)** Do not use starting prednisolone above 25 mg for uncomplicated PMR; a high requirement suggests GCA.

15-SECOND ANSWER SKELETON

Define (age >50, girdle pain and stiffness) → clinical features with constitutional symptoms → ESR/CRP up, CK normal, ultrasound bursitis → differential (elderly-onset RA, myositis, hypothyroidism, myeloma) → GCA association 16–21% and the red-flag symptoms → prednisolone 12.5–25 mg with dramatic response → methotrexate for relapse → bone protection → EULAR 2025 sarilumab / upadacitinib.

EXTRA RECALL BOX

PMR as a reversible cause of frailty is a specifically geriatric examination point: an older person with weight loss, immobility, weakness and depression who is labelled "failure to thrive" may have PMR, and **treatment with corticosteroids reverses the frailty completely**. Always check an ESR in unexplained functional decline in the elderly. Conversely, remember that **corticosteroids themselves** cause osteoporosis, diabetes, hypertension, cataract, skin fragility, myopathy, delirium and infection — in older adults the steroid course frequently causes more morbidity than the PMR.

Exam One-Liners

- Never occurs below — **age 50**.
- Key negative test — **normal CK**.
- Starting dose — **prednisolone 12.5–25 mg/day**; GCA **40–60 mg**.
- Diagnostic response — within **24–72 hours**.
- Not recommended — **infliximab**.
- New preferred biologic for relapsing PMR — **sarilumab**.

Question 22. Systemic vasculitides in the elderly 15 MARKS

ANSWER

Textbook Core — 10 Points

1. **Definition and classification.** Inflammation of blood-vessel walls causing ischaemia, necrosis and organ damage. The **Chapel Hill Consensus** classifies by vessel size: **large-vessel** (giant cell arteritis, Takayasu arteritis); **medium-vessel** (polyarteritis nodosa, Kawasaki disease); **small-vessel ANCA-associated** (granulomatosis with polyangiitis, **microscopic polyangiitis**, eosinophilic granulomatosis with polyangiitis); and **small-vessel immune-complex** (IgA vasculitis, cryoglobulinaemic, anti-GBM disease).
2. **Which vasculitides matter in old age. Giant cell arteritis (GCA) is the commonest primary systemic vasculitis in adults** and occurs **almost exclusively over the age of 50**, with peak incidence in the seventies. **ANCA-associated vasculitis — especially microscopic polyangiitis — peaks at 65–75 years.** Drug-induced and malignancy-associated (paraneoplastic) vasculitis are proportionally commoner in the elderly.
3. **GCA — clinical features.** New-onset **temporal headache**, **scalp tenderness**, **jaw claudication** (the most specific symptom), **amaurosis fugax or sudden painless visual loss** (anterior ischaemic optic neuropathy), a tender, thickened or pulseless temporal artery, constitutional symptoms, and overlap with polymyalgia rheumatica. **Large-vessel GCA** causes aortitis, thoracic aortic aneurysm, limb claudication and unequal pulses. GCA should be considered in any older patient with cerebrovascular or vertebrobasilar symptoms.
4. **GCA — investigation and treatment. Markedly raised ESR (often >75 mm/h) and CRP**, normochromic anaemia, thrombocytosis, raised alkaline phosphatase. **Temporal artery biopsy** — take a **1–2 cm segment** because of **skip lesions**; or **temporal artery ultrasound** showing the **"halo sign"** and a positive compression sign; CT/MR angiography or PET-CT for large-vessel disease. **Start prednisolone 40–60 mg daily immediately — IV methylprednisolone if there is visual loss — without waiting for the biopsy**, which remains positive for up to 2 weeks. Add low-dose aspirin, bone protection and gastroprotection.
5. **ANCA-associated vasculitis — clinical features.** A subacute constitutional illness (fever, weight loss, malaise, arthralgia) evolving into a **pulmonary–renal syndrome**. **GPA** — upper airway disease (epistaxis, nasal crusting, sinusitis, saddle-nose deformity, subglottic stenosis), lung nodules and cavities, and rapidly progressive glomerulonephritis. **MPA** — RPGN and alveolar haemorrhage **without** granulomas. **EGPA** — late-onset asthma, eosinophilia, **mononeuritis multiplex** and cardiac involvement.
6. **ANCA — investigations. c-ANCA / anti-PR3** (GPA) and **p-ANCA / anti-MPO** (MPA, EGPA). **Urinalysis and microscopy showing dysmorphic red cells and red-cell casts is the single most important bedside test** — never omit it. Rising creatinine, CXR and HRCT, ENT and ophthalmic assessment, nerve conduction studies, and **renal biopsy** showing **pauci-immune necrotising crescentic glomerulonephritis**.
7. **Treatment of ANCA-associated vasculitis. Remission induction** — glucocorticoids plus **rituximab or cyclophosphamide**; **rituximab is preferred in older adults and in relapsing disease** because it avoids cyclophosphamide's bladder toxicity, infertility and malignancy risk. **Plasma exchange** is reserved for severe alveolar haemorrhage and the most severe renal disease. **Maintenance** — rituximab or azathioprine (or methotrexate/mycophenolate) for 2–4 years. **All doses of cyclophosphamide and rituximab must be reduced for age and renal function.**
8. **Mimics and differential diagnosis in the elderly. Infective endocarditis** (fever, splinter haemorrhages, glomerulonephritis, positive ANCA in some), atrial myxoma, **cholesterol embolisation** (livedo reticularis, blue toes, eosinophilia and AKI after an arterial procedure), antiphospholipid syndrome, **malignancy** (myeloma, lymphoma, myelodysplasia), and **drug-induced vasculitis** (hydralazine, propylthiouracil, minocycline, levamisole-adulterated cocaine — typically very high-titre MPO-ANCA). Chronic infections — **tuberculosis, hepatitis B and C, HIV** — must be excluded before immunosuppression, particularly in India.
9. **Geriatric-specific issues.** Presentation is frequently **non-specific** — pyrexia of unknown origin, weight loss, anaemia, raised inflammatory markers, delirium or unexplained functional decline. **Treatment toxicity, not the vasculitis, is the main cause of death in older patients — infection is a commoner cause of death than active disease.** Therefore: **PJP prophylaxis with co-trimoxazole**, bone protection, glucose and blood-pressure monitoring, gastroprotection, **hepatitis B and TB screening**, and vaccination before rituximab are all mandatory.
10. **Monitoring and prognosis.** Follow CRP, creatinine, **urinalysis** and ANCA titre (an imperfect guide to activity); score activity with the **Birmingham Vasculitis Activity Score (BVAS)** and accumulated damage with the **Vasculitis Damage Index (VDI)**. **Increasing age predicts worse renal and overall survival**; relapse is frequent after treatment withdrawal, and end-stage renal disease is the major long-term morbidity in MPA.

Latest Updates (2023 – present)

11. **GCA — upadacitinib.** The phase 3 **SELECT-GCA** trial (*NEJM* 2025) showed that **upadacitinib 15 mg once daily** with a 26-week steroid taper achieved **sustained remission in 46.4% versus 29.0%** with placebo plus a 52-week taper, with roughly **halved cumulative glucocorticoid exposure**; FDA approval followed in **April 2025**, making it the second approved drug for GCA after tocilizumab. The **2025/2026 EULAR recommendations** now require **referral of suspected GCA within 24 hours** and advise adding **tocilizumab or upadacitinib** in refractory or relapsing disease or where steroid toxicity risk is high.
12. **ANCA-associated vasculitis — steroid minimisation. Avacopan**, an oral **C5a receptor antagonist**, is approved

as an adjunct in severe AAV on the basis of the **ADVOCATE** trial, allowing substantial glucocorticoid reduction with better renal recovery; and the **PEXIVAS**-informed **reduced-dose glucocorticoid regimen** (with restriction of plasma exchange) is now standard. Both are especially valuable in older patients, in whom **steroid toxicity and infection drive mortality**.

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
GCA diagnosis	Temporal artery biopsy	Ultrasound halo sign as first-line imaging; biopsy or imaging, both acceptable; fast-track clinics	Mention both; never delay steroids for either
GCA steroid-sparing	Steroids alone ± methotrexate	Tocilizumab or upadacitinib 15 mg OD as adjunct	Quote SELECT-GCA figures (46% vs 29%)
AAV induction	Steroids + cyclophosphamide	Steroids + rituximab preferred in the elderly; reduced-dose steroid regimen; avacopan adjunct	Emphasise steroid minimisation in older adults
Plasma exchange	Used in severe disease	Restricted to severe alveolar haemorrhage and most severe renal disease (PEXIVAS)	Say "restricted, not routine"

Exam One-Liners

- Commonest primary systemic vasculitis in adults — **giant cell arteritis**.
- Most specific GCA symptom — **jaw claudication**.
- Ultrasound sign — **halo sign**; biopsy problem — **skip lesions**.
- Steroids in GCA — **start before the biopsy**; biopsy positive up to 2 weeks.
- Vasculitis of the 65–75 age group — **microscopic polyangiitis**.
- Single most important bedside test in suspected AAV — **urinalysis with microscopy**.
- Renal biopsy in AAV — **pauci-immune crescentic glomerulonephritis**.
- Induction agent preferred in the elderly — **rituximab**.
- Commonest cause of death in the older vasculitis patient — **infection from treatment**.

Question 23. Late / elderly-onset rheumatoid arthritis — how it differs from young-onset disease, and the relevant investigations 15 MARKS RECURRING

ANSWER

Source note. Late-onset rheumatoid arthritis is **not covered adequately in the uploaded textbooks**. Kane's discusses arthritis in older adults generally and provides the **osteoarthritis versus inflammatory arthritis** comparison table (used below); Pathy's covers polymyalgia rheumatica and general prescribing in old age. The disease-specific comparative content is drawn from current rheumatological literature and guidelines and is clearly separated.

Textbook Core — 10 Points

1. **Definitions and the age threshold. Late-onset rheumatoid arthritis (LORA)**, also called **elderly-onset RA (EORA)**, is rheumatoid arthritis whose **onset occurs at or after 60 years** (the WHO definition of "elderly" being 60–74), although many studies use **65 years**; **young-onset RA (YORA)** is onset before this. There is **no agreed international threshold** — the **Japan College of Rheumatology**, which has issued the **only national guideline** on the subject, recommends the term **LORA**. Roughly **one-third of all new RA now begins after the age of 60**, and this proportion is rising as the population ages.
2. **Epidemiology and sex ratio.** YORA is strongly **female-predominant, about 3:1**, with peak onset between 25 and 45 years. In LORA the female preponderance is **much less marked and approaches 1:1**. The **incidence of RA continues to rise with age** into the seventh and eighth decades, so RA is not a disease that "burns out" at the door of old age.
3. **Pathogenesis — why LORA is different.** LORA arises on a background of **immunosenescence and inflammaging**: thymic involution, expansion of **$CD4^+CD28^-$ senescent T cells**, shortened lymphocyte telomeres, and a high baseline **IL-6** level. Importantly, the **HLA-DRB1 shared-epitope association is weaker in LORA than in YORA** — which is consistent with the higher proportion of seronegative disease and with the clinical overlap with polymyalgia rheumatica.
4. **Mode of onset and joint pattern — the core clinical difference. YORA** characteristically has an **insidious onset** over weeks to months, producing a **symmetrical small-joint polyarthritis of the MCP, PIP, wrist and MTP joints, sparing the DIP joints**. **LORA** tends to have an **abrupt, almost "infection-like" acute onset**, is more often **oligoarticular at presentation**, and shows **more frequent involvement of large, proximal joints — especially the shoulders** — producing a girdle distribution that closely mimics polymyalgia rheumatica. **Pitting oedema of the hands and feet** is characteristic of LORA and rare in YORA.
5. **Systemic and constitutional features. Fever, weight loss, profound fatigue, anorexia and a markedly raised ESR at onset** are all **more prominent in LORA**. This may relate to differences in cytokine profile and to the higher IL-6 tone of ageing. Classical severe extra-articular rheumatoid disease (vasculitis, Felty's syndrome, rheumatoid lung) is **not** more frequent in LORA — the systemic picture is one of constitutional inflammation rather than organ-based rheumatoid complications. Because the presentation is dominated by weight loss, weakness, immobility and low mood, LORA is frequently mislabelled as **"failure to thrive"** or as an occult malignancy.
6. **Serology — and two crucial caveats. LORA is more often seronegative** for rheumatoid factor and anti-CCP than YORA. Caveat one: **rheumatoid factor positivity increases with age in the healthy population** as an expression of age-related immune dysregulation, and therefore **loses diagnostic specificity in older adults** — **anti-CCP is the more useful test in this age group**. Caveat two: **seronegative RA is not a mild form of the disease** — it may carry more inflammatory activity and, in some series, a worse prognosis, and it requires the **same intensive treat-to-target strategy** as seropositive disease.
7. **The three phenotypes of LORA, and the differential diagnosis.** Three recognised subsets: **(i) classical RA-like** — usually seropositive, erosive, and behaves much like YORA; **(ii) PMR-like LORA** — girdle pain and stiffness with a very high ESR, usually seronegative, occurring in about **25% of LORA** (PMR-like YORA is exceptional); **(iii) RS3PE-like** — remitting seronegative symmetrical synovitis with pitting oedema. The critical differential is therefore **polymyalgia rheumatica**: in follow-up studies **more than 20% of patients initially diagnosed as PMR are reclassified as seronegative LORA**, and some authorities regard PMR, seronegative LORA and RS3PE as parts of a single spectrum of inflammatory disease of old age. Other differentials at this age: **polyarticular gout and calcium pyrophosphate disease**, **nodal and erosive osteoarthritis** of the hands, **paraneoplastic polyarthritis**, viral arthritis, and **immune checkpoint inhibitor-induced arthritis**. Kane's comparison of **osteoarthritis versus inflammatory arthritis** is the bedside discriminator to quote:

Clinical feature	Osteoarthritis	Inflammatory arthritis
Duration of stiffness	Minutes	**Hours**
Pain	Usually with activity	**Occurs even at rest and at night**
Fatigue	Unusual	**Common**
Swelling	Common but little synovial reaction	**Very common, with synovial proliferation and thickening**
Erythema and warmth	Unusual	**Common**

8. **Disease course and outcome.** LORA presents with **higher disease activity, more extra-articular manifestations, greater disability, more radiographic damage and a higher ESR at onset** than YORA. Yet **with adequate treatment the probability of achieving remission or low disease activity is similar to — and in some series better than — YORA**, partly because of the higher proportion of seronegative patients. Where outcomes are worse in practice, the reason is largely **under-treatment**: older patients receive **higher glucocorticoid and NSAID doses, fewer DMARDs and lower DMARD doses**, and discontinue treatment more often for adverse events. The correct conclusion is that **LORA is under-treated rather than intrinsically treatment-resistant**.
9. **Investigations to send — the second half of the question. (a) To confirm the diagnosis: rheumatoid factor** and **anti-CCP antibody** (anti-CCP being the more specific in this age group); **ANA**; **ESR and CRP**; **complete blood count** (normocytic anaemia of chronic disease, thrombocytosis; leucopenia would suggest Felty's syndrome); **plain radiographs of hands, wrists and feet** for periarticular osteopenia, marginal erosions, joint space narrowing and deformity — remembering that **coexisting osteoarthritic change is almost universal at this age** and must not be over-interpreted; and **musculoskeletal ultrasound with power Doppler, or MRI of hands and shoulders**, which detects synovitis and erosions earlier and helps **distinguish the synovitis of LORA from the bursitis and tenosynovitis pattern of PMR**. Classification uses the **ACR/EULAR 2010 criteria (score ≥6 of 10)**, which are **less sensitive in seronegative large-joint LORA** and therefore support but never replace clinical judgement. **(b) To exclude the differential diagnoses: serum uric acid** and, decisively, **joint aspiration with polarised light microscopy and culture** for crystals and sepsis; **TSH**; **calcium, phosphate, alkaline phosphatase and 25(OH) vitamin D**; **serum and urine protein electrophoresis with free light chains** to exclude myeloma; **creatine kinase**; **chest radiograph**; **temporal artery ultrasound** if there are any giant cell arteritis features; and **age-appropriate malignancy screening** where a paraneoplastic arthritis is suspected. **(c) Baseline safety and pre-treatment work-up: renal function with eGFR**, **liver function tests**, **hepatitis B and C and HIV serology**, **latent tuberculosis screening with a chest radiograph and Mantoux or IGRA — mandatory in India before any biologic or JAK inhibitor**, **lipid profile with cardiovascular risk assessment**, **DEXA** before or early in glucocorticoid therapy, and a **baseline ophthalmic assessment** before hydroxychloroquine.
10. **How the differences change management.** The **treat-to-target principle and the target itself (remission or low disease activity) are the same as in YORA — age alone is never a reason to withhold a DMARD**. **Methotrexate remains anchor therapy**, but must be **dose-reduced for the age-related fall in GFR**, given with **folic acid**, **avoided if eGFR is below 30**, and monitored closely for cytopenias, hepatotoxicity and pneumonitis. **Minimise glucocorticoids** — long-term low-dose steroid used *instead* of a DMARD is the single commonest and most damaging error in LORA (infection, osteoporosis, diabetes, cataract, skin fragility, delirium). **Use NSAIDs sparingly**: Kane's notes that older patients are particularly susceptible to gastrointestinal, CNS and renal adverse effects, and they are flagged in the Beers criteria. **Biologics are as effective as in younger patients** but carry a higher absolute risk of serious infection. **Screen and vaccinate before immunosuppression** (influenza, pneumococcal, recombinant zoster vaccine, COVID-19), and provide **bone protection** with any steroid course. Assess **comorbidity, polypharmacy, cognition, frailty and adherence** before choosing an agent — a comprehensive geriatric assessment is part of the rheumatology decision here.

Latest Updates (2023 – present)

11. A **2024 systematic review and meta-analysis** (Acuña-Rocha *et al.*, *Cureus* 2024, searching to November 2023) confirmed that **EORA presents with more intense disease activity, a higher prevalence of extra-articular manifestations, greater disability and more pronounced radiographic change at onset**, but that **the probability of achieving remission or low disease activity over one to two years is similar to YORA**. It also formally documented the treatment disparity — **EORA patients receive higher glucocorticoid and NSAID doses and fewer or lower-dose DMARDs** — establishing under-treatment, rather than biology, as the main driver of poorer real-world outcomes.
12. **Guidelines and drug safety.** The **Japan College of Rheumatology** has issued the **first and currently only national guideline specific to LORA**, recommending the term LORA and a treat-to-target approach explicitly adapted for comorbidity and frailty; dedicated **ACR and EULAR guidance for LORA is still awaited and is recognised as an urgent gap** (ACR Open Rheumatology, 2025). On drug safety, the **ORAL Surveillance** trial has led regulators and current EULAR recommendations to advise that **JAK inhibitors should not be used first-line in patients over 65**, or in those with cardiovascular risk factors, a smoking history or malignancy risk, because of increased major adverse cardiovascular events, venous thromboembolism, malignancy and herpes zoster — a restriction that falls disproportionately on exactly the LORA population.

Current Practice Update

Item	Traditional teaching	Current recommendation	Exam approach
Prognosis of LORA	Worse than YORA; more disabling	Higher activity at onset, but **similar remission rates with adequate treatment**; poorer outcomes reflect under-treatment	Say "under-treated, not treatment-resistant"
Seronegative disease	A milder form of RA	**Not mild** — may have more inflammatory activity and a worse prognosis; treat to target	A guaranteed viva point

Rheumatoid factor	A diagnostic test for RA	Loses specificity with age; **anti-CCP preferred** in older adults	Always mention both, and why
Steroids	Convenient and effective in the elderly	**Minimise** — bridge only, with bone protection; never as a substitute for a DMARD	Frame as the commonest management error
JAK inhibitors	An oral alternative to biologics	**Avoid first-line over 65** (ORAL Surveillance)	Name the trial

MNEMONIC ANCHOR

The differences of LORA = **"SALADS"** → **S**ex ratio approaches 1:1 (versus 3:1 female in YORA) · **A**cute, abrupt, infection-like onset (versus insidious) · **L**arge proximal joints, especially **shoulders** (versus small hand joints) · **A**nti-CCP and RF more often negative (seronegative) · **D**isease activity, disability, ESR and radiographic damage higher at onset · **S**ystemic constitutional features prominent (fever, weight loss, fatigue).

NUMERICAL ANCHORS

Onset at or after **60** years (many studies use **65**) · about **one-third** of new RA begins after 60 · female:male **3:1 in YORA versus ~1:1 in LORA** · **PMR-like phenotype in ~25%** of LORA · **>20%** of patients initially labelled PMR are reclassified as seronegative LORA · ACR/EULAR 2010 classification score **≥6 of 10** · methotrexate **avoid if eGFR <30** · JAK inhibitors **not first-line over 65**.

NAMED EXAMINER TRAPS

(a) A positive rheumatoid factor in an older adult may mean nothing — age-related immune dysregulation raises RF positivity in healthy elderly people; always send **anti-CCP**. **(b) Seronegative does not mean mild. (c)** Do not settle for a diagnosis of PMR — a "PMR" that **needs more than 25 mg of prednisolone, relapses on every taper, or develops peripheral synovitis or pitting oedema** is seronegative LORA, and needs a DMARD. **(d) Age is not a contraindication to methotrexate or to biologics** — comorbidity and renal function are. **(e)** Interpreting hand radiographs, **do not attribute the changes of coexisting nodal osteoarthritis to RA**; look specifically for **marginal erosions and periarticular osteopenia**. **(f)** Remember the **drug-induced causes** at this age — checkpoint inhibitors and, for the PMR-like picture, statin myopathy. **(g) Latent TB screening before biologics is not optional in India.**

15-SECOND ANSWER SKELETON

Define LORA and the age threshold, note one-third of RA starts after 60 → sex ratio → immunosenescence and weaker HLA-DRB1 link → run through **SALADS** for the clinical differences → serology with the two caveats → the three phenotypes and the PMR / RS3PE overlap → course and outcome (under-treated, not resistant) → **investigations in three groups: confirm, exclude, pre-treatment safety** → management implications (treat-to-target, methotrexate with renal adjustment, minimise steroids, avoid JAKi over 65, screen and vaccinate) → close with the 2024 meta-analysis and the Japanese LORA guideline.

EXTRA RECALL BOX — THE THREE-WAY COMPARISON TABLE (WRITE THIS AND YOU HAVE THE ANSWER)

Feature	YORA	LORA / EORA	Polymyalgia rheumatica
Age at onset	25–45 peak	≥60 (or ≥65)	Never below 50
Sex ratio (F:M)	3:1	~1:1	2–3:1
Onset	Insidious, weeks–months	**Abrupt, infection-like**	Abrupt or subacute
Joints	Symmetrical small joints — MCP, PIP, wrist, MTP; spares DIP	**Large proximal joints, shoulders**; often oligoarticular; may also involve small joints	**Girdles only** — shoulder and pelvic; no true peripheral synovitis
Pitting oedema of hands	Rare	**Characteristic** (RS3PE-like)	May occur
Constitutional symptoms	Less prominent	**Prominent**	Prominent
ESR / CRP at onset	Raised	**Markedly raised**	Markedly raised (ESR often >40)
RF / anti-CCP	Usually positive	**More often negative**	Negative
Erosions	Yes	Yes — more radiographic damage at onset	**No erosions**
Response to low-dose steroid	Partial	Partial; relapses on taper	**Dramatic within 24–72 h to 12.5–25 mg**
Needs a DMARD	Yes	**Yes**	Only if relapsing (methotrexate / sarilumab)

Indian context. RA prevalence in India is around **0.28–0.75%**, and with a rapidly ageing population LORA is an increasing share of the rheumatology workload. Practical answer points: **latent tuberculosis screening is mandatory before biologics or JAK inhibitors** given India's TB burden; **biosimilar TNF inhibitors and rituximab** have made biologic therapy affordable and are the realistic escalation option; methotrexate is inexpensive and remains the anchor drug; **AB-PMJAY and the Ayushman Vay Vandana Card** cover hospitalisation and joint replacement for eligible older adults; and **vitamin D deficiency and osteoporosis must be addressed at the first steroid prescription**.

Exam One-Liners

- Definition — RA with onset at or after **60 years** (many studies use 65).
- Sex ratio — **approaches 1:1**, unlike the 3:1 female predominance of YORA.
- Onset — **abrupt and infection-like**, with **large proximal joint** involvement.
- Serology — **more often seronegative**; RF loses specificity with age, so send **anti-CCP**.
- Commonest mimic — **polymyalgia rheumatica**; over 20% of "PMR" is reclassified as seronegative LORA.
- Characteristic sign — **pitting oedema of hands and feet** (RS3PE overlap).
- Prognosis — worse at onset, **similar remission with adequate treatment**.
- Anchor drug — **methotrexate**, renally dose-adjusted, with folic acid.
- Avoid first-line over 65 — **JAK inhibitors** (ORAL Surveillance).
- Commonest management error — **long-term steroid instead of a DMARD**.

Question 24. Psoriatic arthropathy 7 MARKS

ANSWER

Textbook Core — 6 Points

1. **Definition and classification.** A **seronegative inflammatory arthritis associated with psoriasis**, belonging to the spondyloarthropathy family. **Moll and Wright's five patterns**: (i) asymmetric **oligoarthritis**, (ii) symmetric **polyarthritis** (RA-like), (iii) **distal interphalangeal (DIP) predominant**, (iv) **spondylitis/sacroiliitis**, (v) **arthritis mutilans**.
2. **Clinical features. Dactylitis** ("sausage digit"), **enthesitis** (Achilles tendon, plantar fascia), **DIP joint involvement with nail disease** (pitting, onycholysis, subungual hyperkeratosis, oil-drop sign), inflammatory back pain, and extra-articular features such as **uveitis**. Skin disease usually precedes the arthritis. **Elderly-onset psoriatic arthritis** tends to be more **polyarticular, more acutely inflammatory (higher ESR/CRP) and more erosive** than younger-onset disease.
3. **Investigations. RF and anti-CCP negative**; ESR and CRP raised; uric acid may be raised (a source of diagnostic confusion). Radiology: **erosions with adjacent new bone formation**, the **"pencil-in-cup" deformity**, periostitis, ankylosis and **asymmetric sacroiliitis**. Diagnosis is made with the **CASPAR criteria**; the **PEST** questionnaire is used to screen psoriasis patients.
4. **Differential diagnosis in the older adult. Rheumatoid arthritis** (symmetric, seropositive, spares the DIP joints), **erosive/nodal osteoarthritis** of the DIP joints (Heberden's nodes — a major overlap in this age group), **gout** (common in older men on diuretics), pseudogout, and reactive arthritis.
5. **Management principles. Treat-to-target**, aiming for minimal disease activity. Physiotherapy, graded exercise, weight reduction, smoking cessation and active **cardiovascular risk reduction** — psoriatic arthritis carries a high burden of metabolic syndrome, diabetes and cardiovascular disease. Local corticosteroid injection for a single inflamed joint or enthesis. NSAIDs help mild peripheral disease but are **relatively contraindicated in older adults** (renal impairment, GI bleeding, hypertension, heart failure — Beers criteria).
6. **Drug therapy.** Conventional synthetic DMARDs — **methotrexate** (monitor renal function, reduce dose for the age-related fall in GFR, give folate), leflunomide or sulfasalazine for peripheral disease; csDMARDs do **not** work for axial disease. Biologics for inadequate response or axial involvement: **TNF inhibitors**, **IL-17 inhibitors** (secukinumab, ixekizumab), **IL-12/23** (ustekinumab) and **IL-23 inhibitors** (guselkumab, risankizumab). Targeted synthetic agents: **apremilast** (PDE4 inhibitor — no laboratory monitoring, well tolerated in frail older adults) and **JAK inhibitors** (tofacitinib, upadacitinib). **Screen for latent tuberculosis and hepatitis B before any biologic** — essential in India.

Latest Update (2023 – present)

7. Following the **ORAL Surveillance** safety data, current **EULAR and GRAPPA** recommendations advise that **JAK inhibitors should not be used first-line in patients over 65** or with cardiovascular risk factors, a smoking history or malignancy risk, because of increased **major adverse cardiovascular events, venous thromboembolism, malignancy and herpes zoster**. **IL-17 and IL-23 inhibitors are preferred** in this group — **bimekizumab** (dual IL-17A/F blockade) was approved for psoriatic arthritis in 2023–24 and **guselkumab** has strong axial and peripheral data — while **apremilast** remains the low-monitoring option for frail older adults with mild disease.

If this appears as a 15-mark question, add: pathogenesis (IL-23/IL-17 axis, HLA-B27 in axial disease, the enthesis as the primary site); full CASPAR criteria with scoring; the six GRAPPA domains (peripheral arthritis, axial disease, enthesitis, dactylitis, skin, nails) and domain-based drug selection; a comparison table of PsA versus RA versus osteoarthritis versus gout in the older patient; comorbidity screening (metabolic syndrome, fatty liver, depression, uveitis, inflammatory bowel disease); and vaccination and TB screening before immunosuppression in the Indian context.

Exam One-Liners

- Five patterns — **Moll and Wright**.
- Classic radiological sign — **pencil-in-cup deformity**.
- Classic clinical signs — **dactylitis, enthesitis, nail pitting, DIP arthritis**.
- Diagnostic criteria — **CASPAR**.
- Avoid first-line over 65 — **JAK inhibitors**.
- Safest low-monitoring agent in the frail — **apremilast**.

Question 25. Sjögren's syndrome 7 MARKS

ANSWER

Textbook Core — 6 Points

1. **Definition and classification.** A chronic **autoimmune exocrinopathy** in which **lymphocytic infiltration of exocrine glands** causes dry eyes and dry mouth. **Primary** Sjögren's occurs alone; **secondary** Sjögren's accompanies rheumatoid arthritis, SLE or systemic sclerosis. Strongly female-predominant (about **9:1**), with onset typically in the fifth to sixth decade and a further peak in older women.
2. **Glandular clinical features. Keratoconjunctivitis sicca** — gritty, burning eyes, photophobia, corneal filaments. **Xerostomia** — difficulty swallowing dry food, altered taste, **rampant dental caries**, oral candidiasis, angular cheilitis, difficulty retaining dentures. Also **parotid or submandibular gland enlargement**, dry skin, dry cough from tracheobronchial dryness, and vaginal dryness with dyspareunia.
3. **Extraglandular features.** Non-erosive arthritis, Raynaud's phenomenon, **interstitial lung disease**, **renal tubular acidosis and interstitial nephritis**, peripheral and small-fibre **neuropathy**, cutaneous vasculitis, and autoimmune thyroid disease. Profound **fatigue** is often the most disabling symptom. **The risk of non-Hodgkin (MALT) lymphoma is increased roughly 5–15 fold** — persistent parotid swelling, low C4, cryoglobulins and palpable purpura are the warning signs.
4. **Investigations. Anti-Ro/SSA and anti-La/SSB** antibodies, ANA and RF positive; **raised ESR with a normal CRP**; polyclonal hypergammaglobulinaemia; cytopenias; low complement. Objective tests: **Schirmer's test ≤5 mm in 5 minutes**, ocular staining score, **unstimulated whole salivary flow ≤0.1 mL/min**, and **labial minor salivary gland biopsy** showing focal lymphocytic sialadenitis with a **focus score ≥1**. Diagnosis uses the **ACR/EULAR 2016 criteria (score ≥4)**.
5. **The key geriatric differential — drug-induced dry mouth.** Age-related salivary hypofunction and, far more commonly, **medication** are the usual causes of dry mouth in an older person: **anticholinergics, tricyclic antidepressants, antihistamines, antipsychotics, diuretics, opioids and bladder antimuscarinics**. Also consider previous head and neck **radiotherapy**, IgG4-related disease, sarcoidosis, hepatitis C, amyloidosis, HIV and diabetes. **Always review the drug chart before diagnosing Sjögren's in an older patient.**
6. **Management.** Largely **symptomatic and preventive**. Eyes — preservative-free artificial tears, ocular lubricant ointment at night, topical ciclosporin, punctal plugs. Mouth — frequent sips of water, sugar-free gum, saliva substitutes, and **muscarinic agonists (pilocarpine or cevimeline)**, which must be used cautiously in the elderly (sweating, bradycardia, avoid in asthma, COPD and narrow-angle glaucoma). **Intensive dental care with topical fluoride** and treatment of oral candidiasis. **Hydroxychloroquine** for arthralgia and fatigue; **glucocorticoids ± rituximab or other immunosuppression** for severe systemic disease (vasculitis, ILD, neuropathy, glomerulonephritis). **Stop or substitute the offending anticholinergic drugs.**

Latest Update (2023 – present)

7. Current EULAR practice directs therapy by **systemic activity scoring using the ESSDAI**, with symptom burden captured by **ESSPRI**, rather than treating everyone identically. More importantly, **2024–2025 phase 2 and phase 3 trials of targeted biologics have for the first time shown disease-modifying benefit**: **ianalumab** (anti-BAFF-receptor), **nipocalimab** (FcRn blocker) and **dazodalibep** (CD40-ligand pathway inhibitor) all met their primary endpoints in Sjögren's disease — signalling the first prospect of therapy beyond symptomatic care.

If this appears as a 15-mark question, add: the full ACR/EULAR 2016 criteria with individual item weights; pathogenesis (epithelitis, type I interferon signature, B-cell hyperactivity and BAFF); a table of causes of xerostomia in the older adult; the detailed lymphoma risk-stratification model; management of renal tubular acidosis and hypokalaemic paralysis (a classic Indian presentation); the ESSDAI domains; and the impact of xerostomia on nutrition, dentition, denture tolerance, taste, speech and quality of life in the elderly.

Exam One-Liners

- Antibodies — **anti-Ro/SSA and anti-La/SSB**.
- Objective tests — **Schirmer ≤5 mm/5 min**; **focus score ≥1** on labial biopsy.
- Classic laboratory pattern — **high ESR with normal CRP**.
- Feared complication — **MALT lymphoma**; warning signs: persistent parotid swelling, low C4, cryoglobulins, purpura.
- Commonest cause of dry mouth in an older person — **drugs, not Sjögren's**.
- Secretagogues — **pilocarpine, cevimeline**.

PART VII

Metabolic Bone Disease

The two metabolic bone questions, which share a laboratory differential and should be revised together.

Question 26. Osteoporosis, DEXA and FRAX 15 MARKS RECURRING

ANSWER

Textbook Core — 10 Points

1. **Definition.** A skeletal disorder of **reduced bone mass with micro-architectural deterioration**, leading to bone fragility and increased fracture risk. The **WHO densitometric definition** is a value **2.5 standard deviations or more below the young adult mean — a T-score ≤ −2.5**. **Osteopenia** = T-score between −1 and −2.5; **severe (established) osteoporosis** = T ≤ −2.5 with a fragility fracture.
2. **DEXA. Central dual-energy X-ray absorptiometry is the standard method** for measuring bone mineral density at the **spine, hip and forearm**. The **T-score** compares with the young adult mean; the **Z-score** compares with age-matched peers and is used in younger patients and to flag secondary osteoporosis when ≤ −2.0. US guidelines recommend **DEXA for all women aged 65 or older**; the UK National Osteoporosis Guideline Group instead uses **FRAX first** and DEXA selectively. **Geriatric pitfall:** spinal osteoarthritis, vertebral fractures and aortic calcification **falsely elevate lumbar BMD** in the elderly — rely on the **total hip / femoral neck**.
3. **FRAX.** An **algorithm integrating clinical risk factors, with or without femoral neck BMD, to compute the 10-year probability of a major osteoporotic fracture and of hip fracture**. Inputs: **age, sex, weight and height (BMI), previous fragility fracture, parental hip fracture, current smoking, glucocorticoid therapy, rheumatoid arthritis, secondary osteoporosis and alcohol ≥3 units/day**. FRAX is **country-specific**, and an **Indian FRAX model** is available.
4. **FRAX — use and limitations.** Its main function is to set an **intervention threshold**: treat when the FRAX probability equals or exceeds the risk of someone with a prior fragility fracture. Limitations — it does **not** capture glucocorticoid dose, the number or recency of fractures, **falls**, lumbar spine BMD or diabetes. Probability can be **modulated** by the **trabecular bone score (TBS)**, glucocorticoid dose, hip axis length, fall history and type 2 diabetes.
5. **Major risk factors for fragility fracture. Age, female sex, low BMI, prior fragility fracture, parental hip fracture, height loss >4 cm, glucocorticoid therapy, smoking and excess alcohol**; plus **secondary osteoporosis** — rheumatoid arthritis, hyperthyroidism, primary hyperparathyroidism, hypogonadism, diabetes, inflammatory bowel disease, aromatase inhibitors, anorexia nervosa, organ transplantation, prolonged immobility, COPD and HIV. **In the oldest old, falls risk drives fracture risk at least as much as BMD does.**
6. **Investigating the older patient with a fragility fracture.** Only **3% of hip fractures in the elderly are pathological**, but **over half of patients are osteoporotic and almost all are osteopenic**; after 80, a woman with age-normal bone density already has a T-score of −2.5, so **DEXA for diagnosis alone is chiefly useful under 75**. Take a full **medication (corticosteroid) and alcohol history** and check **CBC, ESR, calcium (mg/dL), phosphate, alkaline phosphatase, creatinine, liver and thyroid function, 25(OH) vitamin D and serum/urine protein electrophoresis**. Secondary osteoporosis is uncommon in this age group, but **hyperthyroidism is the dominant cause**; also consider malnutrition, low body weight, hypogonadism, hyperparathyroidism and myeloma. Perform **vertebral fracture assessment or spine X-ray** if there is height loss or hyperkyphosis.
7. **Non-pharmacological management — for every patient. Calcium 800–1000 mg/day** (up to 1200 mg), **vitamin D 800–1000 IU/day**, **protein ≥1 g/kg body weight/day**, **daily weight-bearing and resistance exercise**, smoking cessation, alcohol ≤2 units/day, and **multifactorial falls prevention** with home hazard assessment and medication review. **Hip protectors** probably reduce hip fracture in nursing and residential care, but **poor acceptance and adherence limit their use**.
8. **First-line drug therapy. Oral bisphosphonates** — **alendronate 70 mg weekly** or **risedronate 35 mg weekly** (gastro-resistant risedronate may improve adherence). Take **fasting, upright, with plain water, 30 minutes before food**. Contraindications: **eGFR <30–35 mL/min**, oesophageal stricture or achalasia, inability to remain upright, and **uncorrected hypocalcaemia or vitamin D deficiency**. Adverse effects: oesophagitis, acute-phase reaction after IV zoledronate, and rarely **osteonecrosis of the jaw and atypical femoral fracture**. **Zoledronic acid 5 mg IV yearly** is the option when oral therapy fails or is not tolerated, and after hip fracture it reduces both **re-fracture and mortality**.
9. **Other agents and sequencing. Denosumab 60 mg subcutaneously 6-monthly** — usable in renal impairment, but monitor calcium and **never stop it abruptly**: discontinuation causes **rebound multiple vertebral fractures**, so it must be followed by a bisphosphonate for 1–2 years. For **very high or imminent fracture risk**, an **anabolic agent first — teriparatide, abaloparatide or romosozumab** (romosozumab is contraindicated within one year of myocardial infarction or stroke) — **always followed by an antiresorptive**. Menopausal hormone therapy and raloxifene/bazedoxifene are options in younger postmenopausal women; **calcitonin has weak fracture-prevention efficacy**.
10. **Follow-up and duration.** Assess **adherence and side effects**; use **bone turnover markers at 3–6 months to verify compliance** with bone-resorption inhibitors; repeat DEXA about every 2 years. Reassess after **5 years of oral**

or 3 years of intravenous bisphosphonate: **continue in high-risk patients; consider a 2-year drug holiday in low-risk patients, reconsidered yearly**; restart immediately if an incident fracture occurs. **Fracture Liaison Services** — systematic case-finding and treatment after every fragility fracture — are the best-established service model, and their benefits are well documented.

Latest Updates (2023 – present)

11. **Screening works; supplements alone do not.** The **SCOOP** randomised trial (*Lancet*) showed that **community FRAX-based screening of older women reduces hip fractures**, supporting systematic case-finding. Conversely, a meta-analysis of 33 randomised trials in 51,145 participants (**Zhao et al., JAMA**) found that **calcium, vitamin D, or both were NOT associated with a lower fracture risk in community-dwelling older adults** — supplements are a necessary adjunct to, but never a substitute for, specific anti-osteoporosis therapy.
12. **The "very high risk" category and anabolic-first sequencing.** Current international guidance (ESCEO/IOF, AACE, Endocrine Society and 2023–2025 updates) formally defines **very high risk** — a fracture within the last 24 months, a fracture while on treatment, multiple fractures, T-score ≤ −3.0, or very high FRAX probability — and recommends starting with an **anabolic agent (romosozumab or teriparatide) followed by an antiresorptive** in this group, because **sequence matters**: anabolic-then-antiresorptive produces substantially greater BMD and fracture-risk reduction than the reverse order.

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
Who to treat	T-score ≤ −2.5 (or ≤ −2.0 per NOF)	Fracture probability (FRAX ± BMD) above an intervention threshold, with a defined very-high-risk group	Give the WHO T-score definition, then say treatment is now risk-based
Calcium + vitamin D	"First line of defence"	Essential adjunct, but does not reduce fracture on its own in community dwellers	Quote the JAMA meta-analysis
Drug sequencing	Start with a bisphosphonate	Anabolic first (romosozumab/teriparatide) in very high risk, then antiresorptive	Say "sequence matters"
Denosumab	Effective antiresorptive	Must never be stopped without follow-on bisphosphonate — rebound vertebral fractures	A guaranteed viva question
Case finding	Opportunistic	Fracture Liaison Service + FRAX-based community screening (SCOOP)	Name FLS as the service model

MNEMONIC ANCHOR

FRAX inputs = **"SCRAP + GAP + BMI (± BMD)"** → **S**moking, **C**orticosteroids, **R**heumatoid arthritis, **A**lcohol ≥3 units, **P**revious fragility fracture · **G**ender, **A**ge, **P**arental hip fracture · plus **BMI** and, optionally, **BMD** (± secondary osteoporosis).

NUMERICAL ANCHORS

T ≤ −2.5 osteoporosis · −1 to −2.5 osteopenia · Z ≤ −2.0 suggests secondary cause · height loss >4 cm · alcohol ≥3 units/day · calcium 800–1200 mg · vitamin D 800–1000 IU · protein ≥1 g/kg · alendronate 70 mg weekly · risedronate 35 mg weekly · zoledronate 5 mg yearly · denosumab 60 mg 6-monthly · eGFR cut-off for bisphosphonates <30–35 · review at 5 years oral / 3 years IV · very high risk if T ≤ −3.0 or fracture within 24 months · only 3% of elderly hip fractures are pathological.

NAMED EXAMINER TRAPS

(a) T-score versus Z-score — know exactly which is used where. **(b) Never stop denosumab** without a follow-on bisphosphonate. **(c) Correct vitamin D deficiency and hypocalcaemia BEFORE** giving a potent antiresorptive — otherwise symptomatic hypocalcaemia. **(d) Lumbar spine DEXA is unreliable in the elderly** — use the hip. **(e)** FRAX **without** BMD is a valid and intended use — it is the entry point in the NOGG pathway. **(f)** FRAX **underestimates** risk in recurrent fallers, in high-dose steroid users and after a very recent fracture. **(g)** A fragility fracture at any T-score is enough to justify treatment — do not wait for the DEXA.

15-SECOND ANSWER SKELETON

Define with WHO T-score → DEXA (sites, T vs Z, elderly pitfall) → FRAX (inputs, 10-year probability, intervention threshold, limitations) → risk factors including falls → exclude secondary causes → lifestyle + calcium/vitamin D/protein/exercise/falls prevention → oral bisphosphonate first line with administration rules and contraindications → zoledronate/denosumab/anabolic sequencing → monitoring, duration and drug holiday → Fracture Liaison Service → SCOOP and anabolic-first updates.

EXTRA RECALL BOX — INDIAN CONTEXT

Osteoporosis is **under-diagnosed and under-treated in India**, with a large **treatment gap** even after hip fracture. Practical points: **vitamin D deficiency is near-universal** in Indian older adults (limited sun exposure, skin pigmentation, covered dress, vegetarian diets), so **check and replete 25(OH) vitamin D first**; **ICMR-NIN** recommends 1000 mg/day calcium for older adults, and dietary calcium intake is typically low; the **ISBMR (Indian Society for Bone and Mineral Research) position statements** guide Indian practice; the **Indian FRAX model** should be used rather than the UK/US one; and **orthogeriatric co-management with early surgery (<48 h) and comprehensive geriatric care after hip fracture** improves function and survival (Prestmo *et al.*, *Lancet* 2015).

Exam One-Liners

- WHO definition — **T-score ≤ −2.5**.
- Gold standard measurement — **central DEXA of hip and spine**.
- FRAX output — **10-year probability of major osteoporotic and hip fracture**.
- FRAX omits — **falls, steroid dose, fracture recency and number, lumbar BMD, diabetes**.
- First-line drug — **oral bisphosphonate**; if eGFR <30 — **denosumab**.
- After hip fracture — **zoledronic acid reduces re-fracture and mortality**.
- Best service model — **Fracture Liaison Service**.

Question 27. Paget's disease of bone — epidemiology, aetiology, pathophysiology, clinical manifestations and management

15 MARKS RECURRING

ANSWER

Source note. Paget's disease is **not covered adequately in the uploaded textbooks**. Pathy's 6th ed. carries only a single index entry (p. 1026), and Kane's mentions it in three places only — the metabolic bone disease laboratory table, the table of disorders of hearing in older adults, and the table of medical illnesses associated with depression. **Those textbook fragments are used below and marked**; the remaining disease-specific content is drawn from the Endocrine Society and UK Paget's Association clinical guidelines and is clearly separated.

Textbook Core — 10 Points

1. **Definition.** Paget's disease of bone (**osteitis deformans**) is a **focal disorder of bone remodelling** in which greatly increased and disorganised **osteoclastic bone resorption** is followed by **vigorous but disorganised compensatory osteoblastic new bone formation**. The result is **expanded, thickened, hypervascular but structurally weak woven bone** with a characteristic **mosaic pattern of irregular cement lines**. It may be **monostotic** or **polyostotic**, and — a key examination point — **once established, it does not spread to previously uninvolved bones**; the extent at diagnosis is the lifelong extent.
2. **Epidemiology.** A disease of **later life** — **rare below 40 years**, with prevalence rising steadily with age to about **1–2% of those over 55** in the United Kingdom. **Male predominance**, roughly **3:2**. There is striking **geographic clustering**: highest rates in the **United Kingdom** (classically Lancashire), Western Europe, Australia, New Zealand and North America; it is **rare in Scandinavia, Asia and Africa** and **uncommon in India**. The **incidence, prevalence and severity have all fallen substantially over the past three decades**, which is strong indirect evidence for an environmental cause.
3. **Aetiology — genetic factors. 15–40% have a positive family history**, with autosomal dominant inheritance and incomplete penetrance. Mutations in **SQSTM1**, which encodes the protein **p62** in the RANK–NF-κB signalling pathway, are the commonest — found in about **40–50% of familial** and **5–10% of sporadic** cases, the **P392L** mutation being most frequent. Other susceptibility loci involve **TNFRSF11A (RANK), TNFRSF11B (osteoprotegerin), CSF1, OPTN and TM7SF4/DC-STAMP** — all genes governing osteoclast formation and function.
4. **Aetiology — environmental factors.** The longest-standing hypothesis is **chronic paramyxovirus infection of osteoclasts** (measles, canine distemper or respiratory syncytial virus), supported by **nuclear inclusion bodies resembling paramyxovirus nucleocapsids** in pagetic osteoclasts — but this remains **unproven and controversial**. Other proposed factors: low dietary calcium and vitamin D in youth, **repetitive mechanical loading** of the skeleton, cattle and rural exposure, and environmental toxins. The falling incidence in the absence of any genetic change points firmly to an environmental contribution.
5. **Pathophysiology — the three phases.**

Phase	Bone biology	Radiological correlate
1. Osteolytic (lytic)	Greatly increased number and size of **osteoclasts with abnormally numerous nuclei**; intense resorption	**Osteoporosis circumscripta** in the skull; **"blade of grass" or "flame-shaped"** advancing lytic front in a long bone
2. Mixed	Vigorous compensatory **osteoblastic** bone formation with **marrow fibrosis and marked hypervascularity**; **alkaline phosphatase rises sharply**	Mixed lysis and sclerosis; cortical thickening begins
3. Sclerotic (burnt-out)	Dense, disorganised **woven bone** with a **mosaic of irregular cement lines**; turnover falls	**Bone expansion, thickened cortex, coarse trabeculae**; "cotton wool" skull, "picture frame" vertebra

   The consequences flow directly from this biology: the bone is **bigger but weaker** (deformity and fracture), **hypervascular** (warmth, bleeding at surgery, arteriovenous shunting), and **distorts adjacent structures** (nerve compression, secondary osteoarthritis).
6. **Distribution.** Involvement is **asymmetric and axially predominant**. In descending order of frequency: **pelvis** (commonest), **lumbar spine, femur, skull, tibia, humerus and sacrum**. Skull and long-bone involvement account for most of the clinically important complications.
7. **Clinical manifestations — general. 70–80% of patients are asymptomatic** and are detected incidentally on a radiograph taken for another reason, or through an **isolated raised alkaline phosphatase**. Kane's specifically notes that **mild asymptomatic elevations of alkaline phosphatase are common in the elderly, but liver disease and Paget's disease should be considered if the elevation is moderate**. When symptomatic, the features are: **bone pain** — deep, boring, **worse at rest and at night** and **not relieved by rest** (unlike osteoarthritis); **bone deformity** — anterolateral bowing of the tibia (**"sabre tibia"**), femoral bowing, **increasing skull size so that the hat no longer fits**, frontal bossing, kyphosis and loss of height; and **increased warmth over the affected bone** from hypervascularity. Kane's also lists **Paget's disease among the medical illnesses that may present with or be accompanied by depression**.

8. **Skeletal complications. Pathological fracture** — characteristically **transverse "chalk-stick" fractures** of a bowed long bone. **Secondary osteoarthritis** of the hip and knee — in practice **the commonest cause of pain** in a patient with Paget's disease. **Protrusio acetabuli**, spinal stenosis and vertebral collapse. Rarely, **osteosarcoma in under 1%** — heralded by a **sudden increase in pain, a new soft-tissue mass and a further rise in alkaline phosphatase**, and carrying a very poor prognosis.
9. **Neurological, otological and cardiac complications. Deafness** is the classic complication of skull disease and is **mixed** — conductive from ossicular and cochlear capsule involvement, and sensorineural from cochlear involvement and eighth nerve compression. Kane's lists Paget's disease among the causes of hearing loss in older adults and states that it **"may lead to both kinds of hearing loss and should be evaluated radiologically and by an alkaline phosphatase determination"**. Skull base disease causes **platybasia and basilar invagination** with brainstem compression and hydrocephalus; spinal disease causes **cord and nerve root compression**, sometimes by a vascular steal mechanism. Extensive polyostotic disease involving more than roughly **15–20% of the skeleton** can cause **high-output cardiac failure** through arteriovenous shunting. Also seen: **hypercalcaemia of immobilisation** and hyperuricaemia with gout.
10. **Investigations and management. Biochemistry** — **serum total alkaline phosphatase** is the key screening and monitoring test; Kane's metabolic bone table gives the diagnostic pattern for Paget's disease as **normal or high calcium, normal or high phosphate, HIGH alkaline phosphatase and NORMAL parathyroid hormone**. Use **bone-specific ALP or P1NP** if there is coexisting liver disease. **Radiology** — **plain radiographs of the relevant regions confirm the diagnosis**; a **radionuclide bone scan** is then done to **map the extent** of disease (more sensitive but less specific). Biopsy only if malignancy is suspected. **Indications to treat** — symptomatic bone pain due to active disease, and to prevent or limit complications: **before elective surgery on pagetic bone** (reduces operative bleeding), neurological compression, hypercalcaemia of immobilisation, high-output cardiac failure, and active disease at **critical sites** (skull, spine, weight-bearing long bones, bone adjacent to a major joint). **Drug of choice** — a **single 5 mg intravenous infusion of zoledronic acid**, which produces a more rapid, more complete and more sustained response than oral bisphosphonates, with **biochemical remission in about 90%** of patients, often lasting many years. Alternatives: **risedronate 30 mg daily for 2 months**, **alendronate 40 mg daily for 6 months**, or intravenous pamidronate; **calcitonin** only if bisphosphonates are contraindicated. **Correct vitamin D deficiency and hypocalcaemia before infusion**; caution if eGFR is below about 35 mL/min; warn about the **acute-phase reaction** after the first dose. **Monitor** total alkaline phosphatase at 3–6 months and then 6–12 monthly, and **retreat no sooner than 12 months** after zoledronate if pain recurs or ALP rises. **Adjunctive care** — analgesia (paracetamol; NSAIDs only with great caution in older adults), physiotherapy, walking aids, a **shoe raise or orthosis for leg-length discrepancy**, **hearing aids and audiological review**, **joint replacement for secondary osteoarthritis**, and surgical decompression for cord or nerve compression.

Latest Updates (2023 – present)

11. **PRISM and PRISM-EZ have overturned the "treat to normalise alkaline phosphatase" doctrine.** The **PRISM** trial randomised 1324 patients to intensive bisphosphonate therapy aimed at normalising bone turnover versus symptomatic treatment; its extension, **PRISM-EZ**, continued 502 patients with **zoledronic acid as the first-choice agent in the intensive arm**, giving a total follow-up of about **7.3 years**. Intensive therapy produced **no reduction in fractures, orthopaedic procedures, progression of deafness, bone pain or quality of life**; indeed the intensive arm showed a signal of **more fractures and more orthopaedic surgery**. The authors concluded that in established Paget's disease, **bisphosphonate therapy should focus on the control of symptoms rather than on the suppression of bone turnover**.
12. **Guidelines and the genetics of prevention.** The **Endocrine Society clinical practice guideline** and the **UK Paget's Association guideline (JBMR 2019)** agree on the substantial fall in incidence, on a similar approach to evaluation (plain radiographs to confirm, then a bone scan to define extent), and both name **a single 5 mg intravenous dose of zoledronate as the treatment of choice** where there is no contraindication. The **ZiPP randomised controlled trial** of **prophylactic zoledronic acid in asymptomatic carriers of SQSTM1 mutations** showed that treatment can prevent or modify the development of new bone lesions but **did not alter clinical outcomes** over the trial period — so **genetic screening with pre-emptive treatment is not routine practice**.

Current Practice Update

Item	Textbook / traditional position	Current recommendation	Exam approach
Treatment target	Suppress bone turnover; normalise alkaline phosphatase	**Treat symptoms, not the number** — intensive therapy does not reduce fracture, surgery or deafness (PRISM-EZ)	State the old doctrine, then answer with PRISM-EZ
First-line drug	Calcitonin and older oral bisphosphonates (etidronate, pamidronate)	**Single 5 mg IV zoledronate**; remission in ~90%, sustained for years	Name the drug, dose and route in one line
Asymptomatic disease	Treat all active disease	Treat only for **critical sites, planned surgery or complication risk**	Give the indication list, not a blanket rule
Genetic testing	Not available	**SQSTM1** testing available, but pre-emptive treatment of carriers is not	Useful closing update line

		routine (ZiPP)	
Retreatment	Repeat when ALP rises	Retreat for **recurrent symptoms**, and not sooner than **12 months** after zoledronate; otherwise re-evaluate the cause of pain	Links to the "pain is usually OA" trap

MNEMONIC ANCHOR

Complications = **"BONE PAIN"** → **B**one pain (deep, night, rest) · **O**steoarthritis (secondary — the commonest cause of pain) · **N**erve compression and deafness · **E**xpansion and deformity (sabre tibia, skull enlargement) · **P**athological "chalk-stick" fracture · **A**rteriovenous shunt → high-output cardiac failure · **I**mmobilisation hypercalcaemia · **N**eoplasia (osteosarcoma <1%).

NUMERICAL ANCHORS

Rare below **40** years · about **1–2%** over 55 in the UK · male:female **3:2** · family history in **15–40%** · SQSTM1 in **40–50% familial / 5–10% sporadic** · **70–80% asymptomatic** · osteosarcoma **<1%** · high-output failure if **>15–20%** of skeleton involved · **zoledronate 5 mg IV single dose**, remission in **~90%** · risedronate **30 mg daily × 2 months** · alendronate **40 mg daily × 6 months** · minimum retreatment interval **12 months** · PRISM-EZ total follow-up **7.3 years**.

NAMED EXAMINER TRAPS

(a) Serum calcium and phosphate are characteristically normal — a raised calcium means immobilisation, a recent fracture, or a coexisting primary hyperparathyroidism or malignancy, not Paget's disease itself. **(b)** The commonest cause of pain in these patients is **secondary osteoarthritis, not active Paget's disease** — so pain with a normal ALP will not respond to a bisphosphonate, and the cause must be re-evaluated. **(c) Paget's disease never spreads to new bones** — new lesions on a repeat scan should make you doubt the diagnosis. **(d)** A **sudden increase in pain with a soft-tissue mass and a further ALP rise = osteosarcoma** until proved otherwise. **(e) Correct vitamin D and calcium before zoledronate**, or you will precipitate symptomatic hypocalcaemia. **(f)** ALP may be **normal in limited monostotic disease**, so a normal ALP does not exclude the diagnosis. **(g)** Give a bisphosphonate **before elective orthopaedic surgery** on pagetic bone to reduce intra-operative haemorrhage.

15-SECOND ANSWER SKELETON

Define (focal disorder of remodelling, osteitis deformans, mosaic woven bone, never spreads to new bones) → epidemiology (rare <40, 1–2% over 55, M>F, geographic clustering, falling incidence, rare in India) → aetiology (SQSTM1/p62 plus putative paramyxovirus) → three phases with radiological correlates → distribution (pelvis, spine, femur, skull, tibia) → 70–80% asymptomatic; bone pain, deformity, warmth → complications by the BONE PAIN mnemonic → investigations (ALP, normal Ca/PO_4/PTH; X-ray to confirm, bone scan to map) → indications to treat → single 5 mg IV zoledronate → monitoring and adjunctive care → close with PRISM-EZ.

EXTRA RECALL BOX — THE METABOLIC BONE DISEASE TABLE (KANE'S), AND THE INDIAN CONTEXT

This table answers half the metabolic bone questions in the paper and should be reproduced verbatim:

Disease	Calcium	Phosphate	Alkaline phosphatase	PTH
Hyperparathyroidism	High	Low / normal	High / normal	High
Osteomalacia	Low / normal	Low	High / normal	High
Hyperthyroidism	High	High	High / normal	Low
Osteoporosis	Normal	Normal	Normal	Normal / high
Paget's disease	**Normal / high**	**Normal / high**	**HIGH**	**NORMAL**

Indian context. Paget's disease is **genuinely rare in India and in people of Indian origin**, and the few reported series come mainly from western India. Therefore, in an older Indian patient with an **isolated raised alkaline phosphatase**, the far more likely diagnoses are **osteomalacia** (very common — low vitamin D, low or normal calcium, low phosphate, raised PTH), **hepatobiliary disease**, and **skeletal metastases** (breast, prostate, lung) — and this differential, worked through the table above, is what earns the marks. Practical Indian points: **vitamin D deficiency must be corrected before any potent bisphosphonate**; zoledronic acid is available and affordable as a generic; and joint replacement for secondary osteoarthritis is covered under **AB-PMJAY**.

Exam One-Liners

- Alternative name — **osteitis deformans**.
- Histological hallmark — **mosaic pattern of irregular cement lines in woven bone**.
- Commonest gene — **SQSTM1 (p62)**, P392L mutation.
- Commonest site — **pelvis**.
- Skull lytic sign — **osteoporosis circumscripta**; sclerotic sign — **"cotton wool" skull**.
- Long-bone lytic sign — **"blade of grass" / flame-shaped front**; fracture — **transverse "chalk-stick"**.
- Biochemistry — **high ALP with normal calcium, phosphate and PTH**.

- X-ray confirms the diagnosis; **bone scan defines the extent**.
- Drug of choice — **single 5 mg IV zoledronic acid**.
- Feared malignant complication — **osteosarcoma (<1%)**.
- Cardiac complication — **high-output cardiac failure** from arteriovenous shunting.
- Current treatment principle — **treat symptoms, not the alkaline phosphatase**.

PART VIII

Pressure Injury and Prescribing Safety

Two geriatric syndromes of iatrogenesis — the injury that marks quality of nursing care, and the prescribing that causes more admissions than any single disease.

Question 28. Pressure ulcers — staging and management

15 MARKS RECURRING

ANSWER

Textbook Core — 10 Points

1. **Definition.** Localised injury to skin and/or underlying tissue, usually over a **bony prominence**, resulting from **sustained pressure, or pressure in combination with shear**. The current NPUAP/NPIAP term is **"pressure injury"**, which better reflects that damage can occur under intact skin.
2. **Pathogenesis.** Sustained pressure exceeding **capillary closing pressure** causes tissue ischaemia. **Shearing forces** — for example when the head of the bed is elevated and the torso slides down, transmitting force to the sacral area — stretch and angulate subcutaneous tissues, leading to **thrombosis of small blood vessels** and destruction of skin from beneath. **Friction** from repeated movement across sheets increases shear, and both are worsened by the **loose, folded skin** that is common in the elderly from loss of subcutaneous tissue and dehydration. **Moisture** from bathing, sweat, urine and faeces compounds the damage.
3. **Sites. More than 90% of pressure ulcers occur in the lower body** — mainly the **sacral and coccygeal areas, the ischial tuberosities and the greater trochanter**; also heels, malleoli and occiput. Critically, **the area of damage beneath the ulcer can be much larger than the visible ulcer**, because pressure and shear are transmitted to deeper subcutaneous tissues.
4. **Risk factors.** Being **bed- or chair-bound**, inability to reposition without assistance, difficulty with ambulation, history of **stroke**, **faecal incontinence**, low body weight, **lymphopenia**, difficulty with independent feeding, impaired nutritional intake, **non-blanchable erythema of intact skin (a Stage 1 injury)**, and dry sacral skin. **Advanced age has NOT been identified as an independent risk factor** — it is the coexisting impairments in mobility, nutrition and skin health that create risk.
5. **Risk assessment.** Commonly used tools are the **Braden, Norton and Waterlow scales**. Current recommendation: apply a risk-assessment tool **on admission to a facility and regularly thereafter**. Because pressure injury shares risk factors with falls, incontinence and functional dependence, **multifactorial interventions delivered by a multidisciplinary team** are effective, just as for other geriatric syndromes.
6. **Staging (NPIAP). Stage 1** — acute inflammatory response limited to the epidermis; **intact skin with non-blanchable erythema** persisting more than 30 minutes; may look red, blue or purple in darker skin; skin unbroken; often over a bony prominence. **Stage 2** — extension through the dermis to the junction of subcutaneous fat; a **blister, abrasion or shallow ulcer** with distinct edges. **Stage 3** — **full-thickness** loss through subcutaneous fat, down to but not through fascia; presents as a **crater with undermining**; base often necrotic and foul-smelling. **Stage 4** — extension through deep fascia, with **bone, tendon or muscle visible**; extensive undermining and **sinus tracts**; **osteomyelitis and septic arthritis** may be present. **Unstageable** — base obscured by slough or eschar. **Deep tissue pressure injury** — persistent non-blanchable deep red, maroon or purple discolouration, or a blood-filled blister.
7. **Staging rules the examiner will test. Medical device-related pressure injuries are staged**, and often **conform to the shape of the device**. **Pressure injuries of mucous membranes are NOT staged** — they are documented only. **Reverse staging is inaccurate for assessing healing**; instead use the validated **PUSH tool (Pressure Ulcer Scale for Healing)**, which scores **size, exudate amount and tissue type** and is sensitive to change over time.
8. **Prevention — the highest-yield section. Identify patients at risk**; **decrease pressure, friction and skin folding**; regular repositioning; use **support surfaces** — non-powered (foam, gel, air or water overlays and mattresses) or powered (alternating-pressure surfaces, which are far more costly); **keep skin clean and dry**; **avoid excessive bed rest — optimise and encourage function**; **avoid over-sedation**; and provide **adequate nutrition and hydration: 30–35 kcal/kg/day, protein 1–1.5 g/kg/day and fluid 1 mL/kcal**.
9. **Management of Stage 1 and 2.** Apply **all preventive measures** to stop progression, plus intensive local skin care. **Clean with warm normal saline or water**; avoid pressure and moisture; **cover open wounds with an occlusive dressing** selected on the basis of granulation and necrotic tissue, type and amount of drainage, surrounding tissue and evidence of infection; prevent further injury and infection, **using antibiotics very judiciously**; and **manage the associated pain**. No single local technique is superior to another — **the important factor is the attention the skin receives, above all relief from pressure**.
10. **Management of Stage 3 and 4. Debride necrotic tissue** — autolytic, chemical/enzymatic, mechanical, sharp or surgical; **undermine and remove eschar** if it is hiding necrotic or infected tissue; **irrigate and cleanse two to three times daily** and dress the wound. **Stage 3** — **routine wound swabs are not warranted** (they grow multiple organisms, miss anaerobes and reflect colonisation, not infection); systemic antimicrobials do not reach adequate concentration in the ulcer and should be reserved for **confirmed bacteraemia, sepsis, osteomyelitis or cellulitis**. **Stage 4** — take a **tissue or bone biopsy for aerobic and anaerobic culture**, give systemic antimicrobials, and obtain **surgical consultation for possible flap repair**. Manage pain at every stage.

Latest Updates (2023 – present)

11. The **EPUAP/NPIAP/PPPIA International Clinical Practice Guideline** and its subsequent implementation updates recommend **prophylactic multilayer silicone foam dressings** over the sacrum and heels in high-risk patients (strong evidence for prevention in ICU and emergency transport), **repositioning every 2–4 hours matched to the support surface and the individual** rather than a rigid 2-hourly rule, and **sub-epidermal moisture (SEM) measurement** to detect impending damage **before visible erythema appears**.
12. On adjunctive therapies, the current evidence base is clear: **high-protein oral nutritional supplements enriched with arginine, zinc and antioxidants accelerate healing of Stage 2–4 ulcers**, whereas there is **insufficient evidence for hyperbaric oxygen, topical oxygen or biological dressings**, and only limited evidence for platelet-derived growth factor. **Preventing pressure injury and managing the underlying causes — rather than focusing on topical dressings — remains what is most likely to be effective.**

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
Terminology	Pressure sore/ulcer, Stages I–IV	Pressure injury, Stages 1–4 plus Unstageable and Deep Tissue Pressure Injury	Use current terms; mention the old ones once
Assessing healing	Staging	Never reverse-stage; use the PUSH tool	Certain viva question
Cleansing	Saline or peroxide	Normal saline or potable water; avoid cytotoxic antiseptics on granulating tissue	Say "saline, not antiseptic"
Repositioning	Regular repositioning	Every 2–4 hours, individualised to the support surface	Do not quote a rigid 2-hourly rule
Prophylactic dressings	Not described	Multilayer silicone foam over sacrum and heels in high-risk patients	High-value latest-update line

MNEMONIC ANCHOR

Risk factors = **"PRESSURE"** → **P**ressure and immobility · **R**educed nutrition and low body weight · **E**lderly friable skin · **S**ensory loss (stroke, neuropathy) · **S**hear and friction · **U**rinary and faecal incontinence (moisture) · **R**educed perfusion (anaemia, peripheral vascular disease, hypotension, lymphopenia) · **E**xisting Stage 1 erythema.

NUMERICAL ANCHORS

>90% occur in the lower body · Stage 1 erythema persists >30 minutes · reposition every 2–4 hours · energy **30–35 kcal/kg/day** · protein **1–1.5 g/kg/day** · fluid **1 mL/kcal** · irrigate 2–3 times daily · PUSH tool scores 3 components (size, exudate, tissue type).

NAMED EXAMINER TRAPS

(a) Never reverse-stage a healing ulcer — a Stage 4 that improves is a "healing Stage 4". **(b) Mucosal pressure injuries are not staged. (c)** Do **not** send routine wound swabs — they reflect colonisation. **(d)** Systemic antibiotics do **not** penetrate a Stage 3 ulcer — reserve them for cellulitis, osteomyelitis or sepsis. **(e) Advanced age is not an independent risk factor. (f)** Do not debride a **stable, dry, adherent eschar on an ischaemic heel** — it acts as a biological dressing. **(g)** Unstageable means you cannot see the base — it is not a separate depth.

15-SECOND ANSWER SKELETON

Define (pressure ± shear over a bony prominence) → pathogenesis (capillary closure, shear, friction, moisture) → sites >90% lower body → risk factors and Braden/Norton/Waterlow on admission → the four stages plus unstageable and DTPI → staging rules (devices staged, mucosa not, no reverse staging, PUSH tool) → prevention bundle with nutrition figures → Stage 1–2 management → Stage 3–4 debridement and the culture/antibiotic rules → silicone foam and nutrition updates → "prevention beats dressings".

EXTRA RECALL BOX

Pressure injury is a geriatric syndrome, sharing risk factors with falls, incontinence and functional dependence — which is why **multidisciplinary, multicomponent intervention** works, exactly as in delirium prevention. Two further points examiners like: **(i) an unavoidable pressure injury** is a recognised concept at the end of life (Kennedy terminal ulcer) — documentation and comfort, not blame, is the response; and **(ii) pressure injuries are a recognised marker of quality of care and of elder neglect** — in India, an unexplained Stage 3–4 sacral ulcer in a dependent older person should trigger consideration of **neglect under the Maintenance and Welfare of Parents and Senior Citizens Act, 2007**, and referral through **Elder Line 14567**.

Exam One-Liners

- Definition — injury from **pressure, or pressure with shear**, over a bony prominence.
- Commonest sites — **sacrum, ischial tuberosity, greater trochanter, heel**.

- Stage 1 — **non-blanchable erythema of intact skin**.
- Stage 4 — **bone, tendon or muscle visible**.
- Risk tools — **Braden, Norton, Waterlow**.
- Healing tool — **PUSH**; never reverse-stage.
- Nutrition — **30–35 kcal/kg, protein 1–1.5 g/kg, fluid 1 mL/kcal**.
- Single most effective measure — **relief of pressure**.

Question 29. Beers criteria, STOPP/START and anticholinergic burden 15 MARKS

RECURRING

ANSWER

Textbook Core — 10 Points

1. **The three forms of suboptimal prescribing. Overuse** (drugs without a valid indication), **misuse** (potentially inappropriate medications, wrong dose or inadequate monitoring) and **underuse** (omission of indicated, beneficial drugs). **Polypharmacy** — conventionally five or more drugs — is the principal modifiable driver of adverse drug reactions, together with the **number of comorbid conditions and the number of prescribers**.
2. **Scale of the problem.** In the **Three-City (3C) study**, representative of community-dwelling French adults aged 65 and over, **21.7% were receiving an inappropriate medication** — **6.4% an anticholinergic** and **9.2% a long half-life benzodiazepine**. European studies using Beers or McLeod lists report rates of **10–20%**; a French geriatric short-stay unit found **66% had at least one inappropriate medication on admission**. Rates in **nursing homes are much higher** and are linked to hospitalisation and death. Commonly implicated: cerebral vasodilators, long half-life benzodiazepines, anticholinergic antidepressants, and two or more psychotropics of the same class; also PPIs continued without indication and antipsychotics over-prescribed in nursing homes.
3. **Beers criteria — what they are.** An **explicit list**, first developed by **Mark Beers in 1991** for institutionalised older people using a literature review and **Delphi method**, since adapted for ambulatory patients and **updated regularly by the American Geriatrics Society**. It applies to adults **≥65 years in ambulatory, acute and institutional settings — but not in hospice or end-of-life care**.
4. **Structure of the Beers criteria.** Five core tables plus supporting tables: **(i)** potentially inappropriate medications to avoid in most older adults; **(ii)** PIMs to avoid because of **drug–disease or drug–syndrome interactions**; **(iii)** drugs to **use with caution**; **(iv)** clinically important **drug–drug interactions** to avoid; **(v)** drugs to avoid or **dose-adjust for reduced kidney function**; plus a table of **drugs with strong anticholinergic properties**. Classic examples: benzodiazepines and Z-drugs (falls, fractures, delirium), first-generation antihistamines, tricyclic antidepressants, antipsychotics for behavioural symptoms of dementia (increased stroke and mortality), NSAIDs, skeletal muscle relaxants, sliding-scale insulin, and PPIs beyond 8 weeks without indication.
5. **Limitations of the Beers criteria.** It was designed for **collective (population and quality-indicator) evaluation, not for individual patients** — a criticism Beers himself accepted. It **does not cover underuse**; it is **US-specific**, and in one European study about **half the listed medications were unavailable in most European countries**; and **few studies have demonstrated a clinical benefit** from applying the criteria. Some analyses found Beers-listed drugs account for only a small proportion of actual ADRs.
6. **The drugs that actually cause harm.** In Budnitz *et al.*, only **3.6%** of emergency admissions for adverse drug events involved drugs "always inappropriate" by Beers and 5.2% those inappropriate in certain conditions, whereas **33.3% followed just three drugs — warfarin (17.3%), insulin (13%) and digoxin (3.2%)**. Pirmohamed *et al.* similarly implicated **low-dose aspirin, diuretics, warfarin and NSAIDs**. The lesson: **encourage good prescribing and monitoring rather than merely stigmatising "inappropriate" drugs** — most avoidable errors occur at the **monitoring stage (60–80%)**.
7. **STOPP and START.** Developed by **Irish geriatricians using a Delphi method** and organised **by physiological system**, which makes them more usable at the bedside. **STOPP** = Screening Tool of Older Persons' Prescriptions — detects potentially inappropriate prescriptions. **START** = Screening Tool to Alert to Right Treatment — detects **prescribing omissions**. In 715 older patients admitted acutely, an ADR was identified in 90 (12.5%), of which **STOPP identified 91% versus 48% for Beers**; STOPP-detectable prescriptions contributed to **11.5% of admissions versus 6% for Beers**. STOPP is therefore especially useful when the presentation is non-specific, such as **falls or delirium**.
8. **START and the problem of underuse.** Applied to 600 acutely admitted patients over 65, **at least one potentially useful medication had been omitted in 57.9%**, rising to **72.2% in those over 85**, with **women at twice the risk of men**. The omissions were mainly cardiovascular: **statins in atherosclerotic disease (26%), anticoagulants in atrial fibrillation (9.5%), antiplatelets in arterial disease (7.3%), and calcium and vitamin D in osteoporosis with fracture (6%)**. START takes **under 3 minutes** to apply once the list of conditions and treatments is available.
9. **Anticholinergic burden.** The **cumulative anticholinergic effect of multiple drugs**, each individually regarded as only mildly anticholinergic. **Peripheral effects**: dry mouth, blurred vision, constipation, urinary retention, tachycardia, reduced sweating and heat intolerance. **Central effects**: sedation, confusion, **delirium, falls and accelerated cognitive decline**. Older adults are more susceptible because of reduced central cholinergic reserve, increased blood–brain barrier permeability, and reduced hepatic and renal clearance. Common culprits: **amitriptyline, oxybutynin and tolterodine, chlorpheniramine, hydroxyzine, promethazine, olanzapine and clozapine, hyoscine, dicyclomine, trihexyphenidyl, prochlorperazine**. Quantify with the **Anticholinergic Cognitive Burden (ACB) scale**, Anticholinergic Risk Scale or Anticholinergic Drug Scale — an **ACB score ≥3** is associated with cognitive decline, falls and mortality. Prescribing an antimuscarinic bladder drug alongside a **cholinesterase inhibitor** is a classic **prescribing cascade** and a pharmacological contradiction.
10. **Other tools and the practical approach.** The **Medication Appropriateness Index (MAI)** is an **implicit** tool that evaluates **ten criteria for each drug**: indication, efficacy, dosage, correct directions, practical directions, drug–drug interactions, drug–disease interactions, duplication, duration and cost. A workable **deprescribing sequence**: **(i)** list

every drug including OTC and herbal preparations, **(ii)** confirm a current indication for each, **(iii)** apply STOPP/START and Beers, **(iv)** calculate the anticholinergic burden, **(v)** rank by risk–benefit against the patient's goals and life expectancy, **(vi)** withdraw **one drug at a time**, tapering where withdrawal effects are expected, and **(vii)** monitor for withdrawal syndromes and disease recurrence.

Latest Updates (2023 – present)

11. **2023 AGS Beers Criteria update** (*J Am Geriatr Soc* 2023;71:2052–81) — key changes: **avoid initiating aspirin for primary cardiovascular prevention**, and **consider deprescribing** it in existing users; **avoid warfarin as initial therapy** for VTE or non-valvular atrial fibrillation (DOACs preferred; **rivaroxaban avoided**); **avoid ALL sulfonylureas**; **use SGLT2 inhibitors with caution** (euglycaemic ketoacidosis, urogenital infection); **avoid initiating oral or transdermal oestrogen**; anticholinergics reorganised into **antihistamine, CNS/antiparkinson and gastrointestinal** groups with explicit emphasis on **cumulative anticholinergic burden**; ticagrelor and skeletal muscle relaxants added; ~28–33 rarely used drugs removed; and a caution added **against abruptly stopping digoxin in HFrEF**. AGS also published an **"Alternative Treatments" companion (JAGS 2025)** giving safer pharmacological and non-pharmacological substitutes.
12. **STOPP/START version 3 (2023, *Age and Ageing*)** expanded the tool to **133 STOPP and 57 START criteria**, with new sections covering **antithrombotics, drugs that add to anticholinergic burden, drugs that predictably worsen frailty and falls, and drugs to avoid in limited life expectancy**. Meanwhile the **OPERAM** and related multicentre trials show that structured medication review reduces drug-related hospital admissions **only when the recommendations are actually implemented — implementation, not detection, is now the bottleneck**.

Current Practice Update

Item	Textbook	Current recommendation	Exam approach
Aspirin	Widely used; a common cause of ADR	2023 Beers: avoid initiating for primary prevention; consider deprescribing	Quote it as a named 2023 change
Anticoagulation	Warfarin standard; a leading ADR cause	Avoid warfarin as initial therapy; DOAC preferred, rivaroxaban avoided	Pair with "warfarin caused 17.3% of ADR admissions"
Sulfonylureas	Not specifically restricted	Avoid all sulfonylureas; SGLT2 inhibitors with caution	High-yield diabetes overlap
STOPP/START	2008 version, 65 STOPP / 22 START	Version 3 (2023): 133 STOPP / 57 START	Quote both versions and the numbers
Anticholinergics	Considered drug by drug	Cumulative burden quantified (ACB); target a score below 3	Name the scale and the threshold

MNEMONIC ANCHOR

"STOPP the wrong · START the missing · SCORE the anticholinergics." And for the deprescribing sequence: **"LIST – INDICATION – SCREEN – SCORE – RANK – ONE AT A TIME – MONITOR."**

NUMERICAL ANCHORS

Polypharmacy ≥5 drugs · Beers applies from age 65 · Three-City 21.7% inappropriate (6.4% anticholinergic, 9.2% long-acting benzodiazepine) · 66% of geriatric short-stay admissions had ≥1 PIM · STOPP detected 91% vs Beers 48% of ADRs · admissions attributable 11.5% vs 6% · omission in 57.9%, rising to 72.2% over 85 · MAI has 10 criteria · STOPP/START v3 = 133 + 57 · ACB threshold ≥3 · warfarin 17.3%, insulin 13%, digoxin 3.2% of ADR admissions.

NAMED EXAMINER TRAPS

(a) Beers is **US-specific** and **excludes hospice and end-of-life care**. **(b)** Remember that **START is about underuse** — candidates routinely forget it. **(c)** "Potentially inappropriate" is **not** "absolutely contraindicated" — it requires clinical judgement and shared decision-making. **(d) Do not abruptly stop digoxin** in a current user with HFrEF (2023 Beers caveat). **(e)** The drugs causing the most ADR admissions — warfarin, insulin, digoxin, antiplatelets — are largely **NOT** on the Beers list, so the criteria are a supplement to, not a substitute for, good monitoring. **(f)** Most avoidable errors occur at the **monitoring** stage, not the prescribing stage.

15-SECOND ANSWER SKELETON

Three types of suboptimal prescribing (overuse, misuse, underuse) → scale of the problem with figures → Beers: origin, Delphi, ≥65, five tables, examples → limitations of Beers → what actually causes ADRs (warfarin, insulin, digoxin) → STOPP/START: system-based, detects underuse, better ADR yield with figures → anticholinergic burden: mechanism, culprits, ACB ≥3, prescribing cascade → MAI and the seven-step deprescribing sequence → 2023 Beers changes and STOPP/START v3.

EXTRA RECALL BOX — INDIAN CONTEXT

Indian-specific prescribing hazards for the older adult: widespread **over-the-counter availability** of antibiotics, NSAIDs and benzodiazepines despite **Schedule H1**; heavy use of **irrational fixed-dose combinations**; concurrent **AYUSH and allopathic** prescribing with unrecognised interactions (for example ashwagandha with sedatives, or bhasma preparations with heavy-metal content); multiple prescribers with no shared record; and cost-driven **non-adherence and self-tapering**. Practical answer points: use a **single reconciled medication list at every transition of care**, engage the family caregiver, prefer once-daily and fixed-dose regimens for adherence in the frail, and note that **no Indian consensus PIM list has been formally adopted nationally** — Beers and STOPP/START are used with local adaptation, since many listed drugs differ in availability.

Exam One-Liners

- Polypharmacy — **≥5 medications**.
- Beers — **explicit** list, AGS, age ≥65, not for hospice.
- STOPP — inappropriate prescriptions; **START — prescribing omissions**.
- STOPP versus Beers for detecting ADRs — **91% versus 48%**.
- MAI — **implicit** tool, **10 criteria per drug**.
- Anticholinergic scale and threshold — **ACB ≥3**.
- 2023 Beers headline change — **avoid aspirin for primary prevention**.
- Latest tool version — **STOPP/START v3 (133 + 57)**.

APPENDIX

Consolidated Night-Before Master Sheets

The three original rapid-recall grids, retained in full. Question numbers in these sheets refer to the original question sets; use the Table of Contents to map them to the numbering used in this volume.

Night-Before Master Sheet — Questions 63 to 75

A. The single highest-yield line for each topic

Q	Topic	The one sentence that earns the mark
63	Herpes zoster / PHN	Antiviral within **72 hours for 7 days**; PHN = pain beyond **3 months**; prevention is the **recombinant zoster vaccine from age 50**.
64	CAUTI	All chronic catheters are bacteriuric — **treat the patient, not the culture**; the best prevention is **early removal**.
65	Asymptomatic bacteriuria	**Do not screen and do not treat**, except before urological procedures with mucosal bleeding.
66	IPC and AMS	**Hand hygiene** is the most effective IPC measure; **NAP-AMR 2.0 (2025–29)** makes IPC mandatory in every Indian facility.
67	Leptospirosis and dengue	In dengue the elderly die of **fluid overload as often as of shock**; in leptospirosis, **doxycycline early, dialysis early**.
68	COVID-19	**Delirium and silent hypoxia** are the presentations to know; antiviral within **5 days**, steroids only if hypoxic.
69	PMR	Girdle pain with a **normal CK** and a **dramatic response to 12.5–25 mg prednisolone**; watch for **GCA**.
70	Psoriatic arthropathy	**Seronegative** arthritis with **dactylitis, enthesitis, nail disease and pencil-in-cup**; avoid JAK inhibitors over 65.
71	Systemic vasculitides	**GCA above 50, MPA at 65–75**; start steroids before the biopsy; **infection kills more older patients than the vasculitis**.
72	Sjögren's syndrome	**Anti-Ro/La**, Schirmer ≤5 mm, focus score ≥1; the commonest cause of dry mouth in an older person is a **drug**.
73	Osteoporosis / DEXA / FRAX	**T ≤ −2.5**; FRAX gives 10-year probability; **never stop denosumab** without a follow-on bisphosphonate.
74	Pressure ulcers	Four stages plus **unstageable and DTPI**; **never reverse-stage**; prevention beats dressings.
75	Beers / STOPP-START / ACB	**STOPP the wrong, START the missing, score the anticholinergics (ACB ≥3)**.

B. Steroid-sparing agents — the whole rheumatology block on one line each

Condition	First line	Steroid-sparing / advanced
Polymyalgia rheumatica	Prednisolone 12.5–25 mg/day	**Sarilumab** preferred (EULAR 2025); tocilizumab; methotrexate
Giant cell arteritis	Prednisolone 40–60 mg (IV if visual loss)	**Tocilizumab** or **upadacitinib 15 mg** (SELECT-GCA: 46% vs 29%)
ANCA-associated vasculitis	Steroids + **rituximab** (preferred in elderly)	**Avacopan**; reduced-dose steroid regimen (PEXIVAS)
Psoriatic arthritis	Methotrexate (peripheral only)	**IL-17 / IL-23 inhibitors**; apremilast if frail; avoid JAKi over 65
Sjögren's syndrome	Symptomatic + hydroxychloroquine	Rituximab for systemic disease; ianalumab / nipocalimab emerging

C. Numbers most likely to be asked

Number	What it belongs to
72 hours / 7 days / 3 months	Zoster antiviral window, course, PHN definition
51% and 66%	Zostavax reduction in herpes zoster and PHN
≥10^5 CFU/mL	Significant bacteriuria (voided specimen)
45 minutes / >40 mm/h / >75 mm/h	PMR morning stiffness; PMR ESR; ESR raising suspicion of GCA

12.5–25 mg vs 40–60 mg	Prednisolone in PMR vs GCA
16–21%	PMR patients who develop GCA
46% vs 29%	SELECT-GCA sustained remission, upadacitinib vs placebo
T ≤ −2.5 / −1 to −2.5 / ≤ −3.0	Osteoporosis / osteopenia / very high risk threshold
800–1200 mg and 800–1000 IU	Daily calcium and vitamin D
5 years oral / 3 years IV	Bisphosphonate review point before a drug holiday
30–35 kcal/kg, 1–1.5 g/kg protein, 1 mL/kcal	Nutrition target in pressure injury
>90% / >30 minutes / 2–4 hourly	Lower-body ulcers, Stage 1 erythema, repositioning interval
91% vs 48%	STOPP vs Beers detection of ADRs
57.9% and 72.2%	Prescribing omission, all ages ≥65 and over 85
133 + 57 / ACB ≥3	STOPP/START v3 criteria; anticholinergic burden threshold

D. Indian policy and programme hooks to drop into any answer

Programme / instrument	Where it fits
NAP-AMR 2.0 (2025–2029), launched 18 Nov 2025	CAUTI, asymptomatic bacteriuria, IPC and stewardship (Q64, 65, 66)
ICMR AMRSN and ICMR AMSP guidelines	Hospital antibiogram, stewardship programme structure (Q66)
NCVBDC dengue and leptospirosis programmes; **TAK-003 approved 2026 for ages 4–60**	Dengue and leptospirosis (Q67)
NPHCE — geriatric clinics, district and regional geriatric centres	Vaccination access, falls and osteoporosis services, chronic care (Q63, 68, 73)
ISBMR position statements; **Indian FRAX** model; **ICMR-NIN** calcium recommendation	Osteoporosis (Q73)
MWPSC Act 2007 and **Elder Line 14567**	Neglect presenting as a Stage 3–4 pressure injury (Q74)
Schedule H1; AYUSH–allopathy co-prescribing; irrational fixed-dose combinations	Prescribing safety and stewardship (Q66, 75)
AB-PMJAY, **Rashtriya Vayoshri Yojana**, **ADIP-ALIMCO**	Financing of fracture surgery, mobility and assistive devices (Q73, 74)

FIVE SENTENCES WORTH MEMORISING VERBATIM

1. "Bacteriuria in older persons is common and usually asymptomatic; in the absence of obstructive uropathy there is no evidence to support routine antimicrobial therapy."
2. "Advanced age has not been identified as an independent risk factor for pressure injury — it is the coexisting impairments in mobility, nutrition and skin health that create the risk."
3. "Polymyalgia rheumatica is a totally reversible cause of frailty that is often misdiagnosed; corticosteroids reverse the frailty it produces."
4. "Prevention and managing the underlying causes, rather than focusing on topical dressings, is most likely to be effective in pressure injury."
5. "It is more relevant to encourage good prescribing practices with the aim of reducing avoidable iatrogenic events than to stigmatise inappropriate treatments."

Night-Before Master Sheet — Questions 168 and 169

A. The one sentence per topic

Q	Topic	The sentence that earns the mark
168	Paget's disease	Focal disorder of remodelling with **high ALP but normal calcium, phosphate and PTH**; X-ray confirms, bone scan maps; **single 5 mg IV zoledronate**; **treat symptoms, not the alkaline phosphatase**.
169	Late-onset RA	**SALADS** — sex ratio 1:1, acute onset, large proximal joints, seronegative, higher disease activity, systemic features; **under-treated, not treatment-resistant**.

B. Numbers most likely to be asked

Number	What it belongs to
1–2% over 55; rare below 40; M:F 3:2	Paget's disease epidemiology
SQSTM1 in 40–50% familial, 5–10% sporadic	Paget's genetics; P392L mutation
70–80% asymptomatic; osteosarcoma <1%	Paget's presentation and worst complication
>15–20% of skeleton	Threshold for high-output cardiac failure
Zoledronate 5 mg once; remission ~90%; retreat ≥12 months	Paget's drug of choice
Risedronate 30 mg × 2 months; alendronate 40 mg × 6 months	Oral alternatives in Paget's
Onset ≥60 (or 65); one-third of RA	LORA definition and burden
F:M 3:1 versus ~1:1	YORA versus LORA sex ratio
PMR-like in ~25%; >20% of PMR reclassified	LORA phenotypes and the PMR overlap
ACR/EULAR 2010 score ≥6/10; eGFR <30	RA classification; methotrexate cut-off

C. Two trials and two guidelines to name

Trial / guideline	What to say about it
PRISM / PRISM-EZ	Intensive bisphosphonate therapy to normalise turnover gave **no reduction in fracture, orthopaedic surgery, deafness or quality of life**, with a signal of harm — **treat symptoms, not the number**.
ZiPP	Prophylactic zoledronic acid in **SQSTM1 carriers** modified new lesion development but did not change clinical outcomes — genetic screening with pre-emptive treatment is **not routine**.
Endocrine Society / UK Paget's Association	Both name **single 5 mg IV zoledronate** first-line; X-ray to confirm, bone scan to define extent.
ORAL Surveillance	**JAK inhibitors not first-line over 65** — MACE, VTE, malignancy, herpes zoster.

THREE SENTENCES WORTH MEMORISING VERBATIM

1. "Paget's disease may lead to both conductive and sensorineural hearing loss and should be evaluated radiologically and by an alkaline phosphatase determination." (Kane's)
2. "In patients with established Paget's disease of bone, bisphosphonate therapy should focus on control of symptoms rather than suppression of bone turnover." (PRISM-EZ)
3. "Seronegative rheumatoid arthritis is not a mild form of the disease — it requires the same intensive treat-to-target therapy as seropositive disease."

THE LINK BETWEEN THE TWO QUESTIONS

Both are **diseases of bone and joint in old age that are frequently missed because the presentation is constitutional rather than musculoskeletal**. Paget's is usually found through an **isolated raised alkaline phosphatase**; LORA is usually found through **weight loss, fatigue and a very high ESR**. In each case the examiner is testing whether you will **work systematically through the differential — the metabolic bone table for one, the OA-versus-inflammatory-arthritis table for the other — rather than jumping to the diagnosis in the question.**

Night-Before Master Sheet — Questions 103 to 116

A. The single highest-yield line for each topic

Q	Topic	The sentence that earns the mark
103	DOTS and DR-TB	**BPaLM for 6 months** is the preferred MDR/RR-TB regimen; XDR (2021) = pre-XDR + resistance to **bedaquiline or linezolid**.
104	GeneXpert	Cartridge PCR detecting **MTB + rifampicin resistance in 2 hours** via the ***rpoB* hot-spot**; **never use for test of cure**.
105	FUO	In over-65s, **GCA/PMR is the commonest identifiable cause**; the highest-yield "tests" are the **repeated examination and the drug chart**.
106	Shock and septic shock	Septic shock = **vasopressor-dependent MAP <65 plus lactate >2**; **no antibiotic substitutes for source control**.
107	Procalcitonin	**Suppressed by interferon-γ**, so it stays low in viral infection; best proven role is **shortening antibiotic duration**.
108	Cerebral malaria	**IV artesunate 2.4 mg/kg at 0, 12, 24 h then daily**; exclude and correct **hypoglycaemia**; no steroids.
109	Chikungunya	**Lymphopenia** (not thrombocytopenia); **no NSAIDs until dengue is excluded**; chronic arthritis in 40–50%.
110	Scrub typhus	**Hunt for the eschar in hidden moist sites**; doxycycline 100 mg BD with **defervescence in 48 hours**.
111	Ebola	Death is from **hypovolaemic shock, not haemorrhage**; **Ervebo ring vaccination** and **Inmazeb/Ebanga** for Zaire only.
112	*C. difficile*	**Fidaxomicin first-line**; **soap and water, not alcohol gel**; test only diarrhoeal stool, never a test of cure.
113	Influenza	**High-dose/adjuvanted/recombinant vaccine from 65**; oseltamivir **30 mg BD if CrCl 30–60**.
114	Vaccination	**Immunosenescence** drives the schedule: influenza annually, PCV20/21 from 50, RZV ×2 from 50, RSV from 75.
115	Acute pyelonephritis	Classic triad may be absent — **delirium and falls may be the only features**; **white cell casts** mean parenchymal disease.
116	Recurrent UTI	**Vaginal oestrogen first, methenamine second, antibiotics last**; systemic HRT does not work.

B. The geriatric principles that run through the whole module (quote these anywhere)

1. "Febrile response may be blunted or absent in some older individuals with bacterial infections… A poor febrile response may also be a negative prognostic factor." (Kane's)
2. "The absence of leucocytosis in older patients should also not exclude consideration of a bacterial infection." (Kane's)
3. "Hypothermia in older patients should promptly be treated as sepsis unless proven otherwise." (Kane's)
4. "Acute unexplained functional deterioration should alert the physician to a potential acute infectious process." (Kane's)
5. "A useful rule in geriatric care is to suspect tuberculosis when a patient is inexplicably failing." (Kane's)
6. "The frequency of gram-negative bacilli increases in each category" of infection in older adults — so empirical cover must include them. (Kane's)
7. "Bacteriuria in older persons is common and usually asymptomatic… in the absence of obstructive uropathy, no evidence exists to support the routine use of antimicrobial therapy." (Kane's)

C. Numbers most likely to be asked

Number	What it belongs to
BPaLM 6 months; bedaquiline 400 mg → 200 mg thrice weekly	MDR/RR-TB regimen and dosing
81-bp *rpoB*; 2 hours; 16 CFU/mL (Ultra)	GeneXpert target, turnaround, Ultra limit of detection
>38.3 °C, >3 weeks; LTC fever >37.8 °C	FUO definition and its geriatric modification
SOFA ≥2; MAP <65; lactate >2; mortality >40%	Sepsis-3 and septic shock
30 mL/kg in 3 h; antibiotics <1 h; MAP 60–65 if ≥65 y	Septic shock bundle and SSC 2026
Rises 2–4 h, peaks 12–24 h; >0.5 ng/mL	Procalcitonin kinetics and antibiotic threshold

Artesunate 2.4 mg/kg at 0, 12, 24 h; GCS ≤11	Cerebral malaria
Eschar in 20–50%; doxycycline 100 mg BD × 7 d; response in 48 h	Scrub typhus
Incubation 2–21 days; semen persistence ≥18 months	Ebola
WBC ≥15,000 or creatinine >1.5 mg/dL; recurrence 20–25% then 40–60%	*C. difficile* severity and recurrence
HR 0.75 hospitalisation, 0.52 death; oseltamivir 30 mg BD if CrCl 30–60	Influenza vaccine benefit and antiviral dosing
PCV from 50; RZV ×2 from 50; RSV all ≥75	Current adult immunisation schedule
2 in 6 months or 3 in 12 months; methenamine 1 g BD; fluids 1.5 L	Recurrent UTI

D. Indian policy and programme hooks

Programme / instrument	Where it fits
NTEP, Ni-kshay portal, **Ni-kshay Poshan Yojana ₹1000/month**, Pradhan Mantri TB Mukt Bharat Abhiyaan	DOTS and drug-resistant TB (Q103)
Universal drug susceptibility testing; CBNAAT; indigenous **Truenat**	GeneXpert and TB diagnostics (Q103, 104)
NAP-AMR 2.0 (2025–2029); ICMR treatment guidelines and AMRSN	Sepsis, procalcitonin, *C. difficile*, pyelonephritis, recurrent UTI (Q106, 107, 112, 115, 116)
NCVBDC; National Framework for Malaria Elimination; pre-referral rectal artesunate	Cerebral malaria, chikungunya, scrub typhus (Q108–110)
NPHCE geriatric clinics; API / Geriatric Society of India adult immunisation guidance	Vaccination delivery — no adult UIP in India (Q113, 114)
AB-PMJAY and **Ayushman Vay Vandana Card**	Financing of hospitalisation for sepsis, TB and severe infection

THE THREAD THAT LINKS THIS WHOLE MODULE

Every answer in this block turns on the same three geriatric facts: **(i) the febrile and leucocyte responses are unreliable**, so the presentation is delirium, falls and functional decline rather than fever; **(ii) the pathogen spectrum shifts towards Gram-negative organisms**, so empirical cover and local antibiograms matter more; and **(iii) the greatest iatrogenic risks are over-treatment of colonisation, unadjusted drug doses, and fluid overload during resuscitation**. If you open any answer in this module with those three points and close it with the relevant Indian programme, you will have framed it as a geriatrics answer rather than a general medicine one.

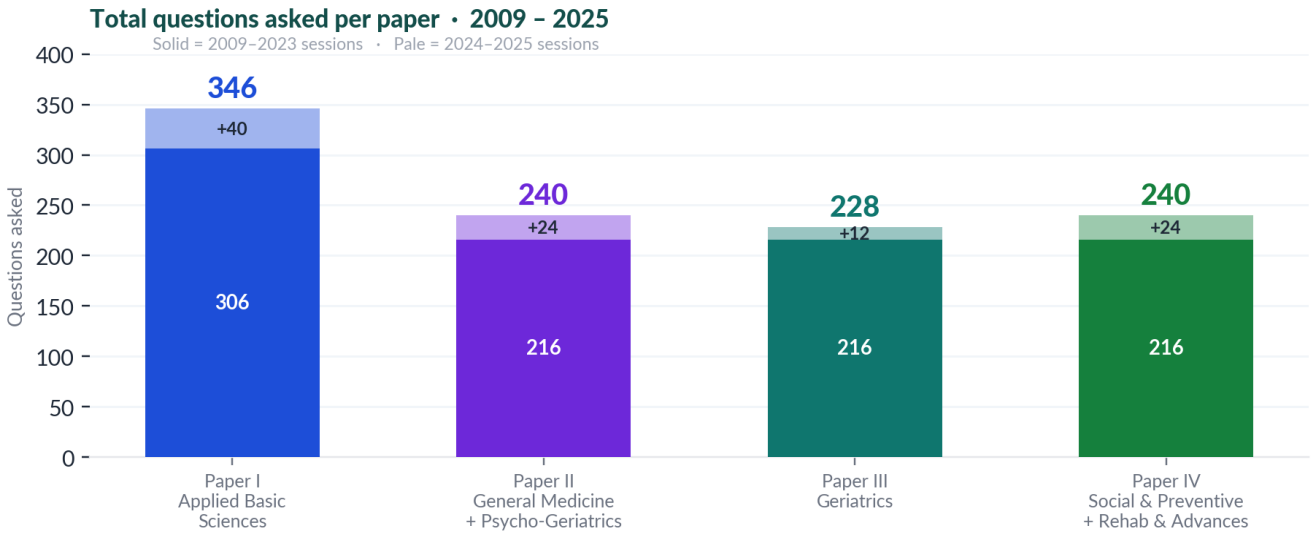
Part A · How this paper is examined

HOW TO READ THIS DOCUMENT



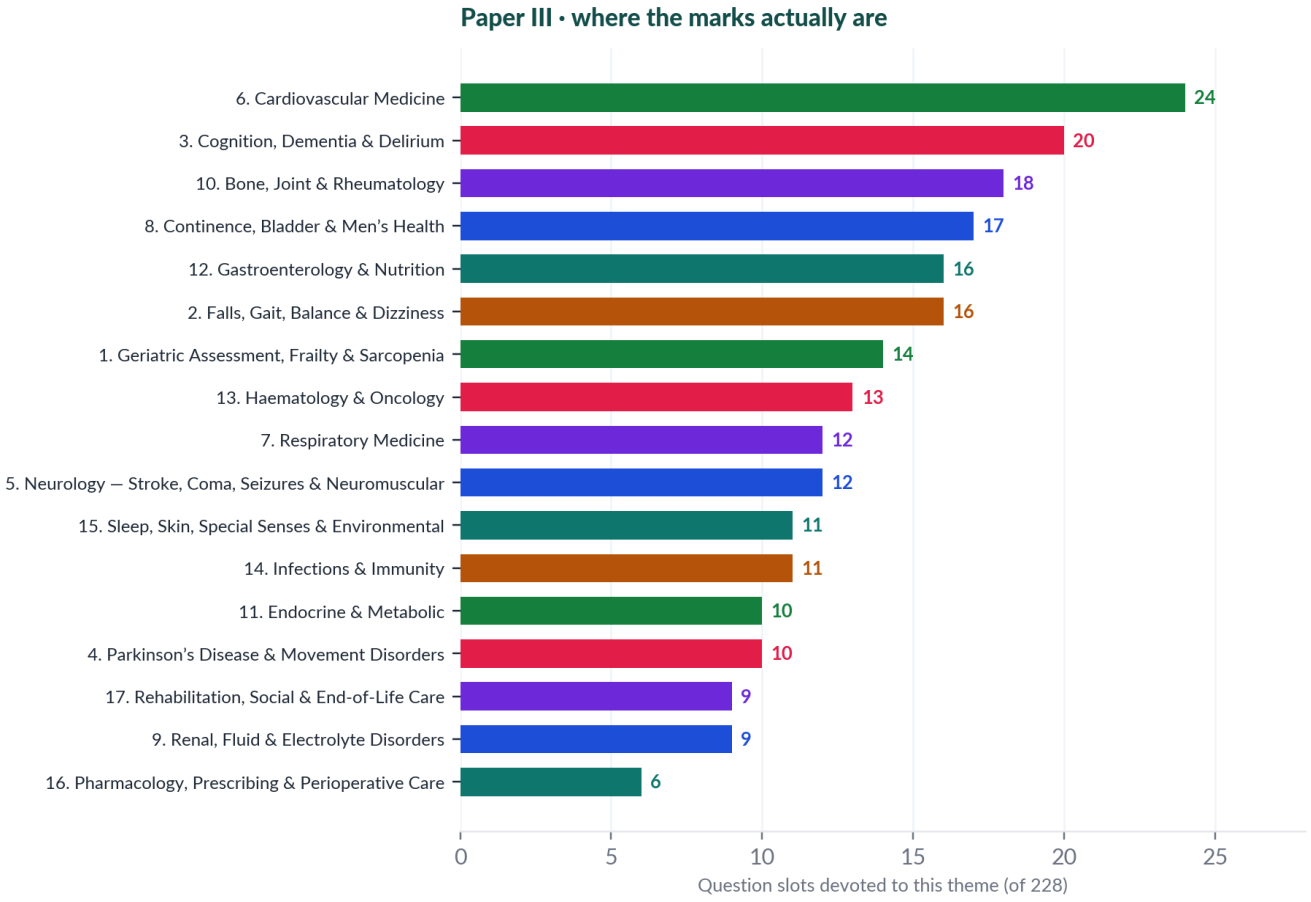
Every question ever set in Paper III between March 2009 and October 2025 has been extracted, merged with the Ebenezer question bank, stripped of year tags and repeats, and re-grouped by system and theme. Nothing has been dropped: the 228 original question slots have each been traced into one of the 181 unique entries in Part B, and the mapping was verified programmatically before this document was generated.

Question counts across all four papers

The four papers do not carry equal question loads. Paper I uses a six-subject short-note format with twenty questions per session, while Papers II, III and IV each use two long essays plus ten short notes — twelve questions per session. Counts below are taken from the question papers available in the source archive.

Paper	Sub. Code	Sessions available	Questions per session	Total questions
Paper I — Applied Basic Sciences	2059 / 4041	17	20 (4+4+3+3+3+3)	**346**
Paper II — General Medicine incl. Psycho-Geriatrics	2056 / 4042	20	12 (2 essays + 10 notes)	**240**
Paper III — Geriatrics	2057 / 4043	19	12 (2 essays + 10 notes)	**228**
Paper IV — Social & Preventive Geriatrics	2060 / 4044	20	12 (2 essays + 10 notes)	**240**
All four papers combined	—	76	—	**1,054**

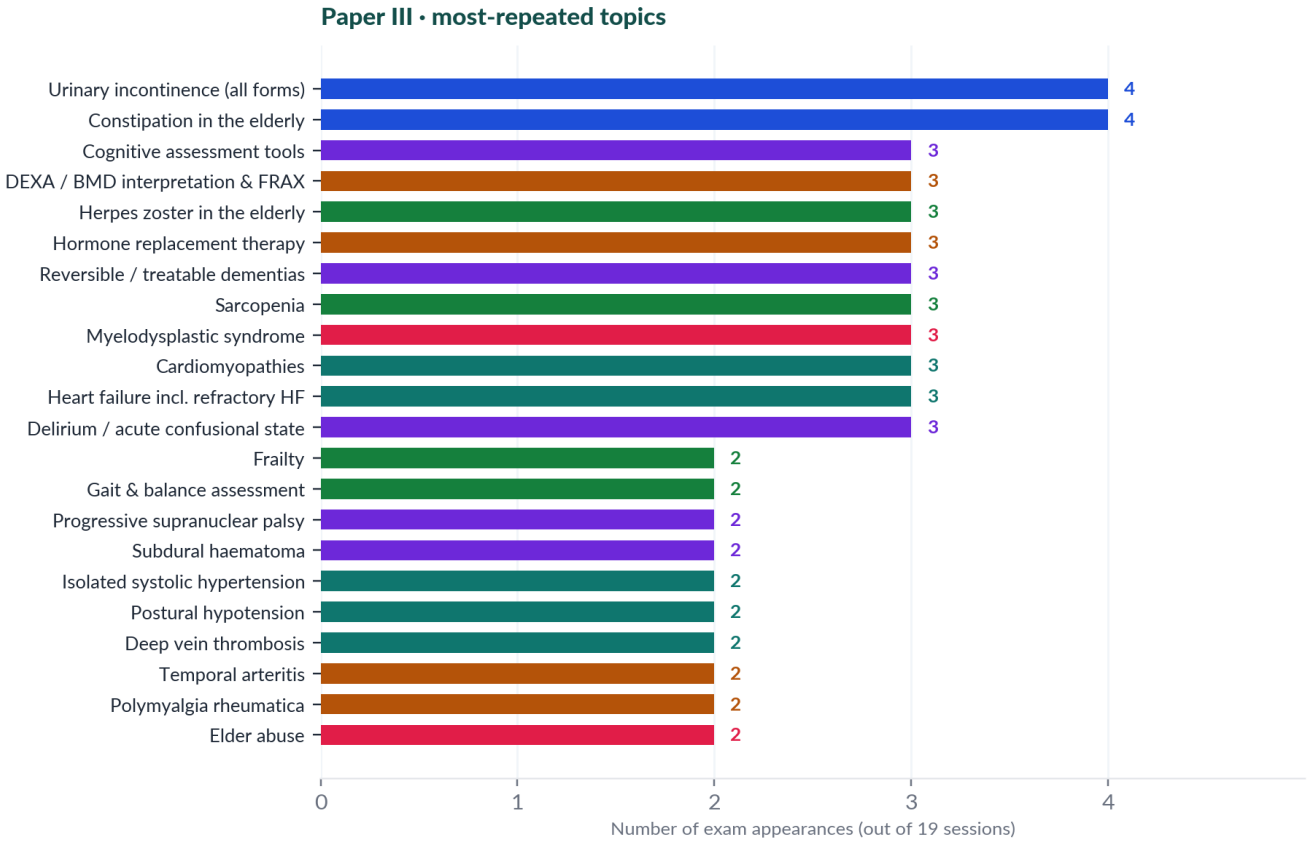
Paper I is missing the October 2013, 2014, 2015 and December 2024 Paper III sessions from the archive; the October 2024 Paper III paper is also absent. Counts reflect what is actually in the source files rather than every session the university has ever conducted.



The Paper III mark scheme

Two formats have been used. Sessions up to March 2010 set two 20-mark essays and ten 6-mark notes. From May 2011 onward the paper has settled into two 15-mark essays and ten 7-mark notes, and this is the format you should calibrate every answer to. Each question in Part B carries its mark-format descriptor so you can size your answers correctly.

Period	Section I	Section II	Answer calibration
2009 – 2010	2 × 20 marks	10 × 6 marks	Historic format — treat 20-mark stems as 15-mark essays
2011 – 2025	2 × 15 marks	10 × 7 marks	Essay: ~11 pages / 35 min. Note: ~4 pages / 10 min



Where the marks actually are

Grouping all 228 question slots by theme shows where this paper actually concentrates. Cardiovascular medicine is the single largest block, and together with cognition and delirium, bone and joint disease, continence, and gastroenterology and nutrition it accounts for close to half the paper. The classical geriatric-syndrome sections — assessment, frailty and falls — are smaller than most candidates expect. Paper III is examined as clinical general medicine seen through a geriatric lens, not as a syndromes paper.

The most-repeated topics

Constipation leads the paper outright with four appearances. Nine further topics have been asked three times each — reversible dementias, sarcopenia, myelodysplastic syndrome, herpes zoster, bone densitometry, hormone replacement therapy, cognitive assessment tools, cardiomyopathy, and the heart-failure cluster. If you prepare nothing else thoroughly, prepare these. The chart counts distinct question slots, so a topic asked once as an essay and twice as a note scores three.

What has changed in the examiner's style

SHIFT 1 · FROM TOPIC LABELS TO NAMED-PATIENT VIGNETTES

Early papers set bare topic labels — "Dementia", "Syncope", "Immobility". Increasingly the examiner builds a patient around the topic: the 75-year-old smoker who became abusive and incoherent on day three of a fever, the 60-year-old on four culprit drugs with recurrent falls, Mr. Alagappan with a PSA of 10 ng/ml, Ms. Ratna asking whether she will inherit her father's Lewy body dementia. Answer in stages — differentials, then investigations, then ward management, then follow-up and counselling.

SHIFT 2 · THE EXAMINER ASKS YOU TO INTERPRET, NOT JUST RECALL

A growing group of questions hands you a test and asks what it means: how the bone mineral density report is interpreted, the FRAX tool, red cell indices, the rise and fall of cardiac enzymes drawn as a graph, BMI cut-offs for Asians. Practise drawing and labelling these — several questions explicitly demand a diagram or a table.

SHIFT 3 · CRITERIA, SCORES AND CLASSIFICATIONS ARE FAIR GAME

Paper III rewards precise instruments: Fried's criteria, clinical frailty scales, GOLD and the ABCD groups, the Mini Nutritional Assessment, FRAX, the WHO classification of myelodysplastic syndrome, the 5 Ms. Learn the actual cut-offs and component lists rather than the general concept.

SHIFT 4 · PRESCRIBING SAFETY HAS BECOME A THEME IN ITS OWN RIGHT

Principles of drug therapy (2013), polypharmacy (2018), drug holiday (2022) and rational prescribing (2023) show a clear and strengthening line of interest, reinforced by drug-induced renal impairment, drug-induced thrombocytopenia and atypical femur fractures due to drugs. Know Beers, STOPP/START, anticholinergic burden and the prescribing cascade, and quote Indian cost and availability where it helps.

Part B · Master question list

All 228 questions ever asked in Paper III, de-duplicated into 181 unique entries and grouped by system and theme rather than by year. Where a topic has been asked more than once, the wording of the fullest version has been kept and the repeat count is shown as a badge. Mark-format badges tell you what length of answer to prepare.

Badge key

ASKED ×3+ · ASKED ×2 · 15-mark essay · 7-mark note

No badge on repeat count means the question has been asked once. High-yield items — asked three or more times — carry a coral badge.

1 Geriatric Assessment, Frailty & Sarcopenia

CGA, functional and frailty assessment, sarcopenia, deconditioning, theories of ageing

1. What is Comprehensive Geriatric Assessment?
   7-mark note
2. Tools of functional assessment / functional assessment in the elderly.
   ASKED ×2 · 7-mark note
3. Describe the pathogenesis, diagnosis, prevention and management of frailty; and its pathophysiology, evaluation and management.
   ASKED ×2 · 15-mark essay
4. Fried's criteria.
   7-mark note
5. Clinical frailty scales.
   7-mark note
6. Sarcopenia in the elderly — etiology, pathogenesis and evaluation.
   ASKED ×3 · 15-mark essay + 7-mark note
7. Write a brief note on deconditioning and its prevention.
   7-mark note
8. Immobility.
   7-mark note
9. Elaborate on the 5 Ms of Geriatrics.
   7-mark note
10. Theories of ageing.
    7-mark note

2 Falls, Gait, Balance & Dizziness

Recurrent falls, risk factors, gait and balance, post-fall syndrome, vertigo, syncope

11. Discuss the approach to recurrent falls in the elderly, with emphasis on prevention and management.
    15-mark essay

12. A 60-year-old known diabetic and hypertensive with coronary artery disease and depression, on oral antidiabetics, diuretics, antihypertensives and antidepressants, presents with recurrent falls over the past week. How will you evaluate and manage the patient?
15-mark essay

13. What are the intrinsic risk factors for falls?
7-mark note

14. Falls prevention strategy in the elderly.
7-mark note

15. Post-falls syndrome.
7-mark note

16. Long lie.
7-mark note

17. Gait and balance assessment.
ASKED ×2 7-mark note

18. What are the phases in human walking? Describe in detail with appropriate diagrams.
7-mark note

19. How will you approach a patient with dizziness?
15-mark essay

20. How would you diagnose and manage a case suspected to have Benign Paroxysmal Positional Vertigo?
ASKED ×2 7-mark note

21. Vestibular rehabilitation.
7-mark note

22. Syncope.
7-mark note

23. Hypersensitive carotid sinus syndrome.
ASKED ×2 7-mark note

3 Cognition, Dementia & Delirium

Dementias, mild cognitive impairment, cognitive tools, BPSD, delirium

24. Discuss dementia in the elderly and its management.
ASKED ×2 20-mark essay + 6-mark note

25. Compare and contrast the clinical features and the areas of the brain involved in the four common dementias.
7-mark note

26. The neurodegenerative disorders associated with Tau, Progranulin or TDP-43 pathology — pathology, clinical presentation, course, prognosis and treatment modalities.
15-mark essay

27. Write a note on Lewy body dementia; and counsel a daughter whose father has been newly diagnosed — etiology, clinical features, treatment, progression, her own risk and whether it can be prevented.
ASKED ×2 7-mark note

28. What is Pick's disease? What is its pathology and treatment?
7-mark note

29. What are the reversible / treatable dementias? How would you investigate and manage them, and what investigations rule them out?
ASKED ×3 7-mark note

30. Mild cognitive impairment — diagnostic criteria, progression and treatment modalities.
15-mark essay

31. Cognitive assessment tools / tests of cognition and rating scales.
ASKED ×3 7-mark note

32. Behavioural symptoms of dementia.
7-mark note

33. Discuss the aetiology, pathogenesis, differential diagnosis and management of acute confusional state in the elderly.
15-mark essay

34. A 75-year-old diabetic and hypertensive smoker developed cough and fever for three days and became incoherent, abusive and drowsy on the third day with stable vitals. What are your differentials and the trigger factors? How would you evaluate and manage him on the ward?
15-mark essay

35. Assessment of delirium.
7-mark note

36. Strategies for prevention of delirium in elderly inpatients.
7-mark note

37. Normal pressure hydrocephalus.
7-mark note

4 Parkinson's Disease & Movement Disorders

Parkinson's disease, parkinsonism-plus, tremor, levodopa and motor fluctuations

38. What are the pathology, pathogenesis and treatment of Parkinson's disease — with emphasis on choice of drug, side effects, newer treatment modalities and the treatment of non-motor symptoms?
15-mark essay

39. Parkinsonism.
6-mark note

40. Drug treatment for Parkinson's disease.
7-mark note

41. Levodopa.
6-mark note

42. Motor fluctuations in Parkinson's disease.
7-mark note

43. Non-motor symptoms of Parkinson's disease.
7-mark note

44. Etiopathogenesis, clinical presentation and management of the Parkinson-plus syndromes in older adults.
15-mark essay

45. Progressive supranuclear palsy — clinical features, management and prognosis.
ASKED ×2 7-mark note

46. Benign essential tremor — clinical presentation, differential diagnosis and treatment.
7-mark note

5 Neurology — Stroke, Coma, Seizures & Neuromuscular

Cerebrovascular disease, coma, epilepsy, cord and nerve disorders, myopathy

47. Discuss coma in the elderly.
20-mark essay

48. Lacunar infarcts.
6-mark note

49. Management of extracranial carotid artery stenosis; and the pros and cons of carotid angioplasty versus carotid endarterectomy in a patient with 80% stenosis of the artery supplying the infarcted territory.
ASKED ×2 7-mark note

50. How would you assess swallow at the bedside in a patient with a recent stroke?
7-mark note

51. Brief note on subdural haematoma.
ASKED ×2 7-mark note

52. Definition, pathophysiology, clinical features, investigations and treatment of epilepsy in the elderly.
15-mark essay

53. Motor neuron disease — presentation, evaluation and treatment modalities.
7-mark note

54. Subacute combined degeneration of the cord — presentation and treatment.
7-mark note

55. Neuritic pain.
6-mark note

56. Inflammatory myopathies.
7-mark note

6 Cardiovascular Medicine

Hypertension, heart failure, arrhythmias, thromboembolism, lipids

57. Discuss the management of hypertension in the elderly.
20-mark essay

58. Isolated systolic hypertension and its management.
ASKED ×2 7-mark note

59. Postural hypotension — evaluation and management.
ASKED ×2 7-mark note + 6-mark note

60. What is the etiology, clinical features, diagnostic evaluation and management of a patient with congestive cardiac failure? What categories of drugs would you use, with their indications and side effect profile? What is your approach to refractory heart failure?
15-mark essay

61. Congestive heart failure — diagnostic evaluation.
7-mark note

62. Refractory cardiac failure.
7-mark note

63. Diastolic dysfunction.
7-mark note

64. Cardiomyopathies — pathophysiology, etiology, clinical features, diagnosis and treatment; including dilated cardiomyopathy.
ASKED ×3 15-mark essay + 7-mark note

65. Infective endocarditis.
7-mark note

66. Atrial fibrillation and its management.
7-mark note

67. Cardiac pacemaker.
6-mark note

68. Write a note on sick sinus syndrome.
7-mark note

69. Explain, with an appropriate diagram, the rise and fall of cardiac enzymes following an acute coronary syndrome.
7-mark note

70. Calcium channel antagonists.
6-mark note

71. Use of statins in the elderly.
7-mark note

72. Causes, treatment and prevention of deep vein thrombosis.
ASKED ×2 7-mark note

73. The causes, diagnosis and management of pulmonary embolism.
15-mark essay

74. Venous thromboembolism and post-operative management of anticoagulation.
7-mark note

75. Anticoagulants in geriatric practice — indications and agents.
7-mark note

7 Respiratory Medicine

COPD, pneumonia, interstitial disease, respiratory failure, sleep apnoea, tuberculosis

76. Describe the risk factors, pathology and clinical features of Chronic Obstructive Pulmonary Disease. How will you differentiate it from bronchial asthma? Discuss the management and complications of COPD.
15-mark essay

77. GOLD criteria for assessment of COPD and treatment options based on this assessment; the new GOLD criteria and the changes from the previous criteria, with a note on the ABCD criteria.
ASKED ×2 7-mark note

78. Metered dose inhalers.
7-mark note

79. Long term oxygen therapy.
7-mark note

80. Discuss the etiology, clinical features and management of community-acquired pneumonia in the elderly.
15-mark essay

81. Interstitial lung disease.
7-mark note

82. Respiratory failure — types, causes and management.
7-mark note

83. Discuss the types, clinical features and management of bronchogenic carcinoma.
15-mark essay

84. Sleep apnoea.
7-mark note

85. Polysomnography.
7-mark note

86. Extrapulmonary tuberculosis.
7-mark note

8 Continence, Bladder & Men's Health

Urinary incontinence, lower urinary tract symptoms, prostate, catheters

87. Classify urinary incontinence and discuss its evaluation and treatment; and discuss the types, diagnosis, management and reversible causes of incontinence in the elderly.
ASKED ×2 15-mark essay

88. Urinary incontinence in males — types, epidemiology, pathogenesis, risk factors, screening, diagnostic evaluation and management.
15-mark essay

89. A 65-year-old normotensive, non-diabetic lady presents with frequent urination, nocturia and intermittent involuntary leakage of urine for six months. What are the causes, and how will you evaluate and manage her?
15-mark essay

90. Bladder retraining protocol.
7-mark note

91. Overactive bladder.
7-mark note

92. Chronic indwelling catheter usage in the elderly.
7-mark note

93. Catheter-associated urinary tract infections — prevention and management.
7-mark note

94. Recommendations regarding treatment of complicated urinary tract infection in males.
7-mark note

95. Algorithm to investigate and treat an elderly male with lower urinary tract symptoms; and the next steps in the investigative and management pathway for a man with LUTS whose PSA is 10 ng/ml.
ASKED ×2 7-mark note

96. Prostate specific antigen.
7-mark note

97. Uroflowmetry.
7-mark note

98. Medical management of benign prostatic hypertrophy.
7-mark note

99. Write a short note on the clinical features, investigation and treatment of obstructive uropathy.
7-mark note

100. What are the causes of erectile dysfunction and what treatment options are currently available?
7-mark note

101. Andropause.
7-mark note

9 Renal, Fluid & Electrolyte Disorders

Acute kidney injury, electrolytes, acid-base balance, renal bone disease

102. Discuss fluid and electrolyte disturbances in the elderly and their management.
15-mark essay

103. Approach to the evaluation and treatment of hyponatremia.
7-mark note

104. Hypocalcemia.
7-mark note

105. Metabolic acidosis.
7-mark note

106. Enumerate the causes and outline the treatment of acute kidney injury in an elderly male; and the differentials and investigations in a 65-year-old male with acute kidney injury.
ASKED ×2 7-mark note

107. Drug-induced renal impairment in the elderly.
7-mark note

108. Renal osteodystrophy — laboratory and radiological abnormalities, and treatment.
7-mark note

109. Anaemia of chronic kidney disease — type, investigation and treatment modalities.
7-mark note

10 Bone, Joint & Rheumatology

Osteoporosis, fracture risk assessment, arthritis, vasculitis, connective tissue disease

110. What is osteoporosis? Describe in detail its risk factors, pathology, clinical features, investigations, management and complications.
ASKED ×2 15-mark essay + 6-mark note

111. Dual energy X-ray absorptiometry — DEXA scan and its clinical uses; and how the bone mineral density test is interpreted, with a note on the FRAX tool.
ASKED ×3 7-mark note

112. FRAX score.
7-mark note

113. A 68-year-old woman had surgery for fracture of the left neck of femur two months ago and asks whether treatment for osteoporosis will benefit her. What is her risk of another fragility fracture? What further tests would you do and what are her treatment options?
7-mark note

114. Atypical femur fractures due to drugs.
7-mark note

115. Selective estrogen receptor modulators.
6-mark note

116. Osteoarthritis management.
6-mark note

117. Late-onset rheumatoid arthritis.
7-mark note

118. Psoriatic arthropathy.
7-mark note

119. Polymyalgia rheumatica.
ASKED ×2 7-mark note + 6-mark note

120. Discuss temporal arteritis.
ASKED ×2 7-mark note

121. Sjögren's syndrome — definition, epidemiology, pathophysiology, presentation and management.
7-mark note

122. Paget's disease.
7-mark note

11 Endocrine & Metabolic

Thyroid disease, glycaemic control, hormone replacement, androgens

123. Treatment of hypothyroidism.
6-mark note

124. Subclinical hypothyroidism.
7-mark note

125. Solitary thyroid nodule.
7-mark note

126. Evaluation and management of hypoglycaemia.
7-mark note

127. SGLT2 inhibitors in type 2 diabetes mellitus.
7-mark note

128. Discuss hormone replacement therapy / hormone replacement in geriatric patients.
ASKED ×3 7-mark note

129. Gynaecomastia.
6-mark note

130. Hirsutism and baldness in elderly women.
7-mark note

12 Gastroenterology & Nutrition

Gastrointestinal bleeding, motility, malabsorption, constipation, nutritional assessment

131. Approach to upper gastrointestinal bleed / haematemesis.
ASKED ×2 7-mark note

132. Gastro-oesophageal reflux disease.
ASKED ×2 7-mark note

133. Gastrointestinal motility disorders in the elderly.
7-mark note

134. Malabsorption / malabsorption syndrome in the elderly.
ASKED ×2 7-mark note

135. Management of chronic constipation, its pharmacological management, and the management of constipation in the elderly.
ASKED ×4 7-mark note

136. How would you assess a patient's nutrition? Write a note on the various methods used and their advantages and disadvantages.
7-mark note

137. What is the Mini Nutritional Assessment score? What are its components, how will you score and interpret it, and what interventions can you suggest?
7-mark note

138. What are the tools used in screening for malnutrition? Enumerate at least three of them, and add a table on Body Mass Index and their cut-offs in Asians.

7-mark note

139. Total parenteral nutrition.

7-mark note

140. Vitamin deficiencies.

7-mark note

13 Haematology & Oncology

Anaemia, myelodysplasia, lymphoma, cancer screening, paraneoplastic disease

141. Anaemia of chronic disease.

7-mark note

142. Blood transfusion.

7-mark note

143. What are the mechanisms of drug-induced thrombocytopenia?

7-mark note

144. Myelodysplastic syndrome — classification, etiology, clinical features, differential diagnosis, investigations and treatment in the elderly.

ASKED ×3 15-mark essay + 7-mark note

145. What are the types of Non-Hodgkin's lymphoma? What are their clinical presentations and prognosis, and what are the principles of therapy?

7-mark note

146. Tumour lysis syndrome — presentation, investigation and treatment.

7-mark note

147. Paraneoplastic syndrome.

7-mark note

148. Hormone therapy in malignancy.

6-mark note

149. Mammography.

6-mark note

150. A 62-year-old woman has a suspicious breast lump on her recent mammogram. What is the ideal approach to a suspicious breast lesion in an older woman?

7-mark note

151. Discuss currently accepted strategies for cancer screening in the elderly.

15-mark essay

14 Infections & Immunity

Atypical presentation, sepsis, vaccination, immunosenescence, specific infections

152. Atypical presentations of infections in the elderly.
6-mark note

153. A 65-year-old male, a known diabetic with chronic kidney disease, is admitted to the emergency ward with altered sensorium, fever, elevated total leucocyte count and hypotension. How will you evaluate and manage this patient?
15-mark essay

154. Approach to pyrexia of unknown origin in older adults.
15-mark essay

155. Herpes zoster infection in the elderly — etiology, clinical features and management.
ASKED ×3 7-mark note

156. Influenza vaccination.
7-mark note

157. Vaccines for the elderly.
7-mark note

158. Immunology and ageing — elaborate on the innate and adaptive immune systems and the impact of ageing, with a note on immunosenescence and cancer.
ASKED ×2 15-mark essay + 7-mark note

159. Clostridium difficile colitis.
7-mark note

15 Sleep, Skin, Special Senses & Environmental

Sleep disorders, pressure ulcers, vision, pruritus, heat-related illness

160. What are the common sleep disorders in the elderly and what is their line of management?
7-mark note

161. Describe the pathophysiology of insomnia and its management.
7-mark note

162. Sleep hygiene.
7-mark note

163. Discuss the assessment and management of chronic pressure ulcers in the elderly, and the prevention of pressure sores.
ASKED ×2 20-mark essay + 7-mark note

164. How would you deal with constant itching in an elderly patient?
7-mark note

165. Visual impairment — enumerate the age-related causes and how you would approach them.
ASKED ×2 7-mark note

166. Macular degeneration — clinical presentation, etiology, diagnosis, treatment and prevention.
7-mark note

167. Heat stroke.
7-mark note

168. Heat exhaustion.
7-mark note

16 Pharmacology, Prescribing & Perioperative Care

Principles of drug therapy, polypharmacy, deprescribing, surgery in old age

169. Describe the principles of drug therapy in the elderly.
15-mark essay

170. Rational drug prescribing in older adults.
7-mark note

171. What do you mean by polypharmacy? How would you prevent it?
7-mark note

172. Drug holiday.
7-mark note

173. Perioperative assessment and management in older people; and a patient admitted with fracture neck of femur after a fall at home, who is diabetic, hypertensive and has COPD and is posted for surgery — what assessments should be done before surgery, and how should he be managed post-operatively and at follow-up?
ASKED ×2 15-mark essay

17 Rehabilitation, Social & End-of-Life Care

Rehabilitation team, therapists, elder abuse, transitional care, palliative care

174. Rehabilitation team.
6-mark note

175. Role of physiotherapy in the elderly.
6-mark note

176. What is the role of an occupational therapist in the life of an elderly person with mobility issues living with an ageing spouse?
7-mark note

177. You are the doctor in charge of a transitional care home accommodating 30 people. What would be your prerequisites for admitting and discharging a patient? Whom would you appoint to manage your patients and what would be their role?
7-mark note

178. Elder mistreatment / elder abuse.
ASKED ×2 7-mark note + 6-mark note

179. Advanced care planning.
7-mark note

180. End of life care issues.
7-mark note

181. Enumerate and expand the principles of palliative care that one should use to treat a patient with end-stage cardiac failure. What are the social issues one should address in this condition?

15-mark essay

Part C · Ebenezer's bank — Paper III topics not yet asked

Every Paper III-relevant heading in Ebenezer's Geriatric Question Bank was cross-checked against the 181 questions in Part B. The topics below appear in the bank but have **never** been set in a Paper III university paper. They are the highest-value gap list you have: a compiler thought them worth including, and the examiner has not yet used them.

Cardiovascular

1. Cardiac cycle, cardiac output and the Frank–Starling law in cardiac failure.
2. Aortic stenosis, aortic sclerosis and mitral regurgitation in the elderly.
3. Unstable angina — pathology, pathophysiology and management.
4. Beta blockers in heart failure.
5. Accelerated hypertension and hypertensive emergency.
6. Secondary hypertension — evaluation and management.
7. Ankle brachial index and toe pressures — indications and interpretation.
8. Head-up tilt test — indication, procedure and interpretation.
9. Complete heart block and tachyarrhythmias in the older adult.
10. Chronic pulmonary thromboembolism.
11. In-stent stenosis — etiopathogenesis and management.
12. Lifestyle modification to reduce cardiovascular risk.
13. CHADS2-VASc score — uses and clinical significance.
14. Drug-eluting stents — pros and cons.
15. Newer cardiac biomarkers in myocardial infarction.

Respiratory

16. ARDS — recognition and management.
17. Pulmonary nodule — approach, investigation and treatment.
18. Pleural effusion — approach, evaluation, differential diagnosis and management.
19. Hospital-acquired pneumonia and aspiration pneumonia.
20. Senile emphysema.
21. Role of CPAP in diseases of the elderly.
22. Pneumococcal vaccination.
23. DOTS, MDR-TB and XDR-TB — regimens and dosing.
24. Diffuse parenchymal lung disease — classification, approach and treatment.

Neurology & Psychogeriatrics

25. Complex partial seizures.
26. Electroconvulsive therapy in the elderly.

27. Cluster headache and tension headache.
28. Wernicke encephalopathy.
29. Transient ischaemic attacks.
30. Thrombolysis in stroke.
31. Stroke rehabilitation.
32. Drug-induced parkinsonism.
33. Multiple system atrophy — clinical features, types, diagnosis and treatment.
34. Hypoxic ischaemic encephalopathy.
35. Traumatic brain injury — post-acute management.
36. Wallenberg syndrome.
37. Approach to meningitis in the elderly.
38. Restless leg syndrome — risk factors, criteria and management.
39. Peripheral neuropathy — common causes, evaluation and management.
40. Ring-enhancing lesion on CT brain.
41. Myasthenia gravis — presentation, laboratory evaluation and treatment.
42. Geriatric depression scale and depression in late life.
43. Suicide risk assessment in older adults.
44. Late-onset schizophrenia and late-life psychotic disorders.
45. Diogenes syndrome.

Gastroenterology, Renal & Metabolic

46. Drug-induced jaundice.
47. Hepatitis B and C infection — investigation and treatment.
48. Ascites — causes and management; liver transplantation.
49. Chronic liver disease and hepatic encephalopathy.
50. Helicobacter pylori and its clinical relevance.
51. Diabetic ketoacidosis and hyperosmolar non-ketotic coma.
52. Alpha glucosidase inhibitors and newer oral hypoglycaemic agents.
53. Diabetic foot syndrome.
54. Ezetimibe — indications, mode of action and side effects.
55. Acute glomerulonephritis and acute pyelonephritis.
56. Chronic kidney disease — conservative management in the elderly.
57. Renal replacement therapy — criteria, haemodialysis and peritoneal dialysis.
58. Hyperkalemia and hypercalcemia — investigation and treatment.
59. Types of shock and septic shock — etiopathogenesis and diagnosis.
60. Faecal incontinence — evaluation and management.

Haematology, Oncology & Infection

61. Multiple myeloma and plasma cell dyscrasias.
62. Chronic lymphocytic leukaemia — classification and treatment.
63. Bone marrow transplant.
64. PET scanning in the older adult.
65. Methotrexate — major side effects of low-dose therapy.
66. Prostate cancer — to screen or not to screen.
67. Fever of unknown origin — evaluation of prolonged fever.
68. Malaria and cerebral malaria — drugs, prophylaxis and management.
69. Leptospirosis — investigation and management.
70. Sterile pyuria and asymptomatic bacteriuria.
71. COVID-19 in the older adult.

Rheumatology, Endocrine & Miscellaneous

72. Hashimoto's thyroiditis.
73. Gout — management in the older adult.
74. Vertebral secondaries with unknown primary.
75. Diffuse idiopathic skeletal hyperostosis.
76. Dermatomyositis and POEMS syndrome.
77. Serotonin syndrome and neuroleptic malignant syndrome.
78. Rhabdomyolysis.
79. Tinnitus.
80. Chronic fatigue syndrome and inanition.
81. Anorexia of ageing.
82. Interleukin-6, telomeres and sirtuins in ageing.

Social, Ethical & Rehabilitative

83. Caregiver burden and how to manage it.
84. Alcoholism in the elderly.
85. Informed consent and decisional capacity.
86. Euthanasia and physician-assisted suicide.
87. Breaking bad news.
88. Assistive devices, mobility aids and artificial limbs.
89. Community-based rehabilitation.
90. NPHCE and the National Policy on Older Persons.
91. Home-based care and long-term care services.
92. Hospice and respite care; bereavement.

WHY THIS LIST MATTERS

92 topics sit in the Ebenezer bank without ever having been examined in Paper III. Several of them — thrombolysis in stroke, stroke rehabilitation, depression and the Geriatric Depression Scale, multiple myeloma, hyperkalaemia and hypercalcaemia, faecal incontinence, and conservative management of chronic kidney disease — are so central to modern geriatric practice that their continued absence is itself a prediction signal. Note in particular that Paper III has never once set a psychogeriatric short note, despite psychiatry sitting squarely in the syllabus.

Part D · Predicted questions

Predictions are built from three signals: how often a topic has been asked, how long it has been since it last appeared, and whether the recent literature has given the examiner a fresh angle. Probability labels are relative, not absolute — treat "very high" as a topic you cannot afford to walk in without, and "moderate" as one worth a prepared skeleton answer.

Paper III · most likely 15-mark essays

Predicted essay	Odds	Reasoning
Comprehensive Geriatric Assessment — domains, tools, evidence base and application in Indian practice.	Very high	Asked only as a 7-mark note in 2013 despite being the organising concept of the whole paper. Paper IV has twice used it as an essay; Paper III never has.
Urinary incontinence — classification, evaluation, reversible causes and management, including incontinence in the male.	Very high	Four appearances, three of them essays (2011, 2016, 2019). The single most reliable Paper III essay stem and unasked since 2019.
Delirium / acute confusional state — aetiology, differentials, prevention and ward management.	Very high	Three essays in scenario form (2016, 2017, 2019) plus notes on assessment and prevention. The examiner clearly favours the ward-scenario framing.
Frailty and sarcopenia — overlapping constructs, assessment instruments and management.	High	Frailty has four entries and sarcopenia three; both were last set around 2019–20 and the AWGS 2019 and Clinical Frailty Scale updates give a fresh angle.
Falls — approach to recurrent falls with drug review, assessment and prevention.	High	Essay in 2011 and as a polypharmacy scenario in 2017. Eight sessions have passed since the last dedicated essay.
Parkinson's disease — motor and non-motor management, and the parkinsonism-plus syndromes.	High	The most frequently examined single disease in Paper III with nine separate entries. Essays in 2012 and 2023.
Dementia — comparison of the four common dementias with investigation of reversible causes.	Moderate	Essay in 2009; reversible dementias recurred in October 2025. A combined stem is the natural next version.
Perioperative assessment of the older surgical patient.	Moderate	Essay in 2022 and again in October 2025 — back-to-back appearances suggest the examiner currently favours it.

Paper III · most likely 7-mark notes

Predicted note	Odds	Reasoning
Cognitive assessment tools — MMSE, MoCA, AMT and clock drawing	Very high	Three appearances (2013, 2017, 2021) — the most repeated short note in the paper.
Constipation in the elderly — evaluation and stepped management	Very high	Four appearances across 2011, 2013, 2017 and 2019 — the highest-frequency short note in Paper III.
DEXA and bone mineral density interpretation with the FRAX tool	Very high	Four entries including October 2025; interpretation-style framing is now the examiner's preference over simple description.
Herpes zoster in the elderly and zoster vaccination	High	Three appearances (2011, 2013, 2023); the recombinant zoster vaccine is the untouched modern angle.

Predicted note	Odds	Reasoning
Hormone replacement therapy	High	Three appearances (2013, 2015, 2020) on a roughly five-year cycle.
Gait and balance assessment	High	Two appearances (2017, 2020) and pairs naturally with the falls theme.
Vaccination in older adults beyond influenza	High	Influenza and generic vaccines have appeared; pneumococcal, zoster and RSV vaccines have never been set in Paper III.
Polypharmacy, deprescribing and the drug holiday	High	Polypharmacy 2018, rational prescribing 2023, drug holiday 2022. Beers and STOPP/START criteria remain unasked by name.
Myelodysplastic syndrome — classification and management	Moderate	Three entries; last set as a full essay in 2021.
Deep vein thrombosis and anticoagulation in geriatric practice	Moderate	DVT twice, VTE prophylaxis once, anticoagulants once; DOAC-era content is overdue.
Pressure ulcers — staging, prevention and stage-wise treatment	Moderate	Essay in 2009 and a note in 2011, then nothing — a fourteen-year gap.
Sleep apnoea and polysomnography	Moderate	Sleep apnoea 2022, polysomnography 2019; the pair runs on a short cycle.

A model predicted Paper III

If you want a single paper to mock-write against, this is the twelve-question set the frequency and recency analysis produces.

	Question	Marks
I.1	An 80-year-old admitted after two days of fever becomes agitated and disoriented on the ward. Discuss the aetiology, differential diagnosis, assessment and prevention of delirium, and outline your management.	15
I.2	Urinary incontinence in the older adult — classification, reversible causes, evaluation and management, with specific reference to incontinence in the male.	15
II.1	Constipation in the elderly — evaluation and stepped pharmacological management.	7
II.2	Reversible dementias — causes and the investigation panel.	7
II.3	Cognitive assessment tools — MMSE, MoCA and AMT, with their limitations in Indian practice.	7
II.4	Interpretation of bone mineral density and the FRAX tool.	7
II.5	Deprescribing — Beers, STOPP/START and anticholinergic burden.	7
II.6	Sarcopenia — AWGS 2019 criteria, assessment and management.	7
II.7	Herpes zoster in the older adult, including recombinant zoster vaccine.	7
II.8	Hyponatraemia and SIADH — evaluation and safe correction.	7
II.9	Heart failure with preserved ejection fraction — diagnosis and four-pillar therapy.	7
II.10	Gait and balance assessment — bedside and instrumented tests.	7

Cross-paper watchlist — Papers I, II and IV

Paper III does not sit in isolation: the same themes recirculate across papers with a different emphasis. These are the highest-probability areas for the other three papers based on the same frequency and recency analysis.

Paper I — Applied Basic Sciences

1. Anatomy: conduction system and blood supply of the heart; bronchopulmonary segments; innervation of the urinary bladder; dermatomes; portocaval anastomosis.
2. Physiology: ageing changes in the heart; Frank–Starling law; lung volumes; the nephron and sites of electrolyte exchange.
3. Biochemistry: gout and purine metabolism; vitamin D; lipid metabolism; bone turnover markers.
4. Pharmacology: pharmacokinetic and pharmacodynamic changes with ageing; oral anticoagulants; drugs in benign prostatic enlargement.
5. Pathology: iron deficiency anaemia and red cell indices; fatty liver; Lewy bodies; inflammaging.
6. Microbiology: inflammatory markers in ageing; pneumococcal vaccines; antibiotic choice in lower urinary tract infection.

Paper II — General Medicine including Psycho-Geriatrics

1. Behavioural and psychological symptoms of dementia — types and management.
2. Depression in older adults and antidepressant choice.
3. Parkinson's disease — motor and non-motor symptoms and drug side effects.
4. COPD by GOLD criteria and asthma by GINA guidelines.
5. Hypercalcaemia work-up; hyperkalaemia in the diabetic.
6. Late-onset rheumatoid arthritis versus early-onset disease.
7. Recurrent urinary tract infection and urinary incontinence in the male.
8. Vertigo, chronic liver disease and peripheral neuropathy.

Paper IV — Social and Preventive Geriatrics

1. NPHCE, NPOP and the social security system for older people in India.
2. Elder abuse, advance directives and the living will.
3. Comprehensive Geriatric Assessment and integrated care of older people.
4. Vaccination schedules and immunosenescence.
5. Rehabilitation team composition and the role of each therapist.
6. Palliative and end-of-life care; breaking bad news.
7. Falls prevention including sensor devices.
8. Cancer screening strategies and stopping rules.

FINAL NOTE ON USING PREDICTIONS

Prediction is a way of ordering revision, not of restricting it. Constipation, reversible dementias and the cognitive assessment tools are near-certainties over any two-session horizon, but every paper carries three or four genuinely novel questions — the 5 Ms of Geriatrics, psoriatic arthropathy and atypical femur fractures were all new in the last two sessions. Prepare the high-frequency core to essay depth, keep a one-page skeleton for everything in Part C, and you will have something structured to write for any question on the paper. One practical caution: December 2024 Paper III is missing from the source set, so a topic that looks overdue here may in fact have been cleared in that session.

MD Geriatric Medicine — High-Yield Examination Answers

Set 1: Assessment, Function, Cognition, Capacity and Geriatric Syndromes

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition; supported by Kane's Essentials of Clinical Geriatrics and current international and Indian guidelines.

QUESTION 1

Comprehensive Geriatric Assessment — What It Is and Its Usefulness in Clinical Practice

A. 20 High-Yield Points

Definition and Concept

1. **Comprehensive geriatric assessment (CGA)**, also called **multidimensional geriatric assessment**, is a **diagnostic process, usually interdisciplinary**, that determines an older person's **medical, psychosocial, functional and environmental** resources and problems.
2. Its stated objective is to **develop an overall plan for treatment and long-term follow-up**. An assessment **without a linked care plan is NOT a CGA** — a favourite examination point.
3. It **differs from a standard medical evaluation** in three ways: it targets older people with complex problems, it **emphasises functional status and quality of life**, and it uses **interdisciplinary teams with quantitative scales**.
4. A purely psychosocial or environmental home visit **without a medical evaluation** also does not qualify as CGA, because multidimensionality is incomplete.
5. **Historical origin: Dr Marjory Warren**, London infirmary, **late 1930s**. Through evaluation, mobilisation and rehabilitation she got long-bedfast patients out of bed and home, and advocated **assessment and rehabilitation before any long-term institutionalisation**.

Rationale — Why in the Elderly? (five textbook reasons)

6. **Multi-morbidity and complexity** — systematic assessment helps set priorities among multiple conditions.
7. **Unrecognised problems** — many problems are never reported, often because they are **falsely thought to be non-modifiable effects of ageing**.
8. **Chronic conditions** — a diagnosis without information on **functional relevance** is of limited therapeutic value.
9. **Social and environmental interaction** — home layout and social network determine whether a person can stay at home.
10. **Functional status** — the main goal of geriatric medicine is to **prevent or delay functional decline**; benefit is greatest when intervention occurs **early** in the path from robustness to frailty to disability.

Components — What Is Assessed

11. CGA begins with a **functional status "review of systems"** built on three measures: **frailty, basic ADLs, and IADLs**.
12. **Principle of hierarchy / parsimony:** if a patient is **severely ADL-dependent, do not assess frailty**; if the patient is **robust or pre-frail, do not assess basic ADLs**.
13. Frailty is measured by two models — the **phenotype model** (Fried phenotype, Frailty Trait Scale, FRAIL index) and the **cumulative deficit model** (Frailty Index, Clinical Frailty Scale).
14. **Dimensions and tools (Table 96.1):** BADL — **Katz, Barthel, Lawton PSMS**; IADL — **Lawton, OARS**; Social — **Lubben Social Network Scale**; Affective — **Geriatric Depression Scale, Zung**; Cognitive — **MMSE (Folstein), Kahn MSQ**; Gait and balance — **Tinetti, Get-Up-and-Go**; Nutrition — **MNA**; Senses — **whispered voice test, Snellen**; Oral — **GOHAI**.
15. Two screens are **mandatory** in any older person with functional disability: **cognitive impairment and depression**.

Process in Office and Clinic Practice

16. **Step 1 — set priorities:** work first on the problem that **most bothers the patient**, or the problem on which resolution of others depends (**alcoholism, depression**).
17. **Step 2 — task and symptom analysis:** define the exact nature of the impairment and correlate it with **new drugs or dose changes (including over-the-counter), change in living conditions, and intercurrent acute illness**. Then examination, laboratory tests, therapist and social-work input, and a **long-term follow-up / case-management plan**.

Settings and Team

18. **Settings:** home (preventive visits), office and outpatient clinic, **day hospital**, **acute care for the elderly (ACE) unit**, post-acute rehabilitation unit, nursing home (**Resident Assessment Instrument**), and hospital-at-home programmes. Inpatient and day-hospital settings give intensity and speed for the frail; outpatient settings are cheaper.
19. **Team (minimum):** physician, nurse, social worker, physiotherapist, occupational therapist; **optimally** dietician, pharmacist, ethicist, home-care specialist. The **interdisciplinary team conference is critical** — present in most successful trials; teams mature through **forming, storming, norming, performing**.

Evidence of Usefulness — The Exam Core

20. **Proven benefits:** CGA **improves function and survival while reducing healthcare utilisation and costs**. Supporting data:

- **Improved diagnostic accuracy — 1 to more than 4 new diagnoses per patient**.
- **1993 Stuck/Rubenstein meta-analysis (28 trials, ~10,000 patients):** mortality down **22%** (hospital-based, 12 months) and **14%** (all programmes); living at home up **47%** (hospital-based) and **26%** (all); readmissions down **12%**; cognitive improvement up **47%**; physical function up **72%** on hospital units.
- **2011 Cochrane meta-analysis:** inpatient CGA increases the likelihood of being **alive and in one's own home**, with potential cost reduction.
- **Better prescribing** — CGA reduces unnecessary and inappropriate medication use.
- **Targeting matters:** best results when patients are at **high risk of deterioration yet retain rehabilitation potential** — exclude those **"too well or too ill."**
- **Programmes with hands-on care and/or long-term follow-up** outperform purely consultative programmes.
- **Weak areas:** outpatient CGA showed **no mortality benefit** in one meta-analysis; **preventive home visits are not recommended routinely** (benefit only with CGA-based extended follow-up in relatively well elders; **number needed to visit about 40** to prevent one nursing-home admission).
- **Oncology (SIOG task force):** CGA detects many problems missed by regular assessment and is associated with **fewer treatment side effects**.

B. Latest Updates (2023–Present)

1. German DGG S3 Guideline on CGA in Hospital (2024) — the first S3-level CGA guideline. Twelve evidence-based and eight consensus-based recommendations. Strongest evidence in **acute geriatric, oncology and orthopaedic/trauma wards**; weaker in emergency departments and general surgery. Core elements: **minimum CGA duration of 15 minutes** and **six core dimensions — self-help ability, mobility, cognitive function/delirium, affect, nutrition and social situation**; the **G8 questionnaire** is recommended for screening mainly in oncology.

2. Italian National CGA Guideline (2024) — 25 scientific societies plus the National Institute of Health, GRADE methodology. Sixteen recommendations from **117 studies** across primary care, clinics, emergency departments, hospital wards and nursing homes. CGA **reduces hospitalisation, mortality, institutionalisation and delirium risk**, improves prescribing appropriateness, and **maintains functional activities**. The **Multidimensional Prognostic Index (MPI)** is specifically recommended to predict negative outcomes.

3. Japanese CGA-Based Healthcare Guidelines 2024. The main objective of CGA is stated to be **personalised care through holistic management plans and targeted interventions — not merely status evaluation or prognostication**.

4. ASCO Geriatric Oncology Guideline Update (2023). Geriatric assessment should be used in **all patients over 65 with cancer**; all older adults with GA-identified deficits should receive **GA-guided management**, and the **Practical Geriatric Assessment (PGA)** is the recommended tool. Evidence base: **GAP70+** and **GAIN** trials.

5. ASCO Global (Resource-Stratified) Geriatric Assessment Guideline (2025) — adapts the 2023 guideline for **resource-limited settings** using ADAPTE methodology. Directly relevant to Indian practice.

6. Cochrane 2022 — Community CGA. Twenty-one studies, 7,893 participants, 10 countries, evaluating domiciliary CGA and CGA in general practice, with outcomes of death, nursing-home admission, unplanned hospital admission and emergency visits.

7. Meta-analysis of CGA in acute hospitalisation (2025) — CGA **may improve short-term survival and reduce readmission rates** after acute hospitalisation.

8. Perioperative CGA is now mainstream. The **2023 World Society of Emergency Surgery guidelines** advocate frailty assessment and multidisciplinary geriatric-surgical management in older trauma patients; the UK **NELA Best Practice Tariff (April 2023)** mandates perioperative team involvement in frailer laparotomy patients. CGA outperforms traditional preoperative risk models in predicting **postoperative delirium, infection and prolonged stay**.

9. Indian context. Evidence is predominantly from high-income countries and hospitalised patients; research on CGA in primary care and community settings in low- and middle-income countries is lacking. Under **NPHCE**, community services are delivered by **ASHA workers** with clinics at PHCs, but implementation is inconsistent. Short culturally adapted tools such as **EHSAS** are being validated for rural India because full CGA is impractical with the available workforce.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Standardisation	Deliberately broad; "no single optimal blueprint"	**Minimum standards defined** — German S3: at least 15 minutes, six mandatory core domains
Prognostic tool	Many scales listed; none preferred	**MPI specifically recommended** (Italian guideline)
Oncology tool	SIOG could not recommend any specific tool	**PGA specifically recommended** (ASCO 2023)
Oncology strength	CGA "possibly" improves survival	**GA mandatory at 65 and above**; GA-guided management proven to cut severe chemotoxicity
Outpatient CGA	"Less impressive"; no mortality benefit	Italian guideline **supports** primary-care CGA for reducing hospitalisation and institutionalisation
Preventive home visits	Cannot be recommended as routine practice	**Largely unchanged** — Cochrane 2022 still shows uncertain benefit
Perioperative CGA	Not covered	Now **embedded in surgical pathways** (NELA BPT, WSES 2023, POPS model)
Emergency department	Not addressed	Recognised as important but **evidence still weak** (German S3)

D. Exam One-Liners

- **CGA without a care plan and follow-up is not a CGA.**
- **Marjory Warren, 1930s London** — mother of CGA and of British geriatrics.
- **Function is the common language of geriatrics; assessment is its core method.**
- **Hierarchy rule:** ADL-dependent, skip frailty testing; robust or pre-frail, skip basic ADL testing.
- **Targeting rule:** benefit is greatest in those **"not too well, not too ill"** — high risk with rehabilitation potential.
- **Hands-on care plus long-term follow-up** separates effective from ineffective programmes.
- **1993 meta-analysis:** mortality down 22%, living at home up 47%, physical function up 72% on hospital units.
- **Two mandatory screens** in functional disability: **cognition and depression**.
- **German S3 six core domains:** self-care, mobility, cognition/delirium, affect, nutrition, social situation.
- **ASCO 2023:** every cancer patient 65 and above gets a geriatric assessment, using the **PGA**.
- **Italian 2024:** use the **MPI** for prognosis.
- **India:** CGA delivery constrained by workforce — hence short screening tools within **NPHCE**.

QUESTION 2

Tools of Functional Assessment

A. 20 High-Yield Points

Framework

1. **Functional assessment** measures **what a person actually does in daily life**, not merely what diseases they have. Tools exist to make this measurement **standardised, reproducible and comparable across settings**.
2. **Purpose of using standardised tools:** they allow **information exchange between acute, rehabilitation and community settings**, permit **measurement of effectiveness**, foster **comparison of treatments**, and **minimise repeated collection of identical information** by different team members.
3. **Three levels of measurement (ICF, 2001): impairment** (body function or structure), **activity limitation** (difficulty executing a task), and **participation restriction** (problems in involvement in life situations). Different tools address different levels.
4. **Three functional core measures** in CGA: **frailty, basic ADLs, and IADLs**. The **hierarchy rule** determines which to use — severely ADL-dependent patients are not tested for frailty; robust patients are not tested for basic ADLs.
5. **Two methods of data capture: report** (by the patient or a proxy — tells you what they do under real living conditions) and **performance testing** (tells you what they can do under standard conditions). **Discrepancies between the two are common and informative.**

Basic ADL Tools

6. **Katz Index (1963)** — six items: **bathing, dressing, toileting, transferring, continence, feeding**. Graded independent/dependent, letters A to G. The classic **hierarchy of ADL loss**.
7. **Barthel Index (1965; modified 1988)** — ten items: feeding, bathing, grooming, dressing, bowels, bladder, toilet use, transfer, mobility, stairs. Scored **0–100** (or 0–20). It is an **observation of what the patient does**, and is the **RCP/BGS-endorsed ADL scale**, but has a **ceiling effect in ambulatory patients**.
8. **Lawton Physical Self-Maintenance Scale (PSMS, 1969)** — six items: **toileting, feeding, dressing, grooming, physical ambulation, bathing**. Each graded on **five levels**, dichotomised to a total of **0–6** (6 = independent). Published in the same paper as the Lawton IADL scale.

IADL Tools

9. **Lawton IADL scale (1969)** — eight items: **telephone, shopping, food preparation, housekeeping, laundry, transport, medications, finances**. IADLs need "instruments," and are the **first functions to be lost**.
10. **OARS Multidimensional Functional Assessment Questionnaire** — assesses IADLs alongside social and economic resources; widely used in surveys.
11. **Clinical rule:** if difficulty is reported, always ask **"how does she manage?"** — is the task neglected, or is someone else doing it?

Mobility, Gait and Balance Tools (high-yield numbers)

12. **Gait speed** over a 4-metre track: **below 0.6 m/s is abnormal**; **0.6–0.8 m/s is high-risk**. Each **0.1 m/s fall in gait speed equals a 7% rise in fall risk**.
13. **Timed Get-Up-and-Go (Mathias, Nayak and Isaacs, 1986): more than 12 seconds indicates high fall risk** (sensitivity 77%, positive predictive value 93% in the community).
14. **Tinetti Performance-Oriented Mobility Assessment (1986):** 14 tasks, **score below 24 out of 28 indicates fall risk**; takes 10–15 minutes.
15. **Short Physical Performance Battery (SPPB):** combines gait speed, **30-second chair stand** and the **4-stage balance test** (each position held **10 seconds**). **Berg Balance Scale:** 14 items, 0–56 (0–20 wheelchair-bound, 21–40 walks with assistance, 41–56 independent).

Composite, Global and Domain-Specific Tools

16. **Functional Independence Measure (FIM)** — scores **18 functions** across self-care, sphincter control, mobility, locomotion, communication and social cognition; the standard rehabilitation outcome measure.
17. **RCP/BGS endorsed scales (Table 98.3):** ADL — **Barthel Index**; vision, hearing and communication — **Lambeth Disability Screening Questionnaire**; memory — **Abbreviated Mental Test (10 items)**; depression — **Geriatric Depression Scale (30-item, 15-item short form)**; morale — **Philadelphia Geriatric Center Morale Scale**.
18. **Other domain tools (Table 96.1):** nutrition — **Mini Nutritional Assessment (MNA)**, SNAQ; special senses — **whispered voice test, Hearing Handicap Inventory, Snellen chart**; oral health — **GOHAI**; social network — **Lubben Social Network Scale**; cognition — **MMSE**; mood — **GDS, Zung**.
19. **Frailty tools: Fried phenotype** (weight loss, exhaustion, weakness, slow gait, low activity); **FRAIL scale** (Fatigue,

Resistance, Aerobic, Illnesses more than 5, Loss of weight 5%) — answerable in 15–30 seconds; **SOF index** (weight loss, cannot rise from chair 5 times without arms, reduced energy); **Clinical Frailty Scale** (9 points, seconds to apply); **Frailty Index** (30 or more deficits, continuous 0–1).

20. **Screening questions usable at the bedside:** "*Do you need help at home?*" (function) · "*Do you have trouble walking or lose your balance? Have you had a fall? Are you afraid of falling?*" (mobility) · "*Are you sad?*" (mood) · "*Have you lost weight?*" (nutrition) · "*Are you on seven or more medicines?*" (polypharmacy) · "*Do you wet yourself?*" (continence).

B. Master Comparison Table

Domain	Screening tool	Assessment tool	Key threshold
Frailty	FRAIL scale, Clinical Frailty Scale	Fried phenotype, Frailty Index	3 or more of 5 = frail
Basic ADL	—	**Katz, Barthel, Lawton PSMS**	Barthel below 60 = dependent
IADL	—	**Lawton IADL, OARS**	Loss precedes ADL loss
Gait / mobility	Gait speed, TUG	Tinetti POMA, SPPB, Berg	Gait below 0.8 m/s; TUG above 12 s; Tinetti below 24
Cognition	Mini-Cog, AD8	MMSE, MoCA, SLUMS	MMSE below 24
Mood	PHQ-2	GDS-15/30, PHQ-9, CSDD	GDS-15 of 5 or more
Nutrition	MNA-SF, SNAQ	MNA full, BMI, weight loss	MNA-SF 11 or less
Vision	Snellen	Formal ophthalmic review	Below 6/18
Hearing	Whispered voice test	Audiometry, HHIE	Fails at 2 feet
Social	Lubben Social Network Scale	OARS social section	LSNS-6 below 12
Rehabilitation outcome	—	**FIM**	18 items

C. Latest Updates (2023–Present)

1. WHO ICOPE — from deficit to capacity. The ICOPE 5-step pathway (screen, assess, intervene, follow up, community engagement) screens **six domains — mobility, cognition, vitality/nutrition, vision, hearing and psychological well-being** — either by a professional or by self-assessment through the **ICOPE Monitor** app. Step-2 tools are named explicitly: **SPPB for mobility; Mini-Cog, MoCA, MMSE or GPCOG for cognition; MNA, DETERMINE, MUST or SNAQ65+ for nutrition; PHQ-9 for mood; pure tone and speech audiometry for hearing**.

2. Minimum data sets are now mandated. The **German S3 guideline (2024)** requires **six core dimensions in at least 15 minutes**; the **Italian guideline (2024)** recommends the **Multidimensional Prognostic Index (MPI)** for prognosis; **ASCO 2023** mandates the **Practical Geriatric Assessment (PGA)** in oncology. The trend is **domain-mandated but tool-agnostic**.

3. Gait speed is being repositioned as the single best functional marker. A 2025 Age and Ageing study of about 3,600 older adults found that among all components of frailty and sarcopenia, **low physical performance (slow gait speed) was the best single predictor of incident basic and instrumental ADL disability**; sarcopenia as a whole construct was not associated with increased disability risk. **EWGSOP2 defines low physical performance as gait speed of 0.8 m/s or less.**

4. Automated and digital tools. The **electronic frailty index (eFI2)** is replacing the original eFI in English primary care from 2025, allowing **population-level functional risk stratification from routine records**. mHealth and wearable-based functional assessment gives **objective, quantitative data** in place of subjective observer-rated scales, but a 2024 systematic review found **high risk of bias and minimal integration into daily practice**.

5. Diagnostic accuracy data for screening instruments. In emergency-department settings, seven screens pooled across 1,663 participants gave **sensitivity 0.85 and specificity 0.77** against full CGA; **PRISMA-7 was the most sensitive (0.84–0.98)** and the **Clinical Frailty Scale the most specific**, both with AUROC around 0.90.

6. Indian use. LASI applies Katz-type ADL and Lawton-type IADL items; grip strength was the **most discriminant frailty component in Indian men (79.1%)** and physical activity in women (81.6%). **AWGS (not EWGSOP2) cut-offs** should be used for sarcopenia-related functional measures in Indians, and **BIA rather than DXA** is the practical mass-measurement modality.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Choice of tool	Broad menu; "no consensus on the best scale"	**Domain mandated, tool still flexible**, but specific tools named per setting
Gait speed cut-off	Below 0.6 m/s abnormal; 0.6–0.8 high-risk	**0.8 m/s or less** operative threshold (EWGSOP2/AWGS); best single predictor of disability
Who administers	Trained professional or therapist	**Self-assessment and digital screening validated**; community health workers in LMICs
Data source	Interview and bedside observation	**Automated extraction from electronic records** (eFI2); wearables and sensors
Framing	Deficit-based (ADL/IADL loss)	Complemented by **capacity-based** framing (WHO intrinsic capacity)
Sarcopenia link	Not integrated	Functional tools now feed directly into **sarcopenia case-finding** (SARC-F, grip strength, gait speed)

E. Exam One-Liners

- **Katz and Barthel measure ADL; Lawton measures IADL; Tinetti and TUG measure mobility; MNA nutrition; GDS mood; MMSE cognition; Lubben social.**
- **Barthel is what the patient does, not what they can do** — and has a **ceiling effect** in ambulant patients.
- **FIM has 18 items** across six areas and is the rehabilitation standard.
- **TUG above 12 seconds; Tinetti below 24 of 28; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **0.1 m/s slower gait equals 7% higher fall risk.**
- **PSMS has grooming and ambulation; Katz has continence and transferring** — the classic distinguishing point.
- **Report tells you what they do; performance tells you what they can do** — measure both.
- **WHO ICOPE six domains:** mobility, cognition, vitality, vision, hearing, psychological.
- **A tool is only useful if its result changes the care plan.**

QUESTION 3

Functional Assessment in the Elderly

A. 20 High-Yield Points

Why Function Matters

1. **Functional assessment** means measuring **what the person actually does in daily life**. In geriatrics, **function is the common language** and assessment is the core method.
2. In an older person, **function predicts outcome better than diagnosis**. There is **no direct relationship between disease and functioning** — the same illness produces very different disability in different people, so function must be measured separately.
3. Functional decline results from **medical, functional, psychological, social and environmental** risk factors acting together. Hence assessment must be **multidimensional**.
4. A **baseline functional measure is essential** so that progress can be monitored and the effect of treatment or rehabilitation judged. **Reassess at least weekly during rehabilitation.**
5. Three levels are assessed: **impairment** (the deficit) → **activity restriction** (ADL/IADL loss) → **participation restriction** (loss of social role). Participation restriction is **unique to the individual** and depends largely on the ability to adapt.
6. Mobility must always be tested — **about half of people aged 85 and over report difficulty walking**, and gait disorders threaten independence and cause falls.

The Core Measures

7. The functional "review of systems" rests on three measures: **frailty, basic ADLs, and IADLs**.
8. **Principle of hierarchy:** if the patient is **severely ADL-dependent, do not test frailty**; if **robust or pre-frail, do not test basic ADLs**. Match the depth of assessment to the patient and the setting.
9. **Basic ADLs (personal care):** bathing, dressing, toileting, transferring, continence, feeding, grooming — **Katz, Barthel, Lawton PSMS**.
10. **IADLs (tasks needing instruments):** cooking, shopping, housework, laundry, telephone, transport, money, medicines — **Lawton IADL, OARS**.
11. **IADLs are lost first, ADLs later**, so IADL loss is the earlier warning sign. Always ask **"how does she manage?"**
12. **Always record premorbid function as well as present function**, especially after acute illness, a fall or hospital admission.

Domains to Cover

13. **Mobility, gait and balance:** gait speed (**below 0.6 m/s abnormal; 0.6–0.8 high-risk**), **TUG above 12 seconds**, **Tinetti below 24 of 28**, 30-second chair stand, 4-stage balance test, SPPB, Berg Balance Scale.
14. **Two screens are mandatory** in any older person with functional disability: **cognition** (MMSE) and **depression** (GDS or Zung).
15. **Other essential domains:** nutrition (**MNA**, SNAQ, weight loss), **special senses** (whispered voice test, Snellen), **oral health** (GOHAI), **continence**, and **social network and support** (**Lubben Social Network Scale**).
16. **Also assess:** pain, polypharmacy (Beers/STOPP-START), continence, sleep, alcohol (CAGE, SMAST-G), caregiver capacity, financial resources, and **home environment**.

How to Do It in Practice

17. Use **both report and performance**. Reports tell you what the person does **under real living conditions**; performance tests tell you what they can do **under standard conditions**.
18. **Grade each task** as: independent without difficulty / independent but with difficulty or an aid / needs human help / unable even with help. Distinguishing "independent with difficulty" adds prognostic value.
19. **Perform a task analysis** of the specific problem. *Example:* "difficulty dressing" may be due to choosing clothes, remembering to finish, buttoning, reaching overhead, or bending for shoes — pointing respectively to **cognitive impairment, poor finger mobility, or shoulder, back or hip disease**. Each demands a different treatment.
20. **Correlate any new functional loss** with **new drugs or dose changes (including over-the-counter)**, **changes in living conditions**, and **intercurrent acute illness (even mild)**. Remember the **cascade** — impaired gait leads to depression and withdrawal, and **immobility of any cause produces deconditioning that persists after the cause is removed**. Finally, **link assessment to a plan**: rehabilitation steps of **assessment, goal setting, therapy, aids and adaptations, education, psychological support, evaluation and follow-up**.

B. Practical Bedside Scheme

Step 1 — History Premorbid and current ADL/IADL status · exact task that fails · duration and rate of decline · pain · falls · continence · drugs (including over-the-counter) · nutrition and weight change · mood and motivation · social support and caregiver capacity · housing and environment.

Step 2 — Examination Postural blood pressure · vision and hearing screening · **observation of gait** · musculoskeletal (tone, power, joint range of motion, feet) · neurological (focal signs, sensation, proprioception) · **skin over pressure areas** · cognition (MMSE/MoCA) and mood (GDS).

Step 3 — Performance testing Gait speed over 4 metres · Timed Up-and-Go · 30-second chair stand · 4-stage balance · grip strength · observed transfer and stair climbing.

Step 4 — Baseline investigations Complete blood count, blood chemistry, **serum calcium (mg/dL), sodium (mEq/L), creatinine (mg/dL)**, thyroid function, vitamin B12, **25-hydroxy vitamin D**, haemoglobin (g/dL), fasting glucose or HbA1c, urinalysis.

Step 5 — Formulate and act Identify **reversible causes** → treat disease and pain → **deprescribe** → refer to physiotherapy, occupational therapy, dietician and social work → prescribe aids and adaptations → set goals with the patient → arrange **follow-up and case management**.

C. Latest Updates (2023–Present)

1. WHO ICOPE and intrinsic capacity. The five-step pathway screens **six domains — mobility, cognition, nutrition/vitality, vision, hearing and psychological well-being** — and can be done by a professional or by self-assessment through the **ICOPE Monitor** app. Reference centiles for intrinsic capacity and real-world screening data were published in *Nature Aging* (2023, 2024).

2. German DGG S3 Guideline (2024) defines minimum requirements — **six core dimensions in at least 15 minutes** — the first guideline to set a floor standard for functional assessment in hospital.

3. Age-Friendly Health Systems "4Ms." What Matters, Medication, Mentation and Mobility. In an eight-hospital 2024 evaluation of 3,103 admissions, patients receiving all 4Ms had **fewer 30-day emergency visits (16% vs 22%)**; **Mobility generated the highest "act-on" rate (83%)** of the four.

4. Gait speed as the single best marker. A 2025 longitudinal study found **slow gait speed the best single predictor of incident ADL and IADL disability**, outperforming both frailty and sarcopenia as constructs.

5. Italian CGA guideline (2024) — across 117 studies, CGA **maintains functional activities** and reduces hospitalisation, mortality, institutionalisation and delirium.

6. Oncology. ASCO 2023 requires geriatric assessment including **physical function** in all patients over 65 on systemic cancer therapy, using the **Practical Geriatric Assessment**.

7. Indian data. LASI wave-1 (31,464 adults aged 60 and above) found **about 3% with severe ADL disability and about 6% with severe IADL disability**, with **7.4% ADL dependency**. Rural surveys show far higher figures — **ADL disability 13.7% and IADL disability 38.7%** in rural Goa — associated with sex, education, financial dependence, comorbidity, alcoholism and **sensory impairment**. Functional tools are being adapted for community health worker delivery under **NPHCE**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Core concept	Function measured as **deficit** (ADL/IADL loss)	**WHO shift to intrinsic capacity** — measure **reserve**, not only deficit
Number of domains	Broad, flexible list	**Standardised minimum sets** — ICOPE six domains; German S3 six dimensions in 15 minutes
Gait speed cut-off	Below 0.6 m/s abnormal	**0.8 m/s or less** widely used; slow gait now the best single predictor of incident disability
Who assesses	Interdisciplinary professional team	**Self-assessment and digital screening validated**; community health worker delivery in LMICs
Hospital framing	ACE units and geriatric assessment programmes	**4Ms Age-Friendly framework** — Mobility as a named, auditable care process
Sarcopenia	Not integrated into functional assessment	Functional assessment now **routinely linked to sarcopenia case-finding**

E. Exam One-Liners

- **Function is the common language of geriatrics.**
- **IADLs go first, ADLs later** — IADL loss is the earlier warning.
- **Two screens you must never omit: cognition and depression.**
- **Hierarchy rule:** ADL-dependent, skip frailty; robust, skip basic ADLs.
- **Record premorbid function, not just current function.**

- **TUG above 12 s; Tinetti below 24; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **New functional decline equals a new drug, a new illness, or a new living situation** until proved otherwise.
- **Task analysis converts a vague complaint into a treatable diagnosis.**
- **WHO ICOPE six domains; 4Ms — What Matters, Medication, Mentation, Mobility.**
- **India (LASI): about 3% severe ADL and 6% severe IADL disability; 7.4% ADL dependency.**
- **Assessment without a linked care plan is not an assessment.**

QUESTION 4

Tests of Cognition and Rating Scales

A. 20 High-Yield Points

Principles

1. **Purpose of cognitive testing:** to establish **strengths and weaknesses of various functions relative to a standardised, norm-referenced scoring system**, so that the **nature and extent of cognitive deficits** can be determined, informing diagnosis and management and acting as a **comparator for past and future assessments**.
2. **A cognitive screen is not a diagnosis.** The MMSE and similar tools give an overall assessment of cognitive function, but **their use alone is not sufficient to establish a diagnosis of Alzheimer's disease or any dementia**.
3. **Cognitive screening is one of only two mandatory screens** (with depression) in any older person with functional disability.
4. **Key aspects of the mental status examination:** state of consciousness · general appearance and behaviour · orientation · **memory (short and long term)** · language · visuospatial function · **executive control functions** · other cognitive functions (calculations, proverb interpretation) · **insight and judgement** · thought content · mood and affect.
5. **Test all three components of memory: immediate recall** (repeating digits), **recent memory** (recalling three objects after a few minutes), and **remote memory** (details of early life).
6. **Executive function** involves the **planning, sequencing and execution of goal-directed activities**, and is **critical to the ability to perform IADLs**. Screen with the **clock-drawing test** (a component of the Mini-Cog) or **verbal fluency** (listing 12 animal names in one minute is normal).
7. **Interpretation depends on education and age.** The MMSE score is **dependent on sociocultural level and subject to a ceiling effect** — a crucial caveat in the Indian population, where illiteracy is common.
8. **Assess premorbid intellectual status** where possible (for example the National Adult Reading Test) to interpret other test scores correctly.
9. **Adapt tests to deficits.** In language impairment or dyspraxia, **recognition memory tests reduce the demand for expressive language** required by recall tests.
10. **Always include a standardised measure of mood** — depression is the commonest mimic of cognitive impairment.

Screening and Assessment Tools

11. **Recommended tools in primary care (Table 72.2):** - **Delirium: Confusion Assessment Method (CAM)** - **Dementia screening: AD8**, **Mini-Cog** - **Dementia assessment: SLUMS**, **MMSE**, **MoCA**
12. **Mini-Cog** screens **both memory (three-item recall) and executive function (clock drawing)** — quick, and relatively education-independent.
13. **MoCA and Addenbrooke's Cognitive Examination-Revised (ACE-R)** are described as **well-validated screening options**; ACE-R **incorporates the MMSE and clock-face drawing**.
14. **MMSE severity bands in Alzheimer's disease: mild 20–24, moderate 10–19, severe below 9.**
15. **Global staging scales combining cognition and ADLs: Global Deterioration Scale (GDS, Reisberg)** and the **Clinical Dementia Rating (CDR) scale**.
16. **Severe Impairment Battery (SIB)** was developed for subjects **too cognitively impaired for standard testing**.
17. **Memory-specific screens:** the **five-word test** and the **Memory Impairment Screen (MIS)** assess **anterograde verbal memory** at an initial consultation. For detailed evaluation, **free and cued recall** paradigms — the **Grober and Buschke test (Free and Cued Selective Reminding Test)** and the **California Verbal Learning Test** — distinguish mild Alzheimer's disease from healthy subjects with **more than 90% precision**, even when MMSE scores are similar.
18. **Domain-specific battery (Table 62.4 — Cardiff memory clinic):**

Domain	Tests
Premorbid ability	**National Adult Reading Test (NART)**
Cognitive screen / battery	**MMSE, MoCA, RBANS, Frontal Assessment Battery (FAB)**
Attention and concentration	Digits forward, digits backward, digit span
Language	**Boston Naming Test**, Irving Names Learning Test
Memory	Story recall (immediate and delayed), Kendrick tests, **California Verbal Learning Test**
Executive function	**Trail-Making Test A and B**, clock drawing
Visuospatial function	**Rey–Osterrieth Complex Figure**, clock drawing
Mood	**GDS-15**

Delirium Instruments

19. **Confusion Assessment Method (CAM)** — the standard; **sensitivity 94%, specificity 89%** with high inter-rater reliability. **Inattention** is tested at the bedside by **months of the year backwards, days of the week backwards, or digit span 3 or 4 backwards**. - **3D-CAM:** a structured **three-minute** screen — **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% in those without**. - **Best single item: "months of the year backwards"** (sensitivity 83%, specificity 69%). Best two items: months backwards plus "what is the day of the week?" (sensitivity 93%, specificity 64%). - **CAM-ICU** for intubated patients — inattention tested by squeezing on the letter A in "SAVEAHAART"; level of consciousness by **RASS score other than 0**.

Practical Conduct of Testing

20. Tests must be **acceptable to the person and contain nothing belittling**. **Consent must be obtained**, the purpose explained, and **sensory and physical limitations accommodated** — adequate lighting, earphone amplifiers, suitable seating, minimal distractions. Provide **realistic reassurance with positively phrased feedback that highlights strengths as well as weaknesses**, and at the end **allow patients to comment on their own performance**. Ideally an experienced psychologist or neuropsychologist performs formal testing, though **much useful information can be obtained by any suitably trained professional**. Introduce questions **non-threateningly**, because many patients with early deficits respond defensively.

B. Comparison of the Main Cognitive Tools

Tool	Items / time	Domains	Main strength	Main limitation
AMT (Hodkinson)	10 questions, 2 min	Orientation, memory	Very quick; RCP/BGS endorsed	Crude; misses executive and visuospatial deficits
Mini-Cog	3 min	3-word recall + clock drawing	**Relatively education-independent**; screens executive function	Screen only
AD8	8 items, informant	Change over time	Informant-based, detects change	Needs a reliable informant
MMSE	30 points, 10 min	Orientation, registration, attention, recall, language, construction	Most widely known; severity bands defined	**Education- and culture-dependent; ceiling effect; poor for executive function**; copyrighted
MoCA	30 points, 10–15 min	Adds executive, abstraction, visuospatial, attention	**Superior for mild cognitive impairment and executive dysfunction**	Lower specificity; education adjustment (+1 if 12 years or less)
SLUMS	30 points, 10 min	Adds executive and clock tasks	Free to use; education-stratified cut-offs	Less international validation
ACE-R / ACE-III	100 points, 20 min	Five domains; incorporates MMSE	Differentiates **Alzheimer's from frontotemporal dementia**	Long
RBANS	30 min	Repeatable battery	Serial testing without practice effect	Requires training
Frontal Assessment Battery	6 items	Frontal/executive	Detects subcortical and frontal deficits	Narrow
CAM / 3D-CAM / CAM-ICU	3–5 min	Delirium	**Gold standard for delirium**	Needs training; misses hypoactive cases if hurried
GDS (Reisberg) / CDR	Interview	Global staging	Combines cognition and function	Time-consuming
SIB	40 min	Severe dementia	Usable when MMSE floor is reached	Specialist tool

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria — Alzheimer's disease is now defined biologically. Diagnosis rests on **Core 1 biomarkers** — a positive **plasma p-tau217**, a positive **amyloid PET**, or abnormal **CSF ratios (p-tau181/Aβ42, t-tau/Aβ42, Aβ42/40)**. Cognitive testing now defines the **clinical stage**, not the disease itself. This is the single biggest conceptual change in the field.

2. Blood-based biomarkers have entered clinical use. Diagnostic models combining **plasma p-tau217 with age and ApoE genotype** achieve **AUC around 0.94** for Alzheimer's disease. In very elderly nursing-home and hospital populations, **plasma p-tau181, p-tau217 and GFAP differ significantly between cognitively normal and probable Alzheimer's groups**, while **Aβ42, Aβ40 and the Aβ42/40 ratio do not** — an important practical point, since amyloid ratios perform poorly in the oldest old.

3. Cognitive screens are being repositioned as triage. Rather than diagnosing, MMSE and MoCA increasingly serve to **decide who proceeds to biomarker testing**. Clinical trials now use combinations such as **CDR global score 0.5–1.0**

plus MMSE 21 or above plus a positive Core 1 biomarker for entry.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — has emerged as an **early indicator of dementia risk that may precede measurable cognitive decline**, and is being studied alongside plasma p-tau217.

5. Digital and mobile cognitive assessment. Mobile cognitive assessment systems have demonstrated **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening; future direction is **composite risk scores combining digital tests, wearables and plasma p-tau217**. Regulatory and ethical frameworks for data security, algorithmic transparency and equitable access are still being established.

6. Standardised inclusion in assessment frameworks. Cognition/delirium is one of the **six mandatory core dimensions** of the German S3 CGA guideline (2024); **cognition** is one of the **six WHO ICOPE domains**, with **Mini-Cog, MoCA, MMSE or GPCOG** named as step-2 assessment tools; **Mentation** is one of the **4Ms** of Age-Friendly Health Systems.

7. Indian context. In LASI wave-1, **impaired cognition was present in 9.3%** of adults aged 60 and above. Culture- and education-fair instruments are essential: **Hindi Mental State Examination (HMSE)**, **Vernacular MoCA versions**, **Rowland Universal Dementia Assessment Scale (RUDAS)**, **Indian Council of Medical Research Neuro-Cognitive Tool Box**, and **AIIMS Comprehensive Neuropsychological Battery in Hindi** are used in place of a directly translated MMSE, because **the standard MMSE penalises illiteracy heavily**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Basis of Alzheimer's diagnosis	Clinical, supported by cognitive tests and imaging	**Biological — 2024 NIA-AA criteria** based on Core 1 biomarkers
Role of MMSE/MoCA	Screening and severity grading	**Staging and triage** to biomarker testing; no longer diagnostic on their own
Biomarkers	CSF amyloid and tau "in some centres"	**Plasma p-tau217 in routine diagnostic pathways**; AUC around 0.94 with age and ApoE
Amyloid ratios	Presented as useful	**Aβ42/40 performs poorly in the oldest old**; p-tau217 and GFAP superior
Delivery	Face-to-face testing by trained staff	**Mobile and computerised assessment shown equivalent to MMSE/MoCA**
Preclinical detection	Subjective cognitive decline and MCI	Adds **mild behavioural impairment (MBI)** as an early neurobehavioural marker
Indian practice	MMSE with education caveat	**Education-fair tools mandatory** — HMSE, RUDAS, vernacular MoCA, ICMR NCTB

E. Exam One-Liners

- **A cognitive screen is not a diagnosis** — MMSE alone cannot diagnose Alzheimer's disease.
- **MMSE bands:** mild 20–24, moderate 10–19, severe below 9.
- **MMSE is education- and culture-dependent with a ceiling effect** — the key limitation in India.
- **MoCA beats MMSE for mild cognitive impairment and executive dysfunction.**
- **Mini-Cog = 3-word recall plus clock drawing** — screens memory and executive function in three minutes.
- **Clock drawing and verbal fluency screen executive function**, which drives **IADL** performance.
- **CAM sensitivity 94%, specificity 89%; 3D-CAM takes three minutes.**
- **Best single delirium item: months of the year backwards.**
- **ACE-R incorporates the MMSE and clock drawing** and helps separate Alzheimer's from frontotemporal dementia.
- **Free and cued recall (Grober–Buschke) separates mild Alzheimer's from normal with over 90% precision** even at similar MMSE scores.
- **Global staging: Reisberg GDS and CDR** combine cognition with function.
- **SIB is for patients too impaired for standard testing.**
- **2024 NIA-AA: Alzheimer's disease is now a biological diagnosis** — plasma **p-tau217**, amyloid PET, or CSF ratios.
- **Always pair cognitive testing with a mood scale**, and obtain consent and premorbid ability first.

QUESTION 5

Cognitive Assessment Tools

A. 20 High-Yield Points

Classification — the Framework to Open With

1. Cognitive assessment tools fall into **four functional groups**, and stating this classification first earns marks: - **Delirium instruments** — CAM, 3D-CAM, CAM-ICU, 4AT - **Brief screening tools** — Mini-Cog, AD8, AMT, GPCOG, MIS, six-item screener - **Cognitive screening batteries** — MMSE, MoCA, SLUMS, ACE-III, RUDAS - **Detailed neuropsychological batteries and staging scales** — RBANS, CVLT, Trail-Making, FAB, Boston Naming, Rey–Osterrieth; CDR and Reisberg GDS for staging
2. **A second axis is the informant dimension — performance-based** (patient does the task: MMSE, MoCA) versus **informant-based** (a relative reports change: **AD8, IQCODE**). Informant tools detect **change from a personal baseline** and are invaluable when education confounds performance tests.
3. **The tool must match the question:** *Is this delirium?* → CAM. *Is there any cognitive problem?* → Mini-Cog or AD8. *How severe and in which domain?* → MoCA, MMSE, SLUMS. *Which dementia is it?* → ACE-III with a full battery. *How advanced is it?* → CDR or Reisberg GDS.

Delirium Tools

4. **CAM** — sensitivity **94%**, specificity **89%**, high inter-rater reliability. Four features: **acute onset and fluctuating course, inattention, disorganised thinking, altered level of consciousness** (features 1 and 2 plus either 3 or 4).
5. **Inattention testing at the bedside: months of the year backwards, days of the week backwards, digit span 3 or 4 backwards**; or the examiner may simply observe **inappropriate distraction or loss of the thread of conversation**.
6. **3D-CAM** — three-minute structured version: **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% without dementia**. **CAM-ICU** for intubated patients uses the "SAVEAHAART" letter-A task and the **RASS**.

Brief Screens

7. **Mini-Cog — three-item recall plus clock drawing**; screens **memory and executive function** in about three minutes and is **relatively education-independent**, making it the most practical screen in Indian outpatient settings.
8. **AD8** — an **eight-item informant questionnaire** detecting change over time; useful when the patient's education level makes performance testing unreliable.
9. **Abbreviated Mental Test (Hodkinson, 10 items)** — the **RCP/BGS-endorsed** memory and cognition screen; extremely fast but crude.
10. **Memory Impairment Screen and the five-word test** assess **anterograde verbal memory** specifically at a first consultation.

Screening Batteries

11. **MMSE (Folstein, 1975)** — 30 points across orientation, registration, attention/calculation, recall, language and construction. **Interpretation is complex because thresholds depend on education and age**; it has a **ceiling effect** and **tests executive function poorly**. Severity bands: **mild 20–24, moderate 10–19, severe below 9**.
12. **MoCA (Nasreddine, 2005)** — 30 points; adds **trail-making, cube copy, clock drawing, verbal fluency, abstraction and delayed recall**, so it detects **mild cognitive impairment and executive/subcortical dysfunction far better than the MMSE**. **Add 1 point if formal education is 12 years or less.**
13. **SLUMS (Saint Louis University Mental Status)** — 30 points; free of charge, with **separate cut-offs for those with and without a high-school education**.
14. **ACE-R / ACE-III** — 100 points across **attention/orientation, memory, verbal fluency, language and visuospatial function**; ACE-R **incorporates the MMSE and clock-face drawing**, and the **VLOM ratio helps separate Alzheimer's disease from frontotemporal dementia**.
15. **RUDAS (Rowland Universal Dementia Assessment Scale)** — designed to be **culturally and linguistically fair**, needing no literacy; highly relevant to multilingual, variably literate Indian populations.

Detailed and Domain-Specific Tools

16. **Domain mapping (Table 62.4):** premorbid ability — **NART**; screening battery — **MMSE, MoCA, RBANS, FAB**; attention — **digit span forward and backward**; language — **Boston Naming Test**; memory — **story recall, California Verbal Learning Test**; executive — **Trail-Making A and B, clock drawing**; visuospatial — **Rey-Osterrieth Complex Figure**; mood — **GDS-15**.
17. **Free and cued recall tests** — the **Grober and Buschke test** and the **CVLT** — separate mild Alzheimer's disease from normal ageing with **more than 90% precision**, even when MMSE scores are identical, because they demonstrate a **hippocampal amnestic pattern (cueing does not improve recall)**.

18. **Staging scales: Clinical Dementia Rating (CDR)** and the **Reisberg Global Deterioration Scale** combine cognition with ADL impact. The **Severe Impairment Battery** is used when impairment is too severe for standard testing.

Rules of Use

19. **Practical conduct:** obtain **consent**, explain the purpose, ensure **adequate lighting, hearing amplification, suitable seating and no distractions**, introduce questions **non-threateningly**, phrase feedback **positively**, and give the patient a chance to comment on their own performance at the end. Assess **premorbid intellectual status** first, and **always add a mood scale**.
20. **Two cardinal caveats:** - **Depression and delirium must be excluded before any score is attributed to dementia** — screening tools become unreliable in delirium, and depression is the commonest reversible mimic. - **No cognitive screening test is appropriate for determining decision-making capacity.** Screens of **executive function** such as the **clock-drawing test** or the **Executive Interview** correlate better with decisional capacity than the MMSE, but capacity requires its own task-specific assessment.

B. Comparison Table — Choosing the Right Tool

Clinical question	Tool of choice	Time	Notes
Is this delirium?	**CAM / 3D-CAM / CAM-ICU**	3–5 min	Sensitivity 94%, specificity 89%
Rapid screen in a busy clinic	**Mini-Cog**	3 min	Education-independent; memory + executive
Screen when the patient cannot be tested	**AD8 or IQCODE** (informant)	3 min	Detects change from baseline
General cognitive assessment	**MoCA**	10–15 min	Best for MCI; add 1 point if education 12 years or less
Severity grading in known dementia	**MMSE**	10 min	Mild 20–24, moderate 10–19, severe below 9
Free alternative with education cut-offs	**SLUMS**	10 min	Education-stratified
Differentiating dementia subtypes	**ACE-III**	20 min	VLOM ratio; Alzheimer's vs frontotemporal
Illiterate or multilingual patient	**RUDAS, HMSE, vernacular MoCA**	10 min	Culture- and literacy-fair
Detecting early Alzheimer's memory pattern	**Grober–Buschke, CVLT**	20–30 min	Cueing fails to improve recall
Frontal or subcortical deficit	**FAB, Trail-Making B, verbal fluency**	5–10 min	Subcortical screen
Global staging	**CDR, Reisberg GDS**	Interview	Combine cognition and function
Severe dementia	**SIB**	40 min	Below the MMSE floor

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria define Alzheimer's disease **biologically** through **Core 1 biomarkers — plasma p-tau217, amyloid PET, or CSF p-tau181/Aβ42, t-tau/Aβ42 or Aβ42/40**. Cognitive tools now **stage the disease rather than diagnose it**.

2. Plasma p-tau217 is the practice-changing test. Models combining **plasma p-tau217, age and ApoE genotype** achieve **AUC about 0.94**. In the very elderly, **p-tau181, p-tau217 and GFAP discriminate probable Alzheimer's from normal cognition, while Aβ42, Aβ40 and the Aβ42/40 ratio do not** — so amyloid ratios should not be relied on in the oldest old.

3. Digital cognitive assessment. Mobile cognitive assessment systems show **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening. Future work is on **composite scores integrating digital tests, wearables (for example sleep fragmentation) and plasma p-tau217**, with cross-ethnic validation and regulatory frameworks still pending.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — is now recognised as an early dementia-risk indicator that may **precede measurable cognitive decline**, and is being validated against plasma p-tau217.

5. Mandated inclusion in assessment frameworks. German S3 CGA guideline (2024): cognition and delirium is one of six core dimensions. **WHO ICOPE:** cognition is one of six intrinsic-capacity domains, with **Mini-Cog, MoCA, MMSE and GPCOG** as named step-2 tools. **Age-Friendly 4Ms:** cognition sits under **Mentation**. **ASCO 2023 Practical Geriatric Assessment** includes a cognitive domain for every cancer patient aged 65 and above.

6. Indian tools and data. LASI wave-1 found **impaired cognition in 9.3%** of those aged 60 and above. Because the MMSE penalises illiteracy heavily, Indian practice uses the **Hindi Mental State Examination (HMSE)**, **RUDAS**, **vernacular MoCA versions**, the **ICMR Neuro-Cognitive Tool Box**, and the **AIIMS Comprehensive Neuropsychological Battery in Hindi**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
What the tools do	Screen for and grade cognitive impairment	**Stage the disease** and **triage to biomarker testing**
Diagnosis of Alzheimer's	Clinical, supported by imaging and sometimes CSF	**Biological (2024 NIA-AA)** — Core 1 biomarkers
Blood tests	Not diagnostically useful	**Plasma p-tau217 in routine pathways**; GFAP adds value
Amyloid measures	CSF amyloid used in some centres	**Aβ42/40 unreliable in the oldest old**
Mode of testing	Paper-and-pencil, face to face	**Mobile and computerised testing equivalent to MMSE/MoCA**
Preclinical markers	Subjective cognitive decline, MCI	Adds **mild behavioural impairment**
Cross-cultural use	MMSE with an education caveat	**Literacy-fair instruments mandatory** in India — RUDAS, HMSE, vernacular MoCA

E. Exam One-Liners

- **Four groups of tools:** delirium instruments, brief screens, screening batteries, detailed batteries and staging scales.
- **CAM for delirium; Mini-Cog or AD8 to screen; MoCA or MMSE to assess; ACE-III to subtype; CDR or Reisberg GDS to stage.**
- **Mini-Cog = 3-word recall plus clock drawing**, and is relatively education-independent.
- **AD8 and IQCODE are informant-based** — they measure change from the person's own baseline.
- **MoCA detects MCI and executive dysfunction better than MMSE; add 1 point if education is 12 years or less.**
- **MMSE has a ceiling effect, is education-dependent, and tests executive function poorly.**
- **RUDAS, HMSE and vernacular MoCA are the literacy-fair choices for Indian patients.**
- **Grober–Buschke free and cued recall demonstrates the hippocampal amnestic pattern of Alzheimer's disease.**
- **ACE-R incorporates the MMSE and clock drawing.**
- **Exclude delirium and depression before interpreting any cognitive score.**
- **No cognitive screening test determines decision-making capacity** — executive tests correlate better than the MMSE, but capacity needs its own assessment.
- **2024 NIA-AA: plasma p-tau217, amyloid PET or CSF ratios define the disease; cognition defines the stage.**

QUESTION 6

Assessment of Decisional Capacity in an Older Person

A. 20 High-Yield Points

Concepts and Definitions

1. **Capacity and competence are not the same.** A **clinician evaluates a patient's capacity to make a decision**; **competence is a legal term** implying that a person **has been deemed competent or incompetent by a court of law**. Someone not competent to act on their own behalf **requires an agent to act for them**.
2. **Competence** refers to a person's ability to **act reasonably after understanding the nature of the situation being faced**.
3. **Capacity is decision-specific and time-specific.** A patient may have capacity for one decision and not another, and may regain capacity later.
4. **Capacity is presumed until proved otherwise.** A **diagnosis of dementia — even by type — is not a sufficient indicator of a person's ability to comprehend and express a meaningful preference**. Intellectual deficits are **spotty**: a person may get lost or forget things yet still make decisions **with appropriate prompting**.
5. **The ethical foundation is autonomy** — the capacity of each adult and cognitively competent individual to **process information and freely decide on a course of action that best suits their own values, preferences, goals and desires**. Respect for autonomy underpins **informed consent**.
6. **Preconditions of valid informed consent: competence to understand and decide**, and **voluntariness in deciding**. The **information element** is **disclosure of relevant information** about the condition and the proposed course of action.
7. **An unwise decision is not incapacity.** In a patient with capacity, autonomy means "*you may not do things to me without my permission*" — **even if a patient's decision to refuse treatment seems unwise, if they have capacity their refusal stands**, and the clinician's **duty of care does not diminish**; all other care continues without prejudice.
8. **Just as it is wrong to infantilise patients** by directing questions to others who answer faster, **it is equally wrong to prejudge their ability to participate in decisions about their own care**.

The Four Elements of Decisional Capacity

9. **Decisional capacity is predicated on four elements** — the single most examinable list: - **Understanding** — the ability to comprehend the disclosed information about the nature of the situation or medical problem, the procedures involved, and the risks and benefits of undergoing or not undergoing testing or treatment. - **Appreciation** — of the significance of the disclosed information and the potential risks and benefits **for one's own situation and condition**. - **Reasoning** — the ability to engage in a reasoning process about the risks and benefits. - **Choice** — being able to **express a choice** whether or not to undergo further testing or treatment.
10. **The four US legal standards for determining decisional capacity** (a parallel, equally examinable list): - The patient is **aware of the treatment options and expresses a treatment preference clearly and consistently**. - The patient can give a **conventionally understandable reason** for the decision that is **consistent with their past behaviour**. - The patient **remembers and can tell back the information** about diagnosis, prognosis and treatment options given by the practitioner. - The patient can **state what their decision means for their own state of health**.
11. **The sliding-scale principle (Figure 95.1):** the **standard of decisional capacity required rises with the risk of the intervention**. A **fully cognisant patient with good health literacy** can consent to high-risk options such as a **phase 1 clinical trial**; a **cognitively impaired patient lacking decisional capacity could not consent to experimental treatment** and, given reduced life expectancy in advanced dementia, would be unlikely to benefit from highly toxic therapy even if it is standard of care. **The area between is the domain of best clinical judgement.** Hence **"staging the ageing is as important as staging the cancer."**

Assessment in Practice

12. **Distinguish memory from understanding** — a person may fail a memory test yet understand the decision at hand.
13. **No cognitive screening test is appropriate to determine decision-making capacity.** Screening tools that focus on **executive function** — the **Clock Drawing Test** or the **Executive Interview** — are **more likely to be associated with decisional capacity** than the MMSE.
14. **Formal capacity instruments exist but are difficult for older adults**, because they require consideration of **hypothetical situations and complex abstract thinking**. Examples: **MacCAT-T (MacArthur Competence Assessment Tool for Treatment — the reference standard)**, **Aid to Capacity Evaluation (ACE)**, **Capacity to Consent to Treatment Instrument (CCTI)**, **Hopemont Capacity Assessment Interview**, **Understanding Treatment Disclosures**.
15. **A useful practical criterion** in routine informed consent is to **recheck with the patient after an interval** to be certain that they **understand the situation and consistently state the same preference**.

16. **Maximise capacity before declaring its absence.** Before deciding a person cannot decide: correct **sensory deficits** (a deaf patient may need a hearing aid, many older people need glasses), **treat delirium, depression, pain and infection**, review sedating drugs, use **simple language, repetition and rephrasing**, choose a **quiet, distraction-free environment**, and involve a familiar person. Written material must be legible — a leaflet is useless if **the typeface is too small, the colour contrast is poor, or there is no white space**.
17. **Formal assessment of mental state may be necessary**, but **no specific score is associated with an inability to make decisions about one's personal healthcare** — this is an important negative statement to write in an examination.
18. **Where capacity is absent:** consult any **advance care directive** and the **surrogate or proxy decision-maker**. A proxy may be formally appointed through an **enduring power of attorney**, or the patient's wishes may be recorded in an **advance directive**; if none exists, the lead clinician must decide in the patient's **best interests**, or apply for **guardianship**.
19. **Hierarchy of treatment decision-makers** (Australian model, quoted in the textbook): **enduring guardian with authority → guardian with authority → adult son or daughter → parent → sibling → primary unpaid carer → other person with a close personal relationship and frequent contact**. The clinician goes to the first person who is **18 or older, has full legal capacity, and is reasonably available and willing**.
20. **Communication and documentation:** - **Relatives must not be given the impression that the decision is theirs to make** — they may suffer significant distress from the emotional burden. Their role is to provide **valuable information about what would be in the patient's best interests**. - Where families cannot bear to decide, the humane option is **"informed assent"** — explicitly offering them the choice to **defer to the provider's judgement**, documented clearly in the record. - **Anticipate decisions early in admission** so the patient can be involved as much as possible and **proxy decision-making is avoided**. - Clinicians must disclose: **the condition being treated; the nature of the proposed treatment or procedure; anticipated results; recognised alternatives; and recognised serious risks, complications and benefits, including of non-treatment.** - **Document the assessment, the reasoning and the outcome.**

B. Structured Approach to a Capacity Assessment

Step	Action
1. Define the decision	Capacity is **decision-specific** — state exactly which decision is in question
2. Presume capacity	Start from presumption; a diagnosis alone never establishes incapacity
3. Optimise the person	Treat delirium, pain, depression, infection; correct vision and hearing; review sedatives; choose the best time of day and a quiet setting
4. Disclose	Condition, proposed treatment, expected outcome, alternatives, serious risks, and the consequences of non-treatment — in **plain language**
5. Test the four elements	**Understanding** ("tell me in your own words") · **Appreciation** ("what does this mean for you?") · **Reasoning** ("how did you weigh those up?") · **Choice** ("so what would you like to do?")
6. Apply the sliding scale	Higher risk demands a higher standard of capacity
7. Recheck	Re-ask after an interval to confirm **consistency** of preference
8. Conclude and act	If capacity present, the decision stands even if unwise. If absent, consult advance directive, then surrogate, then best interests or guardianship
9. Document	Record the specific decision, the disclosure made, the four elements, the conclusion and the reasoning

C. The Indian Legal Framework

1. **Mental Healthcare Act (MHCA), 2017** is the governing statute across India and was rewritten after India ratified the **UNCRPD in 2007**. Capacity has a **pivotal role**.
2. **Section 4, MHCA 2017:** every person is **presumed to have the capacity to make mental healthcare and treatment decisions** if they can **understand the information, appreciate the foreseeable consequences of the decision, or communicate the decision by speech, gesture or any other means**.
3. **Memory loss, cognitive deficits, or even a formal diagnosis of dementia do not imply incapacity automatically** — the Act emphasises **establishing capacity**, and gives **preference to the choices and wishes of a person who has capacity**.
4. **The opinion of the assessor or a third party that a decision is "unwise" must not influence the capacity assessment.** Capacity is **specific to the task and to the time**.
5. **Advance directives — Section 5(3):** an advance directive is **invoked only when the person becomes incapacitated** and **remains effective until they regain capacity**. The Act does not clearly distinguish advance statements from advance directives.

6. **Nominated representative:** decision-making by a nominated representative is **restricted to those lacking capacity for mental healthcare decisions**. **Supported decision-making** ranges from minimal support to complete support.
7. **Other relevant Indian law:** the **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** (maintenance, protection, and transfer-of-property provisions), the **Rights of Persons with Disabilities Act, 2016** (limited guardianship), the **National Trust Act, 1999**, and **Elder Line 14567** for reporting abuse and neglect.
8. **Practical Indian caveat:** the **MacCAT-T, though the international reference standard, is not standardised for the Indian population**, and **family plays a central role in healthcare decision-making** in Indian and other Asian societies — creating real difficulties in operationalising individual autonomy and advance directives.

D. Latest Updates (2023–Present)

1. Indian evidence base is only now emerging. A 2025 descriptive cross-sectional study of mental capacity and advance directives in Indian persons with mental illness confirmed that **published Indian data remain very scarce**, that **the MacCAT-T is regarded as the gold standard but is not standardised for India**, and that the **central role of the family creates practical difficulty in determining advance directives** and enabling individual decision-making about future treatment.

2. Dementia and Indian law. A published analysis of the assessment of dementia under prevailing Indian laws confirms that under **Section 4 of MHCA 2017 a diagnosis of dementia does not itself establish incapacity**, and sets out the four components of the decision-making process as **understanding, appreciating, reasoning and communicating**. It also distinguishes **capacity** (clinical) from **competence** (legal — relating to valid contracts and financial and personal decision-making).

3. UK practice guidance (2024). NHS England guidance restates the functional test as the ability to **understand the relevant information, retain it long enough to make the decision, weigh up the arguments on each side, and communicate the decision** (by talking, signing or any other means). It provides a **practical checklist**: choose a quiet space free from distractions and noise, avoid jargon, **repeat and rephrase questions**, and **identify in advance what the "relevant information" for that specific decision is**. Essex Chambers publishes decision-specific guidance on what constitutes relevant information for different categories of decision.

4. High prevalence of impairment in institutional settings. Older adults evaluated in long-term care have **rates of capacity impairment between 44% and 69%** — an argument for routine, structured assessment rather than ad hoc judgement.

5. Convergence with capacity-based frameworks. The **German S3 CGA guideline (2024)** mandates cognition and delirium assessment as a core dimension; **WHO ICOPE** includes cognition and psychological well-being. Both feed directly into capacity evaluation, and the **Age-Friendly 4Ms** place **"What Matters"** — eliciting the person's own goals — as the first M, operationalising autonomy in routine care.

E. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Legal framework	Generic Western frameworks; Australian guardianship hierarchy quoted	**India: MHCA 2017 governs**, with statutory presumption of capacity and nominated representatives
Effect of a dementia diagnosis	A diagnosis is not a sufficient indicator of incapacity	**Statutorily reinforced** — Section 4 MHCA: dementia does not imply incapacity
Instruments	Formal tools exist but are hard for older adults	**MacCAT-T remains the gold standard but is not standardised for Indian populations**
Cognitive tests	No screening test determines capacity; executive tests correlate better	Unchanged and reaffirmed
Role of family	Consult relatives for best interests, but do not transfer the decision	**In India, family-centred decision-making is normative**, creating tension with individual-autonomy models
Documentation	Recommended	Now expected to be **decision-specific**, recording the relevant information disclosed
Autonomy in routine care	Ethical principle	Operationalised as **"What Matters"** in the 4Ms framework

F. Exam One-Liners

- **Capacity is clinical and decision-specific; competence is legal and determined by a court.**
- **The four elements: Understanding, Appreciation, Reasoning, Choice.**
- **Capacity is presumed** — a diagnosis of dementia never establishes incapacity by itself.
- **An unwise decision is not incapacity.** If the patient has capacity, their refusal stands, and the duty of care does not diminish.
- **Sliding scale:** the higher the risk of the intervention, the higher the standard of capacity required.

- **"Staging the ageing is as important as staging the cancer."**
- **No cognitive screening test determines capacity**; **clock drawing and the Executive Interview** correlate better than the MMSE.
- **No specific MMSE score defines incapacity.**
- **MacCAT-T is the reference instrument** — but is not standardised for India.
- **Maximise capacity first:** treat delirium, depression and pain; correct hearing and vision; simplify language; choose a quiet room and the best time of day.
- **Recheck after an interval to confirm the preference is consistent.**
- **Section 4, MHCA 2017 (India):** presumption of capacity; understand, appreciate consequences, communicate by any means.
- **Section 5(3), MHCA 2017:** advance directive is invoked only on incapacity and lapses when capacity returns.
- **Never make the family feel the decision is theirs** — offer **"informed assent"** where they cannot bear to decide.
- **Anticipate decisions early in the admission** so that proxy decision-making is avoided.

QUESTION 7

Geriatric Syndromes — An Overview

A. 20 High-Yield Points

Concept and Definition

1. **A geriatric syndrome is a clinical condition in older people that does not fit into a discrete disease category.** Geriatric syndromes are **highly prevalent, multifactorial, and associated with substantial morbidity and poor outcomes**.
2. **The defining feature is a many-to-one and one-to-many relationship: multiple contributing causes converge on a single presenting problem**, and **any one problem may arise from many different causes**. This is the opposite of the classical single-disease model.
3. **Because diagnoses often do not tell the whole story in geriatrics, it is more helpful to think in terms of presenting problems.**
4. **The underlying principle is homeostenosis** — the progressive decline in the **reserve capacity of all organ systems** with increasing age, so that **several small deficits combine to cross a threshold** and produce a syndrome that no single deficit would have caused.
5. **The classical list — "the series of I's": Immobility · Instability (falls) · Incontinence · Intellectual impairment · Infection · Impairment of vision and hearing · Irritable colon · Isolation (depression) · Inanition (malnutrition) · Impecunity · Iatrogenesis · Insomnia · Immune deficiency · Impotence.**
6. **Morley's "new geriatric giants"** add **frailty, sarcopenia, anorexia of ageing and cognitive impairment** — reflecting the modern emphasis on pre-disability states.
7. **Illustrative example (immobility):** it may be caused by a **fractured hip, congestive heart failure, a recent fall with fear of falling, or pain from degenerative joint disease** — any or all together. It is essential to **explore the underlying causes with the individual** so that appropriate interventions can be implemented; **pain and fear of falling must be addressed before engaging the person in an exercise programme**.

Shared Risk Factors — the Unifying Concept

8. **Four shared risk factors run across the five best-validated geriatric syndromes** (Tinetti, Inouye, Gill and Doucette, *JAMA* 1995; Inouye et al., *JAGS* 2007): - **Older age** - **Baseline cognitive impairment** - **Baseline functional impairment** - **Impaired mobility**
9. **The five syndromes in which these were demonstrated: pressure ulcers, incontinence, falls, functional decline and delirium.**
10. **Clinical corollary:** because the risk factors are shared, **multiple risk factor reduction is more effective than the regular single-disease medical model**, and **one intervention can prevent several syndromes at once**.
11. **Landmark proof-of-concept trials: Inouye's multicomponent HELP intervention (NEJM 1999)** for delirium prevention, and **Tinetti's multifactorial intervention (NEJM 1994)** to reduce falls in the community — both showing that **targeting shared risk factors works**.
12. **The number of risk factors present determines the total risk**, which rises **proportionally** as they accumulate — demonstrated by Tinetti for dizziness (five to seven significant risk factors).

Iatrogenesis — a Special Emphasis

13. **Iatrogenesis is an all too common problem, and the risk increases with exposure to the care system** — tests, surgical interventions, medications and treatments. In every interaction the **risk–benefit balance must be considered and explained** to the individual and their proxy.
14. **Medication management** needs particular deliberation, because older adults have **marked changes in absorption, metabolism and excretion**. Use **Beers criteria and STOPP-START**, review **anticholinergic burden**, and check **QTc risk with psychotropics**.
15. **Even more dangerous is the careless, hasty application of clinical labels.** A patient who becomes confused in hospital may **not** have dementia; a person with an occasional urinary accident is **not necessarily incontinent**. **Labelling a patient as demented or incontinent is too often the first step towards nursing-home placement — a setting that can make such labels self-fulfilling prophecies.**

Assessment and Management

16. **The clinical method for any geriatric syndrome:** - Treat the **presenting problem as a syndrome, not a diagnosis** - Enumerate **all contributing factors** rather than searching for one cause - Look specifically for the **shared risk factors** — cognition, function, mobility - Search for **reversible contributors**: a **new drug or dose change (including over-the-counter), an intercurrent acute illness, or a change in living conditions** - Intervene on **as many factors as possible simultaneously** - **Link assessment to a care plan and long-term follow-up**

17. **Comprehensive geriatric assessment is the definitive vehicle** for identifying and managing geriatric syndromes, because it is the only method that systematically covers all the contributing domains at once.
18. **Criteria for targeting CGA in diabetes (Table 86.6)** show how syndromes drive referral: **presence of a geriatric syndrome (confusional state, depression, falls, incontinence, immobility, pressure sores)**; pre-frailty or frailty; several coexisting morbidities with complex drug regimens; disability from lower-limb vascular disease or neuropathy requiring rehabilitation; and **absence of a terminal illness or dementing syndrome**.
19. **Cross-syndrome prevention principles: mobilise early ("bed is bad")**, **deprescribe**, **maintain hydration and nutrition**, **correct vision and hearing**, **avoid restraints and catheters**, **screen for cognition and mood**, and **treat pain**. Because pressure injuries, falls, delirium and functional decline share risk factors, **multifactorial interventions delivered by a multidisciplinary team** are effective across all of them.
20. **The major barrier is implementation, not evidence.** Preventive strategies of proven effectiveness for **delirium and falls** exist, but **major barriers have been identified in translating research advances into clinical practice and policy**.

B. The Major Geriatric Syndromes at a Glance

Syndrome	Key shared drivers	First-line action
Falls and instability	Gait/balance impairment, drugs, vision, cognition, environment	Multifactorial assessment; TUG, Tinetti; deprescribe; strength and balance exercise; home hazards
Immobility	Pain, disease, fear, iatrogenesis, environment	Treat pain and cause; early mobilisation; physiotherapy and occupational therapy
Delirium	Cognitive impairment, sensory deficits, drugs, infection, dehydration, immobility	**CAM**; HELP-type multicomponent prevention; treat precipitants
Dementia and cognitive impairment	Age, vascular risk, sensory deficits	Mini-Cog/MoCA; exclude reversible causes; caregiver support
Incontinence	Mobility, cognition, drugs, local pathology	Bladder diary; exclude retention, infection, impaction; timed toileting
Pressure injury	Immobility, nutrition, incontinence, low weight	Braden/Norton; pressure relief; nutrition; skin care
Frailty and sarcopenia	Disease, poor intake, sarcopenia, executive dysfunction	FRAIL screen; resistance exercise plus protein 1 g/kg/day; deprescribe if more than 5 illnesses
Malnutrition and anorexia of ageing	Social, sensory, gastric, hormonal factors	MNA; **MEALS-ON-WHEELS** mnemonic
Polypharmacy and iatrogenesis	Exposure to the care system	Beers, STOPP-START; medication reconciliation
Functional decline	All of the above	CGA and rehabilitation
Depression and isolation	Loss, disability, chronic disease, loneliness	PHQ-2 then GDS-15; social prescribing
Sensory impairment	Age-related	Snellen, whispered voice test; spectacles, cataract surgery, hearing aids
Insomnia	Pain, nocturia, drugs, depression, environment	Sleep hygiene; avoid hypnotics
Elder abuse and neglect	Dependency, caregiver burden, cognitive impairment	Direct enquiry; **Elder Line 14567** in India

C. Latest Updates (2023–Present)

1. The shared-risk-factor model is now the accepted organising principle. The Inouye/Tinetti framework — **four shared risk factors (older age, baseline cognitive impairment, baseline functional impairment, impaired mobility) across five syndromes (pressure ulcers, incontinence, falls, functional decline, delirium)** — remains the definitional basis, with current work focused on **synergistic interactions between risk factors** and on the **basic mechanisms** underlying multifactorial conditions.

2. Screening tools have been packaged. The **Rapid Geriatric Assessment (RGA)** bundles four syndromes — **frailty, sarcopenia, geriatric anorexia and cognitive decline**. Administered to **16,615 people aged 65 and over in Missouri between 2015 and 2024**, it showed that nearly **40% reported five or more illnesses (37.3%)**, linking syndrome screening to multimorbidity risk.

3. Multiple geriatric syndromes are the rule, not the exception. A Chinese community study of 706 adults aged 60 and above (2022–23) assessed **ten syndromes — depressive symptoms, cognitive impairment, pain, falls, sleep disturbance, constipation, polypharmacy, multimorbidity, malnutrition and frailty** — and defined **"multiple geriatric syndromes" as two or more in one individual**. A 2023–24 hospital CGA study in Shanghai similarly evaluated **pain, sleep, constipation, fall risk, urinary incontinence, polypharmacy, nutritional risk and dementia** in a single assessment, using **Mini-Cog, Snellen chart and Timed Up and Go** for in-depth evaluation of those screening positive.

4. Standardised syndrome-based CGA is now guideline-mandated. The **German S3 guideline (2024)** requires **six core dimensions — self-help ability, mobility, cognition/delirium, affect, nutrition and social situation** — which

map almost exactly onto the major geriatric syndromes. The **Italian guideline (2024)**, from 117 studies, showed CGA **reduces hospitalisation, mortality, institutionalisation and delirium risk** and **improves prescribing appropriateness**.

5. WHO ICOPE reframes syndromes as losses of intrinsic capacity. The six domains — **mobility, cognition, vitality/nutrition, vision, hearing and psychological well-being** — are essentially the geriatric syndromes re-expressed as **capacities to be preserved rather than deficits to be treated**.

6. Frailty is now the strongest single predictor of adverse syndrome outcomes. A pooled odds ratio of **9.82 for incident ADL disability in frail older adults** has been reported, and the **NEJM 2024 review by Kim and Rockwood** established **"frailty-guided clinical care"**, stratifying management across **robust, pre-frailty, frailty and end-stage frailty**.

7. Indian burden. LASI wave-1 (31,464 adults aged 60 and above) found **44.3% with no geriatric condition, 32.7% with one, 15.9% with two and 7.1% with three or more**. Individual prevalences: **underweight 26.9%, dizziness 14.5%, impaired vision 13.7%, impaired hearing 9.6%, impaired cognition 9.3%, major depressive disorder 8.2%, injurious falls 5.7%, incontinence 4.0%**, with **7.4% ADL dependency**. **Both a higher number of geriatric conditions and a higher number of chronic conditions predicted ADL dependency.** Frailty affects **29.2%** and pre-frailty **58.8%**. The most disabling multimorbidity combination is **hypertension plus arthritis plus high depressive symptoms**.

D. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Definition	Descriptive list of "I's"; concept acknowledged as poorly defined	**Operationalised** around four shared risk factors across five validated syndromes
Number recognised	14 classical "I's" plus new giants	Studies now routinely screen **8–10 syndromes simultaneously** in one CGA
Screening	Clinician-led, opportunistic	**Packaged instruments (Rapid Geriatric Assessment)** and **guideline-mandated core domain sets**
Framing	Deficits and presenting problems	Complemented by **WHO intrinsic capacity** — the same domains framed as capacities
Frailty	One syndrome among many	The **central organising syndrome**, used to guide treatment intensity ("frailty-guided care")
Evidence gap	Multifactorial interventions effective for falls and delirium	Evidence secure; **the barrier is implementation and policy translation**
Indian data	Not addressed	**LASI provides national prevalence**; over half of Indian elders have at least one geriatric condition

E. Exam One-Liners

- **A geriatric syndrome is a multifactorial condition that does not fit a single disease category.**
- **The core principle is homeostenosis** — reduced reserve across all organ systems.
- **Many causes, one presentation; one presentation, many causes.**
- **The series of I's:** Immobility, Instability, Incontinence, Intellectual impairment, Infection, Impairment of vision and hearing, Irritable colon, Isolation, Inanition, Impecunity, Iatrogenesis, Insomnia, Immune deficiency, Impotence.
- **New geriatric giants:** frailty, sarcopenia, anorexia of ageing, cognitive impairment.
- **Four shared risk factors:** older age, baseline cognitive impairment, baseline functional impairment, impaired mobility.
- **Five validated syndromes:** pressure ulcers, incontinence, falls, functional decline, delirium.
- **Multiple risk factor reduction beats the single-disease model** — proved by Inouye (delirium, 1999) and Tinetti (falls, 1994).
- **Iatrogenesis rises with exposure to the care system.**
- **The careless application of a label is more dangerous than the syndrome** — "demented" or "incontinent" can become a self-fulfilling prophecy leading to institutionalisation.
- **CGA is the definitive vehicle for detecting and managing geriatric syndromes.**
- **India (LASI): 55.7% of elders have at least one geriatric condition; 7.1% have three or more; ADL dependency 7.4%.**
- **The evidence is settled; the barrier is implementation.**

End of Set 1.

MD Geriatric Medicine — High-Yield Examination Answers

Set 3: Frailty • Sarcopenia • Deconditioning • Biology & Immunology of Ageing
Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition • Supplementary: Kane's Essentials of Clinical Geriatrics

Q1. Frailty — Pathogenesis, Diagnosis, Prevention and Management RECURS

15–20 High-Yield Points (Textbook)

A. Definition and Concept

1. **Frailty** is the condition in which a person loses the ability to carry out important, practised social activities of daily living when exposed to **psychological or stressful conditions**.
2. Frailty is a state of **pre-disability** and must be distinguished from **disability** and from **comorbidity**; it is now recognised as a **public health priority**.
3. By Fried's phenotype about **6.9%** of the older population are frail; **women are more often frail than men** of the same age.
4. Vitality peaks between **20 and 30 years**, then declines gradually; the decline is **slowed by exercise** and **accelerated by disease**, but everyone eventually crosses the **frailty threshold** if they live long enough.
5. Frailty begins a cascade: **Healthy → Frailty → Disability → Hospitalisation → Institutionalisation → Death** (recovery is possible at each step).

B. Pathogenesis

6. Causes are **multifactorial**: normal ageing physiology interacts with **genes, lifestyle, environment and disease**.
7. In most people frailty results from failure to generate **adequate muscle power** and/or failure of **executive function** to use the available capacity appropriately.
8. **Chronic disease** causes frailty mainly through **excess cytokines** (reduce muscle mass, food intake and cognition) and through a fall in **testosterone**.
9. **Congestive heart failure**: fall in VO_2max; left-sided failure causes gut wall oedema → **bacterial translocation** → endotoxin → **TNF-α** → anorexia, muscle loss, weight loss, hypoalbuminaemia and hypocholesterolaemia. **Weight loss and hypocholesterolaemia are the best predictors of poor outcome.**
10. Angiotensin II activation cleaves actomyosin with clearance by the **ubiquitin–proteasome system**; **ACE inhibitors reverse weight loss and frailty** in some patients with CHF.
11. **COPD**: loss of endurance, poor intake, raised resting metabolic rate, low testosterone and high cytokines. **Diabetes**: low testosterone, high angiotensin II, high cytokines, neuropathy, sarcopenia, poor executive function and accelerated atherosclerosis — mortality is increased in frail diabetics.
12. **Anaemia** causes reduced endurance, weakness, orthostasis, falls, disability and death; **erythropoietin or darbepoetin-α** can reverse this — an example of **single-cause reversible frailty**.
13. **Anorexia of ageing**: social isolation and low mood, reduced smell and raised taste threshold, reduced gastric compliance and adaptive relaxation causing **early satiety**, excess **cholecystokinin**, and high cytokines. In men falling testosterone raises **leptin** and worsens anorexia.
14. Reversible causes of weight loss are remembered by the **MEALS-ON-WHEELS** mnemonic (Medications, Emotional, Alcohol/abuse, Late-life paranoia, Swallowing, Oral, Nosocomial infection, Wandering/dementia, Hyperthyroidism–hypercalcaemia–hypoadrenalism, Enteral problems, Eating problems, Low-salt/low-cholesterol diets, Stones).
15. **Sarcopenia** is the core biological substrate, driven by falling testosterone (**1% per year after age 30**), low IGF-1, low vitamin D, raised **myostatin**, and raised **TNF-α, IL-6 and CRP**. **Progranulin** is described as a biomarker of frailty.

C. Diagnosis

16. Two conceptual models: the **phenotype model** (Fried's criteria, Frailty Trait Scale, FRAIL scale) and the **cumulative deficit model** (Frailty Index, Clinical Frailty Scale).
17. Three commonly compared scales are the **Cardiovascular Health Study (Fried)**, the **Study of Osteoporotic Fractures (SOF)** index, and the **FRAIL** scale of the International Association of Nutrition and Aging.
18. **Principle of hierarchy**: if a patient is severely ADL-dependent it is not worthwhile assessing frailty; if a patient is robust or pre-frail it is not worthwhile assessing basic ADLs.

D. Management and Prevention

19. Management follows the **FRAIL screen algorithm** (Morley): **F**atigue – exclude depression, sleep apnoea, hypothyroidism, anaemia, hypotension and vitamin B12 deficiency; **R**esistance – treat sarcopenia with **resistance exercise plus protein 1 g/kg/day**; **A**erobic – aerobic and balance exercise; **I**llnesses – if more than five, consider **deprescribing**; **L**oss of weight – look for treatable causes (MEALS-ON-WHEELS).
20. Hormonal approaches described: **testosterone replacement** increases muscle mass, strength and power even in non-hypogonadal men; **selective androgen receptor molecules (SARMs)** — steroidal (nandrolone, oxymetholone, oxandrolone) and non-steroidal (2-quinoline, coumarin, phthalimide, bicalutamide, acetothiolutamide); **creatine with exercise** may improve muscle performance.
21. **Prevention** is lifelong: regular exercise keeps the life-slope above the frailty threshold, along with adequate protein

and energy intake, correction of vitamin D and B12 deficiency, tight control of chronic disease, avoidance of polypharmacy, and **comprehensive geriatric assessment** to detect pre-frailty early.

Extra Points to Remember (Recurring Topic)

- **Frailty vs disability vs comorbidity** (Fried 2004): frailty = loss of physiological reserve; disability = loss of function; comorbidity = two or more diseases. They overlap but are not the same — a favourite examiner question.
- The **stressor** is the key concept: a frail person is precipitated into disability by a minor event (urinary infection, a new drug, a short admission) that a robust person would tolerate.
- **Frailty can be single-cause and fully reversible** — anaemia corrected with iron, folate, vitamin B12 or erythropoietin is the classic example quoted in Pathy.
- Draw the **frailty threshold graph** (VO_2max / cardiac output / balance / muscle strength against age, with an "exercise" line above and a "disease" line below the threshold) — earns marks quickly.
- Remember both mnemonics: **FRAIL** (screening and management) and **MEALS-ON-WHEELS** (weight loss).

Latest Updates (2023–Present)

- **Indian burden is far higher than the textbook figure.** Analysis of **LASI wave-1** published in the *Indian Journal of Medical Research* (2024) found **about 30% of Indians aged 60 and above were frail and 58% pre-frail**; rural 31% versus urban 25.6%; women 32.2% versus men 27.4%. A 2024 meta-analysis of Indian healthcare settings (*J Family Med Prim Care*) reported pooled frailty of **42.3%** and pre-frailty of **39.8%** in clinic and hospital populations.
- **ICFSR International Clinical Practice Guidelines** remain the operative standard: screen all adults over 65 with a validated tool (FRAIL, gait speed or PRISMA-7), then offer **progressive resistance training**, address reversible causes, correct **vitamin D deficiency**, provide protein-energy supplementation where indicated, and review medications. **No drug is approved for frailty.**
- **SPRINTT trial** (Bernabei et al.) showed that a multicomponent physical activity plus nutrition programme reduced incident **mobility disability** in community-dwelling frail and sarcopenic older adults with SPPB 3–9 — the strongest randomised evidence to date.
- **Network meta-analyses (2024–2026)** consistently place **multicomponent exercise (resistance + aerobic + balance, with or without a cognitive task) combined with protein supplementation** at the top of the ranking for reversing frailty; protein target has moved to **1.0–1.5 g/kg/day**.
- The **Japanese Nutritional Management Guidelines for Sarcopenia and Frailty (2025)** recommend energy as well as protein supplementation, noting that effects in frail and sarcopenic elders are at least as large as in healthy elders.
- **Deprescribing** is now formally an anti-frailty intervention; anticholinergics, psychotropics and inappropriately continued statins are specifically implicated in worsening frailty status.
- **WHO ICOPE (2nd edition, 2025)** shifts the operational frame from a single frailty syndrome to **intrinsic capacity** across six domains (locomotion, vitality, cognition, psychological, vision, hearing), which is the model being adopted for primary care screening.
- The **2023 update of the Hallmarks of Ageing** (López-Otín, *Cell*) formally added **chronic inflammation** and **dysbiosis**, giving biological legitimacy to the inflammaging basis of frailty.
- **India-specific service context**: NPHCE geriatric clinics and Regional Geriatric Centres, the **Ayushman Vay Vandana Card** (free cover of Rs 5 lakh for all citizens aged 70 and above, irrespective of income), **Rashtriya Vayoshri Yojana** for assistive devices, and **Elder Line 14567** for social support — all relevant to a frailty care plan in an Indian answer.

Current Practice Update

Issue	Textbook (Pathy 6e)	Current Evidence (2023–present)
Prevalence	About 6.9% of older people are frail	Highly population-dependent; **India ~30% frail, 58% pre-frail** (LASI); up to 42% in Indian clinical settings
Drug therapy	Considerable emphasis on testosterone, SARMs, creatine, ACE inhibitors	**No pharmacological agent is recommended for frailty**; testosterone is not an anti-frailty indication; exercise and nutrition are first-line
Protein target	1 g/kg/day	**1.0–1.5 g/kg/day**, higher in acute illness, with leucine-enriched supplements where intake is poor
Exercise prescription	Resistance plus aerobic and balance exercise	**Multicomponent programme** (resistance + power + balance + aerobic, ideally with a cognitive/dual task) for 3–5 months, ranked superior to any single modality
Conceptual frame	Frailty as a discrete pre-disability syndrome	Moving to **intrinsic capacity** (WHO ICOPE 2nd edition) and to a **frailty–sarcopenia continuum**
Medication review	Deprescribe if more than five illnesses	Deprescribing is a **core, evidence-supported intervention** in its own right, independent of illness count

Exam One-Liners

- Frailty = **pre-disability**; disability = established loss of function.
- Fried phenotype prevalence in Pathy = **6.9%**; in India (LASI) = **~30%**.
- Best predictors of poor outcome in CHF-related frailty = **weight loss and hypocholesterolaemia**.
- Management mnemonic = **FRAIL**; weight-loss mnemonic = **MEALS-ON-WHEELS**.
- Only interventions with consistent benefit = **multicomponent exercise + protein + deprescribing + CGA**.
- Biomarker named in Pathy = **progranulin**; inflammatory triad = **TNF-α, IL-6, CRP**.

Q2. Fried's Criteria

15–20 High-Yield Points (Textbook)

1. Fried's criteria constitute the **physical phenotype of frailty**, derived from the **Cardiovascular Health Study (CHS)** and published by Linda Fried and colleagues in 2001.
2. They provide the first **objective, operational definition** of frailty and remain the reference standard against which other tools are compared.
3. **Five components**: unintentional weight loss, exhaustion, weakness, slow walking speed, and low physical activity.
4. **Weight loss**: unintentional loss of **10 lb (about 4.5 kg) in the preceding year** (or 5% of body weight).
5. **Exhaustion**: **self-reported**, based on two items of the CES-D scale ("everything I did was an effort" / "I could not get going" for three or more days in the last week).
6. **Weakness**: **grip strength in the lowest 20%** of the population, adjusted for **sex and body mass index**.
7. **Slowness**: walking speed over **15 feet in the slowest 20%**, adjusted for **sex and height**.
8. **Low physical activity**: weekly energy expenditure in **kcal per week in the lowest 20%**, calculated from a physical activity questionnaire.
9. **Scoring**: **0 = robust; 1–2 = pre-frail (intermediate); 3 or more of 5 = frail**.
10. By this definition about **6.9%** of older people are frail, and **women are classified as frail more often than men** of the same age.
11. The phenotype rests on a **cycle of frailty**: sarcopenia leads to reduced strength and VO_2max, which reduce walking speed and activity, which lower energy expenditure and intake, causing weight loss and further sarcopenia.
12. Fried also separated the concepts of **frailty, disability and comorbidity**, showing they overlap but predict outcomes independently.
13. The phenotype predicts **falls, worsening mobility, incident disability, hospitalisation and death** over three years.
14. **Sarcopenia is regarded as the biological substrate** of the Fried physical phenotype, and the combined construct "physical frailty and sarcopenia" is now used.
15. Two simpler validated alternatives are given alongside it in Pathy: the **Study of Osteoporotic Fractures (SOF) index** and the **FRAIL scale**.
16. **SOF index** (3 items, 2 or more = frail): weight loss; **inability to rise from a chair five times without using the arms**; reduced energy level.
17. **FRAIL scale** (5 items, 3 or more = frail): **F**atigue; **R**esistance (cannot climb one flight of stairs); **A**mbulation (cannot walk one block); **I**llnesses (more than five); **L**oss of weight (5% or more).
18. **Advantages**: objective, reproducible, biologically coherent, extensively validated.
19. **Limitations**: requires a **dynamometer and a measured walking course**; excludes **cognition, mood and social factors**; cannot be applied to wheelchair-bound or acutely ill patients; population-specific cut-offs are needed.

Comparison of the Three Scales (Pathy Table 97.1)

Cardiovascular Health Study (Fried)	Study of Osteoporotic Fractures	FRAIL (IANA)
Weight loss (10 lb in a year)	Weight loss	Fatigue
Exhaustion (self-report)	Inability to rise from a chair five times without using arms	Resistance (climb one flight of stairs)
Weakness (grip strength, lowest 20%)	Reduced energy level	Aerobic (walk one block)
Walking speed (15 ft, slowest 20%)	—	Illnesses (more than five)
Low physical activity (kcal/week, lowest 20%)	—	Loss of weight (5%)
3 or more of 5 = frail	**2 or more of 3 = frail**	**3 or more of 5 = frail**

Latest Updates (2023–Present)

- Fried's phenotype remains the **most used research definition worldwide** and was the instrument used for the national Indian frailty estimates from **LASI wave-1** (modified Fried criteria: exhaustion, weak grip, slow gait, unintentional weight loss, low physical activity).
- Population-specific cut-offs have replaced the original "lowest 20%" approach in clinical use. **Grip strength**: EWGSOP2 uses **<27 kg in men and <16 kg in women**; **AWGS 2019 (Asian, relevant to India)** uses **<28 kg in men and <18 kg in women**. Indian community studies report even lower normative values, so applying Western cut-offs overestimates weakness.
- **Gait speed** cut-off has been standardised at **0.8 m/s or slower** over 4 metres (EWGSOP2); AWGS uses **1.0 m/s** for the Asian population.
- The **Global Leadership Initiative in Sarcopenia (GLIS, 2024)** explicitly separates **sarcopenia** (a muscle disease) from **frailty** (a multisystem syndrome), correcting the earlier tendency to use Fried's criteria as a proxy for sarcopenia.
- Because Fried's phenotype is time-consuming, **FRAIL, PRISMA-7, gait speed alone and the Clinical Frailty Scale**

are preferred for routine screening, with Fried's criteria reserved for research and for confirmation.

- Growing recognition of **cognitive frailty** and **social frailty** (a Social Frailty Index was derived from LASI) as dimensions the purely physical Fried phenotype misses.

Current Practice Update

Issue	Textbook (Pathy 6e)	Current Evidence
Cut-offs	Lowest 20% of the study population for grip, gait and activity	**Absolute, ethnicity-specific cut-offs** (AWGS for Asians: grip <28/<18 kg, gait <1.0 m/s)
Role of the tool	Presented as the primary definition of frailty	Reference standard for **research**; simpler tools (FRAIL, CFS, gait speed) preferred for **clinical screening**
Scope	Physical domain only	Recognition that **cognitive, psychological and social frailty** must be assessed separately
Relation to sarcopenia	Overlapping, sarcopenia as substrate	**GLIS 2024** keeps them conceptually distinct with separate diagnostic pathways

Exam One-Liners

- Fried = **CHS phenotype**, 2001, five criteria, **3 or more = frail, 1–2 = pre-frail**.
- The five: **weight loss, exhaustion, weakness, slowness, low activity**.
- Grip adjusted for **sex and BMI**; gait speed adjusted for **sex and height**.
- Weight loss threshold = **10 lb / 4.5 kg or 5% in one year**.
- Asian (AWGS) grip cut-offs = **28 kg men, 18 kg women**.
- SOF = **2 of 3**; FRAIL = **3 of 5**.

Q3. Clinical Frailty Scales

15–20 High-Yield Points (Textbook)

1. Frailty measurement tools derive from **two different conceptual models**, and the choice of scale follows the model chosen.
2. **Phenotype model** — frailty is a distinct biological syndrome preceding disability. Tools: **Fried's phenotype, Frailty Trait Scale, FRAIL index**. Endorsed by the **ADVANTAGE Joint Action consortium** and the **ICFSR**.
3. **Cumulative deficit model** — frailty is the accumulation of deficits (diseases, functional losses, organ and sensory impairments) with age. Tools: **Frailty Index** and the **Clinical Frailty Scale**.
4. **Rockwood** defined frailty as an **increasing number of disabilities**, which can be regarded as a comorbidity index.
5. **Frailty Index (Mitnitski and Rockwood)**: the proportion of deficits present out of the total number counted (usually 30–70 items). A value of **0.25 or above indicates frailty**; a submaximal limit of about **0.7** is observed.
6. **Clinical Frailty Scale (Rockwood, CMAJ 2005)**: a **global clinical judgement** measure of fitness and frailty, scored on a **9-point pictorial scale**.
7. CFS grades: **1 Very fit, 2 Fit/Well, 3 Managing well, 4 Living with very mild frailty (formerly "vulnerable"), 5 Mildly frail, 6 Moderately frail, 7 Severely frail, 8 Very severely frail, 9 Terminally ill** (life expectancy under 6 months).
8. CFS is **quick, needs no equipment**, and predicts institutionalisation and death; it has also been adapted for **nursing home residents**.
9. The **FRAIL scale** is a five-item questionnaire usable in the clinic without equipment (fatigue, resistance, ambulation, illnesses, loss of weight) and forms the basis of a **management algorithm**.
10. The **SOF index** (weight loss, inability to rise from a chair five times without arms, reduced energy) is a validated three-item alternative shown to predict falls, disability, fracture and death as well as longer indices.
11. The **Frailty Trait Scale** offers a continuous rather than categorical operational definition.
12. Function is assessed alongside frailty with **Katz ADL, Lawton IADL and Barthel Index**; mobility and fall risk with the **Tinetti performance-oriented assessment** and the **Timed Up and Go**.
13. **Principle of hierarchy** in choosing a scale: assess frailty in the robust and pre-frail; assess ADLs in those already dependent. Do not do both.
14. Frailty status must always be interpreted with **environmental and social information** — caregiver support, social network, participation — usually gathered by a nurse or social worker.
15. **Agreement between different frailty scales is limited** (35 published scores show poor concordance), which is the main reason no single scale is universally accepted.
16. No single **biomarker** is adequate for frailty; those studied include TNF-α, IL-6, CRP, HbA1c, testosterone, DHEA, IGF-1, vitamin D, PTH, the **CD4/CD8 ratio**, haemoglobin, albumin, soluble RAGE, DNA methylation and microRNA.
17. Neuroimaging markers are little studied, but **greater white matter hyperintensity volume and loss of white matter integrity** are associated with frailty.

Practical Comparison of Common Scales

Scale	Model	Content	Best use
Fried phenotype	Phenotype	5 physical items, needs dynamometer and walk course	Research reference standard
FRAIL scale	Phenotype	5 questions, no equipment	Clinic and community screening; drives management algorithm
SOF index	Phenotype	3 items including chair rise	Rapid screening, epidemiology
Frailty Index	Deficit accumulation	30–70 deficits, continuous score 0–1	Risk stratification, electronic health records
Clinical Frailty Scale	Deficit accumulation / clinical judgement	9-point pictorial global judgement	Acute hospital, surgical and critical care triage
Edmonton Frail Scale	Multidimensional	9 domains including cognition and mood	Preoperative and multidimensional assessment
PRISMA-7 / Gérontopôle tool	Screening	7 questions / clinician gestalt	Primary care case-finding
Gait speed / TUG	Performance	4 m walk; TUG	Single-item screen (**<0.8 m/s**, TUG **≥20 s**)

Latest Updates (2023–Present)

- **CFS version 2.0** is the current wording: level 4 is now "**living with very mild frailty**" and levels 5–8 are phrased as "living with mild / moderate / severe / very severe frailty", removing stigmatising language.

- The CFS is **only validated in people aged 65 and above** and should **not** be applied to younger adults or to those with stable lifelong disability (cerebral palsy, intellectual disability), where it misclassifies stable disability as frailty — a point emphasised after its widespread use in COVID-19 triage.
- The **electronic Frailty Index (eFI)**, calculated automatically from primary care records, is now used for population-level case-finding; the **Hospital Frailty Risk Score**, derived from ICD-10 codes at discharge, does the same for hospital data.
- CFS is now embedded in routine practice for **perioperative risk assessment, TAVI and cardiac surgery selection, oncology fitness assessment, dialysis decision-making and critical care admission**.
- **Frailty scales are increasingly used as decision aids rather than diagnoses** — a high CFS should trigger comprehensive geriatric assessment and shared decision-making, not automatic withholding of treatment.
- The **WHO ICOPE (2nd edition, 2025)** screening tool is being promoted as the entry point in low- and middle-income settings, measuring **intrinsic capacity** across six domains rather than frailty as such — directly relevant to NPHCE implementation in India.
- Indian validation work has established Hindi and regional-language versions of the **Edmonton Frail Scale, Tilburg Frailty Indicator and FRAIL scale**, but the **modified Fried phenotype** remains the instrument used in national surveys.

Current Practice Update

Issue	Textbook (Pathy 6e)	Current Evidence
CFS wording	Original 2005 labels including "vulnerable"	**CFS 2.0** wording: "living with very mild/mild/moderate/severe frailty"
Population limits	Not specified	CFS **not valid below age 65** or in stable lifelong disability
Frailty Index	Manual count of deficits	**Automated eFI** from primary care records and **Hospital Frailty Risk Score** from ICD-10 data
Purpose	Classification and prognosis	Used as a **trigger for CGA and shared decision-making**, explicitly not as a rationing tool
Screening framework	Frailty scales	**WHO ICOPE intrinsic capacity screening** as the primary-care entry point

Exam One-Liners

- Two models: **phenotype** (Fried, FRAIL, Frailty Trait Scale) and **cumulative deficit** (Frailty Index, CFS).
- Frailty Index = **deficits present / deficits counted**; frail at **≥0.25**; ceiling about **0.7**.
- CFS = **9 points**, 1 very fit to 9 terminally ill; **≥5 = frail**.
- Agreement between published frailty scales is **poor** — the main unsolved problem in the field.
- Single best one-item screen = **gait speed <0.8 m/s**.
- CFS must not be used **below age 65** or in **stable lifelong disability**.

Q4. Sarcopenia — Aetiology, Pathogenesis and Evaluation RECURS

15–20 High-Yield Points (Textbook)

A. Definition and Epidemiology

1. **Sarcopenia** is the excessive loss of muscle mass that occurs in older people, usually defined as lean tissue more than **two standard deviations below** that of young reference subjects.
2. It occurs in **13–24% of people aged 60–70 years** and in **about 50% of those over 80 years**.
3. **Dynapenia** is the age-associated loss of **muscle strength** not due to disease — the counterpart of sarcopenia, which refers to loss of **mass**. Both progress with ageing.
4. **Sarcopenic obesity** ("fat frail") describes those who lose muscle while retaining fat; longitudinally they have the **highest risk of disability and mortality**.
5. **Myosteatosis** — fat infiltration into muscle — is a separate condition linked to insulin resistance: mitochondrial failure or high circulating triglycerides cause intracellular triglyceride accumulation, which alters insulin receptor substrate function and the GLUT transporter.

B. Aetiology

6. Sarcopenia may **originate at birth**: in the **Hertfordshire cohort study** adult grip strength correlated with **birth weight**.
7. **Genetic factors**: people with a single I or double I allele of the **angiotensin-converting enzyme** gene generate more power with regular exercise than those with the D allele. Genome-wide studies implicate **HSD17B11, VCAN, ADAMTSL3, IRS1 and FTO**.
8. The best epidemiological predictors of muscle mass and strength are **age, energy intake, physical activity, IGF-1, testosterone and cytokines**.
9. **Hypovitaminosis D** is associated with reduced muscle strength and falls.
10. Disease-related contributors are the same as for frailty: **heart failure, COPD, diabetes, chronic kidney disease, anaemia, cancer cachexia and inflammatory disease**.

C. Pathogenesis

11. **Testosterone** declines by about **1% per year from age 30 in men** and falls rapidly between ages 20 and 40 in women. It inhibits movement of pluripotential stem cells into the **fat cell lineage** and stimulates the **muscle cell lineage** to produce **satellite cells**, which are essential for repair.
12. Testosterone also **stimulates muscle protein synthesis and inhibits the ubiquitin–proteasome pathway**; replacement increases muscle mass, strength, power and function even in non-hypogonadal men.
13. **Myostatin** is the principal negative regulator of muscle growth, acting through **activin IIb receptors**. Double deletion produces marked hypertrophy in mice ("mighty mouse"), cattle, whippets and one reported human; a **soluble activin IIb receptor** scavenges the ligand and produces muscle and bone hypertrophy.
14. **Motor unit dysfunction**: firing rate falls significantly in the **old-old (over 80)**. **Ciliary neurotrophic factor (CNTF)** declines with age in parallel with strength. **C-terminal agrin fragment** and **neurofilament light chain**, markers of neural degradation, are raised in a subset of sarcopenic patients.
15. **Cytokines**: excess **TNF-α** and **IL-6** cause loss of muscle strength; high **CRP and IL-6** correlate with reduced grip strength and physical performance.
16. **Vascular and metabolic factors**: raised homocysteine and peripheral vascular disease impair muscle blood flow causing atrophy; **creatine with exercise** may improve performance.
17. The final common pathway is an **imbalance of the daily muscle renewal cycle** — either excess atrophy and apoptosis, or reduced hypertrophy and satellite cell production.
18. **Biochemistry (Pathy Fig 97.7)** — **Anabolic arm**: GH / testosterone / creatine → IGF-1 and mechano-growth factor → PI3K → AKT → mTOR → S6K1 → hypertrophy. **Catabolic arm**: glucocorticoids, cytokines (TNF receptor I → IKK → NF-κB), and inactive AKT → **FOXO** → **atrogin-1 (MAFbx)** and **MuRF1** → ubiquitin–proteasome protein degradation → atrophy. **Myostatin–SMAD3** inhibits MyoD; caspase-3 and caspase-8 mediate apoptosis and actomyosin cleavage.

D. Evaluation

19. The best measure is **appendicular skeletal muscle mass by DXA divided by height in metres squared**. Alternatives are **MRI, CT and bioelectrical impedance**; DXA and MRI correlate highly, and **ultrasound** is proving an excellent measure of muscle loss. MRI is superior for visceral compartments, muscle volume, fat infiltration and ectopic fat; **BIA** is the most accessible in primary care but is only an approximation, better for limbs than trunk.
20. Several operational definitions exist — **FNIH Biomarkers Consortium, EWGSOP and AWGS** — and they differ in cut-offs and severity grading, but all agree on including **muscle strength, muscle mass and physical performance**.
21. **Candidate biomarkers**: procollagen type III N-terminal peptide (P3NP), **D3-creatine dilution** (correlates highly with MRI muscle mass), C-terminal agrin fragment, myostatin and follistatin, GDF-11 and GDF-15, and leptin in sarcopenic obesity. None is validated alone.
22. **Treatment**, as given in the frailty chapter, is **resistance exercise plus protein 1 g/kg/day**, correction of vitamin D deficiency, treatment of underlying disease, and consideration of testosterone or SARMs.

> **Extra Points to Remember (Recurring Topic)**

- Learn the **three-word definition triad**: **mass + strength + performance**. Any answer that mentions only muscle mass loses marks.
- Distinguish clearly: **sarcopenia** (mass), **dynapenia** (strength), **myosteatosis** (fat within muscle), **cachexia** (inflammation-driven loss of lean ± fat mass in advanced disease), **sarcopenic obesity** (worst prognosis).
- **Primary sarcopenia** = age-related only. **Secondary sarcopenia** = disease-related, inactivity-related or nutrition-related. **Acute sarcopenia** = under 6 months, typically after hospitalisation; **chronic** = 6 months or more.
- Be able to draw the **anabolic (IGF-1/PI3K/AKT/mTOR) versus catabolic (FOXO/atrogin-1/MuRF1/ubiquitin-proteasome)** diagram — it answers "pathogenesis" in one figure.
- The single most examinable formula: **ASMI = appendicular skeletal muscle mass (kg) / height (m)^2**.
- Sarcopenia has an **ICD-10 code (M62.84)** — it is now formally a disease, not a normal ageing change.

Latest Updates (2023–Present)

- **GLIS — Global Leadership Initiative in Sarcopenia (Delphi consensus, *Age and Ageing* 2024)** produced the first **global conceptual definition**, uniting EWGSOP, AWGS, ANZSSFR, SDOC and the sarcopenic obesity group. Key conclusions: sarcopenia is a **muscle disease**; **low muscle mass is the cardinal, mandatory feature**; **muscle strength** and **muscle-specific function** (function attributable to muscle rather than general physical performance) are the other components; and sarcopenia is **conceptually distinct from frailty, cachexia and malnutrition**.
- The **GLIS outcomes working group consensus (2025)** defined the health outcomes that should be measured once sarcopenia is diagnosed — falls, fractures, disability, hospitalisation, quality of life and mortality — and the preferred tools and cut-offs. A single global **operational** definition with numerical cut-offs is still pending.
- **EWGSOP2 algorithm (Find–Assess–Confirm–Severity)** remains the working clinical pathway: **SARC-F questionnaire ≥4 → assess strength** (grip <27 kg men, <16 kg women; or five-times chair stand >15 s) **→ confirm with muscle mass** (ASMI by DXA <7.0 kg/m^2 men, <5.5 kg/m^2 women) **→ grade severity by performance** (gait speed ≤0.8 m/s, SPPB ≤8, TUG ≥20 s, 400 m walk test).
- **AWGS 2019 Asian cut-offs** are the appropriate ones for Indian patients: grip **<28 kg men, <18 kg women**; ASMI by DXA **<7.0 / <5.4 kg/m^2**, by BIA **<7.0 / <5.7 kg/m^2**; gait speed **<1.0 m/s**; five-times chair stand **≥12 s**. AWGS also introduced "possible sarcopenia" for primary care, allowing lifestyle intervention to start before DXA is available — important given limited DXA access in India.
- Indian community studies report sarcopenia prevalence of roughly **17–25% in community-dwelling elders** and higher in hospital and nursing home populations, with a substantial contribution from **low dietary protein intake** in largely cereal-based diets.
- **Nutrition**: current targets are **1.0–1.5 g/kg/day of protein**, distributed as **25–30 g of high-quality protein per meal**, with **leucine-enriched essential amino acids or HMB** where intake is inadequate, plus correction of vitamin D deficiency. Network meta-analyses (2025) confirm that **resistance exercise plus protein supplementation** is superior to either alone.
- **Pharmacotherapy remains investigational**: myostatin and activin pathway agents (bimagrumab, apitegromab), SARMs, and testosterone have improved lean mass without convincing functional gains. A new practical concern is **preservation of muscle mass during GLP-1 receptor agonist weight loss**, where up to 40% of weight lost may be lean mass — muscle-sparing strategies are an active research area.
- Sarcopenia is increasingly measured opportunistically from **CT scans at the L3 vertebral level** (skeletal muscle index), used as a prognostic marker in oncology and before major surgery.

Current Practice Update

Issue	Textbook (Pathy 6e)	Current Evidence (2023–present)
Definition	Loss of muscle mass more than 2 SD below young adults	**GLIS 2024**: a muscle disease requiring **low muscle mass (cardinal) + low strength + impaired muscle-specific function**
Diagnostic entry point	Muscle mass measurement (DXA)	**Muscle strength first** (EWGSOP2 / AWGS), mass used to confirm; SARC-F for case-finding
Cut-offs	Not specified numerically	EWGSOP2 grip **<27/<16 kg**; **AWGS <28/<18 kg for Asians**; ASMI **<7.0/<5.4–5.5 kg/m^2**
Relation to frailty	Overlapping; "two sides of the same coin"	**Formally distinct entities** with separate pathways (GLIS)
Protein target	1 g/kg/day	**1.0–1.5 g/kg/day**, 25–30 g per meal, leucine-enriched supplements
Drug therapy	Testosterone and SARMs discussed favourably	**No approved drug**; myostatin/activin agents in trials; focus shifted to exercise and nutrition
Disease status	Described as a geriatric syndrome	Recognised disease with **ICD-10 code M62.84**

Exam One-Liners

- Prevalence: **13–24% at 60–70 years, ~50% over 80 years**.

- **ASMI = appendicular skeletal muscle mass / height^2**, measured by DXA.
- Testosterone falls **1% per year after 30**; drives satellite cell production.
- Myostatin acts via **activin IIb receptor**; blockade causes hypertrophy.
- Atrophy genes = **atrogin-1 (MAFbx) and MuRF1**, activated by **FOXO** and **NF-κB**.
- Screening questionnaire = **SARC-F**; score **≥4** is positive.
- Indian/Asian grip cut-offs (**AWGS**) = **28 kg men, 18 kg women**.
- Treatment = **progressive resistance exercise + protein 1.0–1.5 g/kg/day + vitamin D**.

Q5. Deconditioning and Its Prevention

15–20 High-Yield Points (Textbook)

A. Definition and Magnitude

1. **Deconditioning (functional decline)** is the loss of the ability to perform basic activities of daily living, attributed primarily to the effects of immobilisation by **forced bed rest, immobilising devices (catheters, drips), restraint use, and lack of encouragement of independence in self-care**.
2. **Immobility** is defined as restriction of time spent out of bed or chair by **medical orders, restrictive devices, chemical restraints (antipsychotics), lack of mobility aids, or lack of human assistance and encouragement**.
3. **Functional decline occurs in one-third to one-half of hospitalised older patients**; as many as **one-third of older inpatients are restricted to bed or chair rest** during admission.
4. A systematic review of 30 studies found that between **15% and 76%** of hospitalised elders show diminished performance in at least one ADL at discharge; of these, **only half recover function by three months**, and for many the loss of independent living is **permanent**.
5. Functional decline is regarded as a **profound marker of morbidity and mortality**. Just **ten days of bed rest in healthy older adults** produces measurable functional impairment (Kortebein).

B. Causes

6. **Medical**: musculoskeletal (arthritis, osteoporosis, hip and femoral fracture, foot problems), neurological (stroke, Parkinson's disease, neuropathy, normal-pressure hydrocephalus, dementia), cardiovascular (severe heart failure, angina, claudication), severe COPD, acute and chronic pain, malnutrition, and severe systemic illness.
7. **Sensory**: impaired vision, reduced kinaesthetic sense, reduced peripheral sensation.
8. **Iatrogenic and environmental**: forced immobility in hospitals and nursing homes, inadequate mobility aids, cluttered or uneven surroundings, poorly designed chairs and beds, stairs.
9. **Psychological**: depression, apathy, lack of motivation, **fear of falling**, and the health belief that rest is beneficial to recovery.
10. **Drugs**: sedatives and hypnotics (drowsiness, dizziness, ataxia, delirium), typical antipsychotics (rigidity), and antihypertensives causing orthostatic hypotension or bradycardia.
11. **Caregiver-driven dependency**: well-meaning staff and families who bathe, dress and wheel patients who could do these things themselves — "the hospital breeds dependency".

C. Complications of Immobility (system-wise)

12. **Skin**: pressure ulcers (risk multiplied by immobility plus low serum albumin). **Musculoskeletal**: muscle atrophy and loss of strength and endurance, reduced fibre size and capillarity, contractures, disuse osteoporosis with increased bone resorption and reduced formation, degenerative joint disease, **hypercalcaemia**.
13. **Cardiovascular**: deconditioning, reduced plasma volume, **orthostatic hypotension**, deep vein thrombosis and pulmonary embolism. **Respiratory**: reduced tidal volume, atelectasis, aspiration pneumonia.
14. **Gastrointestinal and genitourinary**: anorexia, constipation, faecal impaction and incontinence, urinary retention, urinary infection, bladder calculi, functional incontinence.
15. **Metabolic**: negative **nitrogen and calcium** balance, impaired glucose tolerance, altered body composition and altered drug pharmacokinetics. **Psychological**: sensory deprivation, delirium, depression and anxiety.
16. Reduced bone mass from decreased weight-bearing increases the likelihood that a fall will cause **serious injury**; balance and coordination problems increase fall incidence itself.

D. Risk Factors and Prevention

17. **Risk factors for functional decline in hospitalised elders** (Kane): age **75 and above**, cognitive impairment (missing more than 15 of the first 21 MMSE items), **dependence in two or more IADLs before admission**, presence of a pressure sore, baseline functional dependency, and a history of low social activity.
18. **Prevention begins with the bed rest order**: careful consideration is warranted before prescribing bed rest, and mobility should be assessed for the ability to move in bed, transfer and ambulate safely, including the need for assistance and assistive devices.
19. **Promote mobility actively**: nursing staff should encourage and assist position change in bed, transfer to a chair and ambulation; **organised group walks** on the ward at set times provide diversion and involve the patient in recovery; **bed and toilet seat height should be matched to the patient's lower leg height** to allow safe transfers.
20. **Refer to physiotherapy and occupational therapy** for problems; rehabilitation therapists may supply transfer aids — trapeze, transfer pole or bar, or a raised one-quarter or half-length siderail attached near the top of the bed as a bed-mobility device.
21. **Avoid physical restraints and restrictive full-length siderails**: research demonstrates restrictive devices can be safely eliminated and are associated with strangulation, asphyxiation and the full spectrum of immobility complications. Avoid unnecessary catheters and infusion lines that tether the patient.
22. **Facilitate observation instead of restraint**: nurse high-risk patients near the nursing station, encourage time out of the room, encourage family visits at mealtimes and at night, provide communal dining, and use volunteers or paid companions where family cannot stay.
23. **Multicomponent programmes**: the **Hospital Elder Life Program (HELP)** prevents cognitive and functional decline

in hospitalised elders; **acute geriatric units staffed by an interdisciplinary team** using multidimensional functional evaluation improve outcomes; environmental modification (primary colours, lower windows, better furniture and room design) helps older patients retain function.

24. **Assessment of the immobile patient** should cover the perceived cause of immobility, medical conditions and treatments, pain, mood, fear and motivation, nutritional status including **protein and 25-hydroxy vitamin D**, and both the physical and social environment including caregiving interactions.

Latest Updates (2023–Present)

- **"New horizons in hospital-associated deconditioning" (*Age and Ageing*, 2024)** reframed the syndrome as **a global condition of body and mind**: it is not only loss of muscle (i.e. **acute sarcopenia**) but also **cognitive deconditioning**, defined as delayed mental processing lying on a spectrum with frank delirium at its severe end.
- Quantitative figures now commonly quoted: muscle deconditioning begins within **two days** of immobility, with **2–5% loss of muscle mass per day** when the legs are inactive, and up to **20% loss of baseline strength within one week**.
- Accelerometer studies show hospitalised older adults are **sedentary for over 80% of the day**, and that most in-hospital walking occurs in short, unsupervised bouts — the target of current quality improvement work.
- **CHERISH cluster randomised trial (*JAMA Internal Medicine*, 2022)** — the ward-based **Eat Walk Engage** programme (nutrition, mobility and cognitive engagement embedded in ward routine) reduced hospital-associated complications in older inpatients.
- The **Frailty Care Bundle (2024)** — mobilisation, nutrition and cognitive engagement delivered by nursing staff — reduced hospital-associated decline in older orthopaedic trauma patients and is the current implementation template.
- Campaign-style interventions endorsed by the **British Geriatrics Society (2023)** — **"End PJ Paralysis"** and **"Get Up, Get Dressed, Get Moving"** — are now standard ward culture initiatives, targeting daily out-of-bed time before 11 a.m., own clothing, and removal of unnecessary lines and catheters.
- **Prehabilitation** (structured exercise, nutrition and psychological preparation before elective surgery or chemotherapy) has become a mainstream strategy for preventing perioperative deconditioning in older patients.
- In critical care, the **ABCDEF bundle** with early mobilisation reduces ICU-acquired weakness and post-intensive care syndrome; in general medicine, **hospital-at-home** and **early supported discharge** models reduce deconditioning by avoiding the ward environment altogether.
- Post-discharge, trials of **high-intensity progressive home-based physical therapy** (2024) improved function but did not consistently outperform good-quality usual care, indicating that **frequency and consistency of therapy matter as much as intensity**.
- **Indian relevance**: deconditioning is aggravated by high nurse-to-patient ratios, dependence on family attendants who often do everything for the patient, limited inpatient physiotherapy, and low protein intake. Practical measures — **training the family attendant** as a mobility coach, early removal of catheters, and daily chair transfer targets — are the highest-yield interventions in Indian wards.

Current Practice Update

Issue	Textbook (Pathy 6e / Kane)	Current Evidence (2023–present)
Concept	Physical functional decline from immobility	**Whole-body and mind syndrome** including **cognitive deconditioning** and **acute sarcopenia**
Speed of loss	Described qualitatively; 10 days of bed rest harmful	Quantified: **2–5% muscle loss per day**, up to **20% strength loss in a week**, starting within **48 hours**
Measurement	ADL scales at discharge	**Accelerometry** and direct observation of sedentary time as ward quality metrics
Intervention model	Individual nursing and therapy measures; HELP; geriatric units	**Bundled, ward-culture interventions** — CHERISH/Eat Walk Engage, Frailty Care Bundle, End PJ Paralysis
Timing	Prevention during admission	**Prehabilitation before** admission and structured rehabilitation **after** discharge
Setting	Acute ward with restraint reduction	**Hospital-at-home and early supported discharge** to avoid the ward entirely where feasible

Exam One-Liners

- Deconditioning = **loss of ability to perform basic ADLs** due to immobilisation.
- Occurs in **one-third to one-half** of hospitalised older patients; **only half recover by 3 months**.
- Muscle loss = **2–5% per day** of inactivity; strength loss up to **20% in one week**.
- Immobility causes **negative nitrogen and calcium balance** and **hypercalcaemia**.
- Key hospital risk factors: **age 75+, cognitive impairment, prior IADL dependence, pressure sore, low social**

activity.

- Bed and toilet seat height should equal the patient's **lower leg height**.
- Prevention programmes: **HELP, ACE units, CHERISH/Eat Walk Engage, Frailty Care Bundle, End PJ Paralysis**.

Q6. Theories of Ageing

15–20 High-Yield Points (Textbook)

A. General Principles

1. Ageing is now accepted to be a **multifactorial process**; extended longevity is consistently associated with **enhanced metabolic capacity and stress response**.
2. Genetics matters — each species has a characteristic longevity — but **heritability accounts for only about 35% or less of the variance in lifespan**, while **environmental factors account for more than 65%**.
3. **Genes specifically selected to promote ageing are unlikely to exist**; ageing is not a programmed adaptive trait.
4. Kane groups all theories into **three categories**: (i) **accumulation of damage to informational molecules**, (ii) **regulation of specific genes**, and (iii) **depletion of stem cells**.

B. Damage-Based (Stochastic) Theories

5. **Somatic mutation theory**: greater susceptibility to mutagenesis or defective DNA repair drives ageing. Support: **species longevity correlates positively with DNA repair enzyme capacity**. Against: the human spontaneous mutation rate is **too low** to account for the changes required, and there is no evidence of a general failure of repair systems — though limited maintenance may allow somatic damage to accumulate.
6. **Error catastrophe theory (Orgel)**: errors in DNA, RNA and protein synthesis each amplify the others until an error catastrophe occurs; translation was thought the likeliest source. Against: increased translational errors have **not** been found in vivo or in vitro, and **amino acid substitutions do not increase with age**, although post-translational changes such as glycosylation may alter enzyme activity.
7. **Free radical / oxidative damage theory (Harman)**: superoxide radicals, the major by-product of oxidative metabolism, react with DNA, RNA, proteins and lipids to cause cellular damage. Scavenging enzymes and vitamins C and E are protective.
8. Evidence **against** a simple free radical theory: there is **no significant loss of scavenging enzymes with age**, and vitamins C and E do **not** increase longevity in experimental animals.
9. Evidence **for**: overexpression of antioxidative enzymes retards age-related oxidative damage and extends maximum lifespan in **transgenic fruit flies**, and **caloric restriction lowers oxidative stress and extends maximum lifespan in rodents**.
10. **Loss of molecular fidelity (Hayflick)**: genes do not drive ageing — the general loss of molecular fidelity does. Every molecule becomes subject to **thermodynamic instability**. This distinguishes ageing from disease, because ageing occurs in every multicellular animal that reaches a fixed size at reproductive maturity, occurs after reproductive maturity in all species, and has the same universal molecular aetiology.

C. Programmed and Genetic Theories

11. **Evolutionary theory (Darwin)**: current organisms result from an incrementally accumulative evolutionary process — "survival of the fittest" — organisms surviving longer had more opportunity to breed and propagate their design.
12. **Gene regulation theory**: specific genes regulate ageing. Genes extending lifespan have been found in **yeast, nematodes and fruit flies**, and they reinforce the importance of **metabolic capacity and stress response**. DNA microarray work found relatively few genes changed in ageing human fibroblasts, with **downregulation of mitosis-control genes** proposed as a general cause — but the pattern is not reproduced in other tissues, suggesting different mechanisms in different tissues.
13. **Replicative senescence (Hayflick limit)**: cells in culture divide a fixed number of times and then enter **replicative senescence**. Human fibroblasts manage about **50 doublings** (most cell types 60–70); replicative life in vitro correlates inversely with donor age. Replicative senescence is believed to have **evolved to protect higher organisms from cancer**.
14. **Telomere theory**: with each division a portion of the terminal chromosome (the **telomere**) is not replicated and shortens — about **50–100 base pairs are lost per replication**. **Telomerase** adds bases back; transfection of its catalytic component into senescent cells extends telomeres and replicative lifespan and restores a young pattern of gene expression.
15. Telomere caveats: relevance in vivo remains unknown; **studies of the oldest old show no relationship between telomere length and mortality**, though healthy centenarians had significantly longer telomeres than unhealthy ones. **Telomerase inhibitors are potential anticancer therapies**. **Stress-induced premature senescence** shows that oxidative stress and oncogene activation can produce an identical senescent phenotype without telomere shortening.
16. **Stem cell depletion**: convergence of the above mechanisms reduces proliferative potential. Cells are of three types — continuously replicating (epidermal, gastrointestinal, haematopoietic), replicating on challenge (liver), and non-replicating (neurons, cardiac and skeletal muscle) — and in non-replicating tissues, cell loss produces a **permanent deficit** (for example, loss of dopaminergic neurons affecting gait and balance).

D. Systemic and Integrative Theories

17. **Neuroendocrine theory (Dilman)**: age-related hypothalamic functional decline from **reduced sensitivity to feedback**. Controversial, because pituitary secretion also depends on sex, body composition, stress, illness, comorbidity, medication, frailty, caloric intake, immune status, activity and cognition.
18. **Immunological theory**: thymic involution after puberty with falling **thymosins**, reduced **IL-2** production and receptor expression, and diminished lymphocyte proliferative response — predisposing to infection, autoimmunity and cancer.

19. **Network and remodelling theories (Franceschi)**: ageing is **active remodelling**, not simple decline, with **inflammaging** at its centre. The **"seven pillars"** of ageing and age-related disease are adaptation to stress, loss of proteostasis, stem cell exhaustion, metabolic derangement, macromolecular damage, epigenetic modification and inflammation.
20. **Hormesis**: stress is not necessarily deleterious — **low-intensity stimulation activates maintenance and repair mechanisms** and improves health, whereas stress exceeding the organism's adaptive capacity causes disease. This is the theoretical basis for exercise, caloric restriction and the Mediterranean diet.
21. **Nine mechanisms are given as the fundaments of ageing** in Pathy: **genomic instability, telomere attrition, epigenetic modifications, loss of proteostasis, deregulated nutrient sensing, mitochondrial dysfunction, cellular senescence, stem cell exhaustion and altered intercellular communication**.
22. **Caloric restriction** and mutations in nutrient and growth signalling pathways extend lifespan by **30–50%** in preclinical models; in humans, long-term caloric restriction and intermittent fasting produce favourable metabolic changes but are not feasible for most people and may have adverse effects.
23. **Cautions from the textbook**: the reductionist single-marker approach fails because a living system is **homeodynamic**, with tolerance, compensation and adaptation — illustrated by failed beta-amyloid trials in Alzheimer's disease and by the unproven benefit of lengthening telomeres. The "hormonal fountain of youth", from Brown-Séquard's testicular extract onward, has been a consistent disappointment.

Summary Table (Kane Table 1-2)

Theory category	Mechanisms	Manifestations
Accumulation of damage to informational molecules	Spontaneous mutagenesis; failure of DNA repair; errors in DNA, RNA and protein synthesis; superoxide radicals and loss of scavenging enzymes	Copying errors; error catastrophe; oxidative cellular damage
Regulation of specific genes	Appearance of specific protein(s)	Genetically programmed senescence
Depletion of stem cells	Convergence of the above mechanisms	Proliferative potential decreases

Latest Updates (2023–Present)

- **"Hallmarks of Ageing: An Expanding Universe" (López-Otín, Blasco, Partridge, Serrano, Kroemer, *Cell*, January 2023)** expanded the original nine hallmarks to **twelve**, adding **disabled macroautophagy, chronic inflammation and dysbiosis**. The three defining criteria remain: the hallmark must manifest with age, accentuating it must accelerate ageing, and targeting it must decelerate, stop or reverse ageing.
- The twelve are grouped as **primary** (genomic instability, telomere attrition, epigenetic alterations, loss of proteostasis, disabled macroautophagy), **antagonistic** (deregulated nutrient sensing, mitochondrial dysfunction, cellular senescence) and **integrative** (stem cell exhaustion, altered intercellular communication, chronic inflammation, dysbiosis).
- The **2022 Copenhagen ageing meeting** proposed additional candidates — **altered mechanical properties and splicing dysregulation** — giving up to fourteen hallmarks in some frameworks.
- **Geroscience hypothesis**: ageing is the common upstream driver of the major chronic diseases, so targeting ageing biology should compress morbidity across many diseases simultaneously — the rationale for trials such as **TAME (Targeting Aging with Metformin)**.
- **Epigenetic clocks** (Horvath, Hannum, PhenoAge, GrimAge, DunedinPACE) are the most developed biological age measures, but the textbook's caution holds: a study cited in Pathy found the **frailty index outperformed DNA methylation age** as an indicator of biological age, and frailty is associated with the epigenetic clock but **not with telomere length**.
- **Senolytics** (dasatinib plus quercetin, fisetin) and **senomorphics** are in early human trials; newer approaches include **senolytic CAR-T cells**, **SGLT2 inhibitors such as canagliflozin** (senescent cell clearance via AMPK activation) and **anti-PD-1 antibodies** that clear PD-L1-positive senescent cells.
- **Partial cellular reprogramming** with Yamanaka factors reverses age-associated features in animal models, and **mTOR inhibition** (rapalogs) improves immune function in older humans — the two most-cited proofs of principle that ageing is modifiable.
- Nothing has yet translated into clinical geriatrics: the **only interventions with proven benefit for healthspan remain physical activity, adequate protein and micronutrient intake, avoidance of smoking and excess alcohol, management of vascular risk, sleep, and social engagement** — framed globally by the **WHO Decade of Healthy Ageing 2021–2030** and operationalised through **ICOPE**.

Current Practice Update

Issue	Textbook (Pathy 6e / Kane)	Current Evidence (2023–present)
Framework	Three categories (damage, gene regulation, stem cell depletion); nine ageing mechanisms	**Twelve hallmarks (López-Otín 2023)**, adding disabled macroautophagy, chronic inflammation and dysbiosis
Inflammation	Discussed under network/remodelling theory	Now a **formal hallmark** in its own right ("inflammaging")
Microbiome	Not included	**Dysbiosis** recognised as a hallmark of ageing
Biological age measurement	Telomere length; noted to be unreliable	**Epigenetic clocks** dominate research; still **not clinically validated**, and the frailty index remains a better practical marker
Interventions	Caloric restriction, scepticism about hormones	**Senolytics, senomorphics, mTOR inhibitors, metformin (TAME), partial reprogramming** — all investigational
Clinical translation	Warns against reductionism and false promise	Position unchanged — **lifestyle remains the only proven healthspan intervention**

Exam One-Liners

- Heritability of lifespan = **≤35%**; environment = **>65%**.
- Three theory categories = **damage to informational molecules, gene regulation, stem cell depletion**.
- **Hayflick limit** = about **50 doublings** for human fibroblasts; **50–100 base pairs** of telomere lost per replication.
- Hayflick's own view: ageing is **loss of molecular fidelity / thermodynamic instability**, not genes.
- Vitamins C and E do **not** extend lifespan; **caloric restriction** does in rodents (**30–50%**).
- Original hallmarks = **9 (2013)**; current = **12 (2023)**, adding **disabled macroautophagy, chronic inflammation, dysbiosis**.
- **Hormesis** = low-dose stress is beneficial; the theoretical basis of exercise and caloric restriction.
- **Frailty index outperforms DNA methylation age** as an indicator of biological age.

Q7. Immunology and Ageing — Innate and Adaptive Immune Systems; Immunosenescence and Cancer

Note on sources: Pathy's 6th edition does not carry a single dedicated chapter on the ageing immune system. The textbook content below is assembled from the chapters where it is covered — Cancer and Ageing, Geriatric Dermatology, Modern Use of Biomarkers in Geriatric Medicine, Centenarians, and Kane's chapter on the clinical implications of the ageing process.

15–20 High-Yield Points (Textbook)

A. General Concept

1. The immune system is one of the most important **master regulatory systems** in humans; its relationship with ageing has been re-evaluated away from a purely senescent, declining system to one that undergoes **remodelling**, with both **up- and downregulation** of immune functions.
2. **Both the innate and the adaptive immune systems become less effective with age**, leading to increased risk of infection and of malignancy.
3. **Healthy ageing** is believed to result from low pro-inflammatory activity combined with an efficient network capable of neutralising antigenic insults — that is, from successful **immune remodelling** rather than preserved youthful immunity.

B. Changes in the Adaptive Immune System

4. **Thymic involution** occurs after puberty; the **bone marrow diminishes in mass**, and levels of thymic hormones (**thymosins**) fall.
5. **T cells**: **reduced proliferation**, an **increased proportion of memory cells** and a **decrease in naive T cells**; T cells are also **less able to differentiate into specific subtypes**.
6. Lymphocytes from older adults show a **diminished proliferative response to mitogens**, due both to reduced lymphokine production and to reduced response to extracellular signals.
7. **Interleukin-2**: basal and stimulated production and responsiveness both fall, at least partly because of **decreased IL-2 receptor expression**. Conversely, **IL-6 levels rise**.
8. The T-cell defect appears to lie in the **transduction of extracellular signals to intracellular function**: the proliferative defect can be reversed in vitro by **calcium ionophores and activators of protein kinase C**, and some functions are restored by adding thymic hormones in vitro or administering them to aged animals.
9. **B cells**: production of B-cell precursors diminishes, and the ability to **isotype-switch** is altered, reducing the variety of antibodies and the diversity of functional B cells. **B-cell function is intact but dysregulated**, with increased **autoantibody formation** and increased **monoclonal protein production** (the basis of the high prevalence of MGUS in old age).
10. The **immune risk phenotype (IRP)**, defined in the Swedish NONA longitudinal study by Wikby, is a **CD4/CD8 ratio of less than 1**; it is associated with raised **IL-6** in the terminal decline stage and predicts mortality. The CD4/CD8 ratio is listed among the candidate immune biomarkers of frailty.

C. Changes in the Innate Immune System

11. **Neutrophils** show **decreased phagocytic ability**.
12. **Antigen-presenting cells**: there is a **reduction in Langerhans cells** in ageing skin, impairing cutaneous immune surveillance.
13. **Natural killer cells**: NK function is a clinically relevant variable — a prospective cohort study showed that individuals with **better NK cell function had lower rates of cancer ten years later**.
14. Impaired **innate, humoral and cell-mediated immunity within the skin** explains the increased risk of **herpes zoster** and **cutaneous candidiasis** in older people, and the delayed wound healing that follows reduced growth factor sensitivity of aged fibroblasts.

D. Inflammaging

15. **Chronic low-grade inflammation ("inflammaging")** is one of the major hallmarks of individual ageing. **Immunosenescence and inflammaging are described as two sides of the same coin**.
16. The three inflammatory markers most cited as biomarkers of frailty are **TNF-α (and its receptor TNFR2), IL-6 and CRP**; all three predict increased mortality among frail older people, and **pre-operative high IL-6** is a risk factor for post-operative delirium.
17. Franceschi's **network/remodelling theory** and the **hormesis** concept explain why some centenarians tolerate a high inflammatory load: they possess extraordinary **adaptive capacity and functional reserve**. Centenarians are classified as **"survivors", "delayers" and "escapers"**.

E. Immunosenescence and Cancer

18. **Immune dysregulation associated with ageing may contribute to the increased incidence of cancer with age** — reduced T-cell proliferation, fewer naive T cells, altered B-cell regulation, falling IL-2 and rising IL-6, and reduced NK function all impair **immune surveillance**.
19. Ageing and carcinogenesis **share molecular pathways**: DNA damage from random events or free radicals causes either cellular dysfunction and death (ageing) or mutations in proto-oncogenes and tumour suppressors (carcinogenesis). **DNA adduct formation, DNA hypomethylation, and chromosomal breakage and translocation** all increase with age and raise susceptibility to late-stage carcinogens.

20. Yet ageing and cancer are also **at odds**: cancer requires **limitless replicative potential**, whereas **finite replicative potential (replicative senescence) is a hallmark of ageing**. Normal cells manage 60–70 doublings and lose telomeres; malignant cells maintain telomeres through **telomerase** and replicate indefinitely.
21. **Stress-induced premature senescence** — triggered by oncogene mutation or by double-stranded DNA breaks from chemotherapy — drives clonal cells into permanent growth arrest and may be **as effective as apoptosis as an anticancer mechanism**.
22. Clinically, the probability of developing cancer over the age of 70 is **one in three in men and one in four in women**; cancer-specific death rates have fallen in the young while **rising in older individuals**, partly because of delayed diagnosis, incomplete evaluation, undertreatment and **under-representation of older people in clinical trials**.

Latest Updates (2023–Present)

- **Vaccination has become the main clinical application of immunosenescence.** Because standard vaccines respond poorly in older adults, **enhanced formulations** are now preferentially recommended for people aged 65 and above: **high-dose or adjuvanted (MF59) influenza vaccine**, and the **recombinant adjuvanted zoster vaccine (RZV, Shingrix)**, which retains over 90% efficacy in the very old, unlike the older live zoster vaccine.
- **RSV vaccines for older adults** (Arexvy, Abrysvo and the mRNA vaccine mResvia) were licensed from 2023; US ACIP guidance now recommends a single dose for **all adults aged 75 and above** and for adults **50–74 with risk factors** such as COPD, heart failure, diabetes, chronic kidney disease and immunocompromise.
- **Cytomegalovirus** is now recognised as a major driver of immunosenescence: chronic antigenic stimulation causes massive expansion of CMV-specific CD8 T cells with high **PD-1 and TIGIT** expression and reduced cytotoxicity, contributing to the immune risk phenotype and to **poorer vaccine antibody responses** in CMV-seropositive elders.
- The mechanistic picture has been refined to include **reduced dendritic cell phagocytosis, impaired T-cell receptor signalling, accumulation of terminally differentiated CD28-negative T cells, and accumulation of myeloid-derived suppressor cells**, forming a self-reinforcing **immunosenescence–inflammaging loop**.
- **Interventions being tested to rejuvenate immunity**: **mTOR inhibitors** (Mannick's trials showed improved influenza vaccine responses in older adults), **senolytics** (dasatinib plus quercetin, fisetin, senolytic CAR-T cells), **SGLT2 inhibitors** such as canagliflozin, and **anti-PD-1 antibodies** that clear PD-L1-positive senescent cells.
- **Cancer immunotherapy in older adults**: overall efficacy of immune checkpoint inhibitors appears broadly preserved in older patients in pooled analyses, but immunosenescence, inflammaging and cancer cachexia modify response, and older patients remain under-represented in trials. Geriatric assessment (SIOG/ASCO) before immunotherapy is recommended rather than age-based exclusion.
- **Dysbiosis** was added as a formal hallmark of ageing in 2023, linking the gut microbiome to inflammaging and to vaccine responsiveness — a plausible future intervention target.
- **Indian context**: adult immunisation uptake in older Indians remains very low. Association of Physicians of India and Geriatric Society of India recommendations cover annual **influenza**, **pneumococcal (PCV followed by PPSV23)**, **recombinant zoster**, **Tdap**, and COVID-19 boosters for those aged 60 and above; cost is the principal barrier (RZV and RSV vaccines are largely self-financed and not covered by the national immunisation programme). Practical alternatives with proven benefit remain **correction of undernutrition and vitamin D deficiency, control of diabetes, smoking cessation and physical activity**, all of which improve immune competence.

Current Practice Update

Issue	Textbook (Pathy 6e / Kane)	Current Evidence (2023–present)
Core concept	Age-related decline in immune function, with a note that remodelling is a better description	**Immune remodelling** is the accepted model — simultaneous loss of adaptive competence and gain of inflammatory tone
Driver of T-cell change	Thymic involution and reduced IL-2 signalling	Thymic involution plus **chronic CMV-driven antigenic stimulation** and accumulation of **CD28-negative, PD-1/TIGIT-high exhausted T cells**
Vaccination	Not addressed in detail	**Enhanced vaccines mandatory in the old**: high-dose/adjuvanted influenza, recombinant zoster, and new **RSV vaccines for 75+ and at-risk 50–74**
Inflammaging	Described within network/remodelling theory	A **formal hallmark of ageing (2023)**, alongside **dysbiosis**
Cancer immunity	Reduced surveillance; NK function predicts cancer risk	Same principles, plus recognition that **immunosenescence modifies checkpoint inhibitor response**; geriatric assessment rather than age-based exclusion
Reversibility	Some functions restorable with thymic hormones in vitro	**mTOR inhibitors and senolytics** show partial immune rejuvenation in early human trials

> **Exam One-Liners**

- Adaptive changes: **↓ naive T cells, ↑ memory T cells, ↓ proliferation, ↓ IL-2, ↓ isotype switching, ↑ autoantibodies, ↑ monoclonal proteins**.
- Innate changes: **↓ neutrophil phagocytosis, ↓ Langerhans cells, altered NK function, ↑ IL-6**.
- **Immune risk phenotype = CD4/CD8 ratio <1** (Wikby, NONA study) — predicts mortality.
- Immunosenescence and inflammaging = **"two sides of the same coin"**.
- Better **NK cell function** predicts **lower cancer incidence ten years later**.
- Cancer needs **limitless replication**; ageing shows **finite replication** — telomerase is the difference.
- Clinical translation = **high-dose/adjuvanted influenza, recombinant zoster and RSV vaccines** in the old.

Q8. Immunosenescence

This overlaps with Question 7; the answer below is written as a focused, self-contained account of the entity itself — definition, mechanisms, measurement, consequences and interventions.

15–20 High-Yield Points (Textbook)

1. **Immunosenescence** is the age-associated remodelling and functional deterioration of the immune system, affecting **both innate and adaptive arms**, and resulting in reduced protection against infection and malignancy with simultaneous **increased autoreactivity**.
2. It is best understood not as simple decline but as **remodelling** — some functions are downregulated and others upregulated — and it is listed among the mechanisms of ageing alongside cellular senescence and inflammaging.
3. **Structural basis**: **thymic involution** after puberty with falling **thymosin** levels, and reduction in **bone marrow mass**, which together restrict output of new naive lymphocytes.
4. **T-cell changes**: fall in **naive T cells**, rise in the proportion of **memory T cells**, impaired differentiation into specific subtypes, and reduced proliferative response to mitogens.
5. **Signalling defect**: reduced **IL-2** production and responsiveness with decreased IL-2 receptor expression; the defect lies in **signal transduction**, since it is reversible in vitro by calcium ionophores and protein kinase C activators.
6. **B-cell changes**: reduced B-cell precursor production, altered **isotype switching**, reduced antibody variety and B-cell diversity; function is preserved but **dysregulated**, with more **autoantibodies** and more **monoclonal protein**.
7. **Innate changes**: reduced **neutrophil phagocytosis**, fewer **Langerhans cells**, and variable NK cell function.
8. **Cytokine shift**: **IL-2 falls while IL-6 rises** — the biochemical signature of the shift from adaptive competence to inflammatory tone.
9. **Inflammaging** is the inseparable companion of immunosenescence — the two are described as **"two sides of the same coin"**, with chronic inflammation a major hallmark of individual ageing.
10. **Immune risk phenotype (IRP)**: defined by a **CD4/CD8 ratio below 1**, associated with raised IL-6 in the terminal decline stage and predictive of mortality in the Swedish NONA longitudinal study.
11. The **CD4/CD8 ratio** is the immune-system biomarker listed for frailty in Pathy's biomarker chapter; inflammatory markers (**TNF-α, IL-6, CRP**) are listed for both frailty and intrinsic capacity.
12. **Clinical consequences — infection**: increased incidence and severity of pneumonia, urinary tract infection, tuberculosis reactivation, **herpes zoster** and cutaneous candidiasis; **atypical presentation** with blunted fever and leucocyte response.
13. **Clinical consequences — vaccination**: reduced antibody titres, faster waning of protection and lower vaccine effectiveness in older adults.
14. **Clinical consequences — malignancy**: impaired immune surveillance contributes to the rise in cancer incidence with age; better **NK cell function predicts lower cancer rates ten years later**.
15. **Clinical consequences — autoimmunity and paraproteins**: rising autoantibody titres and monoclonal gammopathy of undetermined significance.
16. **Clinical consequences — delayed wound healing and impaired skin barrier**, with increased risk of skin infection and cutaneous malignancy compounded by ultraviolet exposure.
17. **Link to frailty**: frailty, inflammation and immunosenescence are explicitly grouped together; the frail phenotype is associated with raised inflammatory and immune markers in the Singapore Longitudinal Ageing Studies and elsewhere.
18. **Successful ageing**: centenarians appear to combine **low pro-inflammatory activity** with an efficient neutralising network, and possess exceptional adaptive capacity and functional reserve.

Summary of Changes with Ageing

Component	Change with ageing	Clinical consequence
Thymus / marrow	Involution; fall in thymosins; reduced marrow mass	Reduced output of naive lymphocytes
Naive T cells	Decreased	Poor response to **new** antigens and new vaccines
Memory T cells	Increased proportion; terminally differentiated	Narrowed repertoire; reactivation of latent infection (zoster, TB)
IL-2	Reduced production and receptor expression	Reduced clonal expansion; poor delayed hypersensitivity
B cells	Fewer precursors; impaired isotype switching	Lower-affinity antibody; poorer vaccine response; **MGUS**, autoantibodies
Neutrophils	Reduced phagocytosis	Bacterial infection risk
Langerhans cells	Reduced in skin	Skin infection and cutaneous malignancy
NK cells	Function variable, often impaired	Reduced tumour surveillance
IL-6 / TNF-α / CRP	Chronically raised (**inflammaging**)	Frailty, sarcopenia, anaemia, atherosclerosis, delirium risk, mortality
CD4/CD8 ratio	Falls below 1 in a subset (**IRP**)	Predicts mortality

Latest Updates (2023–Present)

- **Chronic inflammation** and **dysbiosis** were formally added to the hallmarks of ageing in the 2023 *Cell* update, placing inflammaging and the gut microbiome at the centre of immune ageing.
- **Cytomegalovirus** is now viewed as a principal accelerant: persistent antigenic stimulation drives massive expansion of CMV-specific CD8 T cells expressing **PD-1 and TIGIT** with reduced cytotoxicity, raises intracellular TNF-α in B cells, reduces switched memory B cells, and correlates with **poorer vaccine antibody responses** in seropositive older adults.
- The current mechanistic model adds **loss of CD28 expression on T cells**, **impaired T-cell receptor signalling**, **reduced dendritic cell phagocytic activity**, and **accumulation of myeloid-derived suppressor cells**, creating a self-amplifying **immunosenescence–inflammaging feedback loop** (2024–2025 reviews).
- **Vaccine strategy has been redesigned around immunosenescence**: adjuvanted and high-dose formulations, higher antigen content, recombinant platforms and mRNA platforms — exemplified by **high-dose and MF59-adjuvanted influenza vaccines**, the **AS01B-adjuvanted recombinant zoster vaccine**, and the **adjuvanted and mRNA RSV vaccines** licensed from 2023 for older adults.
- **Pharmacological reversal is being tested**: **mTOR inhibitors** improved influenza vaccine responses in older adults (Mannick trials); **senolytic therapy** (dasatinib plus quercetin, fisetin, senolytic CAR-T cells), **canagliflozin** via AMPK activation, and **anti-PD-1 antibodies** clearing PD-L1-positive senescent cells all reduce senescent cell burden and, in principle, restore vaccine immunogenicity.
- **Practical, presently available measures** that improve immune competence in older people remain **correction of protein-energy undernutrition, correction of vitamin D and zinc deficiency, glycaemic control, regular physical activity, adequate sleep, smoking cessation and age-appropriate vaccination**.
- **Indian relevance**: high background prevalence of latent tuberculosis, near-universal CMV seropositivity, high burden of diabetes and undernutrition, and very low adult vaccination coverage make immunosenescence clinically more consequential; the affordable, high-impact interventions are **influenza and pneumococcal vaccination, nutrition and diabetes control** rather than the newer costly vaccines.

Current Practice Update

Issue	Textbook (Pathy 6e / Kane)	Current Evidence (2023–present)
Terminology	Immunosenescence as decline, with a note that remodelling is more accurate	**Immune remodelling / immunobiography** — the individual's lifetime antigen exposure determines the phenotype
Main external driver	Not emphasised	**Chronic CMV infection** is a principal driver of the immune risk phenotype
Inflammaging	Discussed as an association	**Formal hallmark of ageing**; bidirectional loop with immunosenescence
Microbiome	Not covered	**Dysbiosis** recognised as a hallmark and a modifier of vaccine response
Clinical response	No specific recommendations	**Enhanced vaccine platforms** (high-dose, adjuvanted, recombinant, mRNA) are now standard for older adults
Reversal	Thymic hormones restore some function in vitro	**mTOR inhibitors and senolytics** in early human trials; not yet clinical practice

Exam One-Liners

- Immunosenescence = **age-related remodelling** of innate and adaptive immunity, not pure decline.
- Hallmark cellular change = **↓ naive T cells, ↑ memory T cells** from **thymic involution**.
- Cytokine signature = **IL-2 down, IL-6 up**.
- **Immune risk phenotype = CD4/CD8 <1** — predicts mortality.
- Immunosenescence + inflammaging = **"two sides of the same coin"**.
- B cells: **impaired isotype switching** → poor vaccine response, **↑ autoantibodies and MGUS**.
- Commonest clinical manifestations = **herpes zoster, pneumonia, TB reactivation, poor vaccine response, ↑ cancer**.
- Practical answer to immunosenescence today = **enhanced vaccines + nutrition + vitamin D + exercise + glycaemic control**.

Cross-Question Linking Points (useful for any of these eight answers)

- **One inflammatory axis runs through the whole set**: TNF-α and IL-6 explain sarcopenia, frailty, anaemia, anorexia of ageing, delirium risk and immunosenescence. Naming this axis links five answers together.
- **Sarcopenia is the biological substrate of physical frailty**; **deconditioning is acute sarcopenia**; **immunosenescence and inflammaging are the immunological expression of the same hallmarks of ageing**.
- The single intervention that appears in every answer is **progressive resistance exercise with adequate protein** — it improves frailty, sarcopenia, deconditioning and immune competence.
- For any Indian answer, quote **LASI** for epidemiology, **NPHCE** and the **Ayushman Vay Vandana Card** for service delivery, and **AWGS 2019** cut-offs rather than European cut-offs for muscle measurements.

Falls, Gait, Syncope & Dizziness

MD Geriatric Medicine — High-Yield 15-Mark Answers

Questions 1–14

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition
(Ch. 75 Disorders of the Vestibular System; Ch. 78 Gait, Balance and Falls; Ch. 79 Hip Fracture and Orthogeriatrics)
Supplementary textbook: Kane's Essentials of Clinical Geriatrics (Ch. 9 Falls; Ch. 10 Immobility)

Latest Updates sections drawn from guidelines and peer-reviewed evidence, 2023–present
Indian epidemiology, units and programme context integrated throughout

Contents

1. Approach to recurrent falls in the elderly — prevention and management
2. 60-year-old diabetic, hypertensive, CAD and depression on multiple drugs with recurrent falls over one week — evaluate and manage
3. Intrinsic risk factors for falls
4. Post-fall syndrome
5. Long lie
6. Balance and gait assessment
7. Phases in human walking (gait cycle) with diagrams
8. Postural hypotension — evaluation and management
9. Syncope
10. Hypersensitive carotid sinus syndrome
11. Benign paroxysmal positional vertigo — diagnosis and management
12. Approach to a patient with dizziness
13. Evaluation of dizziness / drop attacks
14. Vestibular rehabilitation

> **How to use this set.** Every answer is written to the same shape: numbered high-yield points under labelled subheadings, then **Latest Updates (2023–present)**, then a **Current Practice Update** table wherever textbook and current evidence differ, then **Exam One-Liners**. Textbook content and post-textbook evidence are kept in separate blocks. Where a topic is not covered by name in the uploaded textbooks, this is stated openly at the start of that answer.

Q1. Approach to recurrent falls in the elderly, with emphasis on prevention and management

15–20 High-Yield Points (Textbook)

A. Definition and Burden

1. A **fall** is defined as an **"unexpected event in which the patient comes to rest on the ground, floor, or lower level"**. **Recurrent falls** means two or more falls in twelve months.
2. About **one-third of community-dwelling adults aged 65 and above fall every year**. Among **nursing home residents, one in two falls each year**.
3. **One in five falls causes serious injury** such as a **fracture or head trauma**. In the United States falls cause 3 million emergency visits and 800,000 hospitalisations yearly.
4. Common injuries are fractures of the **hip, femur, humerus, wrist and ribs**, soft-tissue injury, and **subdural haematoma**. Neurological signs appearing days to weeks after a fall should raise suspicion of subdural haematoma.
5. Even without injury, falls cause disability through **fear of falling, loss of self-confidence and restricted walking**, and are an important reason for **institutionalisation**.

B. Why Older People Fall

6. Falls are a **geriatric syndrome**. There is usually an **acute trigger acting on multiple chronic impairments** that have destroyed the person's ability to compensate. **A fall is rarely due to a single factor.**
7. Causes are divided into **intrinsic** (ageing neuromuscular physiology, disease) and **extrinsic** (medications, environment) factors. Risk rises **exponentially as factors accumulate**.
8. The mnemonic **AGAIN I'VE FALLEN** is used to check risk factors systematically: **A**gain fallen, **G**ait and balance problems, **A**DL loss, **I**mpaired mental status, **N**umber and type of drugs, **I**llness, **V**estibular disorders, **E**yes/Ears, **F**oot disorders, **A**lcohol, **L**ower extremity weakness, **L**ow blood pressure, **E**nvironmental hazards, **N**eurological disorders.
9. **Medication is the commonest and the most modifiable risk factor.** High-risk classes are **benzodiazepines, non-benzodiazepine hypnotics, antipsychotics, all antidepressants (TCA, SSRI, SNRI, trazodone, bupropion), antihistamines and anticholinergics, opioids and NSAIDs, muscle relaxants, alpha blockers, digoxin, amiodarone, antihypertensives and diuretics, insulin, Parkinson drugs and cholinesterase inhibitors**.
10. Risk is **highest in the days to weeks immediately after a drug is started or its dose is changed**. New drugs should ideally be started during periods of increased supervision.
11. In hospital, **delirium is the leading cause of falls**. In the community, environmental triggers are wet floors, poor lighting, uneven surfaces, rugs, steps and unstable furniture.

C. Evaluation

12. The **first step in history is to decide whether the event was a fall, a syncope or a seizure**, since management differs completely.
13. The CDC **STEADI algorithm** (Stopping Elderly Accidents, Deaths & Injuries) is the recommended step-wise approach. Ask every older adult about falls in the past year, or screen with the **Stay Independent 12-item questionnaire** or the **three key questions**.
14. Those who screen positive get a risk assessment using three performance tests: **Timed Up and Go Test (TUGT)**, **30-second chair stand** and **four-stage balance test**.
15. **There is no routine need for laboratory or imaging tests** in a fall assessment. **MRI brain** only if a treatable neurological cause is suspected (infarcts, demyelination, posterior fossa malformation, cerebellar degeneration, hydrocephalus). **EEG is rarely helpful** and only if seizure is strongly suspected.
16. The **minimum investigations in a patient who falls are lying and standing blood pressure and a 12-lead ECG**. A medical cause must be actively sought: **postural hypotension, vasovagal syncope, carotid sinus hypersensitivity**.

D. Management and Prevention

17. **Principles of management**: (i) assess and treat physical injury, (ii) treat the underlying conditions, (iii) prevent future falls by physiotherapy and education — gait and balance retraining, muscle strengthening, ambulation aids, properly fitted shoes, adaptive behaviours, and (iv) alter the environment — safe furniture of correct height, removal of loose rugs and obstacles, proper lighting, rails on stairs and in the bathroom.
18. **Exercise is the single most effective intervention.** In the Cochrane review by Sherrington, **balance and functional exercise reduced the rate of falls by 24%** (RR 0.76), **multiple exercise types (balance plus resistance) by 34%** (RR 0.66), and **tai chi by 19%** (RR 0.81). Walking alone or resistance training alone without balance work has uncertain benefit.
19. **Vision**: routine screening alone did not help, but **assessment and treatment of vision impairment combined with exercise reduces falls**. **Cataract surgery reduces falls in older women** (second-eye surgery does not give the same benefit). Replacing multifocal with single-vision lenses for outdoor use helps.
20. **Home hazard assessment and modification reduces falls**, especially with severe visual impairment, and is **more effective when done by an occupational therapist** — grab bars, better lighting on stairs, removal of rugs, socket covers, cupboard locks.
21. **Reducing high-risk medication, particularly withdrawal of psychotropics, is validated as effective. Vitamin D** does not help all older adults but benefits those with **low baseline levels** and **nursing home residents**.
22. What does **not** work: **physical restraints** (they worsen delirium, pressure ulcers and aspiration), **chemical restraints**, **bed rails** and **bed alarms**. **Hip protectors** give a small reduction in hip fracture in care homes (RR 0.82) but **no clear benefit in the community**; adherence is the main barrier.
23. **Cardiac pacing** is an effective single-factor intervention in patients with **carotid sinus hypersensitivity**.

Latest Updates (2023–Present)

- **World Falls Guidelines 2022 (Age and Ageing)** is now the global reference and has replaced the AGS/BGS 2011 and NICE 2013 framework quoted in the textbook. It uses a **three-tier risk stratification — low, intermediate and high**. Low risk: no fall in the past year, or one fall without gait/balance impairment → education and exercise advice. Intermediate risk: one non-injurious fall with impaired gait and balance → tailored balance and strength exercise. **High risk**: **two or more falls in 12 months, or one fall with injury requiring medical treatment, frailty, a long lie of one hour or more, or suspected transient loss of consciousness** → comprehensive multifactorial assessment and personalised multidomain intervention.
- World Falls Guidelines make a **strong recommendation (GRADE 1B)** that multifactorial assessment must include a **cardiovascular assessment — cardiac history, auscultation, lying and standing blood pressure, and a surface 12-lead ECG**. If this is normal, **no further cardiovascular testing is needed unless syncope is suspected** (witnessed syncope/pre-syncope or recurrent unexplained falls) (GRADE 1C).
- The guidelines formally add **concerns about falling (fear of falling)** to the multifactorial assessment, and emphasise **e-health, opportunistic case finding** and **applicability to low- and middle-income countries** — directly relevant to Indian practice.
- **USPSTF 2024 recommendation statement (JAMA)** for community-dwelling adults 65 years and above at increased risk of falls: **exercise interventions — Grade B** (moderate net benefit); **multifactorial interventions — Grade C**, decision to be individualised because net benefit is small. Vitamin D was removed from the scope of this statement.
- **Indian data (LASI wave-1)**: self-reported falls in **11.6–12.5% of adults aged 60 and above**, higher in women and rising with age; **injurious falls in 5.7%** and **dizziness in 14.5%**. Determinants include female sex, underweight BMI, tobacco and alcohol use, chronic joint disease, prior fracture and sensory impairment. **Multimorbidity independently raises fall risk (AOR 1.29)**. **Frailty prevalence is about 30%** and frail elders have higher falls (15.4% vs 11.9%) and multiple falls (7.7% vs 5.3%).
- **Indian service context**: falls prevention is delivered through **NPHCE** geriatric clinics and district geriatric units; assistive and mobility devices through **Rashtriya Vayoshri Yojana** and the **ADIP scheme (ALIMCO)**; hospitalisation for fall-related fracture covered under **AB-PMJAY** and the **Ayushman Vay Vandana Card** for those aged 70 and above; **Elder Line 14567** for elders living alone.

Current Practice Update

Issue	Textbook position (Pathy 6e / Kane)	Current position (2023-present)
Guideline framework	AGS/BGS 2011 and NICE 2013; CDC STEADI screen-assess-intervene	**World Falls Guidelines 2022** three-tier low/intermediate/high risk stratification is the global standard; STEADI retained as a screening tool
Cardiovascular workup	Minimum — lying/standing BP and 12-lead ECG	Same core, now a **strong graded recommendation (1B)**, with an explicit **stopping rule**: no further cardiac testing if initial assessment normal and no suspected syncope
Multifactorial intervention	Recommended broadly for all fallers	**USPSTF 2024 downgraded to Grade C** — individualise; **exercise remains Grade B** and is the strongest single component
Fear of falling	Described as a risk factor and consequence	Now a **formal mandatory domain** of multifactorial assessment (World Falls Guidelines 2022)
Long lie	Not named as a risk category	**Inability to rise for ≥1 hour is an explicit high-risk criterion**
Vitamin D	Kane advises at least 800 IU/day for all	Targeted only — deficiency and care-home residents; **removed from USPSTF falls statement**; high intermittent bolus doses avoided

Exam One-Liners

- Fall = unexpected event coming to rest on ground, floor or lower level. Recurrent = ≥2 falls in 12 months.
- One-third of community elders and one-half of nursing home residents fall each year; 1 in 5 falls injures.
- India (LASI): falls 11.6–12.5%; injurious falls 5.7%; frailty ~30%.
- First question in history: fall, syncope or seizure?
- Minimum tests: lying/standing BP + 12-lead ECG. No routine bloods or imaging.
- Cochrane: balance+functional exercise ↓24%, multiple exercise types ↓34%, tai chi ↓19%.
- High risk (WFG 2022): ≥2 falls, injurious fall, frailty, long lie ≥1 h, or TLoC.
- Restraints, bed rails and bed alarms do NOT prevent falls.

Q2. A 60-year-old diabetic, hypertensive, with CAD and depression on multiple drugs, presents with recurrent falls over one week — evaluate and manage

> **Key insight for the examiner:** falls clustering over **one week** in a previously stable patient indicate an **acute precipitant superimposed on chronic risk factors** — this is a "**premonitory fall**" pattern (Kane) and demands a search for acute illness, delirium or a recent drug change, not merely a routine falls assessment.

15–20 High-Yield Points (Textbook)

A. Framing the Problem

1. This patient has **four independent fall risk domains**: **diabetes** (neuropathy, retinopathy, hypoglycaemia, autonomic dysfunction), **hypertension** (drug-induced hypotension; orthostatic hypotension is commonest in uncontrolled hypertension), **CAD** (arrhythmia, low output, nitrates), and **depression** (antidepressants, poor concentration, deconditioning).
2. **Polypharmacy is the dominant modifiable factor.** More than four drugs, and use of psychotropic, analgesic, diuretic and antihypertensive drugs, are explicit fall risk factors.
3. **An abrupt cluster of falls over one week signals a new event**: acute illness ("premonitory fall"), delirium, a recent drug initiation or dose change, or a new cardiac or neurological event.

B. History

4. Take a **detailed history of each fall** — location and time of day, activity, whether alone or witnessed, and whether the patient was **aware of the impending fall**, tripped or slipped, or the fall was totally unexpected.
5. Ask about **relationship to change of posture, turning of the head, cough, urination, a meal, or medication intake** — each points to a different mechanism (orthostatic, carotid sinus, situational, postprandial hypotension, drug effect).
6. Ask for **premonitory and associated symptoms**: light-headedness, dizziness, vertigo, palpitations, chest pain, breathlessness, focal neurological symptoms (weakness, sensory disturbance, dysarthria, ataxia, aphasia), aura, incontinence of urine or stool.
7. Ask specifically about **loss of consciousness**, what is remembered immediately after the fall, **whether the patient could get up and how long it took**, and whether any witness can confirm loss of consciousness. Loss of consciousness suggests a **cardiac event or seizure**.
8. Obtain a **complete drug chart including doses, recent changes, over-the-counter drugs and alcohol**, and note any drug started or up-titrated in the preceding two weeks.

C. Examination

9. **Vital signs first.** Fever, tachypnoea, tachycardia or hypotension should prompt a search for **acute illness — pneumonia or sepsis, myocardial infarction, pulmonary embolism, gastrointestinal bleeding**.
10. **Postural blood pressure and pulse supine, sitting, and after 1 and 3 minutes of standing** are critical. A fall of **more than 20 mmHg systolic** is significant. Also check for **postprandial hypotension** if events occur within two hours of a meal.
11. If the history suggests carotid sinus sensitivity, **gently massage the carotid for 5 seconds** and observe for **profound bradycardia (50% reduction in heart rate) or a long pause**.
12. **Cardiovascular examination** for arrhythmia and **aortic stenosis**. Both are treatable, serious, and hard to detect clinically — refer for **continuous monitoring and echocardiography** if suspected. Syncope in aortic stenosis is an indication to evaluate for valve replacement.
13. **Neurological examination**: mental status, focal signs, muscle weakness, rigidity or spasticity, **peripheral neuropathy especially posterior column signs (position and vibration sense)** given diabetes, cerebellar signs (heel-shin, heel tapping), and features of Parkinson's disease.
14. **Visual acuity** for uncorrected refractive error, cataract and diabetic retinopathy. Examine the **feet** for deformity, painful lesions (calluses, bunions, ulcers), neuropathic changes and **poorly fitting or worn-out footwear**.
15. Examine **skin, extremities and painful soft-tissue areas for injury**, and specifically consider **subdural haematoma** if there is head injury or new neurological signs days to weeks later.
16. Perform **gait and balance assessment** — more useful for finding remediable problems than the standard neuromuscular examination. Use the **Get Up and Go test**, and the STEADI trio of **TUGT, 30-second chair stand and four-stage balance test**.

D. Investigations

17. Directed, not routine: **capillary and fasting glucose, HbA1c**; **haemoglobin g/dL** (occult GI bleed); **sodium and potassium mEq/L**; **blood urea and creatinine mg/dL**; **calcium mg/dL**; **vitamin D**; **TSH**; urine routine and culture; **12-lead ECG**. Continuous cardiac monitoring and echocardiography only if clinically indicated; the arrhythmia must be **temporally associated with symptoms** before it is blamed.

E. Management

18. **Treat the acute precipitant first** — infection, hypoglycaemia, dehydration, anaemia, electrolyte disturbance, delirium, ischaemia.
19. **Deprescribe and rationalise**: withdraw or reduce sedatives and hypnotics; review antidepressant choice and dose; reduce or space antihypertensives and diuretics if postural drop is present; review nitrates and alpha blockers; avoid sulfonylureas and reduce insulin to **relax glycaemic targets in a faller**; stop anticholinergics.
20. **Correct the specific causes found**: support stockings, leg elevation, slow staged rising and, if needed,

mineralocorticoid or midodrine for postural hypotension; podiatry and correct footwear; ophthalmology referral; pacemaker if cardio-inhibitory carotid sinus hypersensitivity; antiparkinsonian drugs if indicated.

21. **Rehabilitation and environment**: refer to physiotherapy for **gait and balance retraining and lower limb strengthening**, and to occupational therapy for **home hazard assessment**. Prescribe and train in the correct use of a walking aid. Assess osteoporosis and start calcium and vitamin D; consider bone-specific therapy.
22. **Ensure safety in this recurrent faller by urgent intervention**, review response at short interval, and educate patient and family about the heightened risk in the days after any drug change.

Latest Updates (2023–Present)

- By **World Falls Guidelines 2022** criteria this patient is **high risk** (≥2 falls in 12 months) and must receive a **comprehensive multifactorial falls risk assessment with co-designed, personalised multidomain intervention** — not a single-issue fix.
- The mandated **cardiovascular assessment (GRADE 1B)** — cardiac history, auscultation, lying and standing BP, 12-lead ECG — is particularly important here because of CAD; further cardiac investigation is justified only if syncope is suspected or falls remain unexplained.
- **Fall-Risk-Increasing Drugs (FRIDs)** is now the standard framework (EuGMS Task and Finish Group). The **STOPPFall tool** gives structured deprescribing steps for psychotropics and cardiovascular drugs, and is a better exam answer than "review medications". Note that the **OPTIMISE trial** showed antihypertensive deprescribing in older people is feasible but does not automatically improve outcomes — deprescribing must be individualised and monitored.
- **Glycaemic targets in a frail faller**: current ADA and IDF/ISPAD-aligned geriatric guidance supports relaxing to **HbA1c 7.5–8.0%** (and up to 8.5% in very frail or limited life expectancy), avoiding sulfonylureas and prandial insulin, and preferring **metformin, DPP-4 inhibitors or SGLT2/GLP-1 agents** where affordable and appropriate — because hypoglycaemia is a direct precipitant of falls.
- **Blood pressure targets**: the **2024 ESC hypertension guideline** pushes systolic to 120–129 mmHg but explicitly exempts patients with **symptomatic orthostatic hypotension, frailty and limited life expectancy**. **STRIDE (2020)** showed that a pragmatic multifactorial fall-injury intervention did not reduce serious fall injuries, reinforcing that **exercise plus targeted correction of specific deficits beats a generic checklist**.
- **India-specific**: use the **NPHCE district geriatric clinic** for follow-up, **AB-PMJAY / Ayushman Vay Vandana Card** for fracture care, **Rashtriya Vayoshri Yojana / ADIP (ALIMCO)** for free walking aids and spectacles, and note the high burden of **vitamin D deficiency and undiagnosed osteoporosis** in Indian elders.

Current Practice Update

Issue	Textbook position	Current position
Medication review	Withdraw psychotropics; list of offending classes	**FRIDs concept** with the structured **STOPPFall** deprescribing tool; monitored, individualised withdrawal
Diabetes control	Caution with hypoglycaemia-inducing agents	Explicit **relaxed targets (HbA1c 7.5–8.5%)** in frail fallers; avoid sulfonylureas and prandial insulin
BP target	Antihypertensives increase fall risk in new users	Intensive targets (SBP 120–129) recommended generally but **explicitly relaxed in symptomatic orthostatic hypotension and frailty**
Multifactorial package	Broadly recommended	STRIDE showed generic packages fail; **exercise plus targeted correction of identified deficits** is what works

Exam One-Liners

- Falls clustering within a week = look for an acute precipitant (premonitory fall).
- Check vitals, postural BP at 1 and 3 minutes, and a 12-lead ECG in every case.
- Loss of consciousness → suspect cardiac cause or seizure, not a simple fall.
- Carotid massage 5 s: positive if 50% fall in heart rate or a long pause.
- Deprescribing framework = FRIDs + STOPPFall.
- Relax HbA1c to 7.5–8.5% and avoid sulfonylureas in a frail faller.
- Refer to PT for gait/balance and OT for home hazards; assess osteoporosis.

Q3. Intrinsic risk factors for falls

15–20 High-Yield Points (Textbook)

A. Concept

1. Falls result from an interaction between **intrinsic factors** (arising within the patient) and **extrinsic factors** (medications, environment, assistive devices). **Rarely is a fall due to a single factor**, and risk rises **exponentially as intrinsic factors accumulate**.
2. **Intrinsic factors** comprise three groups: (i) **normal age-related physiological change**, (ii) **disease-related impairment**, and (iii) **psychological factors** such as fear of falling.

B. Age-Related Physiological Changes

3. **Diminished proprioception** from reduced conduction velocity in sensory and motor nerves. Peripheral sensation is the most critical afferent control of standing balance in healthy older people.
4. **Slower righting reflexes and slowed reaction time**, so the person cannot recover after a trip.
5. **Increased postural sway**, mainly anterior-posterior; both magnitude and velocity of sway increase with age.
6. **Loss of muscle mass (10–40%)** with preferential loss of **type II (fast twitch) fibres**, and prolonged contraction and relaxation time — the basis of **sarcopenia**.
7. **Stiffer joint capsules and ligaments** from cross-linking and loss of elastic fibres in articular cartilage.
8. **Gait changes**: gait speed falls **12–16% per decade** (up to 20% for maximum gait speed), with **reduced step length** and **increased time in double limb support**. Older men develop a flexed, wide-based, short-stepped gait; older women a narrow-based, waddling gait. Feet are not picked up as high, increasing tripping.
9. **Reduced baroreflex sensitivity** leading to **orthostatic hypotension** (about 20% of older persons) and **postprandial hypotension**.
10. **Impaired dual-tasking.** Institutionalised older adults who cannot hold a conversation while walking have a high risk of falls.

C. Disease-Related Intrinsic Factors

11. **Neurological**: stroke with residual deficit, **Parkinson's disease** (rigidity, freezing, slow gait), cerebellar disease, **peripheral neuropathy** (diabetes), cervical and lumbar spondylosis with cord or root compression, **normal-pressure hydrocephalus**, seizure disorder, subdural haematoma or tumour.
12. **Cognitive impairment and dementia.** Older adults with cognitive impairment fall at **two to eight times** the rate of cognitively intact peers, and recurrent falls may be the **first presentation of dementia**. Delirium is the strongest inpatient association.
13. **Cardiovascular**: arrhythmias, **aortic stenosis**, **carotid sinus hypersensitivity**, orthostatic and postprandial hypotension, and low cardiac output from heart failure or hypovolaemia.
14. **Musculoskeletal**: degenerative joint disease of neck, lumbosacral spine and lower limbs; healed hip and femur fractures causing an unsteady gait; **lower extremity weakness** and deconditioning from disuse.
15. **Sensory**: impaired visual acuity (cataract, glaucoma, retinopathy, poor near vision), **impaired hearing**, and **vestibular disorders**. Vision becomes more important as other inputs are lost, so visual loss is disproportionately disabling.
16. **Foot disorders**: bunions, calluses, nail disease and joint deformities are **common and correctable** causes of instability.
17. **Genitourinary**: overactive bladder, urge incontinence and **nocturia**.
18. **Chronic musculoskeletal pain** causes antalgic gait and acts as a cognitive distractor forcing dual-tasking; it is associated with falls **even after adjusting for analgesic use**.

D. Psychological

19. **Fear of falling (FoF)** is the lack of self-confidence that normal activities can be performed without falling. It is an **independent predictor of future falls**, and it acts by making the person restrict activity (leading to further deconditioning) and by consuming the cognitive resources needed for gait and balance control.
20. Also intrinsic in effect are **alcohol use**, **loss of ADL function**, **low baseline physical activity** and **previous falls** — a previous fall is the single strongest predictor of the next one.

Latest Updates (2023–Present)

- **World Falls Guidelines 2022** require that every multifactorial assessment covers, as a minimum, **gait and balance, muscle strength, orthostatic blood pressure and cardiovascular status, vision, cognition, continence, foot and footwear, nutrition and vitamin D, medication review, and concerns about falling**.
- **Concerns about falling** have been formally added as an assessment domain; a 2025 systematic review and meta-analysis applying Bradford Hill criteria confirmed that concerns about falling independently predict future falls, though the effect size is modest.
- **Sarcopenia** is now the preferred intrinsic construct for muscle-related fall risk, using **EWGSOP2 / AWGS 2019** criteria (low grip strength, low muscle mass, low gait speed), with **SARC-F** as the practical Indian screening tool.
- **Indian evidence (LASI wave-1)** identifies as significant intrinsic determinants: **female sex, advancing age, underweight BMI, chronic joint disease, previous injury or fracture, sensory impairment, depressive symptoms, poor grip strength and slow gait speed**. **Frailty (Fried phenotype, prevalence ~30%)** independently increases falls (aOR 1.24).
- **Orthostatic hypotension, cognitive impairment and reduced mobility** are now described as an interacting **"Bermuda triangle"** in older fallers, meaning these three should be looked for together rather than separately.

Current Practice Update

Issue	Textbook position	Current position
Muscle weakness	Described as age-related loss of type II fibres and deconditioning	Formalised as **sarcopenia** with operational criteria (EWGSOP2 / AWGS 2019, SARC-F screening)
Fear of falling	Recognised as a consequence and a predictor	**Mandatory assessment domain**; independent predictive value confirmed by 2025 meta-analysis
Frailty	Mentioned only in passing	**Independent high-risk criterion** in World Falls Guidelines 2022; ~30% prevalence in Indian elders

Exam One-Liners

- Intrinsic = age change + disease + psychological; Extrinsic = drugs + environment + devices.
- Peripheral sensation (proprioception) is the most critical afferent for standing balance.
- Gait speed declines 12–16% per decade; type II fibres lost preferentially.
- Orthostatic hypotension in ~20% of older persons.
- Cognitive impairment raises fall rate 2–8 fold; delirium is the main inpatient trigger.
- Previous fall is the strongest single predictor of a future fall.
- Fear of falling is itself an independent risk factor, not just a consequence.

Q4. Post-fall syndrome

> **Textbook coverage statement.** The term **"post-fall syndrome" is not used by name** in the uploaded chapters of Pathy's 6th edition or Kane's Essentials. However, **all of its components are described** — fear of falling, loss of self-confidence, restriction of ambulation (self-imposed or imposed by caregivers), disability and increased risk of institutionalisation and death. The definition and classical description below are therefore drawn from the wider geriatric literature (Murphy and Isaacs, 1982) and are clearly separated from textbook content.

15–20 High-Yield Points

A. Definition and Concept `supplementary`

1. **Post-fall syndrome** (also called **ptophobia**, or the post-fall anxiety syndrome) was described by **Murphy and Isaacs in 1982** as a **disabling psychomotor state occurring after a fall in an older person, characterised by fear of falling, loss of postural confidence and a stereotyped abnormal posture and gait, in the absence of any neurological lesion sufficient to explain it**.
2. It is a **geriatric emergency of function**: the disability is out of all proportion to the physical injury sustained, and it can convert an independent older person into a bed- or chair-bound one within days.
3. It typically follows a fall associated with a **long lie**, an injurious fall, or a fall witnessed by an anxious family.

B. Clinical Features `supplementary`

4. **Psychological component**: intense **fear of falling**, anxiety, loss of self-confidence, refusal to walk, and sometimes frank **depression**.
5. **Postural component (retropulsion)**: the trunk is **thrown backwards** when standing or transferring, with the centre of gravity displaced behind the base of support.
6. **Gait component**: **hesitancy in initiating gait**, short shuffling steps with the feet barely leaving the floor ("**marche à petits pas**"), a wide base, absent arm swing, and **clutching or grasping** at furniture and at the examiner.
7. **Failure of protective reactions**: the person does not put the arms out to save themselves and does not step to correct a perturbation.
8. It is sometimes described in three stages: **acute (immediate fear and refusal to stand)**, **sub-acute (retropulsion and clutching gait)** and **chronic (established immobility and dependency)**.

C. Consequences `textbook`

9. Kane records that **even when the fall does not cause serious injury, substantial disability may result from fear of falling, loss of self-confidence, and restricted ambulation — either self-imposed or imposed by caregivers**.
10. **Impaired mobility** leads to the full spectrum of **complications of immobility**: pressure ulcers, muscular deconditioning and atrophy, contractures, bone loss, cardiovascular deconditioning, **orthostatic hypotension**, venous thrombosis and embolism, reduced ventilation with atelectasis and aspiration pneumonia, constipation and faecal impaction, urinary retention and infection, negative nitrogen balance, and psychologically sensory deprivation, delirium and depression.
11. Reduced activity causes **further loss of musculoskeletal and neurological reserve**, so the risk of the next fall **increases** — a vicious cycle.
12. **Fear of falling reduces the cognitive resources available for gait and balance control** (impaired dual-tasking), which itself worsens gait.
13. End results are **loss of independence, caregiver burden, increased risk of institutionalisation and increased risk of death**.

D. Assessment

14. Recognise it clinically: a patient who **will not stand or walk after a fall despite adequate analgesia and no fracture** has post-fall syndrome until proved otherwise.
15. **Exclude organic causes** of the refusal — occult hip or pelvic fracture, **subdural haematoma** (neurological signs days to weeks after the fall), acute stroke, delirium, pain, and drug effect.
16. **Quantify fear of falling** with a scale: **Falls Efficacy Scale-International (FES-I)** or the short FES-I, or the Activities-specific Balance Confidence (ABC) scale. Quantify gait and balance with the **Tinetti POMA** and **TUG**.

E. Management

17. **Get the patient up early.** The single most important step is **early, supervised, graded mobilisation** — prolonged bed rest converts a reversible syndrome into permanent immobility.
18. **Physiotherapy**: progressive **balance and functional training, lower limb strengthening, transfer and gait retraining**, and specific practice of **backward disequilibrium correction** and protective stepping reactions.
19. **Teach the patient how to get up from the floor** (backward chaining) — this directly reduces the fear and prevents a future long lie.
20. **Cognitive-behavioural approaches and psychological support**, treatment of coexisting depression, and reassurance and education of the family, who are often the source of the restriction ("don't walk, you will fall again").
21. **Occupational therapy** for home hazard modification, grab bars and correct-height furniture; appropriate **walking aid** with training; well-fitted footwear.
22. **Provide a personal alarm or pendant** and arrange a check-in system for the elder living alone. Withdraw fall-risk-increasing drugs and treat the underlying cause of the index fall.

Latest Updates (2023–Present)

- **World Falls Guidelines 2022** make assessment of **"concerns about falling"** a formal component of the multifactorial falls risk assessment and recommend **FES-I / short FES-I** as the measurement instrument. The guidelines deliberately prefer the term "concerns about falling" over "fear of falling" because it is less stigmatising and better captures activity restriction.
- A **2025 systematic review and meta-analysis** (Age and Ageing) applying the Bradford Hill criteria confirmed that **baseline concerns about falling independently predict future falls**, supporting its inclusion as a treatment target and not merely an outcome.
- **Cognitive-behavioural therapy-based programmes** such as **"A Matter of Balance"** and CBT delivered by trained lay leaders reduce fear of falling and activity restriction; Cochrane evidence supports **exercise (especially tai chi) plus CBT** as the most effective combination.
- **Teaching floor-rise technique (backward chaining)** is now explicitly recommended by World Falls Guidelines and by the British Geriatrics Society for anyone at risk of a long lie, as both a physical and a psychological intervention.
- **Indian context**: activity restriction after a fall is reinforced by family protectiveness and by the cultural expectation that elders should "rest". Practical measures include family education under **NPHCE** counselling, provision of a walking aid through **Rashtriya Vayoshri Yojana**, home-based physiotherapy where available, and the **Elder Line 14567** for elders living alone.

Current Practice Update

Issue	Textbook position	Current position
Terminology	Term "post-fall syndrome" not used; components described as fear of falling and restricted ambulation	Recognised entity; preferred assessment term is **"concerns about falling"** (World Falls Guidelines 2022)
Measurement	No named scale	**FES-I / short FES-I** recommended as standard instrument
Treatment	Physical therapy, education, environmental change	**Exercise (tai chi) plus CBT**; explicit teaching of **floor-rise / backward chaining**

Exam One-Liners

- Post-fall syndrome = fear + loss of postural confidence + retropulsion + hesitant clutching gait, with no adequate neurological lesion.
- Described by Murphy and Isaacs, 1982; also called ptophobia.
- Disability is out of proportion to the physical injury.
- Measure with FES-I; treat with early mobilisation + physiotherapy + CBT.
- Teach floor-rise (backward chaining) — prevents both fear and future long lie.
- Prolonged bed rest converts a reversible syndrome into permanent immobility.

Q5. Long lie

> **Textbook coverage statement.** The term **"long lie" is not used by name** in the uploaded chapters of Pathy's 6th edition or Kane's Essentials. Kane does, however, make it a key history point — "**Could the patient get up, and if so, how long did it take?**" — and Pathy notes the older person's fear of "**being incapacitated at home, unable to reach help**". The definition and consequences below come from the wider geriatric literature and current guidelines and are clearly separated.

15–20 High-Yield Points

A. Definition `supplementary`

1. A **long lie** is defined as **remaining on the floor or ground for one hour or more after a fall, because the person is unable to get up unaided**.
2. It is a **marker of severity, not a diagnosis** — it indicates that the faller has neither the muscle strength nor the balance nor the help required to rise.
3. Roughly **half of older people who fall cannot get up without help**, and a long lie occurs in about **10–20% of falls** in community-dwelling elders. It is far commoner in those who **live alone**, have **dementia**, are **frail or sarcopenic**, or have **no personal alarm**.

B. Why It Matters

4. It is an **independent predictor of death**: classically about **half of those who lie for more than an hour die within six months**, even if the fall itself caused no serious injury.
5. It is also a strong predictor of **hospital admission and permanent institutionalisation**.

C. Complications

6. **Dehydration** and **hypovolaemia** from prolonged immobility without fluid intake.
7. **Rhabdomyolysis** from sustained pressure on muscle, causing raised creatine kinase, **myoglobinuria** and **acute kidney injury**; monitor **creatinine mg/dL** and **potassium mEq/L**.
8. **Hyperkalaemia, hyperphosphataemia, hypocalcaemia (calcium mg/dL)** and metabolic acidosis from muscle breakdown.
9. **Pressure injury** over the sacrum, heels, trochanters and elbows — pressure damage can begin within two hours of unrelieved loading.
10. **Hypothermia**, which in Indian practice is a real risk in northern winters and in poorly heated homes.
11. **Aspiration pneumonia and hypostatic pneumonia**, and **compartment syndrome** of a dependent limb.
12. **Delirium**, and worsening of any underlying acute illness that caused the fall.
13. **Post-fall syndrome** — the long lie is the classical trigger for profound fear of falling and activity restriction.

D. Management of the Patient Found After a Long Lie

14. Treat as a **medical emergency**. Assess airway, breathing, circulation and **core temperature**; rewarm gradually if hypothermic.
15. **Investigate**: haemoglobin g/dL, sodium and potassium mEq/L, urea and creatinine mg/dL, calcium mg/dL, **creatine kinase**, arterial blood gas, urine for myoglobin, blood glucose, ECG (hyperkalaemic changes), chest X-ray, and imaging of any painful area for fracture.
16. **Aggressive intravenous fluid resuscitation** to prevent or treat AKI from rhabdomyolysis; monitor urine output, potassium and renal function; treat hyperkalaemia.
17. **Full skin inspection** and immediate pressure injury care with redistribution surfaces; treat infection; provide analgesia and nutritional support.
18. **Find and treat the cause of the fall** — including a search for syncope, arrhythmia, stroke, sepsis, hypoglycaemia and drug effects.

E. Prevention

19. **Teach floor-rise technique (backward chaining)** to every at-risk older person and their carer — this is the single most useful preventive skill.
20. Provide a **personal alarm, pendant or wearable fall detector**, keep a **charged mobile phone within reach at floor level**, arrange **daily check-in calls or visits**, and consider a key-safe so help can enter.
21. **Strength and balance exercise** to maintain the ability to rise; treat sarcopenia; keep a low bed and clear floor space; avoid a locked bathroom door.

Latest Updates (2023–Present)

- **World Falls Guidelines 2022** make the long lie an explicit part of risk stratification: an adult who **"was laying on the floor unable to rise independently for at least one hour"** is to be regarded as at **high risk of future falls**, alongside injurious falls, recurrent falls, frailty and suspected transient loss of consciousness. This has moved the long lie from a descriptive observation to a formal **triage criterion**.
- The guidelines also recommend directly asking about the **ability to get up from the floor** as part of the fall history, and teaching floor-rise strategies.
- **Technology**: wearable and ambient fall-detection systems (accelerometer-based pendants, smartwatch fall detection, radar and depth-camera ambient sensors, smart-home floor sensors) are the focus of current research to shorten the time on the floor. Evidence to date shows they **shorten time-to-help but have not yet been shown to reduce mortality**, and false alarms and non-wearing remain limiting; guidelines therefore describe them as **promising adjuncts, not**

replacements for exercise and floor-rise training.

- **Ambulance and emergency service pathways** increasingly include a “fallen and unable to get up” response with lifting equipment and an on-scene falls assessment rather than automatic conveyance, with referral to a falls service.
- **Indian relevance**: with rising numbers of elders living alone or with children abroad, long lie is under-recognised. Practical measures are a **charged mobile phone kept at floor level**, ASHA/ANM home visits under **NPHCE**, neighbourhood senior citizen associations, police senior-citizen registration schemes, and the national helpline **Elder Line 14567**.

Current Practice Update

Issue	Textbook position	Current position
Status of long lie	Not named; time taken to get up is a history question only	**Formal high-risk triage criterion (≥1 hour) in World Falls Guidelines 2022**
Floor-rise training	Not mentioned	**Explicitly recommended** for all at-risk older adults
Detection	Not addressed	Wearable and ambient **fall-detection technology** recommended as an adjunct; shortens time-to-help

Exam One-Liners

- Long lie = on the floor ≥1 hour, unable to rise unaided.
- Around half of fallers cannot get up unaided; ~50% of those with a long lie die within 6 months.
- Complications: dehydration, rhabdomyolysis → AKI, hyperkalaemia, pressure injury, hypothermia, pneumonia, delirium, post-fall syndrome.
- Always check creatine kinase, potassium mEq/L and creatinine mg/dL; give aggressive IV fluids.
- Prevention = floor-rise (backward chaining) + personal alarm + phone at floor level + strength training.
- WFG 2022: long lie ≥1 hour = automatic high fall risk.

Q6. Balance and gait assessment

15–20 High-Yield Points (Textbook)

A. Definitions and Physiology

1. **Balance (equilibrium)** is the ability to maintain the **centre of mass of the body within the base of support with minimal postural sway**.
2. Balance depends on the integration of **proprioception, vestibular input, visual input, central coordination and neuromuscular responses**.
3. When standing, changes in orientation are first perceived by **cutaneous proprioceptive sensors in the feet**; the **vestibular apparatus** detects linear and angular acceleration of the head; **vision** detects motion of the visual field. **On a fixed level surface proprioception predominates; when the surface is irregular or moving, vestibular input becomes essential.**
4. **Gait** is the pattern of trunk and limb movement during locomotion over a solid surface — the "manner of walking" or "sequence of foot movements".
5. **Gait assessment is a critical part of the comprehensive geriatric assessment.** At least **one-fifth of community-dwelling older adults report difficulty walking**, rising to **one-half in those aged 85 and above**.

B. Tools for Assessing Balance

6. **30-second chair stand** — number of chair stands completed in 30 seconds with arms crossed on the chest. The most practical tool in a busy clinic; measures both **balance and strength**. It is one component of the **Short Physical Performance Battery (SPPB)**.
7. **Short Physical Performance Battery (SPPB)** — repeated chair stands plus balance testing with **side-by-side, semitandem and tandem stands**, plus gait speed.
8. **4-Stage Balance Test** — side-by-side, semitandem, tandem and one-foot stand. **Normal balance = holding each position for 10 seconds.**
9. **Berg Balance Scale** — a **14-item** test of everyday tasks (sitting unsupported, sit-to-stand, stand-to-sit, transfers, standing unsupported, eyes closed, feet together, tandem standing, one-leg stand, turning the trunk, retrieving objects from the floor, turning 360 degrees, stool stepping, reaching forward). Total score **0–56**. Interpretation: **0–20 wheelchair bound, 21–40 walks with assistance, 41–56 independent**. Validated originally in older stroke patients; predicts functional and motor performance and future falls.
10. **Functional reach test** — dynamic standing balance. The subject stands behind a line and reaches the arm as far forward as possible without stepping. **Fall risk is suspected if reach is less than 10 inches.** It correlates with other balance measures and **predicts future decline in ADLs**, though it may not reliably predict falls.

C. Tools for Assessing Gait

11. **Gait speed** is the simplest and most standardised global measure of health and function. Measured over a **pre-measured 4 metre distance**. **0.6–0.8 m/sec identifies a high-risk population and 0.6 m/sec is the generally accepted cut-off for abnormal gait speed.**
12. **Get Up and Go Test (GUGT) / Timed Up and Go (TUGT)** — rise from a chair, walk a set distance, turn, walk back and sit down. In the inpatient setting sensitivity is **91%** but specificity only **22%**. Even an **untimed** GUGT is clinically useful for identifying specific balance and gait problems. Kane recommends a simple "get up and go" test in **all** patients who have fallen.
13. **Tinetti's Performance-Oriented Mobility Assessment (POMA)** — 14 performance tasks split into balance and gait. **Maximum balance score 16, maximum gait score 12, total 28. Score below 19 = high risk of falls; 19–24 = at risk.** Mean sensitivity 82%, specificity 65%. Takes 10–15 minutes, so it is harder to use in a busy clinic. Interrater agreement is over 85%.
14. The Tinetti **balance** items are: sitting balance, arises, attempts to arise, immediate standing balance (first 5 seconds), standing balance, nudged, eyes closed, turning 360 degrees, sitting down. The **gait** items are: initiation of gait, step length and height, step symmetry, step continuity, path, trunk, and walking stance.
15. **Kane's performance-based assessment** grades each manoeuvre as **normal, adaptive or abnormal**: sitting balance, arising from chair, immediate standing balance (first 3–5 seconds), standing balance, **Romberg**, **sternal nudge** (examiner pushes with light even pressure over the sternum three times), walking, turning balance through 360 degrees, **neck turning**, and **back extension**. This is **more useful than the standard neuromuscular examination for identifying remediable problems**.
16. **Dual-task testing** — walking while counting backwards from 100 by sevens, GUGT while holding a full glass of water, or one-leg stand with eyes closed. Institutionalised older adults who **cannot keep up a conversation while walking have a high risk of falls**. Both young and old prioritise gait over the secondary cognitive task. Clinical utility is still unclear because of variability across studies.

D. Age-Related Findings to Look For

17. Expect **slower gait, reduced step length, increased time in double limb support, reduced range of motion, and increased anterior-posterior postural sway**. Gait speed falls **12–16% per decade**.
18. On perturbation testing, younger people abduct the arms uphill and hinge at hips and trunk to keep the centre of mass away from the tilt; **older subjects have reduced compensatory trunk movement and stretch the arms in the direction of the fall**.
19. Recognise disease-specific gaits: **Parkinson's disease** — gait initiation failure and freezing, better with external visual cues; **post-stroke** — decreased hip and knee flexion during the swing phase; **cerebellar disease** — broad-based ataxic

gait; **vestibular lesion** — veering to the ipsilateral side when walking with eyes closed.

20. **Where to place it in practice**: gait, strength and balance assessment forms the core of the CDC **STEADI** risk assessment using **TUGT, 30-second chair stand and 4-stage balance test**.

Latest Updates (2023–Present)

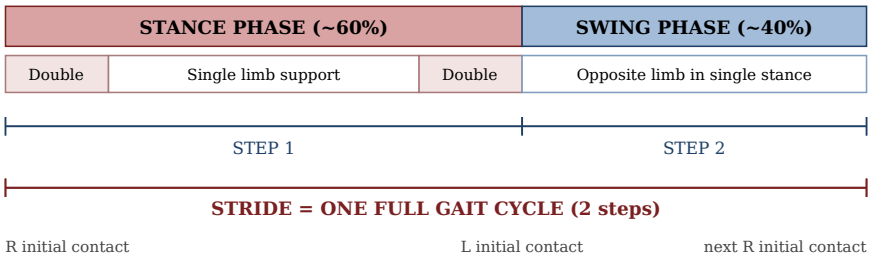
- **World Falls Guidelines 2022** retain gait and balance assessment as the core of risk stratification and specifically recommend **timed up and go, gait speed, and a balance test such as the 4-stage or Berg scale**. Crucially, the guidelines position gait and balance impairment as the factor that separates **intermediate** from **low** risk in a person with a single fall.
- **Gait speed** is now used as a vital sign and as a core criterion for **sarcopenia** in **EWGSOP2** (≤0.8 m/s) and **AWGS 2019** (<1.0 m/s for Asians — the more appropriate cut-off for Indian patients) and for **frailty** in the Fried phenotype.
- **WHO ICOPE (2nd edition, 2025)** uses the **chair rise test** as the primary screening item for the locomotor capacity domain in integrated care for older people, making it the most relevant tool for Indian primary and community-level screening under NPHCE.
- **Dual-task gait assessment** and **gait variability** (stride time variability) are increasingly validated as markers of **cognitive-motor risk**. The **Motoric Cognitive Risk (MCR) syndrome** — slow gait plus subjective cognitive complaint without dementia — predicts incident dementia and falls, and can be diagnosed without any neuropsychological testing.
- **Instrumented and digital gait assessment** using wearable inertial sensors and smartphone applications gives spatiotemporal parameters (variability, asymmetry, turning) with better fall prediction than stopwatch measures; these are still research or specialist tools, and guidelines caution that no instrumented tool has yet replaced clinical assessment.

Current Practice Update

Issue	Textbook position	Current position
Gait speed cut-off	0.6 m/s abnormal; 0.6–0.8 m/s high risk	Retained for falls, but **≤0.8 m/s (EWGSOP2)** and **<1.0 m/s (AWGS 2019, Asian)** are used for sarcopenia — use the **AWGS cut-off in Indian patients**
Screening tool of choice	STEADI trio: TUGT, 30-s chair stand, 4-stage balance	Same trio endorsed; **WHO ICOPE 2025 uses the chair rise test** as the single locomotor screen for community settings
Dual tasking	Proposed screen, clinical utility unclear	Now linked to **Motoric Cognitive Risk syndrome** and used as a cognitive-motor risk marker
Technology	Not addressed	**Wearable inertial sensors / smartphone gait analysis** improve prediction but do not yet replace clinical tests

Exam One-Liners

- Balance = keeping centre of mass within base of support with minimal sway.
- Fixed level surface → proprioception dominant; uneven or moving surface → vestibular dominant.
- Berg Balance Scale: 14 items, 0–56; ≤20 wheelchair, 21–40 assisted, 41–56 independent.
- Functional reach <10 inches = fall risk.
- 4-stage balance test: hold each position 10 seconds.
- Gait speed over 4 m; abnormal <0.6 m/s (use <1.0 m/s AWGS for Asian sarcopenia).
- Tinetti POMA: balance 16 + gait 12 = 28; <19 high risk, 19–24 at risk.
- TUGT: sensitivity 91%, specificity 22% in inpatients.



Q7. Phases in human walking (gait cycle), with diagrams

15–20 High-Yield Points

A. Basic Definitions textbook

1. The **gait cycle** is the sequence of events between one event of one limb and the recurrence of the same event in the same limb. It has two phases: **stance phase** and **swing phase**.
2. **Stance phase** — the period when the foot is in contact with the ground. During **double stance** the weight is transferred from one foot to the other.
3. **Swing phase** — during **single stance** the centre of mass of the body passes over the supporting foot in preparation for shifting to the other limb, while the opposite limb swings forward.
4. **Step** is the period from **initial contact of one limb to the initial contact of the contralateral limb**.
5. **Stride** is the period from the **initial contact of a particular limb to the point of initial contact of the same limb**. **A stride equals one gait cycle, and there are two steps in each stride.**

Figure 1. The walking gait cycle (one stride = one gait cycle)

B. Sub-phases of the Gait Cycle supplementary

> Pathy's Figure 78.4 divides the cycle only into **stance, swing, step and stride**. The eight sub-phases below are the standard Rancho Los Amigos description used in rehabilitation and are given here as supplementary content because they are frequently asked in examinations.

6. **Stance phase (approximately 60% of the cycle)** has five sub-phases: **initial contact (heel strike, 0–2%)**, **loading response (0–10%)**, **mid-stance (10–30%)**, **terminal stance (heel off, 30–50%)** and **pre-swing (toe off, 50–60%)**.
7. **Swing phase (approximately 40% of the cycle)** has three sub-phases: **initial swing (acceleration, 60–73%)**, **mid-swing (73–87%)** and **terminal swing (deceleration, 87–100%)**.
8. **Double support occupies about 20% of the cycle** and occurs twice, at the beginning and end of stance. **Double support disappears in running** — this is the defining difference between walking and running.
9. Functional tasks: **weight acceptance** (initial contact and loading response), **single limb support** (mid-stance and terminal stance), and **limb advancement** (pre-swing to terminal swing).

Phase	Sub-phase	% of cycle	Key event
Stance (~60%)	Initial contact (heel strike)	0–2%	Heel touches ground; limb prepares to accept weight
	Loading response	0–10%	Double support; shock absorption; knee flexes slightly
	Mid-stance	10–30%	Single limb support; body passes over the fixed foot
	Terminal stance (heel off)	30–50%	Heel rises; body advances ahead of the supporting foot
	Pre-swing (toe off)	50–60%	Second double support; push-off; limb unloaded
Swing (~40%)	Initial swing (acceleration)	60–73%	Toe leaves ground; hip and knee flex to clear the foot
	Mid-swing	73–87%	Swinging limb passes the stance limb; ankle dorsiflexes
	Terminal swing (deceleration)	87–100%	Knee extends; limb decelerates ready for next initial contact

C. Neural Control of Walking textbook

10. Human locomotion depends on **higher command and control centres in the brainstem and forebrain**, and the pathway used depends on whether the stimulus is **internal or external**.
11. In **normal, internally cued walking**, the **supplementary motor area (SMA)** of the frontal cortex fires significantly **just before gait initiation**, and this preparatory activity is sent to the **primary motor cortex (M1)**.
12. SMA activity is then **switched off by phasic activity from the basal ganglia (BG)**, which provides a non-specific cue that both triggers the sub-movement and instructs the SMA to prepare the next signal. This **BG–SMA interaction ensures smooth running of predictable, well-learned, automatic movement sequences**.
13. When movement is **externally cued**, the BG–SMA pathway is **bypassed** and sensory information feeds directly into the **pre-motor area (PMA)** through visual, auditory and proprioceptive pathways.
14. The motor cortex, basal ganglia and cerebellum then pass input to the **pedunculopontine nucleus (PPN)**, which projects to the **brainstem reticular nuclei**, from which instructions for gait pass along **non-pyramidal pathways into the ventral spinal cord**.
15. **Clinical correlation — Parkinson's disease**: disordered cueing from the basal ganglia disturbs internal rhythm formation and impairs feedback to the SMA, producing **bradykinesia, gait initiation failure and freezing**. PD patients

therefore rely on intact PMA (external cue) pathways — gait improves with **external cues such as stepping over coloured patterns on the ground**. **Vascular dementia and stroke** show a similar compensatory dependence on PMA pathways.

D. Ageing Changes in the Gait Cycle textbook

16. **Gait speed declines 12–16% per decade**, and maximum gait speed by up to **20%**.
17. **Step length is reduced** and **time spent in double limb support is increased** — the body's way of buying stability at the cost of speed.
18. Gait becomes **slower, more uncertain and uncoordinated, and lacks a full range of motion**, from stiffer joint capsules and ligaments and loss of muscle mass.
19. Feet are **not picked up as high**, increasing the tendency to trip. Older men develop a **wide-based, short-stepped gait**; older women a **narrow-based, waddling gait**. These changes correlate with **white matter changes on MRI** and with subsequent cognitive impairment.
20. After acute stroke, patients may show **decreased hip and knee flexion during the swing phase**, causing foot drag and tripping.

Latest Updates (2023–Present)

- **Gait variability** — particularly **stride time variability** and **swing time variability** — is now recognised as a better predictor of falls than mean gait speed alone, because it reflects the rhythmic control that fails early in ageing and neurodegeneration.
- **Instrumented gait analysis** using body-worn inertial measurement units (usually lower back and shanks) now permits routine measurement of the sub-phases — double support time, swing time asymmetry, turning duration and number of steps to turn — outside a gait laboratory. Prolonged **double support time** and increased **turn duration** are consistent markers of fall risk.
- **Gait is treated as a cognitive task.** Current evidence positions **dual-task gait cost** and **Motoric Cognitive Risk syndrome** (slow gait plus subjective cognitive complaint) as predictors of incident dementia, reinforcing the textbook's BG–SMA and PPN model with clinical evidence.
- **External cueing** for Parkinson's disease freezing — laser-line walking sticks, rhythmic auditory cueing and metronome apps — is now standard rehabilitation practice and is the direct clinical application of the PMA bypass pathway described in the textbook.
- In Indian practice, **barefoot walking, squatting and floor-level activities, uneven flooring and thresholds** materially alter gait mechanics and tripping risk, and should be addressed specifically in gait retraining and home assessment.

> **Exam One-Liners**
> - Gait cycle = stance (~60%) + swing (~40%). Double support ~20%, occurs twice.
> - Step = one limb's contact to the other limb's contact. Stride = same limb to same limb = one gait cycle = 2 steps.
> - Stance sub-phases: initial contact, loading response, mid-stance, terminal stance, pre-swing.
> - Swing sub-phases: initial (acceleration), mid, terminal (deceleration).
> - Running is defined by loss of the double support period.
> - Internal cue pathway: SMA → M1, switched off by basal ganglia → PPN → reticular nuclei → ventral cord.
> - External cue pathway bypasses BG–SMA and goes through the pre-motor area — the basis of visual cueing in Parkinson's disease.
> - Ageing: gait speed ↓12–16% per decade, shorter step, longer double support.

Q8. Postural (orthostatic) hypotension — evaluation and management

15–20 High-Yield Points (Textbook)

A. Definition and Epidemiology

1. **Orthostatic (postural) hypotension** is defined as a **drop in systolic blood pressure of 20 mmHg or more on moving from a lying to a standing position**.
2. It occurs in about **20% of older persons**. **Many are asymptomatic**, but the impaired physiological response still causes instability and precipitates falls.
3. It is more common in older adults with **uncontrolled hypertension**, and it is **specifically in that context that it most strongly predicts falls**.
4. Among **nursing home residents it is common even when asymptomatic and is an independent risk factor for recurrent falls**.
5. **Postprandial hypotension** is a separate entity: a fall in blood pressure after a meal, which worsens when the person then stands. Both orthostatic and postprandial hypotension are **more common in the morning**.

B. Pathophysiology and Causes

6. The ageing basis is **reduced baroreflex sensitivity** together with reduced vascular compliance, reduced renal sodium conservation, and blunted heart rate response.
7. **Low cardiac output** from heart failure or **hypovolaemia** (dehydration, acute blood loss, occult gastrointestinal bleeding).
8. **Overtreatment with cardiovascular medication** — diuretics, antihypertensives, nitrates, alpha blockers.
9. **Autonomic dysfunction** — **diabetes mellitus** and **Parkinson's disease**; also multiple system atrophy, where fludrocortisone or midodrine may be needed for symptomatic postural hypotension. Note the textbook point that **Parkinson's disease medication itself can cause orthostatic hypotension**.
10. **Impaired venous return** — venous insufficiency, varicose veins.
11. **Prolonged bed rest with deconditioning** of muscles and reflexes — a listed complication of immobility.
12. Drug groups to suspect in a faller: **diuretics (hypovolaemia), antihypertensives (hypotension), antidepressants (postural hypotension), antipsychotics (sedation, rigidity and postural hypotension), sedatives, hypoglycaemics and alcohol**. Combinations greatly increase risk. Alpha blockers are specifically associated with hip and femur fracture.
13. Autonomic dysfunction causing repeated falls, syncope and transient loss of consciousness may occur **early in dementia with Lewy bodies**, along with urinary incontinence, constipation, impotence and swallowing difficulty.

C. Evaluation

14. **Correct measurement technique is the whole examination.** Take blood pressure and pulse rate **supine, after 1 minute sitting, and after 1 and 3 minutes of standing**. Pathy's assessment scale states that in older people all blood pressures need to be measured at a **minimum of sitting and standing**, with a check for postural hypotension **at one and three minutes after standing**.
15. Check for **postprandial hypotension** if the person falls, is dizzy, is syncopal, or has a stroke or myocardial infarction **within two hours of a meal**.
16. **Look at the pulse response.** A rise in heart rate suggests volume depletion or drug effect; **failure of the heart rate to rise suggests autonomic failure** or beta blockade.
17. Other blood-pressure pitfalls in older people: **pseudohypertension** from arteriosclerotic vessels (screen with the **Osler manoeuvre**, though sensitivity and specificity are poor); **inter-arm difference** — always treat the higher blood pressure; **white-coat hypertension** — always obtain home readings; and a **wide pulse pressure carries a poor prognosis** in older people.
18. **Investigate for the cause**: haemoglobin g/dL, sodium and potassium mEq/L, urea and creatinine mg/dL, blood glucose, ECG, and where indicated echocardiography and autonomic function testing. Evaluate for occult blood loss if indicated.

D. Management

19. **Non-pharmacological first. Eliminate the offending drugs** or reduce the dose. **Rehydrate as appropriate** and evaluate for blood loss. **Support (compression) stockings**, **leg elevation**, and **adaptive behaviours — pausing and getting up slowly, rising in stages**. Pathy adds that **compression stockings and tools around the home to aid slow rising** are helpful for adults with postural hypotension.
20. **Pharmacological** for autonomic dysfunction or idiopathic cases: **mineralocorticoids (fludrocortisone)** and **midodrine hydrochloride**, in addition to support stockings and adaptive behaviour.
21. Additional practical measures: **head-up tilt of the bed by 15–20%**, a glass of water before rising (kept at the bedside overnight), **liberalised salt and fluid intake** where not contraindicated, **small frequent low-carbohydrate meals** for postprandial hypotension (acarbose is listed as useful), avoiding hot baths, large meals and alcohol, and physical counter-manoeuvres.
22. **Do not chase the numbers.** If the drop is mild and the person can understand and use non-pharmacological measures, reassurance and explanation focused on **managing symptoms rather than absolute values** may be all that is required.

Latest Updates (2023–Present)

- The **consensus definition** used by current guidelines is a fall of **≥20 mmHg systolic or ≥10 mmHg diastolic within 3 minutes of standing** (or head-up tilt to at least 60 degrees). Three patterns are now distinguished: **initial OH**

(transient drop >40/20 mmHg within 15 seconds — needs beat-to-beat monitoring), **classical OH** (within 3 minutes) and **delayed OH** (beyond 3 minutes, often an early marker of autonomic failure).

- **World Falls Guidelines 2022** make **lying and standing blood pressure a mandatory element (GRADE 1B)** of multifactorial falls assessment in every older faller, alongside cardiac history, auscultation and a 12-lead ECG.
- **Active standing at the bedside is preferred to tilt-table testing** for routine diagnosis. **Tilt-table testing (with or without carotid sinus massage) is reserved** for ongoing unexplained recurrent syncope refractory to initial management where reflex or delayed orthostatic hypotension is suspected and the result would change management (ESC syncope guidance).
- **Supine hypertension coexists with orthostatic hypotension in a large proportion of patients** and is now managed actively — avoid supine daytime rest, elevate the head of the bed at night, and use short-acting agents at night if needed. The **2024 ESC hypertension guideline**, while lowering targets to systolic 120–129 mmHg generally, explicitly exempts patients with **symptomatic orthostatic hypotension and frailty**.
- **Droxidopa** (a norepinephrine prodrug) is an additional approved option for neurogenic orthostatic hypotension in some countries; it is not widely available in India, where **fludrocortisone and midodrine remain the mainstays** and are both inexpensive and available. Pyridostigmine is a further option that raises standing blood pressure without worsening supine hypertension.
- **Orthostatic hypotension, cognitive impairment and reduced mobility** are described as an interacting triad in older fallers, and orthostatic hypotension is now also recognised as a risk marker for **incident dementia, stroke and cardiovascular events**, not merely for falls.
- **Indian relevance**: high prevalence of **diabetic autonomic neuropathy**, hot climate with **dehydration and heat-related vasodilatation**, and widespread use of diuretics and alpha blockers make orthostatic hypotension particularly common; salt liberalisation must be balanced against heart failure and hypertension.

Current Practice Update

Issue	Textbook position	Current position
Definition	Fall of >20 mmHg systolic on standing	**≥20 mmHg systolic OR ≥10 mmHg diastolic within 3 minutes**; sub-types **initial, classical, delayed**
Measurement	Supine, 1 min sitting, 1 and 3 min standing	Same, now a **mandatory graded recommendation (1B)** in every older faller; active stand preferred over tilt
Supine hypertension	Not addressed	**Actively managed** — head-up bed tilt, avoid daytime supine rest, short-acting nocturnal agents
Drug therapy	Fludrocortisone and midodrine	Same first line; add **droxidopa** and **pyridostigmine** where available; droxidopa not widely available in India
BP targets	Not linked to OH	2024 ESC targets (SBP 120–129) **explicitly relaxed** in symptomatic OH and frailty
Prognosis	Framed as a fall risk factor	Also an independent risk marker for **dementia, stroke and cardiovascular events**

Exam One-Liners

- OH = SBP fall ≥20 mmHg (or DBP ≥10 mmHg) within 3 minutes of standing.
- Present in ~20% of older persons; often asymptomatic but still causes falls.
- Measure supine, 1 min sitting, then 1 and 3 min standing.
- No rise in heart rate with the BP drop = neurogenic (autonomic failure).
- Check postprandial hypotension if events occur within 2 hours of a meal.
- Osler manoeuvre screens for pseudohypertension; always treat the higher arm.
- Treatment ladder: stop culprit drugs → hydration, salt, stockings, staged rising, head-up bed → fludrocortisone / midodrine.
- Manage supine hypertension at the same time; relax BP targets in symptomatic OH.

Q9. Syncope

> **Textbook coverage statement.** Pathy's 6th edition covers this in **Chapter 52 – Syncope and Non-Epileptic Attacks (pp. 664–673)** and **Chapter 33 – Hypotension (pp. 419–426)**. The uploaded files contain **Chapters 75, 78 and 79 in full plus the index**; the text of Chapters 52 and 33 is **not present** in the uploaded material. The textbook content below is therefore taken from **Kane's Chapter 9** and from the cross-references within Pathy Chapters 78 and 79, and post-textbook evidence is clearly separated.

15–20 High-Yield Points

A. Definition and Importance textbook

1. **Syncope** is **sudden, transient loss of consciousness** with loss of postural tone and spontaneous complete recovery. In the falls setting, **if there is a clear history of loss of consciousness, a cause for true syncope must be sought**.
2. **Distinguishing a fall from syncope and from a seizure is the first step** in evaluating any older person who has fallen — it changes the entire diagnostic pathway.
3. Syncope in the older person is difficult to diagnose because falls are often **unwitnessed**, the patient may not recall the event, and the causes (arrhythmia, TIA, postural hypotension) are **transient**. **A precise cause remains unidentified in 40–60% of older patients.**
4. A history of loss of consciousness after a fall should raise suspicion of a **cardiac event (transient arrhythmia or heart block)** causing syncope or near-syncope, or a **seizure** (especially if there has been incontinence).

B. Causes in Older People textbook

5. **Reflex (neurally mediated)**: **vasovagal responses**; **carotid sinus hypersensitivity**; and **situational** syncope from reflex increase in vagal tone caused by **cough, straining at stool or micturition**, leading to bradycardia and hypotension.
6. **Cardiovascular**: **bradycardia and heart block, tachyarrhythmias, and aortic stenosis**. **Syncope is a symptom of aortic stenosis and is an indication to evaluate the patient for valve replacement.**
7. **Orthostatic**: postural hypotension from hypovolaemia, low cardiac output, autonomic dysfunction, impaired venous return, prolonged bed rest, drugs, and **postprandial hypotension**.
8. **Acute neurological events**: TIA, stroke, seizure. Note that a history of transient vertigo alone is not enough to diagnose a posterior circulation TIA — **one or more other symptoms (visual field cut, dysarthria, ataxia, limb weakness) must accompany the vertigo**.
9. **Other**: **pulmonary embolism** and **metabolic disturbances such as hypoxia and hypoglycaemia**.
10. **Drugs** are a major contributor: antihypertensives, diuretics, antidepressants, antipsychotics, hypoglycaemics and alcohol. **Acetylcholinesterase inhibitors are specifically associated with syncope.**
11. **Dementia with Lewy bodies** is an important cause — **syncope and other transient episodes of unresponsiveness, repeated falls and severe autonomic dysfunction are supportive diagnostic features**.

C. Evaluation textbook

12. The **history is the single most valuable investigation**. Record: circumstances (location, time, activity, whether alone), relationship to **posture change, head turning, cough, micturition, a meal or drug intake**, **premonitory symptoms** (light-headedness, palpitations, chest pain, breathlessness, focal neurology, aura, incontinence), what is remembered immediately after, and whether a witness can confirm loss of consciousness.
13. **Vital signs** to detect an acute illness. **Postural blood pressure and pulse supine, sitting, and at 1 and 3 minutes standing.**
14. If carotid sinus sensitivity is suspected, perform **gentle carotid sinus massage for 5 seconds** and observe for **profound bradycardia (50% reduction in heart rate) or a long pause**.
15. **Cardiovascular examination** for arrhythmia and aortic stenosis. Because both are serious, treatable and difficult to detect clinically, refer for **continuous cardiac monitoring and echocardiography** when suspected. **Echocardiography should be considered in all patients with a suggestive history and a systolic murmur, or a delayed carotid upstroke.**
16. **Cardiac monitoring must document a temporal association between a specific arrhythmia and symptoms before that arrhythmia is diagnosed and treated as the cause** — asymptomatic ectopy is common in older people and must not be over-interpreted.
17. **Do not send all patients for extensive diagnostic studies or cardiac monitoring.** CT or MRI should be reserved for patients with a high suspicion of an intracranial lesion or seizure disorder. Non-invasive vascular studies if the history suggests anterior circulation TIA.
18. The **minimum investigations in a patient who falls** are **lying and standing blood pressure and a 12-lead ECG**.

D. Management textbook

19. Treat the identified cause: **antiarrhythmics for tachyarrhythmias, pacemaker for bradyarrhythmias, valve surgery for aortic stenosis with syncope** — noting that antiarrhythmic and pacing treatment is indicated **only if the cardiac disturbance is clearly related to symptoms**.
20. **Cardiac pacing in carotid sinus hypersensitivity** is one of the single-factor interventions with demonstrated efficacy in fall prevention.
21. Withdraw or reduce culprit drugs, correct volume depletion and anaemia, treat postural hypotension, and give **education on prodrome recognition and safe positioning**.

Latest Updates (2023–Present)

- **Classification (ESC 2018 syncope guidelines, still current)** divides syncope into three groups: **reflex (neurally mediated) — vasovagal, situational, carotid sinus syndrome**; **syncope due to orthostatic hypotension**; and **cardiac syncope — arrhythmic or structural**. Syncope sits within the broader concept of **transient loss of consciousness (TLoC)**, which has four defining characteristics: **short duration, abnormal motor control, loss of responsiveness, and amnesia for the period of loss of consciousness**.
- A **detailed clinical history alone distinguishes syncope from other forms of TLoC in about 60% of cases**. The **initial evaluation** is history, physical examination including orthostatic blood pressure, and a 12-lead ECG.
- **Risk stratification has replaced blanket admission. Low-risk** patients with clear reflex, situational or orthostatic features need **no further tests in the emergency department** — reassurance and counselling suffice. **High-risk** patients need an intensive diagnostic approach, monitoring in a resuscitation-capable area (usually up to 6 hours in the ED and 24 hours in hospital) and expert syncope review, which can often be delivered in an **outpatient syncope unit**. This is reinforced by the **2024 European Society for Emergency Medicine consensus statement**.
- **Tilt-table testing has fallen sharply out of favour.** It is now used only where there is genuine diagnostic uncertainty — suspected reflex syncope, orthostatic hypotension, POTS or psychogenic pseudosyncope — and there is a class III recommendation against using it to select or assess drug treatment.
- **Prolonged rhythm monitoring has become central.** The **implantable loop recorder (ILR)** is recommended early in recurrent unexplained syncope with high-risk features or a likely arrhythmic mechanism, and detects a diagnosis far more often than conventional Holter monitoring. Smartphone-linked and patch monitors are increasingly used where an ILR is not affordable — relevant to Indian practice.
- **Reflex syncope treatment** now emphasises **education and reassurance, adequate fluid and salt intake, physical counter-pressure manoeuvres, and withdrawal of hypotensive drugs**. **Pacing is reserved for older patients with documented spontaneous asystolic pauses** (the ISSUE-3 and BioSync CLS evidence) and is used with caution.
- **Overlap with falls is now formally recognised. World Falls Guidelines 2022** require cardiovascular assessment in every faller and state that further cardiac work-up is needed **only** when syncope is described or witnessed, or falls are recurrent and unexplained — an explicit attempt to stop over-investigation.
- **Indian context**: syncope evaluation is limited by cost and access to ILR and tilt testing; a rigorous history, orthostatic blood pressure, 12-lead ECG, echocardiography and ambulatory ECG will resolve most cases. **Anaemia, dehydration in hot climates, tuberculosis-related autonomic disturbance, and polypharmacy from multiple prescribers** are common contributors, and cardiac procedures are covered under **AB-PMJAY**.

Current Practice Update

Issue	Textbook position	Current position
Framework	List of causes of syncope in older people	**Three-group ESC classification** (reflex / orthostatic / cardiac) within the concept of **TLoC**
Who gets investigated	Do not investigate everyone; monitoring must correlate with symptoms	Formal **low-risk vs high-risk stratification**; low risk discharged from ED without tests; high risk monitored and referred to a **syncope unit**
Tilt-table testing	Not emphasised	**Markedly restricted** — only for genuine diagnostic uncertainty; not for selecting therapy
Rhythm monitoring	Continuous monitoring if arrhythmia suspected	**Implantable loop recorder used early** in recurrent unexplained syncope with suspected arrhythmia
Reflex syncope therapy	Not detailed	**Education, salt and fluid, counter-pressure manoeuvres, drug withdrawal**; pacing only for documented spontaneous asystole

Exam One-Liners

- Syncope = transient LOC from global cerebral hypoperfusion, with spontaneous complete recovery.
- Three ESC groups: reflex, orthostatic hypotension, cardiac.
- Cause remains unidentified in 40–60% of older patients.
- Initial evaluation = history + examination with orthostatic BP + 12-lead ECG; history alone diagnoses ~60%.
- Syncope in aortic stenosis = indication to assess for valve replacement.
- Arrhythmia must be temporally linked to symptoms before it is blamed.
- ILR early for recurrent unexplained syncope; tilt testing now rarely indicated.
- Incontinence after the event and a prolonged post-ictal phase point to seizure, not syncope.

Q10. Hypersensitive carotid sinus syndrome

> **Textbook coverage statement.** Pathy's 6th edition covers carotid sinus hypersensitivity in **Chapter 33 – Hypotension (pp. 419, 423–424)**, with sections on definition and measurement, pathophysiology, prevalence, symptoms, diagnostic criteria, prevention, and non-pharmacological and pharmacological treatment, and in **Chapter 52 (pp. 665, 668)** as carotid sinus syndrome. **The text of these chapters is not present in the uploaded files** — only the index entries. The textbook content below is taken from **Kane's Chapter 9** and from the cross-references in **Pathy Chapters 78 and 79**; the remainder is clearly flagged as supplementary.

15–20 High-Yield Points

A. Definition and Terminology

1. **Carotid sinus hypersensitivity (CSH)** is an **exaggerated reflex response to carotid sinus stimulation**. **Carotid sinus syndrome (CSS)** is the term used when this abnormal response **reproduces the patient's spontaneous symptoms** — syncope, pre-syncope or unexplained falls. **CSH is a finding; CSS is a diagnosis.**
2. It is a form of **reflex (neurally mediated) syncope** and is a recognised **cardiovascular cause of falls** in older people, listed alongside arrhythmias and aortic stenosis.
3. **Some older individuals have sensitive carotid baroreceptors and are susceptible to syncope resulting from a reflex increase in vagal tone** caused by **cough, straining at stool or micturition**, leading to **bradycardia and hypotension**.

B. Pathophysiology supplementary

4. The **carotid sinus baroreceptor** at the carotid bifurcation sends afferents through the **glossopharyngeal nerve (Hering's nerve)** to the **nucleus tractus solitarius** in the medulla, producing **vagal efferent bradycardia** and **sympathetic withdrawal causing vasodilatation**.
5. In CSH this reflex arc is exaggerated. Current thinking is that the abnormality lies **centrally and in the efferent limb** rather than in the sinus itself, with proposed contributions from **sternocleidomastoid muscle denervation and altered central neurotransmission**; it is associated with **ageing, hypertension, coronary artery disease and neurodegenerative disease**.

C. Types

6. **Cardio-inhibitory type** (about two-thirds): predominant **asystole or profound bradycardia**.
7. **Vasodepressor type**: predominant **fall in blood pressure** without significant bradycardia.
8. **Mixed type**: both components present. **This classification determines treatment** — only the cardio-inhibitory and mixed forms respond to pacing.

D. Clinical Features

9. **Syncope, pre-syncope, dizziness and — characteristically in older people — unexplained falls with amnesia for the event**. Many older patients deny loss of consciousness and describe only "my legs gave way".
10. Symptoms are typically **triggered by neck movement** — turning or extending the head, looking up, a tight collar, shaving, or a sudden turn while walking.
11. It is **under-diagnosed** because the events are unwitnessed, brief and often not remembered, and because it is not looked for.

E. Diagnosis — Carotid Sinus Massage

12. **Kane's bedside technique**: if the history suggests carotid sinus sensitivity, **the carotid can be gently massaged for 5 seconds** to observe whether this precipitates **profound bradycardia (a 50% reduction in heart rate) or a long pause**.
13. **Standard formal criteria** supplementary: massage the carotid sinus at the level of the cricoid cartilage, just medial to the sternocleidomastoid, for **5–10 seconds**, with **continuous ECG and beat-to-beat blood pressure monitoring**, right side first, then the left, and repeated **both supine and at 70 degrees head-up tilt** if the supine test is negative. A positive test is **ventricular pause ≥3 seconds (cardio-inhibitory)** and/or a **fall in systolic blood pressure ≥50 mmHg (vasodepressor)**.
14. **Diagnosis of carotid sinus syndrome requires reproduction of the patient's spontaneous symptoms**, not merely an abnormal haemodynamic response.
15. **Contraindications** supplementary: **myocardial infarction, TIA or stroke within the preceding 3 months**, a **carotid bruit** (unless significant stenosis has been excluded by Doppler), and previous ventricular tachycardia or ventricular fibrillation. Complications are uncommon (transient neurological deficit in well under 1%), but resuscitation facilities and atropine should be available.

F. Management

16. **Remove precipitants and aggravating drugs**: avoid tight collars and sudden neck movements; withdraw or reduce **beta blockers, digoxin, alpha blockers, nitrates, diuretics, and cholinesterase inhibitors**.
17. **Non-pharmacological measures for the vasodepressor component**: adequate salt and fluid intake, **compression stockings**, staged rising, and physical counter-pressure manoeuvres.
18. **Cardiac pacing is the definitive treatment for the cardio-inhibitory and mixed forms.** Pathy lists **"pacemaker implants (cardiac pacing) in patients with carotid sinus hypersensitivity" among the single-factor interventions that have demonstrated efficacy in preventing falls**. **Dual-chamber (DDD) pacing is used** because ventricular pacing alone can provoke pacemaker syndrome.
19. **The vasodepressor component does not respond to pacing**, and residual symptoms after pacing usually mean an

unrecognised vasodepressor element — this is the commonest reason for “pacing failure”.

20. Because carotid sinus hypersensitivity is a **correctable cause of falls**, it must be actively sought in any older person with **recurrent unexplained falls**, alongside postural hypotension and vasovagal syncope, with lying and standing blood pressure and a 12-lead ECG as the minimum work-up.

Latest Updates (2023–Present)

- **The evidence for pacing in fallers is genuinely conflicting, and this is the key discussion point.** The landmark **SAFE PACE trial (Kenny et al., JACC 2001)** randomised older patients attending an emergency department after a non-accidental fall who had cardio-inhibitory CSH to dual-chamber pacing or standard care: **falls fell by about two-thirds (odds ratio 0.42)** and syncope by half. However, the trial was **unblinded**. The subsequent **randomised, double-blind, placebo-controlled crossover trial (pacemaker programmed on DDD/RDR versus off ODO, Ryan et al., 2010)** in recurrent fallers with CSH **did not confirm a benefit**, indicating a substantial **placebo and reporting effect** in the unblinded studies.
- Current guidance therefore restricts pacing to patients with a **documented cardio-inhibitory response that reproduces symptoms**, particularly **recurrent unpredictable syncope**, and is far more cautious about pacing for falls alone.
- **World Falls Guidelines 2022** reflect this restraint: cardiovascular assessment (history, auscultation, lying and standing BP, 12-lead ECG) is mandatory in every faller, but **further cardiovascular investigation — including carotid sinus massage — is reserved for those with described or witnessed syncope or pre-syncope, or recurrent unexplained falls**. Routine carotid sinus massage in all fallers is no longer recommended.
- The **high prevalence of asymptomatic carotid sinus hypersensitivity in healthy older people** (rising with age and reaching a substantial proportion of those over 80) is now emphasised. This means a positive test in an asymptomatic person is a **frequent incidental finding**, and the requirement for **symptom reproduction** before diagnosing carotid sinus syndrome has become stricter.
- **Associations with neurodegeneration** — particularly **dementia with Lewy bodies and Parkinson’s disease** — are increasingly recognised, so CSH in an older faller should prompt assessment for cognitive impairment and autonomic failure rather than being treated as an isolated cardiac problem.
- **Indian context**: carotid sinus massage is a **free, bedside, zero-cost test** and is under-used in Indian falls practice; it should be performed with ECG monitoring in any older patient with recurrent unexplained falls or syncope. Permanent pacemaker implantation is covered under **AB-PMJAY**, but given the conflicting trial evidence, pacing should be restricted to documented symptomatic cardio-inhibitory disease.

Current Practice Update

Issue	Textbook position	Current position
Positive test threshold	Kane: 50% fall in heart rate or a long pause on 5 seconds of massage	Formalised as **pause ≥3 seconds and/or systolic fall ≥50 mmHg**, tested **supine and at 70° head-up tilt**
CSH vs CSS	Terms used loosely	**Strict distinction** — carotid sinus syndrome requires **reproduction of spontaneous symptoms**; asymptomatic CSH is common in the very old and should not be treated
Pacing for falls	Listed as an intervention with demonstrated efficacy in fall prevention (SAFE PACE)	**Contested** — the double-blind crossover trial was negative; pacing now restricted to **documented symptomatic cardio-inhibitory disease**, chiefly recurrent unpredictable syncope
Who gets carotid massage	Perform if history suggests it	**Only** with syncope/pre-syncope or recurrent unexplained falls (WFG 2022); not routine in all fallers

Exam One-Liners

- CSH = abnormal response to carotid sinus massage; CSS = abnormal response PLUS reproduction of symptoms.
- Types: cardio-inhibitory (~two-thirds), vasodepressor, mixed.
- Positive test: pause ≥3 seconds and/or systolic BP fall ≥50 mmHg.
- Massage 5–10 seconds, right then left, supine then 70° head-up tilt, with ECG and BP monitoring.
- Contraindicated within 3 months of MI, TIA or stroke; and with a carotid bruit.
- Dual-chamber pacing for the cardio-inhibitory and mixed forms only; vasodepressor component does not respond.
- SAFE PACE (unblinded) showed a two-thirds fall reduction; the double-blind crossover trial was negative.
- Triggers: neck turning or extension, tight collar, shaving, cough, micturition, straining.

Q11. Benign paroxysmal positional vertigo — diagnosis and management

15–20 High-Yield Points (Textbook)

A. Definition and Cause

1. **BPPV** is characterised by **momentary, short-lived episodes of vertigo occurring on assuming specific head positions**, particularly with **neck extension**, and typically appearing when **lying down on one ear, bending forward, or looking up**.
2. It is **the most common clinical syndrome after head injury**, but is also seen in older people as an **idiopathic disorder** or **secondary to vestibular neuritis**. Even **trivial head injury** can cause it, with onset days or weeks later.
3. **Canalithiasis** is the accepted mechanism and explains most of the features: **free-floating particles (otoconia) within a semicircular canal**. With a change of head position the cluster of particles moves in the canal and has a **"plunger" effect within the narrow canal, deflecting the cupula** and causing a brief paroxysm of vertigo and nystagmus.
4. **Cupulolithiasis** is the alternative mechanism, in which the free-floating particles **adhere to the cupula** of a semicircular canal.
5. Although BPPV can affect **each of the semicircular canals, posterior canal involvement is the most common**.

B. Clinical Features in the Older Patient

6. The **vertigo is particularly severe**, and the older patient is **frequently extremely afraid**, because the attacks are very sudden and may cause **a drop to the ground and vomiting**.
7. This leads to **anxiety** — partly fear of embarrassment if an attack happens in a public place, and partly fear of being **incapacitated at home, unable to reach help**.
8. **The diagnosis is frequently overlooked.** The clinician often sees only an extremely anxious older patient who finds it difficult to explain such brief yet severe symptoms.
9. **Frequently the only abnormal clinical sign is benign positional nystagmus of paroxysmal type on the Dix-Hallpike manoeuvre.**

C. The Dix-Hallpike Manoeuvre

10. **Technique**: the patient sits close to the top end of a flat examination couch. The head is held firmly between the examiner's hands and **turned 30–45 degrees to the right or left**. The patient is then **carried rapidly backward with the head over the edge of the couch**, and the eyes are carefully observed. If nystagmus develops it is observed until it disappears, or for two to three minutes until it is clear that it is persistent. The patient is returned upright and the procedure repeated on the other side.
11. **The manoeuvre must be performed briskly and correctly at the first attempt**, because symptoms and signs **adapt and fatigue on repeated testing**.
12. **Peripheral (benign paroxysmal) findings**: after a **latent period of a few seconds** in the head-back position, **severe vertigo develops lasting less than one minute**, during which the patient may be extremely distressed and nauseated. The **nystagmus is rotatory and directed toward the undermost ear**.

Feature	Benign paroxysmal type (peripheral)	Central type
Latent period	**2–20 seconds**	None
Adaptation	**Disappears in 50 seconds**	Persists
Fatigability	**Disappears on repetition**	Persists
Vertigo	**Always present**	Typically absent
Direction of nystagmus	**To the undermost ear**	Variable
Incidence	Relatively common	Relatively uncommon

Cases that do not fit either category, and all "central" patterns, should be investigated for neurological disease.

D. Management

13. **Positional (particle repositioning) manoeuvres** are the treatment. Specific movements of the head allow the **offending debris in the semicircular canal to be moved by gravitation into the utricle**.
14. The **Epley manoeuvre** is the most commonly used manoeuvre for **posterior canal BPPV**. It is **effective in 80–85% of patients at the first attempt and in a further 10% at a second attempt**.
15. **Semont's manoeuvre** is another specific manoeuvre for posterior canal BPPV.
16. **Pre-treatment sedation is not required** except for the most anxious of patients, and **the manoeuvre is as effective in older people as in younger people**.
17. **Relapses may occur, and the manoeuvre should then simply be repeated.**
18. In the small percentage in whom particle repositioning fails, and in **intractable cases with severe disabling symptoms**, **plugging of the posterior semicircular canal, or section of the posterior and ampullary (singular) nerve**, can be considered.
19. **A combination of canalith repositioning manoeuvre and vestibular rehabilitation improves benign positional vertigo in the elderly.** Although the repositioning manoeuvre is the most effective treatment, **vestibular rehabilitation can be added to improve results, particularly given the high recurrence rate** of positional vertigo.
20. **Drugs have a very limited role.** Vestibular sedatives such as **cinnarizine** are of value in acute vertigo but have a very limited role in chronic vestibular syndromes. **Prochlorperazine should be avoided** because of the rare but irreversible syndrome of **extrapyramidal dysfunction**. Psychotropic drugs should be given only for specific psychiatric indications,

as they **interfere with vestibular compensation**.

21. Because the condition causes drop attacks, vomiting and profound anxiety in older people, **a clear explanation of the benign nature of the condition is an essential part of treatment**.

Latest Updates (2023–Present)

- The **AAO-HNSF Clinical Practice Guideline: BPPV (Update)** remains the reference standard and its key action statements are examinable: **diagnose posterior canal BPPV with the Dix-Hallpike test**; if Dix-Hallpike is negative but BPPV is suspected, **perform the supine roll test for lateral (horizontal) canal BPPV** — here the nystagmus is **predominantly horizontal**, geotropic or apogeotropic, in contrast to the **upbeating torsional** nystagmus of posterior canal BPPV.
- Guideline recommendations that differ from older teaching: **do not routinely order imaging or vestibular testing** when the diagnosis is clear; **treat posterior canal BPPV with a canalith repositioning procedure**; **do not impose post-procedural postural restrictions**; **do not routinely use vestibular suppressants such as antihistamines and benzodiazepines**; **observation with follow-up is an acceptable initial option**; **vestibular rehabilitation may be offered**; and **reassess within one month** to confirm resolution.
- The guideline also mandates **assessment for factors that modify management — impaired mobility or balance, CNS disorders, lack of home support and increased risk of falling** — which is precisely the older Indian patient.
- **Canal conversion** is now formally described: lateral canal BPPV may appear **after** an Epley manoeuvre performed for posterior canal BPPV, as debris migrates from the posterior into the lateral canal. Recognise it rather than assuming treatment failure.
- A **2025 network meta-analysis** of 20 randomised trials (2,089 patients) for posterior canal BPPV ranked the **Epley manoeuvre highest for overall effectiveness (SUCRA 97.84%)**, significantly better than **Semont**, **Brandt-Daroff** and control. Epley and Semont were both superior to other interventions for cure rate. **Brandt-Daroff exercises are inferior and should not be first-line.**
- **Modified Epley technique**: a 2023 randomised trial found that **prolonging the healthy-side lying and final head-bowed positions to about 5 minutes** raised first-attempt success from 63% to 85%, achieved 100% success after two attempts and prevented canal switching; a 2024 simulation study supported longer hold times and a modified rotation angle.
- **Recurrence and bone health**: BPPV recurs in about **10–30% within a year**, more with older age, head trauma, osteoporosis and low vitamin D. A 2024 systematic review and meta-analysis confirmed a **higher prevalence of osteoporosis in BPPV patients**, and randomised evidence supports **vitamin D and calcium supplementation in patients with recurrent BPPV and low serum vitamin D** to reduce recurrence. This links BPPV directly to fracture prevention in the older Indian patient, in whom vitamin D deficiency is near-universal.
- **Practical Indian relevance**: BPPV is the commonest treatable cause of dizziness in older adults, needs **no equipment and no investigation**, and is curable in a single outpatient visit — making Dix-Hallpike and Epley among the highest-yield skills in a resource-limited geriatric clinic.

Current Practice Update

Issue	Textbook position	Current position
Canal involved	Posterior canal most common; Dix-Hallpike is the test	Same, plus mandatory **supine roll test** for lateral canal if Dix-Hallpike negative; recognise **canal conversion** after Epley
Post-procedure restrictions	Not addressed	**Explicitly not recommended** — no need to sleep upright or avoid head movement
Drugs	Cinnarizine for acute vertigo only; avoid prochlorperazine	Stronger: **do not routinely use vestibular suppressants at all in BPPV** — they delay compensation and increase falls
Choice of manoeuvre	Epley most common; Semont an alternative	2025 network meta-analysis: **Epley ranks first (SUCRA 97.8%)**; **Brandt-Daroff clearly inferior**. **Modified Epley** with 5-minute holds improves first-attempt success
Recurrence prevention	Repeat the manoeuvre; add vestibular rehabilitation	Same, plus **check and correct vitamin D and calcium**, and assess for osteoporosis
Follow-up	Not specified	**Reassess within one month** to document resolution or persistence

Exam One-Liners

- Mechanism: canalithiasis (free otoconia) or cupulolithiasis (otoconia adherent to cupula); posterior canal commonest.
- Dix-Hallpike: head turned 30–45°, rapid backward to head-hanging position.
- Peripheral nystagmus: latency 2–20 s, lasts <1 min, adapts in 50 s, fatigues, rotatory towards the undermost ear, vertigo always present.
- Central: no latency, persists, does not fatigue, variable direction, vertigo typically absent.
- Epley cures 80–85% at first attempt, a further 10% at second attempt; equally effective in the elderly.
- No sedation needed; no post-procedure postural restrictions; no vestibular suppressants.
- Lateral canal BPPV: supine roll test, horizontal nystagmus.
- Intractable cases: posterior canal plugging or singular neurectomy.

- Correct vitamin D to reduce recurrence; reassess at one month.

Q12. Approach to a patient with dizziness

15–20 High-Yield Points (Textbook)

A. Terminology and Principle

1. **Vertigo** is defined as **“an hallucination of movement”** and is the cardinal manifestation of a disordered vestibular system. **Dizziness** is a lay term meaning “a feeling of being in a whirl or in a daze or as if about to fall”, and is associated with a **multiplicity of general medical disorders**.
2. **This semantic distinction is rarely volunteered by the older patient**, who more often complains of feeling **faint, swimmy or light-headed**. Therefore **all complaints of disorientation are best considered within a single diagnostic approach**.
3. Dizziness in older people is **usually multifactorial** — the result of **central pathology and/or multiple sensory deficits** (uncorrectable visual impairment, neuropathy, vestibular deficits, cervical spondylosis, orthopaedic disorders interfering with joint mechanoreceptors) rather than vestibular degeneration alone. Vestibular degenerative change tends to occur **symmetrically**, and symptoms arise from **asymmetry** of afferent input.
4. **Do not attribute vertigo to ‘age’.** A thorough history and examination will often give a clear direction as to diagnosis, and correct diagnosis allows treatment of many peripheral and central vestibular disorders.

B. History

5. The three key axes are the **character, time course and associated symptoms** of the dizziness.
6. **Character**: **peripheral labyrinthine** disease classically gives **acute, unprecipitated, short-lived attacks of rotational disequilibrium with nausea and vomiting** (rarely diarrhoea); **central vestibular** disease gives a **more insidious, protracted sense of instability**.
7. **Exceptions to remember**: short-lived attacks may also occur in **epilepsy and vertebrobasilar artery ischaemia**; protracted instability may also occur with **uncompensated peripheral vestibular disorders, bilateral vestibular failure and psychogenic disequilibrium**.
8. Other typical vestibular symptoms are a sensation of **being pulled downward or sideways, of the room tilting, and of swimming, floating and light-headedness**. **A clear description of subjective or objective motion raises suspicion of vestibular pathology**, whereas light-headedness, swimminess or faintness suggests a **general medical or neurological disorder**.
9. Always take a full **drug history** (ototoxic and vestibulotoxic drugs, antihypertensives, sedatives), and ask about **hearing loss, tinnitus and aural fullness**, **headache**, and **relationship to posture, head position, meals, cough or micturition**.

C. Causes of Dizziness in the Elderly (Pathy Table 75.1)

10. **General medical — haematological**: anaemia, polycythaemia, hyperviscosity syndromes.
11. **General medical — cardiovascular**: **postural hypotension, carotid sinus syndrome, dysrhythmias, mechanical dysfunction, shock**.
12. **General medical — metabolic/endocrine**: hypo- and hyperglycaemia, thyroid disease, chronic renal failure, alcohol.
13. **Neurological — supratentorial**: trauma, neoplasia, epilepsy, cerebrovascular disease, syncope, psychogenic.
14. **Neurological — infratentorial**: vertebrobasilar insufficiency, subclavian steal, **Wallenberg’s syndrome**, anterior inferior cerebellar artery syndrome, degenerative disorders including neuropathy, tumours including those of the vestibulocochlear nerve, infective disorders (Ramsay-Hunt, neurosyphilis, tuberculosis), foramen magnum abnormalities, cerebellar degeneration, basal ganglion disease, demyelinating disease.
15. **Otological**: drug-induced/ototoxic, degenerative (**BPPV**), post-traumatic syndrome, infection, vascular, tumours, **Menière’s disease**, otosclerosis and Paget’s disease, autoimmune disorders.
16. **Others**: **migraine** and **multisensory dizziness syndrome**.

D. Examination

17. **Otological examination**, with audiological testing where symptoms suggest vertigo — this helps differentiate inner ear from central nervous system involvement.
18. **Vestibulo-ocular assessment**: look for spontaneous nystagmus; perform the **head thrust (head impulse) test** — on a rapid head thrust to one side the eyes move with the head and lose the target, and **corrective saccades** are then required to bring the visual focus back, indicating **vestibular hypofunction on that side**.
19. **The presence of positional nystagmus is a most valuable and most frequently overlooked sign** and should be sought by a **briskly performed Dix-Hallpike manoeuvre** in every dizzy older patient.
20. **Vestibulospinal assessment**: **Romberg** and postural sway; note that older patients with unilateral vestibular hypofunction show **markedly increased postural sway** compared with younger patients with the same disorder. **Gait testing** — ask the patient to walk toward a fixed point with eyes closed; a tendency to **veer to one side** usually indicates an **ipsilateral peripheral vestibular disturbance** but may occasionally be cerebellar. **Broad-based ataxic gait** suggests cerebellar disease.
21. **Anxious older patients tend to fall backward “like a wooden soldier”**, which indicates a non-organic component — but this is **almost always seen in the presence of an underlying abnormality** that will be identified on full examination.
22. **Screening in the CGA**: ask “**Do you get dizzy, or does your head spin around?**” If yes, **check for postural hypotension, perform the Dix-Hallpike manoeuvre for BPPV, check haemoglobin, and apply the Geriatric Depression Scale**.

Latest Updates (2023–Present)

- **The "what do you mean by dizzy?" question has been abandoned.** Symptom quality (vertigo vs light-headedness vs imbalance) is unreliable and inconsistent when patients are re-questioned. The current standard is the **ATTEST / TiTrATE approach**, which classifies by **Timing and Triggers** instead: **Acute Vestibular Syndrome (AVS)**, **Triggered Episodic Vestibular Syndrome (t-EVS)**, **Spontaneous Episodic Vestibular Syndrome (s-EVS)** and **chronic vestibular syndrome**.
- **t-EVS** (seconds, triggered by position change) → test with **Dix-Hallpike and supine roll** → BPPV or orthostatic hypotension. **s-EVS** (minutes to hours, spontaneous) → vestibular migraine, Menière's disease, TIA, arrhythmia, panic. **AVS** (continuous, days, with nausea, nystagmus and gait unsteadiness) → vestibular neuritis versus posterior circulation stroke.
- **HINTS examination** (**H**ead **I**mpulse, **N**ystagmus, **T**est of **S**kew) is used **only in acute vestibular syndrome**. A **central (dangerous) pattern** is a **normal head impulse test, direction-changing gaze-evoked nystagmus, or skew deviation**. **HINTS performed by a trained examiner is more sensitive than early MRI** for posterior circulation stroke in the first 48 hours, since early diffusion-weighted MRI misses up to 15–20% of small posterior fossa infarcts. Adding new hearing loss gives **HINTS-plus**. Applying HINTS to an episodic or chronic presentation is a common and dangerous error.
- **Bárány Society consensus definitions** now standardise the major diagnoses — BPPV, vestibular neuritis, Menière's disease, **vestibular migraine**, **persistent postural-perceptual dizziness (PPPD)** and **presbyvestibulopathy**. Two are particularly relevant here: **vestibular migraine** is now recognised as one of the commonest causes of episodic vertigo at all ages, and **PPPD** explains chronic non-spinning dizziness with unsteadiness worsened by upright posture, motion and complex visual environments — treated with vestibular rehabilitation, SSRIs and CBT, not with vestibular sedatives.
- **Presbyvestibulopathy** is a defined entity for age-related bilateral vestibular hypofunction with chronic imbalance and mild bilateral VOR deficits — it validates the textbook's "multisensory dizziness syndrome" but gives it operational criteria.
- **Video head impulse testing (vHIT)** now allows objective, quantitative bedside measurement of the VOR gain in all six semicircular canals and detects covert saccades missed by the naked eye.
- **Indian context**: dizziness is reported by **14.5% of Indian adults aged 60 and above (LASI wave-1)** and is a major driver of falls and activity restriction. The commonest treatable causes in an Indian geriatric clinic are **BPPV, orthostatic hypotension, anaemia (haemoglobin g/dL), drug effects, hypoglycaemia and vitamin B12 deficiency** — all diagnosable at the bedside or with basic tests.

Current Practice Update

Issue	Textbook position	Current position
Classification approach	Character (vertigo vs light-headedness) plus time course and associated symptoms	**Timing and triggers (ATTEST/TiTrATE)** — symptom quality is unreliable; classify as AVS, t-EVS, s-EVS or chronic
Distinguishing stroke from neuritis	Vertigo alone is not enough to diagnose posterior circulation TIA; needs other symptoms	**HINTS / HINTS-plus in acute vestibular syndrome**, more sensitive than early MRI; retains the principle but operationalises it
Head thrust test	Bedside test for vestibular hypofunction	Same, now quantifiable by **video head impulse testing (vHIT)** across all six canals
Chronic non-spinning dizziness	Attributed to anxiety plus underlying abnormality; multisensory dizziness syndrome	Defined as **PPPD** and **presbyvestibulopathy** with Bárány criteria; treated with vestibular rehabilitation, SSRIs and CBT
Episodic vertigo	Menière's, BPPV, vertebrobasilar ischaemia, migraine mentioned	**Vestibular migraine** now a leading and formally defined cause of spontaneous episodic vertigo

Exam One-Liners

- Vertigo = hallucination of movement; dizziness = lay term with many general medical causes.
- Never attribute dizziness in an older person to age alone.
- Dizziness in the elderly is usually multifactorial — central pathology plus multiple sensory deficits.
- Ask about timing and triggers, not "what kind of dizzy" (ATTEST/TiTrATE).
- Dix-Hallpike in every dizzy older patient — positional nystagmus is the most overlooked sign.
- Head impulse test: corrective saccades = ipsilateral vestibular hypofunction.
- HINTS is only for acute vestibular syndrome; normal head impulse + direction-changing nystagmus + skew = central.
- India (LASI): dizziness in 14.5% of those aged 60 and above.

Q13. Evaluation of dizziness / drop attacks

> The dizziness component overlaps with Q12; this answer therefore concentrates on the **practical evaluation algorithm** and on **drop attacks**, which are examined separately.

15–20 High-Yield Points (Textbook)

A. Drop Attacks — Definition and Concept

1. A **drop attack** is described as **sudden leg weakness causing a fall without loss of consciousness**. It is listed as one of the causes of falls in older persons, alongside accidents, syncope and dizziness/vertigo.
2. Drop attacks are **often attributed to vertebrobasilar insufficiency and are often precipitated by a change in head position**.
3. **Only a small proportion of older people who fall have truly had a drop attack.** The **underlying pathophysiology is poorly understood, and care should be taken to rule out other causes.**
4. **Vertebrobasilar insufficiency and mechanical compression of the vertebral arteries by cervical osteophytes when the head is turned are both poorly documented, probably over-diagnosed, and should not be used as the cause of a fall simply because nothing else can be found.** This is a high-yield examination statement.
5. The **essential distinction** is: **syncope = sudden loss of consciousness**; **drop attack = sudden fall with preserved consciousness**; **seizure = loss of consciousness with abnormal motor activity, often with incontinence and a post-ictal phase**.

B. Differential Diagnosis of Drop Attacks

6. **Vertebrobasilar ischaemia** and posterior circulation TIA — but the diagnosis of a posterior circulation TIA requires **one or more other symptoms (visual field cut, dysarthria, ataxia, limb weakness, which can be bilateral) in association with vertigo**; transient vertigo alone is not sufficient.
7. **Carotid sinus hypersensitivity** — a treatable cause of unexplained falls, often precipitated by head turning, in which the patient may deny loss of consciousness.
8. **Cardiac** — transient arrhythmia, heart block, aortic stenosis, causing near-syncope with a fall.
9. **Otolithic crisis of Tumarkin** in **Menière's disease** supplementary — sudden violent falls without loss of consciousness. Pathy notes that in **BPPV** too, attacks are very sudden and **may cause a drop to the ground**.
10. **Neurological** — atonic (astatic) seizure; **normal-pressure hydrocephalus**; cervical or lumbar spondylosis with cord or root compression; cerebellar disease; Parkinson's disease with freezing; **cataplexy** associated with narcolepsy supplementary; and **subclavian steal syndrome**.
11. **Musculoskeletal** — sudden knee buckling from quadriceps weakness or arthritis, which patients frequently describe as a drop attack.

C. Evaluation — Structured Approach

12. **Step 1: Characterise the event.** Was consciousness lost? Was there an aura, incontinence, tongue biting or a post-ictal phase? Could a **witness** confirm loss of consciousness? What is remembered immediately after? **Could the patient get up, and how long did it take?**
13. **Step 2: Establish the trigger.** Relationship to **change of posture, turning of the head, cough, micturition, a meal, or drug intake**. Note location, time of day, activity and whether alone.
14. **Step 3: Search for premonitory symptoms** — light-headedness, dizziness, vertigo, palpitations, chest pain, breathlessness, sudden focal neurological symptoms.
15. **Step 4: Vital signs and postural blood pressure** supine, sitting, and at 1 and 3 minutes standing; look for fever, tachypnoea, tachycardia and hypotension indicating acute illness.
16. **Step 5: Targeted bedside tests** — **carotid sinus massage for 5 seconds** under monitoring if the history suggests it; **Dix-Hallpike manoeuvre**; **head impulse test**; **Romberg** and eyes-closed gait testing; cardiovascular examination for arrhythmia and aortic stenosis.
17. **Step 6: Neurological and musculoskeletal examination** — mental status, focal signs, muscle weakness, rigidity or spasticity, peripheral neuropathy with posterior column signs, cerebellar tests (heel-shin, heel tapping), parkinsonian signs; and examine the feet and footwear.
18. **Step 7: Investigations, kept targeted. 12-lead ECG and lying/standing blood pressure are the minimum. Echocardiography** in all patients with a suggestive history and a systolic murmur or a delayed carotid upstroke. **Continuous cardiac monitoring** only where an arrhythmia can be temporally correlated with symptoms. **Non-invasive vascular studies** if anterior circulation TIA is suspected. **CT or MRI reserved** for a high suspicion of an intracranial lesion or seizure disorder. **EEG only** where there is a high degree of clinical suspicion of seizure. Basic bloods: haemoglobin g/dL, glucose, sodium and potassium mEq/L, creatinine mg/dL, calcium mg/dL.
19. **Step 8: In parallel, evaluate the dizziness itself** — character, time course and associated symptoms, with the full differential of general medical, neurological and otological causes, and screen with the CGA question "do you get dizzy, or does your head spin around?" followed by **postural blood pressure, Dix-Hallpike, haemoglobin and the Geriatric Depression Scale**.
20. **Step 9: Treat what you find** — pacemaker for symptomatic cardio-inhibitory carotid sinus hypersensitivity; Epley for BPPV; drug withdrawal and volume repletion for orthostatic hypotension; valve surgery for aortic stenosis with syncope; shunt for normal-pressure hydrocephalus; anticonvulsants for seizure; physiotherapy, strengthening and gait retraining for musculoskeletal causes; and **do not label the event vertebrobasilar insufficiency by exclusion**.

Latest Updates (2023–Present)

- The term **“drop attack” is being retired as a diagnosis** and treated as a **symptom description requiring a mechanism**. Current practice is to reclassify every drop attack as **syncopal (unrecognised transient loss of consciousness), vestibular (Tumarkin otolithic crisis, BPPV), neurological (atonic seizure, cataplexy, NPH, myelopathy) or musculoskeletal (knee buckling)**. **Vertebrobasilar insufficiency as a default explanation is explicitly discouraged.**
- **Unwitnessed falls with amnesia are now assumed to be syncopal until proved otherwise** in older people. **World Falls Guidelines 2022** class **suspected transient loss of consciousness** as an automatic **high-risk** criterion, and mandate cardiovascular assessment — cardiac history, auscultation, lying and standing blood pressure and a 12-lead ECG — in every faller, with further cardiac work-up reserved for suspected syncope or recurrent unexplained falls.
- **Implantable loop recorders** in older adults with recurrent unexplained falls detect clinically significant bradyarrhythmias in a meaningful proportion, supporting the view that many “drop attacks” are unrecognised arrhythmic syncope. Availability and cost limit this in India, where **prolonged Holter or patch monitoring** is the practical alternative.
- **Timing- and trigger-based classification (ATTEST/TiTrATE)** and the **HINTS examination in acute vestibular syndrome** have replaced symptom-quality-based evaluation of the dizzy patient, with HINTS by a trained examiner outperforming early MRI for posterior circulation stroke.
- **Tumarkin’s otolithic crisis** is now formally recognised within the **Bárány Society criteria for Menière’s disease** and is a specific indication for escalating treatment because of the injury risk.
- **Indian practice point**: in a resource-limited clinic, the highest-yield sequence in a patient with drop attacks is a **careful witness history, lying and standing blood pressure, 12-lead ECG, carotid sinus massage, Dix-Hallpike, haemoglobin and blood glucose** — almost all of which are free or very low cost, and which together will identify the mechanism in the majority.

Current Practice Update

Issue	Textbook position	Current position
Status of “drop attack”	A listed cause of falls, pathophysiology poorly understood, often attributed to vertebrobasilar insufficiency	**A description, not a diagnosis** — must be reclassified into a mechanism; vertebrobasilar insufficiency by exclusion is discouraged
Unwitnessed falls	Loss of consciousness often impossible to document	**Assume syncope until proved otherwise**; suspected TLoC is an automatic high-risk criterion
Rhythm monitoring	Only if arrhythmia can be temporally correlated	**Implantable loop recorder** in selected recurrent unexplained fallers; patch/prolonged Holter as the affordable alternative
Dizziness evaluation	Character, time course, associated symptoms	**Timing and triggers (ATTEST/TiTrATE)**, with **HINTS** restricted to acute vestibular syndrome

> **Exam One-Liners**
> - Drop attack = sudden fall from leg weakness WITHOUT loss of consciousness.
> - Only a small proportion of falls are true drop attacks; the mechanism is poorly understood.
> - Never diagnose vertebrobasilar insufficiency simply because nothing else is found.
> - Posterior circulation TIA needs another symptom besides vertigo (visual field cut, dysarthria, ataxia, limb weakness).
> - Tumarkin otolithic crisis = sudden violent fall in Menière’s disease without LOC.
> - Minimum work-up: witness history, lying/standing BP, 12-lead ECG, carotid sinus massage, Dix-Hallpike.
> - EEG only with high clinical suspicion of seizure; imaging only with high suspicion of an intracranial lesion.
> - Unwitnessed fall with amnesia in an older person = syncope until proved otherwise.

Q14. Vestibular rehabilitation

15–20 High-Yield Points (Textbook)

A. Principle — Cerebral Compensation

1. After an acute unilateral vestibular upset the patient experiences vertigo, but symptoms are usually **short-lived and resolve in 6–12 weeks** by processes collectively known as **cerebral compensation**. **Vestibular rehabilitation exists to drive and accelerate this compensation.**
2. Restoration of balance involves **reducing or abolishing the asymmetry in postural and ocular motor tone** and **recalibrating the gain of dynamic vestibular reflexes** to ensure symmetrical vestibulospinal and vestibulo-ocular reflex action during head and body movement.
3. Compensation depends on **brainstem, cerebellar and cortical structures together with sensory inputs including vision, somatosensory afferents and the remaining labyrinthine input**.
4. In the older patient **the plasticity of the CNS is compromised, so recovery is often slower and is rarely complete**. Contributing factors to failed compensation or intermittent decompensation include **cerebellar damage, impaired proprioception, visual impairment, mild cerebral dysfunction and psychological disorders**.
5. **Decompensation** can be triggered by an **intercurrent illness or a psychological upset such as bereavement**, and then presents as vague floating, rocking or depersonalisation rather than true rotational vertigo.

B. Cawthorne–Cooksey Exercises

6. **Physical exercise regimes were introduced as early as the mid-1940s (the Cawthorne–Cooksey exercises)** as a means of **expediting recovery from peripheral vestibular disorders**.
7. They are a **graduated series of exercises aimed at encouraging head and eye movements, which systematically provoke dizziness and facilitate vestibular compensation**. The therapeutic principle is **deliberate, controlled provocation of symptoms**, not avoidance.
8. **The exercises are not an endurance test.** In the older patient it is important to **modify the regime within the limits of the patient's physical abilities**.
9. Progression follows a standard order supplementary: **eye movements alone (up-down, side-to-side, focusing on a finger), then head movements with eyes open and then closed, then movements while sitting (shoulder shrugging, bending forward to pick objects), then standing (sit-to-stand with eyes open and closed, throwing a ball), then moving about (walking across the room with eyes open and closed, walking up and down a slope and steps, ball games, and activities requiring bending and stretching)**.

C. Evidence and Effects

10. **The passage of time has supported the efficacy of these exercises.**
11. **Successful vestibular rehabilitation improves activities of daily living and reduces fall risk** — the key statement linking this topic to the falls syllabus.
12. **Significant improvement has been shown in patients with peripheral vestibular dysfunction and also in patients with central balance disorders.**
13. **There is no evidence that age is a negative prognostic factor.** Older patients should therefore be offered vestibular rehabilitation on exactly the same basis as younger patients.
14. **"Customised" exercises tailored to the individual patient are equally effective** as the standard regime.
15. **Introduce vestibular rehabilitation and gait strategy exercises in the elderly early and emphatically** — this is one of the chapter's key points.

D. Relationship with Repositioning Manoeuvres

16. **Specific positional manoeuvres for benign positional vertigo, such as the Epley manoeuvre, form an important element of vestibular management** and are distinct from vestibular rehabilitation.
17. **A combination of canalith repositioning manoeuvre and vestibular rehabilitation improves benign positional vertigo in the elderly.** Although the **repositioning manoeuvre is the most effective treatment**, **vestibular rehabilitation can be added to improve results, particularly given the high recurrence of positional vertigo**.

E. Drugs and Vestibular Rehabilitation

18. **Vestibular sedatives such as cinnarizine are of value in managing acute vertigo but have a very limited role in managing chronic vestibular syndromes**, because they suppress the very asymmetry signal that drives compensation.
19. **Anti-emetics such as prochlorperazine should be avoided** because of the **rare but irreversible syndrome of extrapyramidal dysfunction** — a particularly important warning in older patients.
20. **Psychotropic drugs should be administered only for specific psychiatric indications, as such medication may interfere with compensatory mechanisms** for peripheral vestibular disorders.
21. **Surgery**: in the elderly the indications for otological surgery must be carefully weighed against the general medical state and the likely extent of postoperative recovery. **Destructive surgical procedures should not be considered until detailed neuro-otological investigations have been performed and medical management has been tried exhaustively**, and **the risk of persisting imbalance after vestibular destruction must be borne in mind**.

Latest Updates (2023–Present)

- The **updated Clinical Practice Guideline on Vestibular Rehabilitation for Peripheral Vestibular Hypofunction** (Academy of Neurologic Physical Therapy, APTA, 2022; a revision of the 2016 guideline) is now the reference standard and gives, for the first time, **explicit exercise dosing**.

- **Strong recommendation**: clinicians **should offer vestibular rehabilitation** to adults with unilateral and bilateral vestibular hypofunction who have impairments, activity limitations or participation restrictions, and **should offer supervised vestibular rehabilitation** rather than an unsupervised home programme alone.
- **Gaze stabilisation dosing**: at least **12 minutes daily, in 3 sessions, for acute or sub-acute unilateral vestibular hypofunction**; at least **20 minutes daily, in 3 to 5 sessions, for chronic unilateral hypofunction**; and a **higher total daily dose (typically 20–40 minutes) for bilateral vestibular hypofunction**, which also needs a longer progression.
- **Strong recommendation against**: do **not** use **voluntary saccadic or smooth-pursuit eye movements in isolation** (that is, without head movement) to promote gaze stability — the guideline judged harm to outweigh benefit. Retinal slip produced by **head movement** is the necessary error signal for VOR adaptation. This is an important update, because "eye exercises" are still widely prescribed.
- **Early initiation** of vestibular physical therapy, ideally **within 2 weeks of acute onset of unilateral vestibular hypofunction**, may optimise outcomes.
- **Balance and gait training** should accompany gaze stabilisation, using a variety of modalities: low-technology exercise, **virtual reality**, **optokinetic stimulation**, platform perturbations, **vibrotactile and augmented sensory feedback**, dual-task walking, obstacle negotiation, uneven surfaces and turning, and task-specific ADL practice (sit-to-stand, stairs, bed mobility, tight-space turning).
- The guideline gives **expanded recommendations on factors that modify outcome**, specifically **medications** (vestibular suppressants and psychotropics impair compensation) and **mild cognitive impairment** — which supports and updates the textbook's warning about drugs and about failed compensation in the older brain.
- **Persistent postural-perceptual dizziness (PPPD)** is now a defined Bárány Society entity treated with **vestibular rehabilitation plus SSRI/SNRI plus cognitive behavioural therapy**, not with vestibular sedatives — the modern equivalent of the "anxious elderly patient with chronic disequilibrium" described in the textbook.
- **Indian delivery**: formal vestibular physiotherapy services are scarce outside tertiary centres. Practical approaches are **therapist-taught, home-based customised Cawthorne–Cooksey and gaze stabilisation programmes with a written or illustrated schedule in the local language**, family-supervised practice, telerehabilitation, and integration with **NPHCE** geriatric clinics and district physiotherapy services. This is supported by the textbook's own finding that **customised exercises are equally effective** and that **age is not a negative prognostic factor**.

Current Practice Update

Issue	Textbook position	Current position
Exercise dose	Graduated exercises, modified to the patient's ability; not an endurance test	**Explicit dosing**: gaze stabilisation ≥12 min/day in 3 sessions (acute/subacute UVH); ≥20 min/day in 3–5 sessions (chronic UVH); 20–40 min/day (BVH)
Eye exercises	Head and eye movement exercises encouraged	**Strong recommendation against isolated saccadic or smooth-pursuit eye exercises without head movement**
Supervision	Customised exercises equally effective	**Supervised programmes recommended (strong evidence)**; customisation retained
Timing	Introduce early and emphatically	Quantified — **within 2 weeks of acute onset** may optimise outcomes
Modalities	Cawthorne–Cooksey exercises	Plus **virtual reality, optokinetic stimulation, vibrotactile and augmented sensory feedback, dual-task and gait training**
Drugs	Vestibular sedatives limited to acute vertigo; avoid prochlorperazine; psychotropics interfere with compensation	Unchanged and reinforced — medication effect is now a formal outcome-modifying factor in the guideline

Exam One-Liners

- Vestibular rehabilitation works by driving cerebral compensation — abolishing tone asymmetry and recalibrating VOR gain.
- Cawthorne–Cooksey exercises (mid-1940s): graduated head and eye movements that deliberately provoke dizziness.
- Progression: eyes → head → sitting → standing → moving about.
- Improves ADLs and reduces fall risk; effective in peripheral AND central balance disorders.
- Age is NOT a negative prognostic factor; customised exercises are equally effective.
- Dose (APTA 2022): ≥12 min/day acute UVH; ≥20 min/day chronic UVH; 20–40 min/day BVH.
- Do NOT prescribe isolated eye movements without head movement.
- Avoid vestibular sedatives in chronic vertigo; avoid prochlorperazine (extrapyramidal risk).
- Epley + vestibular rehabilitation together give the best outcome in elderly BPPV.

DELIRIUM / ACUTE CONFUSIONAL STATE IN THE ELDERLY

MD Geriatric Medicine — 15-Mark Exam Answers | Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th ed. (Ch. 61) with Kane's Essentials of Clinical Geriatrics (Ch. 6) | Updates to August 2026

RECURRING TOPIC ALERT. All five questions in this set are variations of a single core theme — **delirium**. Examiners repeat this topic because it is the commonest geriatric syndrome in hospital, the most under-diagnosed, and the most preventable. Master **one** framework (Predisposing + Precipitating → Screen → Treat cause → Non-pharmacologic bundle → Drugs only as last resort) and it will answer every version. Extra recall points are given at the end.

Q1. Aetiology, pathogenesis, differential diagnosis and management of acute confusional state in the elderly

18 High-Yield Points (Textbook)

1. **Definition:** Delirium (acute confusional state, "**acute brain failure**", altered mental status) is an **acute disturbance of attention, awareness and cognition**, developing over hours to days, **fluctuating** through the day, and caused by an underlying medical condition, drug or withdrawal.
2. **Key clinical features:** impaired consciousness, **global cognitive impairment of acute onset**, disorientation, **disturbed sleep–wake cycle**, altered psychomotor behaviour, illusions, visual hallucinations and paranoid delusions. It is typically **worse at night**, with lucid intervals in between.
3. **Rates (Pathy):** ICU **30–80%**; hospice care 26–44%; general medical and oncology wards **18–35%**; nursing home / post-acute care 16%. Surgical rates: cardiac and vascular surgery 29–50%, hepatobiliary and general surgery 17–24%, hip fracture repair 12–48%.
4. **Phenotypes:** classically **hyperactive, hypoactive and mixed**. Newer recognised phenotypes are ICU delirium (sedative, septic, hypoxic, metabolic subtypes), **postoperative delirium (POD)** vs **postoperative cognitive dysfunction (POCD)**, emergence delirium, delirium at end of life (replaces "terminal restlessness"), **subsyndromal delirium**, persistent/chronic delirium and **delirium superimposed on dementia (DSD)**.
5. **DSD is the hardest phenotype:** worse outcomes, longer stay, hardest to diagnose, and takes longer to resolve than other phenotypes.
6. **Pathogenesis — Systems Integration Failure Hypothesis (SIFH):** several interacting processes — **neuronal ageing, oxidative stress, neuroendocrine changes, diurnal dysregulation and neuroinflammation** — damage the neurotransmitter systems and break down **neuronal network connectivity**. This combination produces the outward picture of acute brain failure.
7. **Neurotransmitters involved:** dopaminergic, adrenergic, **muscarinic (cholinergic)**, histaminic and serotonergic pathways are all disturbed, but to an unmeasurable degree in any given patient.
8. **Why the pathogenesis matters in exams:** (a) it explains the very wide spectrum of presentations, and (b) it explains **why antipsychotic trials keep failing** — these drugs hit several receptors at once to unpredictable degrees, and correcting one pathway may disturb another.
9. **Vulnerability model:** a patient with many **predisposing** factors is highly vulnerable, so only a **tiny precipitant** (e.g. a single dose of oral diphenhydramine for insomnia) is needed to tip them into delirium. Many factors are both predisposing and precipitating.
10. **Aetiology — the Pathy mnemonic "DELIRIUM IS VERY PAINFUL"** covers the entire differential of causes and contributors (table below).
11. **Deliriogenic drugs (Pathy list):** antipsychotics, **benzodiazepines** (especially intravenous — paradoxical reactions), corticosteroids, **H2-receptor antagonists in renal impairment**, narcotics (especially **pethidine/meperidine** and IV opioids), muscle relaxants, **antimuscarinics for overactive bladder**, first-generation antihistamines, and non-benzodiazepine benzodiazepine-receptor agonist hypnotics such as **zolpidem**.
12. **Differential diagnosis:** dementia, delirium superimposed on dementia, depression (pseudodementia), late-onset psychosis or mania, **non-convulsive status epilepticus**, Wernicke's encephalopathy, and drug/alcohol/benzodiazepine withdrawal.
13. **Best discriminator from dementia:** focus on the **core criteria — attention, awareness and level of consciousness — not on the behaviour**. Behavioural symptoms are shared; inattention with acute fluctuating onset is not.
14. **Diagnosis: DSM-5 and ICD-10 remain the gold standard**. DSM-5 requires disturbed attention/awareness/cognition, acute onset, fluctuation, not better explained by a neurocognitive disorder, not in coma, and evidence of a medical cause, substance or multiple aetiologies. ICD-10 adds detail on perceptual distortion, psychomotor and sleep–wake disturbance.
15. **Bedside screening: CAM** (sensitivity 94%, specificity 89%), 3D-CAM, CAM-ICU, 4AT, bCAM. Screen **all hospitalised older adults at least daily**.
16. **Targeted investigation:** laboratory and imaging tests are guided by the clinical assessment. **Neuroimaging, lumbar puncture and EEG are NOT required in every patient.** CT/MRI only for new focal deficit, suspected stroke, fall or head trauma, unexplained reduced consciousness, or fever with suspected viral encephalitis; LP if meningitis/encephalitis suspected; EEG if seizure suspected.
17. **Management — four sequential steps:** (i) identify and treat every predisposing/precipitating factor; (ii) institute **multicomponent non-pharmacologic care as the mainstay**; (iii) use the **T-A-DA method** — **T**olerate behaviours that are not dangerous, **A**nticipate needs, **D**on't **A**gitate; (iv) drugs only if severe agitation endangers the patient or others.

18. **Drug rules: no drug is approved by the FDA or EMA for delirium. Benzodiazepines must not be used** (they precipitate and prolong delirium) — the **only two exceptions are benzodiazepine withdrawal and alcohol withdrawal**. Antipsychotics carry a **black-box warning** for increased mortality in dementia; AGS/ACS advise **lowest dose, shortest duration, only after non-pharmacologic measures fail**; PADIS advises against routine use in the ICU; and their use in delirium is listed under **Choosing Wisely — "Things We Do for No Reason"**.

Table 1. Causes and contributors — "DELIRIUM IS VERY PAINFUL" (Pathy Table 61.1)

	Factor	Key exam point
D	Drugs & drug withdrawal	Commonest reversible cause; high index of suspicion in the vulnerable brain
E	Eyes, Ears	Visual/hearing impairment — mainly *predisposing*
L	Low O_2 / low perfusion	MI, pulmonary embolism, stroke, cardiac or pulmonary failure, anaemia, anoxia
I	Infection	Even *mild* infection can precipitate delirium in the vulnerable; do not over-treat behaviour as "infection"
R	Retention of urine	**Cystocerebral syndrome** — sudden delirium, muteness, restlessness
I	Indwelling urinary catheter	Infection risk + a "one-point restraint" that impairs mobility
U	Underhydration	**BUN : creatinine ratio > 17:1** is associated with delirium and delirium risk
M	Metabolic	Hypercalcaemia, hypokalaemia, hyponatraemia, hypernatraemia, hyperammonaemia
I	Immobility & inactivity	Early mobilisation reduces delirium rate and duration
S	Sleep problems	Sleep deprivation, sleep–wake reversal, sleep apnoea
V	Vascular changes / volume loss on CT-MRI	Predisposing when interpreted with the history
E	Endocrinopathies	Thyroid and adrenal disorders, hyper- and **hypoglycaemia**
R	Restraints	Wrist restraints, IV lines, catheters, pneumatic compression devices, casts
Y	ps**Y**chiatric disorders	Anxiety, depression, schizophrenia, bipolar disorder — predisposing
P	Pain	Uncontrolled pain precipitates; but do **not** use opioids for behaviour. Regular paracetamol reduces opioid need
A	Attachments	IV lines, telemetry — anything that tethers or annoys the patient
I	Impaction	Severe constipation / faecal impaction
N	Neurological injury	Subdural haematoma, intracerebral bleed, head trauma, stroke, tumour, encephalitis, meningitis, seizures
F	Frailty	Major predisposing factor
U	Undernutrition	Contributor; alters protein binding of drugs
L	Lights, loud noises	Environmental; sensory input is misperceived

Table 2. Delirium vs Dementia (Kane's, Table 6-3)

Feature	Delirium	Dementia
Onset / course	Hours to days; days to weeks duration; marked **fluctuation**	Gradual over months to years; slowly progressive
Consciousness	**Altered and changing**	Unchanged until very late
Attention	**Short attention span (core deficit)**	Attention span preserved
Psychomotor	Marked change — lethargic or agitated	Baseline activity maintained
Speech	Often **incoherent**	Word-finding difficulty, aphasia
Hallucinations	Common, usually **visual**; illusions	Unusual until late (except Lewy body dementia)
Sleep–wake cycle	Disrupted	Sleep disturbed, but cycle less affected
CAM screen	Positive	Negative
Acute illness / drug	Usually evident	No evidence of acute illness

Latest Updates (2023–Present)

- **APA Practice Guideline for the Prevention and Treatment of Delirium (Sept 2025)** — the first full revision since 1999 (brief update 2004). It shifts the emphasis firmly to **prevention**, mandates a thorough medication and risk-factor history, restricts restraints to situations of **"imminent harm"**, and adds structured guidance on **transitions of care** (medication reconciliation, delirium follow-up, patient and caregiver psychoeducation).
- **NICE CG103 (updated January 2023)** — new recommendations on assessing and diagnosing delirium; the **4AT** is now the NICE- and SIGN-endorsed bedside tool.
- **SCCM PADIS Focused Update 2025** (Crit Care Med 2025) — suggests **dexmedetomidine over propofol** when light sedation and/or delirium reduction are priorities; suggests **enhanced mobilisation/rehabilitation** and **melatonin**; explicitly suggests **not** using haloperidol, atypical antipsychotics, dexmedetomidine, statins or ketamine **to prevent** delirium; and could issue **no recommendation for or against antipsychotics for treatment** because effects on outcomes are minimal.

- **AGS Beers Criteria 2023** — anticholinergics are now split into antihistamines, CNS antiparkinsonian agents and GI antispasmodics, with explicit warning that **combined anticholinergic burden** raises the risk of delirium, falls, cognitive decline and possibly dementia. The companion **AGS Beers Alternatives List (2025)** supplies safer substitutes for drugs used in insomnia, anxiety, delirium and chronic pain.
- **Epidemiology refresh:** a 2025 systematic review and meta-analysis of 35 studies (12,097 medically hospitalised older patients) found a **pooled prevalence of 23.6%** and a **pooled incidence of 13.5%**, with frailty, physical restraints, previous falls, illness severity, cognitive impairment and older age as the leading risk factors — validating the Pathy risk-factor table.
- **Ormseth et al. (JAMA Network Open 2023)** — large systematic review confirming that predisposing and precipitating factors are almost always **multifactorial** rather than single-cause.
- **Biomarkers:** genetic and proteomic risk-factor studies (Nature Aging 2026) are beginning to define a biological risk signature for delirium — not yet clinically usable.
- **Indian data:** tertiary-care studies continue to show marked under-recognition — delirium accounts for only about 0.4% of total inpatients when identified through psychiatry referral, but Indian ICU studies using CAM-ICU report **~30% prevalence in non-ventilated elderly ICU patients, with hypoactive delirium commonest (~45%)**. The gap between referral-based and screening-based figures is itself an exam point.

Current Practice Update

Issue	Pathy 6th edition (textbook)	Current practice (2023–2026)
Guideline anchor	AGS/ACS 2015 postoperative delirium statement; SCCM PADIS 2018	**APA 2025 delirium guideline** + **PADIS Focused Update 2025** + NICE CG103 (2023)
Antipsychotics for treatment	Evidence does not support use; reserve for severe agitation	Position hardened — PADIS 2025 could issue **no recommendation either way**; APA 2025 restricts to imminent harm
Antipsychotics for prevention	Not supported	**Explicitly recommended against**, along with statins and ketamine
Sedative of choice in ICU	Propofol or dexmedetomidine over benzodiazepines	**Dexmedetomidine preferred over propofol** when light sedation / delirium reduction are the priority (watch bradycardia)
Melatonin	Not recommended	**Conditionally suggested** in ICU patients (PADIS 2025)
Screening tool emphasis	CAM family emphasised	**4AT** endorsed by NICE and SIGN for rapid ward and ED use
Restraints	Avoid; no evidence of benefit	Restricted to **"imminent harm"** only (APA 2025)
Discharge	Comprehensive discharge planning	Formal **transition-of-care** block — medication reconciliation, delirium follow-up, caregiver education

Exam One-Liners — Q1

- Delirium = **acute brain failure**; the core deficit is **inattention**, not agitation.
- Pathogenesis = **Systems Integration Failure Hypothesis** (Maldonado).
- Mnemonic = **DELIRIUM IS VERY PAINFUL**.
- Cystocerebral syndrome = delirium from **urinary retention**.
- **BUN : creatinine > 17:1** = dehydration-associated delirium risk.
- CAM: sensitivity **94%**, specificity **89%**.
- Gold standard diagnosis = **DSM-5 / ICD-10**; CAM/4AT are screens.
- Mainstay of treatment = **multicomponent non-pharmacologic care**; behaviour tool = **T-A-DA**.
- **No drug is FDA/EMA approved** for delirium; benzodiazepines only for alcohol or benzodiazepine withdrawal.
- Up to **30–40% of delirium is preventable**.

Q2. A 75-year-old diabetic, hypertensive smoker presents with cough, fever and altered sensorium; he is incoherent and abusive — differential diagnosis, trigger factors, evaluation and ward management

> **One-line formulation:** This is **hyperactive delirium** in a multi-morbid older adult, most probably precipitated by **community-acquired pneumonia**. The abusive, incoherent behaviour is a **symptom of acute brain failure, not a psychiatric illness** — the task is to find and treat the precipitant, not to sedate the patient.

18 High-Yield Points

A. Recognising the syndrome

1. Acute onset over hours–days, incoherent speech, abusive and restless behaviour with fever indicates **delirium, hyperactive subtype**, until proven otherwise. Confirm with **CAM or 4AT** at the bedside: acute onset with fluctuation **plus inattention**, plus either disorganised thinking or altered consciousness.
2. Test inattention immediately — **months of the year backwards**, days of the week backwards, or digit span. Do not "make excuses" for a positive item because the patient is old, febrile or sleepless.
3. Remember the **hypoactive** phase may follow; delirium waxes and wanes, so a single normal assessment does not exclude it.

B. Differential diagnosis of altered sensorium in this patient

4. **Infective:** community-acquired pneumonia with delirium (most likely), **sepsis / septic encephalopathy**, aspiration pneumonia, **pulmonary tuberculosis or miliary TB** (important in India), influenza/COVID, meningitis, viral encephalitis, brain abscess, urinary sepsis with an incidental cough.
5. **Respiratory / hypoxic: hypoxaemia** and **hypercapnic encephalopathy** (smoker → COPD), pulmonary embolism, acute pulmonary oedema.
6. **Metabolic / endocrine: hypoglycaemia** (must be excluded within seconds), diabetic ketoacidosis, hyperosmolar hyperglycaemic state, **hyponatraemia** (SIADH accompanying pneumonia, or thiazide-induced), hypercalcaemia, uraemia, hepatic encephalopathy, thyroid disease.
7. **Neurological:** ischaemic stroke or intracerebral haemorrhage (hypertensive smoker), **subdural haematoma** after an unwitnessed fall, **non-convulsive status epilepticus**, hypertensive encephalopathy, **Wernicke's encephalopathy**.
8. **Drug-related:** anticholinergics, first-generation antihistamines in cough syrups, sedative-hypnotics, opioids, corticosteroids for wheeze, **fluoroquinolone neurotoxicity**, H2-blockers in renal impairment.
9. **Withdrawal states: alcohol withdrawal** (abusive behaviour, tremor, autonomic overactivity), benzodiazepine withdrawal, and **nicotine withdrawal** in a smoker admitted to a smoke-free ward.
10. **Simple bedside causes often missed: urinary retention** (cystocerebral syndrome), **faecal impaction**, uncontrolled pain.
11. **Psychiatric mimics (least likely):** late-onset psychosis, mania, agitated depression, and **delirium superimposed on dementia**. Abrupt onset with fever and inattention argues strongly against a primary psychiatric cause.

C. Trigger factors in this specific patient

12. Map him onto **DELIRIUM IS VERY PAINFUL**: **Infection** (pneumonia), **Low O_2** (smoker with hypoxaemia), **Endocrinopathy** (diabetes — hyper- and hypoglycaemia), **Drugs**, **Underhydration**, **Vascular change** (hypertension, smoking), plus hospital-generated triggers — **Restraints, Attachments, Indwelling catheter, Immobility, Sleep disruption, Lights and noise, Pain**.
13. Predisposing (non-modifiable) factors here: **age ≥ 75**, likely undetected cognitive impairment, frailty, sensory impairment, multimorbidity and polypharmacy. These make him so vulnerable that even a mild pneumonia can precipitate florid delirium.

D. Evaluation

14. **Within the first five minutes:** airway, breathing, circulation; **SpO_2**, respiratory rate, temperature, blood pressure, pulse; **capillary blood glucose**; GCS and RASS; pupils and focal neurological signs; look for neck stiffness; palpate the bladder; examine the perineum/rectum for impaction. Give **thiamine 100 mg IV before glucose** if alcohol use or malnutrition is suspected.
15. **Collateral history is mandatory** — baseline cognition and function, exact time course, complete drug and alcohol history, recent falls, and any drug newly started or stopped.
16. **Laboratory (Indian conventional units):** complete blood count with differential; blood glucose (mg/dL); serum sodium and potassium (mEq/L); calcium (mg/dL); blood urea and creatinine (mg/dL) with **BUN:creatinine ratio**; liver function tests; **arterial blood gas**; CRP or procalcitonin; blood cultures × 2; sputum Gram stain, culture, AFB and **CBNAAT**; urine routine and culture; HbA1c; serum TSH; vitamin B12 if cognition was already impaired; ECG (baseline **QTc before any antipsychotic**); chest radiograph.
17. **Targeted imaging only:** non-contrast CT head if there are new focal signs, suspected stroke, a fall or head injury, unexplained reduced consciousness, or fever with suspected encephalitis. **Lumbar puncture** if meningitis or encephalitis is suspected; **EEG** if non-convulsive seizures are suspected. Routine CT for every confused patient is not indicated.
18. Grade pneumonia severity (**CURB-65**) and screen for sepsis (qSOFA / NEWS2) to decide ward versus HDU care.

E. Ward management

Domain	Action

Treat the precipitant	Empirical antibiotics for CAP per severity and local antibiogram, started **within 1 hour if sepsis is present**; oxygen to target saturation (88–92% if COPD is suspected, otherwise 94–98%); chest physiotherapy; nebulised bronchodilators
Fluids & glucose	Correct dehydration and electrolytes; treat hyperglycaemia with **basal-bolus insulin, avoiding sliding scale alone**; target roughly **140–180 mg/dL**; **hypoglycaemia is more dangerous than modest hyperglycaemia** in delirium
Medication review	Stop every deliriogenic drug; apply **Beers / STOPP-START**; avoid anticholinergics, sedative-hypnotics, pethidine and H2-blockers; regular paracetamol for pain to reduce opioid load
Non-pharmacologic bundle *(the mainstay)*	Repeated **reorientation**; clock, calendar and familiar objects; **spectacles and hearing aids** restored; well-lit room by day, dark and quiet at night; **non-drug sleep protocol**; **early mobilisation three times daily**; oral hydration and feeding assistance; remove tethers — catheter, IV line, telemetry — as early as possible
Behaviour	**T-A-DA:** Tolerate non-dangerous behaviour, Anticipate needs (toilet, thirst, pain, position), Don't Agitate. Give the hands something to do (folding cloths) instead of pulling lines. **Avoid physical restraints** — they worsen delirium
Family	Keep a relative at the bedside for reassurance, orientation, feeding and mobilising. Explain that **fluctuation is expected** and that apparent improvement by day does not mean recovery. In Indian wards the attendant culture is a major asset — use it deliberately
Drugs (last resort)	Only if the patient is **severely agitated or distressed and dangerous to himself or others**, and only after non-pharmacologic measures have failed. **Haloperidol 0.25–0.5 mg** orally or IM, lowest dose and shortest duration, with ECG monitoring for **QTc**; avoid in Parkinson's disease and Lewy body dementia (use quetiapine). **Do not use benzodiazepines** unless this is alcohol or benzodiazepine withdrawal
Nicotine	Consider **nicotine replacement therapy** — withdrawal is a genuine, easily missed precipitant in an admitted smoker
Complication prevention	Aspiration precautions and swallow assessment; VTE prophylaxis; **pressure-injury prevention**; falls precautions with low bed and floor mats rather than restraints; bowel and bladder care
Monitoring & discharge	**Daily CAM/4AT screening**; document trajectory; medication reconciliation at discharge; cognitive reassessment at 4–8 weeks because delirium may unmask or accelerate dementia

Latest Updates (2023–Present)

- **APA 2025** guideline explicitly links delirium management to **medication history and deprescribing** as a first-line intervention, and confines restraints to situations of **imminent harm** — directly relevant to the "abusive" patient in this vignette.
- **NICE CG103 (2023)** names **benzodiazepines, opioids and anticholinergics** as the commonest pharmacological precipitants and recommends the **4AT** for rapid ward assessment.
- **AGS Beers 2023 / Alternatives List 2025** emphasise **cumulative anticholinergic burden** and offer non-drug alternatives for insomnia and agitation — useful when the ward wants "something for sleep".
- **Non-pharmacologic prevention remains the only intervention with consistent benefit**; a 2025 meta-analysis of **family involvement** in critically ill patients supports formally recruiting relatives into the delirium care plan.
- **Antipsychotic caution reinforced:** the **AID-ICU trial** and the **PADIS 2025 focused update** together show haloperidol has minimal or no effect on length of stay or duration of delirium — it is a behavioural rescue, not a treatment.
- **Indian relevance:** in a febrile elderly patient with cough and confusion, **CBNAAT for tuberculosis** should be sent early; TB remains a leading cause of subacute confusion with fever in Indian older adults and is easily missed when pneumonia is assumed.

Current Practice Update

Issue	Textbook position	Current practice
Sedating the abusive patient	Antipsychotic in lowest dose only if dangerous	Same, but with an explicit **"imminent harm"** threshold, mandatory **baseline ECG** and a documented stop date
Glycaemic target	Individualised control	Ward target roughly **140–180 mg/dL**; **avoid sliding-scale-only** insulin; hypoglycaemia treated as a delirium precipitant
Routine CT head	Not required in all	Unchanged and reinforced — targeted imaging only
Family role	Encouraged	A **formal, evidence-supported component** of the care bundle
Tuberculosis	Not emphasised	In India, **CBNAAT early** in any elderly patient with fever, cough and confusion

Exam One-Liners — Q2

- Abusive + incoherent + fever = **hyperactive delirium**, not psychosis.
- **Check glucose before anything else**; thiamine before glucose if alcohol is possible.
- Commonest precipitants in this patient: **infection, hypoxia, drugs, dehydration, retention**.
- CURB-65 for pneumonia severity; qSOFA/NEWS2 for sepsis.
- **Restraints worsen delirium** — low bed and a bedside relative are safer.
- Haloperidol **0.25–0.5 mg** is a rescue, not a treatment; check QTc.

- Don't forget **nicotine withdrawal** in an admitted smoker.
- Reassess cognition **4–8 weeks** after discharge.

Q3. A 65-year-old diabetic with chronic kidney disease presents with altered sensorium, fever, leucocytosis and hypotension — how will you evaluate and manage?

> **One-line formulation:** Fever + leucocytosis + hypotension + altered sensorium = **sepsis / septic shock with sepsis-associated delirium**, on a background of **diabetes and CKD** which both predispose to infection and to metabolic and drug-induced encephalopathy. This is a **time-critical emergency**: the altered sensorium is itself an organ-failure marker (SOFA/qSOFA).

18 High-Yield Points

A. Frame the problem

1. **Sepsis-3:** life-threatening organ dysfunction from a dysregulated host response to infection. **Altered mentation is one of the three qSOFA items** (altered mentation, systolic BP ≤ 100 mmHg, respiratory rate ≥ 22/min). **Septic shock** = vasopressor requirement to keep MAP ≥ 65 mmHg plus lactate > 2 mmol/L after adequate fluids.
2. In older adults, **delirium and falls may be the only presenting features of sepsis**; fever may be blunted or absent, and hypothermia carries a worse prognosis.
3. Delirium here is **multifactorial**: infection + hypoperfusion (Low O_2/low perfusion) + metabolic derangement + drug accumulation + ICU environment — the whole left column of **DELIRIUM IS VERY PAINFUL** operating at once.

B. Likely sources of sepsis in a diabetic with CKD

4. **Urinary tract:** acute pyelonephritis, **emphysematous pyelonephritis or cystitis**, perinephric abscess, obstructed infected system, catheter-associated UTI. **Diabetes plus CKD makes urosepsis the single commonest source.**
5. **Skin and soft tissue: diabetic foot infection**, cellulitis, necrotising fasciitis, pressure injury.
6. **Respiratory:** community-acquired or aspiration pneumonia, **tuberculosis**.
7. **Vascular access:** haemodialysis catheter-related bloodstream infection, arteriovenous graft infection, peritoneal dialysis peritonitis if on PD.
8. **Intra-abdominal:** cholangitis, emphysematous cholecystitis, diverticulitis, **rhino-orbito-cerebral mucormycosis** in poorly controlled diabetes.

C. Non-septic contributors to the altered sensorium (must be excluded in parallel)

9. **Uraemic encephalopathy**, metabolic acidosis, **hyperkalaemia**, **hyponatraemia**, hypocalcaemia, hyperphosphataemia.
10. **Hypoglycaemia** — CKD reduces renal insulin clearance and gluconeogenesis, so sulfonylureas and insulin accumulate; this is a classic and lethal miss.
11. **Hyperosmolar hyperglycaemic state** or euglycaemic ketoacidosis if on an SGLT2 inhibitor.
12. **Drug accumulation in CKD: cefepime and carbapenem neurotoxicity**, morphine metabolites, gabapentin/pregabalin, aciclovir, H2-receptor antagonists, metformin-associated lactic acidosis.
13. **Structural / other:** stroke, intracerebral bleed (uraemic platelet dysfunction, anticoagulation), **dialysis disequilibrium syndrome**, non-convulsive status epilepticus, Wernicke's encephalopathy.

D. Evaluation

14. **Immediate bedside:** ABC, airway protection if GCS is falling; large-bore access; **capillary glucose**; continuous SpO_2, BP, ECG; temperature; urine output via measurement (avoid an unnecessary indwelling catheter, but it is justified in shock); GCS and RASS; **full skin, foot, perineal and dialysis-access examination**; fundus and sinus examination if mucormycosis is possible.
15. **Investigations: serum lactate** (repeat if raised); **two sets of blood cultures before antibiotics** (do not delay antibiotics for them); complete blood count with differential; blood glucose (mg/dL); urea and creatinine (mg/dL) with baseline eGFR for comparison; sodium and potassium (mEq/L); calcium (mg/dL), phosphate, magnesium; arterial blood gas with anion gap; liver function tests; coagulation profile; CRP/procalcitonin; urine routine, microscopy and culture; sputum culture and CBNAAT; pus/wound culture; HbA1c; ECG; chest radiograph; **ultrasound KUB** for hydronephrosis, gas or abscess, with contrast-enhanced CT only when the benefit outweighs contrast risk. Add CT head, EEG or lumbar puncture only if focal signs, seizures or meningism are present.

E. Management

16. **Hour-1 sepsis bundle:** measure lactate, take blood cultures, give **broad-spectrum antibiotics within the first hour**, begin fluid resuscitation for hypotension or lactate ≥ 4 mmol/L, and start **noradrenaline** as the first-line vasopressor to keep **MAP ≥ 65 mmHg**. Add vasopressin if noradrenaline requirement rises; consider hydrocortisone in refractory shock.
17. **Fluids in CKD need judgement, not a fixed recipe.** The 30 mL/kg crystalloid figure is a starting point; in oligo-anuric CKD, established heart failure or dialysis dependence, give **smaller aliquots (250–500 mL) with reassessment after each** using passive leg raise, lactate clearance, capillary refill and lung ultrasound. Prefer **balanced crystalloids**; avoid starches; watch for hyperkalaemia with potassium-containing fluids.
18. **Antibiotics and the kidney:** give a **full loading dose**, then adjust the maintenance dose to renal function; avoid aminoglycosides and other nephrotoxins where possible; stop metformin, NSAIDs, ACE inhibitors/ARBs and SGLT2 inhibitors during the acute illness; de-escalate on culture results. Achieve **source control** within 6–12 hours — drain the abscess, relieve obstruction with a nephrostomy or stent, debride the foot, or remove the infected dialysis catheter.

F. Continuing ward/ICU care

Domain	Action

Glycaemia	Insulin infusion or basal-bolus; target roughly **140–180 mg/dL**; hourly monitoring during infusion; **stop sulfonylureas** (prolonged hypoglycaemia in CKD)
Renal support	Watch for AKI on CKD. RRT indications — **A**cidosis, **E**lectrolytes (refractory hyperkalaemia), **I**ntoxication, **O**verload (fluid), **U**raemic complications (encephalopathy, pericarditis). Continuous modalities are preferred in haemodynamic instability
Delirium care	**ABCDEF bundle** — Assess/prevent/manage pain; Both spontaneous awakening and breathing trials; Choice of sedation; Delirium assess, prevent and manage; Early mobility; Family engagement. Screen with **CAM-ICU** (or 4AT on the ward)
Sedation	Avoid benzodiazepines; if sedation is needed, **dexmedetomidine** is preferred when light sedation and delirium reduction are priorities
Drugs to stop	All deliriogenic and renally accumulating drugs — opioids (especially morphine), gabapentinoids, H2-blockers, anticholinergics; recheck antibiotic doses daily as renal function changes (**cefepime neurotoxicity** presents exactly like this)
Supportive	VTE prophylaxis, stress-ulcer prophylaxis where indicated, nutrition (protein without overloading urea), pressure-injury prevention, early mobilisation, bowel and bladder care, correction of anaemia
Goals of care	Assess pre-morbid frailty and function with **CGA**; discuss ceiling of care, dialysis initiation and resuscitation status early with family — frailty predicts outcome better than age

Latest Updates (2023–Present)

- **Surviving Sepsis Campaign 2026 guidelines** (Crit Care Med, April 2026) — the first full update since 2021, based on evidence to June 2025. Notable directions: **narrower empirical cover** (recommendation against anti-anaerobic agents in patients at low risk of anaerobic infection), acceptance in **low-resource settings that a single set of blood cultures** gives similar yield to multiple sets, stronger emphasis on taking cultures **before** antimicrobials (sensitivity falls by roughly a third within about 70 minutes of the first dose), and a new block on **post-sepsis recovery** — shared decision-making, structured discharge information and follow-up for new long-term impairments.
- **Post-sepsis syndrome** is now formally part of sepsis care: survivors need follow-up for new physical, cognitive and psychological impairment — especially relevant because delirium during sepsis predicts long-term cognitive decline.
- **PADIS Focused Update 2025:** dexmedetomidine over propofol for light sedation; enhanced mobilisation/rehabilitation over usual care; melatonin suggested; **no antipsychotic recommended for prevention or treatment**.
- **KDIGO-aligned practice** continues to stress full loading dose then renal dose adjustment, avoidance of nephrotoxins, and early nephrology involvement rather than fixed creatinine thresholds for RRT.
- **Indian context:** emphysematous pyelonephritis, diabetic foot sepsis, tuberculosis and mucormycosis are disproportionately common causes of septic shock in Indian diabetics. Access to continuous RRT is limited outside tertiary centres; the **Pradhan Mantri National Dialysis Programme** and **AB-PMJAY** cover much of the dialysis cost burden and should be mentioned in the social-care part of the answer.

Current Practice Update

Issue	Textbook / earlier position	Current practice (2023–2026)
Fluid resuscitation	Fixed 30 mL/kg crystalloid bolus	**Individualised, dynamically assessed** boluses — particularly in CKD and heart failure
Empirical antibiotics	Broadest possible cover	Broad but **targeted**; SSC 2026 advises against routine anti-anaerobic cover at low anaerobic risk; daily de-escalation review
Blood cultures	Two or more sets always	Still preferred, but **a single set is acceptable in low-resource settings**; taking them **before** antibiotics matters more than the number
Sedation choice	Propofol or dexmedetomidine over benzodiazepines	**Dexmedetomidine preferred over propofol** for light sedation and delirium reduction
Antipsychotics in ICU delirium	Recommended against routinely (PADIS 2018)	**No recommendation for or against treatment**; explicitly recommended **against for prevention**
After discharge	Little guidance	Formal **post-sepsis follow-up** for cognitive, physical and psychological sequelae

Exam One-Liners — Q3

- **Altered sensorium is an organ-failure sign** in sepsis (qSOFA item).
- Commonest source in a diabetic with CKD = **urinary tract**; think emphysematous pyelonephritis.
- **Cultures before antibiotics; antibiotics within 1 hour.**
- Noradrenaline first-line; target **MAP ≥ 65 mmHg**.
- In CKD — **load fully, then dose-adjust**; think **cefepime neurotoxicity**.
- **Source control within 6–12 hours.**
- RRT indications = **AEIOU**.
- Glucose target roughly **140–180 mg/dL**; stop sulfonylureas.
- Delirium care = **ABCDEF bundle** + CAM-ICU screening.
- Survivors need **post-sepsis follow-up** for cognitive decline.

Q4. Assessment of delirium

18 High-Yield Points

A. Principles

1. Assessment has **two distinct steps**: **screening** (a rapid bedside tool that flags possible delirium) and **diagnosis** (a full clinical evaluation against DSM-5 or ICD-10 criteria). A positive screen is not a diagnosis.
2. **Why delirium is missed:** the cognitive baseline is often unknown; there may be no reliable informant; symptoms **wax and wane**, so one assessment can look completely normal hours later; and **hypoactive delirium** is quiet and easily mistaken for tiredness, depression or "just being old".
3. **Anchor the assessment on the core features — attention, awareness and level of consciousness — not on behaviour.** This is the single most useful strategy when dementia coexists or when no informant is available.

B. Diagnostic criteria (gold standard)

4. **DSM-5:** (i) disturbance of **attention and awareness**; (ii) develops over a **short period**, a change from baseline, with **fluctuation** during the day; (iii) an additional disturbance in **cognition**; (iv) not better explained by a pre-existing, established or evolving neurocognitive disorder and not occurring in **coma**; (v) evidence of an underlying **medical condition, substance intoxication or withdrawal, or multiple aetiologies**.
5. **ICD-10** criteria are similar but add detail on **perceptual distortion (illusions, hallucinations), psychomotor disturbance, sleep–wake cycle disruption and emotional disturbance**.
6. **Kane's practical three questions** for any confused older patient: was the onset **acute** (hours to days)? Are there **physical factors** (illness, drugs, sensory deprivation)? Are there **psychological factors** (depression, psychosis) contributing?

C. Screening instruments (Pathy list)

7. **Confusion Assessment Method (CAM)** — the most widely used. Four features: **(i) acute onset and fluctuating course; (ii) inattention; (iii) disorganised thinking; (iv) altered level of consciousness.** Delirium is screened positive if **(i) AND (ii)** are present, **PLUS either (iii) OR (iv)**. **Sensitivity 94%, specificity 89%**, with high inter-rater reliability.
8. **Testing inattention at the bedside:** months of the year backwards, days of the week backwards, digit span 3 or 4 backwards; or simply observe that the patient is distracted or cannot follow the conversation.
9. **Testing disorganised thinking:** orientation to time and place, and observing an illogical flow of ideas.
10. **3D-CAM** — a structured **3-minute** interview with scripted questions. In patients **with dementia**: sensitivity 96%, specificity 86%. In patients **without dementia**: sensitivity 93%, specificity 96%.
11. **Ultra-brief screens:** the single best item is **"months of the year backwards"** (sensitivity 83%, specificity 69%); the best two-item screen is **"months of the year backwards" + "what is the day of the week?"** (sensitivity 93%, specificity 64%).
12. **CAM-ICU** — for intubated or non-verbal patients. Inattention is tested with the letter task ("squeeze my hand every time you hear the letter A" → **SAVEAHAART**); altered consciousness is any **RASS score other than 0**; disorganised thinking uses yes/no questions ("will a stone float on water?").
13. **Screening for delirium superimposed on dementia (DSD):** best single item = **"What day of the week is it?"**; best two items = **days of the week backwards + day of the week**; best three items add **"What type of place is this?"** and **"Does the patient appear sleepy?"**. Sensitivities are high (84%, 93%, 94%) but specificities low (41%, 30%, 42%) — so a **negative screen helps rule out** delirium, but a positive screen needs fuller evaluation.
14. **Other validated tools named in Pathy:** SPMSQ, Delirium Rating Scale and DRS-R-98, Delirium Symptom Interview, Delirium Assessment Scale, Cognitive Test for Delirium, NEECHAM Confusion Scale, Confusional State Evaluation, **Memorial Delirium Assessment Scale**, Delirium Index, Delirium Severity Scale, Delirium Detection Score, DDT-Pro, **bCAM**, **4AT**, and the Stanford Proxy Test for Delirium. **Prediction** tools: **E-PRE-DELIRIC** and Stanford's Algorithm for Predicting Delirium (SAPD).

D. Frequency and clinical rules

15. **Screening frequency:** hospitalised patients **at least daily**; post-acute care patients **weekly**; long-term care residents **monthly** — and at any time a clinician, carer or relative reports a change from baseline.
16. **Never explain away a positive item.** Do not attribute a failed test to being in hospital, being unwell, being old, having just had analgesia, or having slept badly — **sleep disturbance is itself part of delirium**.
17. **When in doubt, assume delirium.** If collateral history is unavailable or the patient is too drowsy to complete an interview, **delirium should be presumed until proven otherwise** because the adverse outcomes are so severe.
18. **After a positive screen**, proceed to a **comprehensive medical evaluation** — full history including collateral and drug history, examination, targeted investigations, and systematic review of every predisposing and precipitating factor in the DELIRIUM IS VERY PAINFUL table. Neuroimaging, LP and EEG only on specific indication.

Table 3. Choosing a tool

Tool	Time	Best used for	Performance / note
CAM	~5 min	General ward, the reference screen	Sens 94%, Spec 89%; needs the 4-feature algorithm
3D-CAM	3 min	Structured ward screening, including dementia	Sens 93–96%, Spec 86–96%
4AT	<2 min	Ward and emergency department; needs	NICE- and SIGN-endorsed; works in drowsy patients

		no training	
UB-2	<1 min	Very rapid triage screen	Sens 93%, Spec 64% — rule-out only
CAM-ICU	2–3 min	Intubated / non-verbal ICU patients	Uses RASS + letter A task
MDAS / DRS-R-98	10–20 min	Grading **severity** and monitoring response	Research and palliative care settings
E-PRE-DELIRIC	—	**Prediction** of who will become delirious	Used to target preventive resources

Latest Updates (2023–Present)

- **NICE CG103 (January 2023)** issued **new recommendations specifically on assessing and diagnosing delirium**, and the **4AT** is now the recommended short assessment tool in both NICE and SIGN guidance — a shift from CAM-only teaching.
- **APA 2025 guideline** recommends **systematic screening of at-risk patients** with a validated tool rather than clinical impression alone, and adds **assessment at transitions of care**, including before discharge, as a distinct requirement.
- A recurring criticism in the 2025 literature is that the new guideline still does not mandate a **standardised pre-discharge delirium assessment**, despite evidence that a large proportion of patients leave hospital still delirious — a useful discussion point in a viva.
- **Diagnostic label drift:** commentary accompanying the APA guideline notes that delirium is systematically **under-coded** and preferentially recorded as "toxic or metabolic encephalopathy" for reimbursement reasons — a reason why administrative data underestimate its true burden.
- **ICD-11** has replaced ICD-10 in progressive international rollout; delirium remains a neurocognitive disorder with essentially the same core features (disturbed attention, awareness and cognition with acute onset and fluctuation).
- **Indian data** continue to show a wide gap between **referral-detected** delirium (around 0.4% of inpatients) and **screening-detected** delirium (around 30% of elderly ICU patients, ~45% of these hypoactive) — the strongest possible argument for routine tool-based screening rather than waiting for a referral.

Current Practice Update

Issue	Pathy 6th edition	Current practice
Preferred rapid tool	CAM family emphasised; 4AT listed among many	**4AT recommended by NICE and SIGN** for routine ward and ED screening
Diagnostic standard	DSM-5 and ICD-10	DSM-5 remains; **ICD-11** replacing ICD-10 in coding
Screening timing	Daily in hospital, weekly post-acute, monthly in LTC	Unchanged, **plus explicit assessment at care transitions and before discharge**
Severity measurement	Several severity scales listed	Greater emphasis on tracking **severity and trajectory**, not just presence or absence
Under-diagnosis	Acknowledged	Now attributed partly to **coding practice** as well as clinical oversight

Exam One-Liners — Q4

- **Screening ≠ diagnosis.** CAM/4AT screen; DSM-5 / ICD-10 diagnose.
- CAM = **(1 AND 2) PLUS (3 OR 4)**.
- CAM sens **94%**, spec **89%**; 3D-CAM takes **3 minutes**.
- Best single bedside item = **months of the year backwards**.
- CAM-ICU uses **RASS** and the **SAVEAHAART** letter task.
- Screen **daily** in hospital, **weekly** post-acute, **monthly** in long-term care.
- **Never make excuses** for a positive item.
- In doubt — **assume delirium until proven otherwise**.
- DSD screens are **sensitive but not specific** — good for ruling out.
- **Hypoactive delirium is the commonest and the most missed.**

Q5. Strategies for prevention of delirium in elderly inpatients

18 High-Yield Points

A. The case for prevention

1. **Up to 30–40% of delirium is preventable** with multicomponent, non-pharmacologic measures — the single most quotable figure in this answer.
2. **Prevention is worth it because delirium is not benign:** it causes falls, pulled lines, functional decline, longer stay, institutionalisation, PTSD, depression, increased mortality, and a cost burden exceeding **$164 billion a year in the United States**.
3. **Delirium is not always reversible.** Up to **45% are still delirious at discharge**; persistence is **33% at 1 month, 26% at 3 months and 21% at 6 months**. In Alzheimer's disease, an episode of hospital delirium **doubles the rate of cognitive decline for the next five years**. Prevention is therefore the only truly effective intervention.
4. **Because delirium is multifactorial, prevention must be multicomponent.** Single interventions and single drugs fail.
5. **Step one is risk identification and education.** Identify high-risk patients on admission (age, cognitive impairment, frailty, sensory impairment, severe illness, polypharmacy) and **tell the patient and family**. The risk of postoperative delirium should be part of the **routine informed consent** for surgery.
6. **Families are active agents, not visitors.** Relatives should stay at the bedside to reassure and reorient, help with oral intake, and encourage mobility.

B. The Hospital Elder Life Program (HELP) — the original model

7. **HELP** delivers targeted, **protocol-driven interventions** matched to specific risk factors: orientation and cognitively stimulating therapeutic activities; a **non-pharmacologic sleep protocol**; **mobility three times daily** (ambulation, or range-of-motion exercises if non-ambulant); **limiting tethers**; correcting **visual and hearing** impairment; and **preventing dehydration**.
8. **Original HELP trial (Inouye, NEJM 1999):** delirium occurred in **15.0%** on usual-care units versus **9.9%** on the intervention unit (matched OR 0.60, 95% CI 0.39–0.92).
9. **HELP meta-analysis (2018):** across 14 studies, delirium incidence fell significantly (**OR 0.47, 95% CI 0.37–0.59**); three studies showed a **42% reduction in falls**; nine showed cost savings of **$1600–3800 per patient** in hospital costs and **$16,000 per person-year** in long-term-care costs in the following year. HELP now runs in over **200 hospitals worldwide**.
10. **Modified HELP (mHELP)** for elective abdominal surgery used just **three nurse-delivered daily protocols — orienting communication, oral hydration and nutritional assistance, and early mobilisation**. Result: **relative risk of delirium 0.44** (95% CI 0.23–0.83, P = 0.008) and a length of stay **two days shorter**. This is the model to quote for a resource-limited Indian ward.

C. The ICU model — the ABCDEF bundle

11. **ABCDEF bundle** (ICU Liberation Collaborative): **A**ssess, prevent and manage pain; **B**oth spontaneous awakening and spontaneous breathing trials; **C**hoice of analgesia and sedation; **D**elirium — assess, prevent and manage; **E**arly mobility and exercise; **F**amily engagement and empowerment.
12. **Evidence:** in a prospective multicentre cohort of over **15,000 patients in 68 US ICUs**, complete bundle performance reduced delirium (**adjusted OR 0.60, 95% CI 0.49–0.72, P < 0.0001**), increased ICU discharge, and reduced death or discharge to a facility other than home.

D. Medication strategy — the highest-yield single intervention

13. **Medication review is one of the most important areas of prevention.** Review what is prescribed *and* what should be deprescribed on every ward round.
14. **Classes to avoid or minimise:** antipsychotics, **benzodiazepines** (especially IV — paradoxical reactions), corticosteroids, **H2-receptor antagonists in renal impairment**, narcotics (especially **pethidine** and IV opioids), muscle relaxants, **antimuscarinics for overactive bladder**, first-generation antihistamines, and **zolpidem** and related Z-drugs.
15. Use explicit tools — **AGS Beers Criteria** and **STOPP/START** — with a pharmacist-led medication reconciliation, and check **QTc risk** for any psychotropic considered.
16. **Treat pain properly, but do not sedate behaviour.** Regular **paracetamol** reduces total opioid requirement; uncontrolled pain is itself a precipitant.

E. Environmental and systems measures

17. **Ward-level measures:** consistent nursing staff; clocks, calendars and familiar objects; day–night lighting discipline; noise reduction and clustering of night-time care; avoidance of unnecessary ward transfers; early removal of urinary catheters, IV lines and telemetry; falls prevention **without physical restraints**; bowel and bladder regimens to prevent impaction and retention.
18. **System level:** clinicians should not wait for a formal programme — implement the individual components with the interprofessional team, and **advocate for hospital-wide delirium prevention**. Dedicated models such as the **Delirium Room** (a four-bed area within an ACE unit with 24-hour nursing and **no physical restraints**) and the **T-A-DA method** demonstrate that agitated delirious patients can be managed safely without restraint or sedation.

Table 4. Prevention bundle mapped to risk factor

Risk factor	Preventive protocol
Cognitive impairment	Orientation board, repeated reorientation, cognitively stimulating activities, familiar objects, family

	presence
Sleep deprivation	Non-drug sleep protocol — warm drink, relaxation, back rub, noise reduction, no night-time observations or drugs unless essential
Immobility	Ambulation or range-of-motion exercises **three times daily**; minimise tethers; physiotherapy input
Visual impairment	Spectacles, magnifiers, large-print materials, adequate lighting
Hearing impairment	Hearing aids with working batteries, earwax removal, amplification device
Dehydration	Early recognition, oral hydration assistance, volume repletion; monitor **BUN:creatinine ratio**
Undernutrition	Feeding assistance, dentures, nutritional supplements
Pain	Regular assessment; scheduled paracetamol; avoid pethidine
Polypharmacy	Beers / STOPP-START review; deprescribe; pharmacist involvement
Hypoxia / infection	Early detection and treatment; oxygen titration; avoid unnecessary catheters
Constipation / retention	Bowel chart and regimen; bladder scanning; avoid indwelling catheters

Latest Updates (2023–Present)

- **APA 2025 delirium guideline** — its single most important change, in the authors' own words, is the **additional emphasis on prevention**. It requires identification of at-risk individuals, a thorough medication and risk-factor history, and structured **transition-of-care** processes.
- **PADIS Focused Update 2025** — three positive conditional recommendations relevant to prevention: **dexmedetomidine over propofol** for light sedation, **enhanced mobilisation/rehabilitation over usual care**, and **melatonin** in ICU patients. Equally important is the negative recommendation: **do not use haloperidol, atypical antipsychotics, dexmedetomidine, statins or ketamine to prevent delirium**.
- **NICE CG103 (2023)** maintains the multicomponent prevention package and singles out **benzodiazepines, opioids and anticholinergics** as the pharmacological precipitants to target first.
- **Family involvement** in preventing delirium in critically ill patients was supported by a 2025 systematic review and meta-analysis — converting the older "families should help" advice into a formal, evidence-based bundle element.
- **AGS Beers 2023 and the AGS Beers Alternatives List (2025)** make deprescribing actionable by naming **safer substitutes** for insomnia, anxiety, pain and agitation, with a strong "less is more" and non-drug-first orientation.
- **Risk-factor evidence refreshed:** a 2025 meta-analysis identified **frailty, physical restraints, previous falls, illness severity, cognitive impairment and older age** as the dominant modifiable and non-modifiable risks — notably placing **physical restraints** among the leading risk factors, which reinforces restraint-free care.
- **Indian application:** the full HELP programme is resource-intensive, but the **three-protocol mHELP model** (orienting communication, oral hydration and nutrition, early mobilisation) is deliverable by ward nurses and family attendants at negligible cost. Geriatric wards and dedicated staff under **NPHCE**, and the presence of a family attendant in most Indian hospital beds, make an mHELP-style bundle the most realistic national strategy.

Current Practice Update

Issue	Pathy 6th edition	Current practice (2023–2026)
Overall emphasis	Prevention described alongside treatment	**Prevention is now the headline recommendation** (APA 2025)
Drug prophylaxis	Antipsychotics not supported for prevention	**Explicit recommendation against** antipsychotics, dexmedetomidine, statins and ketamine for prevention
Melatonin	Not recommended	**Conditionally suggested** in ICU patients
Mobilisation	Encouraged (three times daily in HELP)	**Enhanced mobilisation/rehabilitation formally recommended** over usual care
Family engagement	Encouraged	**Evidence-supported bundle component** with meta-analytic backing
Restraints	Avoid	Identified as an **independent risk factor**; permitted only for **imminent harm**
Discharge	Comprehensive discharge planning	Structured **transitions of care** — medication reconciliation, delirium follow-up, caregiver psychoeducation

Exam One-Liners — Q5

- **30–40% of delirium is preventable.**
- HELP trial: delirium **15.0% → 9.9%** (OR 0.60); meta-analysis **OR 0.47**, falls down **42%**.
- HELP targets six risk factors: **cognition, sleep, immobility, vision, hearing, dehydration**.
- mHELP = **orienting communication + oral hydration/nutrition + early mobilisation**; RR 0.44, LOS 2 days shorter.
- ICU = **ABCDEF bundle**; full compliance gives adjusted **OR 0.60** for delirium.
- **No drug prevents delirium** — not antipsychotics, statins, ketamine or dexmedetomidine.
- **Medication review is the highest-yield single preventive act.**
- **Physical restraints are a risk factor, not a safety measure.**
- Postoperative delirium risk belongs in the **surgical consent** discussion.

- Delirium Room + **T-A-DA** = restraint-free management of agitated delirium.

Recurring Topic — Extra Points to Remember

> Delirium appears in this question set five times. These are the details that separate a pass from a distinction, and the traps examiners most often set.

1. Numbers worth memorising

Figure	Value
Delirium in ICU	30–80%
Delirium in general medical / oncology wards	18–35%
Delirium in hospice care	26–44%
Delirium in nursing home / post-acute care	16%
Cardiac and vascular surgery	29–50%
Hip fracture repair	12–48%
Pooled prevalence in hospitalised older medical patients (2025 meta-analysis)	23.6%
Pooled incidence in the same group	13.5%
Preventable proportion	30–40%
Still delirious at discharge	up to 45%
Persistent at 1 / 3 / 6 months	33% / 26% / 21%
CAM sensitivity / specificity	94% / 89%
HELP: delirium usual care vs intervention	15.0% vs 9.9% (OR 0.60)
HELP meta-analysis odds ratio	0.47 (95% CI 0.37–0.59)
mHELP relative risk / LOS	RR 0.44; 2 days shorter
ABCDEF bundle (15,000 patients, 68 ICUs)	adjusted OR 0.60
US annual cost of delirium	> $164 billion
BUN : creatinine ratio associated with delirium	> 17 : 1

2. Named things you must be able to expand

- **SIFH** — Systems Integration Failure Hypothesis (Maldonado): the unifying pathophysiological model.
- **T-A-DA** — Tolerate, Anticipate, Don't Agitate.
- **DELIRIUM IS VERY PAINFUL** — the Pathy causes-and-contributors mnemonic (21 items).
- **ABCDEF** — the ICU Liberation bundle.
- **HELP / mHELP** — Hospital Elder Life Program and its three-protocol modification.
- **DSD** — delirium superimposed on dementia; **POD / POCD** — postoperative delirium and postoperative cognitive dysfunction (different entities, different mechanisms).
- **Cystocerebral syndrome** — delirium precipitated by acute urinary retention.
- **Delirium Room** — restraint-free, 24-hour-nursed four-bed area within an ACE unit.
- **E-PRE-DELIRIC / SAPD** — delirium prediction models.

3. Traps and common mistakes

- **Trap:** equating delirium with agitation. **Hypoactive delirium is the commonest subtype and carries the worst prognosis** because it is missed.
- **Trap:** ordering a CT head for every confused patient. Imaging is **indication-driven**.
- **Trap:** giving a benzodiazepine for a restless patient. It **precipitates and prolongs** delirium; the only exceptions are **alcohol and benzodiazepine withdrawal**.
- **Trap:** assuming delirium is always transient and fully reversible. It is not.
- **Trap:** restraining a patient who pulls at lines. Restraints are an **independent risk factor** for delirium; remove the line instead, or occupy the hands.
- **Trap:** attributing behaviour in a patient with dementia to the dementia. This causes **under-diagnosis of delirium and a missed serious illness**.
- **Trap:** writing "prescribe haloperidol" as the management answer. Non-pharmacologic multicomponent care is the mainstay; drugs are a rescue for imminent harm only.
- **Trap:** forgetting the simple bedside causes — **retention, impaction, pain, dehydration, spectacles and hearing aids**. These are what examiners want to hear.

4. Indian context to add for extra marks

- **Under-recognition is worse in India:** referral-based studies detect delirium in under 1% of inpatients while CAM-ICU screening finds around 30% of elderly ICU patients delirious, most of them hypoactive.

- **Family attendants** are present at almost every Indian hospital bed — formally enlisting them for orientation, hydration, feeding and mobilisation converts a staffing constraint into an evidence-based intervention.
- **NPHCE** geriatric wards and regional geriatric centres provide the structure in which a nurse-led mHELP-type bundle can be implemented at almost no cost.
- **AB-PMJAY**, the **Ayushman Vay Vandana Card** for those aged 70 and above, and the **Pradhan Mantri National Dialysis Programme** are the financing routes relevant to the septic CKD patient in Q3.
- **Tuberculosis, emphysematous pyelonephritis, diabetic foot sepsis and mucormycosis** deserve specific mention in Indian sepsis and confusion vignettes.
- **Alcohol withdrawal** is a very common and under-declared cause of ward delirium in Indian men — always take a corroborated alcohol history and give **parenteral thiamine before glucose**.

5. Fifteen-second answer skeleton (use for any delirium question)

> **Define** (acute, fluctuating, inattention, medical cause) → **Burden** (common, costly, preventable, under-diagnosed) → **Pathogenesis** (SIFH) → **Predisposing + Precipitating** (DELIRIUM IS VERY PAINFUL) → **Differentiate** (dementia, depression, psychosis, NCSE) → **Screen and diagnose** (CAM/4AT then DSM-5) → **Targeted workup** → **Treat the cause** → **Multicomponent non-pharmacologic care + T-A-DA** → **Drugs only for imminent harm** → **Prevent** (HELP/mHELP/ABCDEF, medication review) → **Prognosis and follow-up** (persistence, cognitive decline, transitions of care).

EXAMINATION ANSWER COMPILATION

DEMENTIA AND COGNITIVE DISORDERS

Questions 1–10

Primary reference: *Pathy's Principles and Practice of Geriatric Medicine, 6th edition* and *Kane's Essentials of Clinical Geriatrics*

Supplemented with: International guidelines and evidence 2023 – present, with Indian clinical and policy context

Prepared for: Sudarsan — MD Geriatric Medicine, Postgraduate Examination Revision

QUESTION 1

Discuss dementia in the elderly and its management.

15–20 High-Yield Points

A. DEFINITION AND NOSOLOGY

1. Dementia is a **clinical syndrome of sustained, acquired loss of intellectual function and memory**, severe enough to cause **dysfunction in daily living**, occurring in **clear consciousness**. Loss of functional ability due to impaired cognition is the key feature separating dementia from mild cognitive impairment.

2. Its cardinal features are a **gradually progressive course** (months to years) and **no disturbance of consciousness** — the two features that distinguish it from delirium. **DSM-5 renamed dementia "major neurocognitive disorder"** and introduced "mild neurocognitive disorder" for the MCI range.

B. EPIDEMIOLOGY

3. Dementia is broadly grouped into **reversible or partially reversible** and **non-reversible** types. **Reversible dementia accounts for under 4%** of cases, but concurrent treatable medical conditions causing mild cognitive disturbance are far commoner.

4. Alzheimer's disease (AD) and **vascular dementia** account for the vast majority in older people and **frequently coexist in the same patient (mixed dementia)**. **Dementia with Lewy bodies contributes 15–25%** in autopsy and clinical series. Approximately **6–8% of persons over 65 have AD**, with prevalence **doubling every 5 years** so that nearly **30% of those over 85** are affected.

5. Indian data: the **LASI-DAD** nationally representative study estimates dementia prevalence at **7.4% in adults aged 60+**, equating to about **8.8 million Indians**, projected to reach **16.9 million by 2036**. Prevalence is **higher in women than men and in rural than urban areas**, with wide state variation (Delhi 4.5% to Jammu & Kashmir 11.0%).

C. AETIOLOGY AND RISK FACTORS

6. Non-reversible causes are grouped as **degenerative** (AD, Lewy body disease, Parkinson's disease, Pick's disease, Huntington's disease, PSP), **vascular** (multi-infarct, Binswanger's disease, arteritis, post-anoxic), **traumatic** (including dementia pugilistica) and **infective** (HIV, Creutzfeldt–Jakob disease, progressive multifocal leukoencephalopathy, post-encephalitic).

7. Age and family history are the primary risk factors for AD. The **apolipoprotein E ε4 allele on chromosome 19** is the strongest genetic linkage with late-onset AD (relative risk ~2.5 in whites), but it is **neither sensitive nor specific and is not recommended as a screening test**. Rare mutations on **chromosomes 1, 14 and 21** cause early-onset familial AD.

D. PATHOPHYSIOLOGY

8. In AD, **progressive neuronal degeneration produces neurotransmitter abnormalities**, with a **combined cholinergic and glutamatergic dysfunction** underlying the symptomatology — this is the rationale for all currently licensed symptomatic drugs. **Amyloid-β deposition and hyperphosphorylated tau (neurofibrillary tangles)** are the defining neuropathological lesions.

9. Vascular pathology acts additively or synergistically with AD pathology: vascular lesions lower the threshold of AD pathology needed to produce dementia, and AD pathology increases the risk of dementia after stroke. Hence in a patient with AD plus cerebrovascular disease, **both conditions require treatment even if the vascular component seems trivial**.

E. CLINICAL FEATURES AND STAGING

10. Patients most commonly present with **memory loss, poor concentration, depression, behavioural change or language difficulty**. **Questioning both the patient and an informant is vital** to gauge impact on usual activities, lifestyle, history of the cognitive disorder and the key issue of **functional decline**.

11. Severity is graded with the **Global Deterioration Scale (GDS)**, the **Clinical Dementia Rating (CDR)** and the **MMSE — mild 20–24, moderate 10–19, severe below 9**. The **MMSE is dependent on sociocultural level and shows a ceiling effect**; the **Severe Impairment Battery (SIB)** is used when impairment is too severe for standard testing.

12. Neuropsychiatric symptoms occur in 90–98% of people with dementia over the disease course and may **precede the diagnosis**; they drive caregiver burden and institutionalisation.

F. DIAGNOSIS AND INVESTIGATION

13. Recommended baseline studies: complete blood count, **glucose**, blood urea, electrolytes (**sodium mEq/L, potassium mEq/L**), **calcium and phosphorus (mg/dL)**, liver function tests, **TSH (µIU/mL)**, **vitamin B12 (pg/mL)**, and serology for **syphilis and HIV if suspected**, together with **CT or MRI of the head**. Neuropsychological testing is reserved for selected patients.

14. Imaging is done to **exclude treatable structural causes** — subdural haematoma, tumour, normal-pressure hydrocephalus. **Cerebral atrophy alone does not establish AD.** Functional imaging aids differentiation: **HMPAO-SPECT shows temporoparietal hypoperfusion in AD, anterior hypoperfusion in FTD, multiple focal deficits in VaD; FP-CIT SPECT distinguishes DLB and parkinsonian syndromes from AD**.

G. MANAGEMENT

15. General principles: treat any reversible or partially reversible cause; **optimise therapy of comorbid conditions**; counsel families about the stages of dementia, drugs to avoid and excessive alcohol; discuss **behavioural symptom strategies, advance directives and future planning early**. **Treat hypertension** to prevent further lacunar infarcts, provided side effects are avoided.

16. Four pharmacological approaches (Kane's framework): (i) **avoid drugs that worsen cognition**, principally those with strong **anticholinergic activity**; (ii) **agents that enhance cognition and function**; (iii) **treat coexisting depression**; (iv) **treat complications** — paranoia, delusions, psychosis, agitation.

17. Cholinesterase inhibitors — donepezil (1996), rivastigmine (2000), galantamine (2001) — increase available acetylcholine; approved for **mild to moderately severe AD**, with **donepezil also approved for severe AD**. Pooled benefit is a **mean improvement of −2.7 points (95% CI −3.0 to −2.3) on the 70-point ADAS-Cog**.

18. Memantine, a **voltage-dependent, low-affinity, uncompetitive NMDA receptor antagonist**, blocks pathologically elevated glutamate and is approved for **moderate to severe AD**. **Combination of a ChEI with an NMDA antagonist gives better symptomatic effect.** In the **DOMINO trial**, continuing donepezil in moderate-to-severe AD gave **cognitive and functional benefit over 12 months**.

19. Vascular dementia: cholinesterase inhibitors are **not recommended for pure VaD** but should be used in **mixed dementia** once both AD and vascular components are demonstrated. **Antithrombotics need caution when lobar microbleeds are present on MRI** because of amyloid angiopathy and haemorrhage risk. **Levodopa may help apraxic gait** in subcortical ischaemic vascular disease.

20. Non-pharmacological management is central: **physical exercise is the single most efficient strategy for dementia prevention**, with multicomponent aerobic plus strength protocols reducing cortical atrophy in executive-control areas; cognitive interventions build **cognitive reserve**. Caregiver education and support, structured routine, meaningful activity, task simplification and environmental safety form the backbone of behavioural management.

Latest Updates (2023–Present)

- **Lancet Commission on Dementia Prevention, Intervention and Care (2024)** expanded the modifiable risk factor list from 12 to **14**, adding **high midlife LDL cholesterol (PAF 7%)** and **untreated vision loss in late life (PAF 2%)** to low education, hearing loss, hypertension, smoking, obesity, depression, physical inactivity, diabetes, excess alcohol, traumatic brain injury, air pollution and social isolation. **Up to 45% of dementia is theoretically preventable.**
- **Anti-amyloid monoclonal antibodies have entered practice**: **lecanemab** received full FDA approval in **July 2023** on the strength of **CLARITY-AD**, and **donanemab** was approved in **July 2024** following **TRAILBLAZER-ALZ 2**; both slow decline modestly in **early symptomatic AD (MCI or mild dementia) with confirmed amyloid pathology**. The **EMA restricted use to non-APOE ε4 homozygotes**, and **aducanumab was discontinued in 2024**.
- **Amyloid-related imaging abnormalities (ARIA)** dominate safety: serial **MRI monitoring is mandatory**, risk is **APOE ε4 dose-dependent** and greatest in the **first year**. Appropriate-use recommendations advise against treatment in **probable cerebral amyloid angiopathy** and in patients on anticoagulants.
- **Blood-based biomarkers have transformed diagnosis.** The **FDA cleared the Lumipulse G pTau217/β-amyloid 1-42 plasma ratio in May 2025** for symptomatic adults ≥55 years, with **91.7% positive and 97.3% negative concordance with amyloid PET/CSF**. The **Alzheimer's Association Clinical Practice Guideline (AAIC 2025)** recommends blood biomarker tests with **≥90% sensitivity and ≥75% specificity as a triaging test**, and those with **≥90% sensitivity and specificity as a substitute for amyloid PET or CSF**.
- **The 2024 Alzheimer's Association revised criteria** define AD **biologically** by Core 1 biomarkers (amyloid PET, CSF Aβ42/40, p-tau217, p-tau181, p-tau231) and Core 2 biomarkers (tau PET, MTBR-tau243), with **clinical staging separated from biological staging** — a decisive shift from the syndromic NINCDS-ADRDA approach.
- **Agitation now has licensed therapy**: **brexpiprazole was FDA-approved in May 2023** as the first drug for agitation in AD dementia (CMAI effect size ~0.35), and **dextromethorphan–bupropion (AXS-05) was approved in 2026** on the basis of **ADVANCE-1 and ACCORD-2** as the first **non-antipsychotic** option.

- **WHO ICOPE (2nd edition)** embeds **cognitive decline screening within integrated care for older people**, directly applicable to India's **NPHCE** platform.

Current Practice Update

Domain	Textbook position	Current evidence and guidelines (2023 onward)
Diagnosis	Clinical criteria plus structural imaging; biomarkers and amyloid PET largely research tools	**Biological diagnosis by biomarkers**; FDA-cleared **plasma p-tau217** ratio replaces PET/CSF in many pathways
Disease modification	"No disease-modifying drug is available at present"	**Lecanemab and donanemab approved** for early AD with confirmed amyloid; modest benefit, ARIA risk, restricted eligibility
Prevention	Exercise the most efficient strategy; 12 risk factors	**14 modifiable risk factors, ~45% preventable**; LDL cholesterol and vision loss added
Agitation	All drugs off-label; risperidone best short-term evidence	**Brexpiprazole (2023)** and **dextromethorphan–bupropion (2026)** now formally licensed
Indian epidemiology	Global estimates cited	**LASI-DAD: 7.4% of those 60+, 8.8 million cases, 16.9 million by 2036**

Exam One-Liners

- Dementia = acquired, progressive cognitive decline with **functional impairment in clear consciousness**.
- **Functional loss** separates dementia from MCI; **clear sensorium** separates it from delirium.
- India: **7.4% prevalence, 8.8 million cases (LASI-DAD)**.
- **AD + VaD coexist commonly**; mixed pathology outnumbers pure AD at autopsy.
- **APOE ε4** = strongest late-onset risk allele; **not a screening test**.
- MMSE staging: **mild 20–24, moderate 10–19, severe <9**.
- ChEI pooled benefit = **−2.7 ADAS-Cog points**.
- Memantine = **uncompetitive NMDA antagonist**, moderate-to-severe AD.
- **DOMINO** = continue donepezil in moderate/severe disease.
- **Lancet Commission 2024** = **14 risk factors, 45% preventable**.
- **Exercise** = most efficient single preventive strategy.

QUESTION 2

Dementia.

> **Note:** This question repeats Question 1 in condensed form. A **rapid-recall sheet** is given below rather than a repeated full answer — use it for final-night revision and refer to Question 1 for the expanded treatment.

Rapid-Recall Sheet — Dementia

1. DEFINITION IN ONE LINE

Acquired, progressive, sustained decline in memory and other cognitive domains causing loss of function in daily living, in clear consciousness (DSM-5: major neurocognitive disorder).

2. THE THREE-QUESTION TRIAGE BEFORE DIAGNOSING DEMENTIA

1. Was the onset **acute** (hours to days)? → think **delirium**
2. Are there **physical factors** (illness, sensory deprivation, drugs)? → think **reversible contribution**
3. Are there **psychological factors** (depression, psychosis)? → think **pseudodementia**

3. CAUSES — THE NUMERICAL ANCHORS

Type	Share
Alzheimer's disease	**50–60%**
Vascular / vascular cognitive impairment	**15–25%**
Dementia with Lewy bodies	**15–25%** (autopsy series)
Frontotemporal lobar degeneration	**3–20%**; 2nd commonest under 65
Truly reversible	**<4%**

4. CORTICAL VS SUBCORTICAL — THE DISCRIMINATOR TABLE

Feature	Cortical	Subcortical
Memory	Prominent impairment	Milder deficit
Executive function	Usually present	**Prominent**
Cortical signs	Aphasia, apraxia, agnosia	Absent
Mood	Less prominent	**Depression, lability, apathy**
Motor	Field cut, UMN signs	**Gait disturbance, extrapyramidal signs, dysphagia**
Example	AD, large-vessel VaD	Small-vessel VaD, PDD, PSP

5. INVESTIGATION PANEL (MEMORISE AS A BLOCK)

Blood: CBC · glucose · blood urea · electrolytes · **calcium and phosphorus (mg/dL)** · LFT · **TSH (µIU/mL)** · **vitamin B12 (pg/mL)** · VDRL and HIV if suspected **Imaging: CT or MRI head** — mandatory in recent-onset dementia, unexplained picture, or focal signs **Selected:** neuropsychological testing · CSF Aβ42 and p-tau · amyloid/FDG-PET · **plasma p-tau217**

6. MANAGEMENT IN FOUR LINES

1. **Treat reversible causes and comorbidity**; control vascular risk factors
2. **Stop anticholinergics and other cognition-worsening drugs**
3. **ChEI for mild–moderate AD; memantine for moderate–severe; combine for added symptomatic effect**
4. **Non-pharmacological first for behaviour** — DICE approach, caregiver training, exercise, structured routine, safe environment

7. INDIAN CONTEXT IN ONE PARAGRAPH

LASI-DAD: 7.4% prevalence in 60+, 8.8 million cases, projected 16.9 million by 2036, higher in women and rural residents. Care is delivered through **NPHCE** (district geriatric units, regional geriatric centres), **Elder Line 14567**, **AB-PMJAY and the Ayushman Vay Vandana Card** for those 70+, the **Maintenance and Welfare of Parents and**

Senior Citizens Act, 2007 for neglect and abandonment, **Rashtriya Vayoshri Yojana** for assistive devices and **ARDSI** for caregiver support and the Dementia India reports.

8. WHAT CHANGED AFTER THE TEXTBOOK

Anti-amyloid antibodies (**lecanemab 2023, donanemab 2024**) · **plasma p-tau217 FDA-cleared 2025** · **2024 Alzheimer's Association biological criteria** · **Lancet Commission 2024: 14 risk factors, 45% preventable** · **brexpiprazole 2023 and dextromethorphan–bupropion 2026 for agitation**.

QUESTION 3

Mild cognitive impairment — diagnostic criteria, progression and treatment modalities.

15–20 High-Yield Points

A. CONCEPT AND DEFINITION

1. The MCI construct originated with **Ronald Petersen and the Mayo Clinic group**, and has been repeatedly revised as biomarker science advanced, chiefly to locate MCI within the **prodromal phase of Alzheimer's disease**.

2. MCI is defined by **(i) a subjective disorder of memory and/or other cognitive domains, (ii) objective impairment of memory and/or other cognitive domains, and (iii) no significant impact on activities of daily living**. Patients therefore **do not meet accepted diagnostic criteria for dementia**.

3. Old age alone does not cause cognitive impairment severe enough to render a person dysfunctional. Slowed thinking, slowed reaction time, mild recent memory loss and impaired executive function may occur with age and **may or may not progress to dementia** — labelled **MCI** or **cognitive impairment, not dementia (CIND)**.

4. MCI is **heterogeneous**: it may be due to AD (prodromal AD), other neurodegenerative disease, **depression, vascular lesions or traumatic brain injury**.

B. CORE CLINICAL CRITERIA (NIA-AA 2011)

5. Concern regarding a change in cognition — obtained from the patient, an informant, or a clinician observing the patient.

6. Impairment in one or more cognitive domains — performance lower than expected for the patient's **age and education**.

7. Preservation of independence in functional abilities — mild difficulty with complex tasks is common, but independence is maintained **with minimal aids or assistance**.

8. Not demented — changes are mild enough that there is **no significant impairment of social or occupational functioning**. Note that **no defined thresholds** are specified for the degree of cognitive impairment; the syndrome is almost identical to Petersen's original description.

C. RESEARCH CRITERIA AND BIOMARKERS

9. NIA-AA biomarkers fall into three classes: **(i) markers directly reflecting AD pathology** — CSF **low Aβ42**, amyloid PET, CSF **raised total tau or p-tau**; **(ii) non-specific markers of neuronal injury** — atrophy on MRI, hypometabolism or hypoperfusion on FDG-PET/SPECT; **(iii) markers of cell death, synaptic damage, oxidative stress or inflammation**.

10. Levels of diagnostic certainty: MCI due to AD "high likelihood" = positive Aβ **and** positive neuronal-injury biomarker; **"intermediate likelihood"** = one positive with the other untested; **"unlikely due to AD"** = both negative. Results may also be **uninformative** if ambiguous or conflicting.

11. The **International Working Group (Dubois)** criteria for **prodromal AD** run in parallel: **IWG-1** requires abnormal amyloid, tau, FDG-PET or hippocampal atrophy; **IWG-2** requires **abnormal CSF Aβ1-42 and tau, or abnormal amyloid PET**. They also separate **typical AD** (amnestic syndrome of hippocampal type) from **atypical AD** (posterior cortical atrophy, logopenic variant, frontal variant).

12. The **NIA-AA 2018 Research Framework** introduced the **AT(N) classification**: **A** = aggregated Aβ (CSF Aβ42 or Aβ42/40, amyloid PET); **T** = aggregated tau (CSF p-tau, tau PET); **(N)** = neurodegeneration, non-specific and hence bracketed (MRI, FDG-PET, CSF total tau). It uses the label **"Alzheimer's disease with MCI"** rather than "MCI due to AD".

13. DSM-5 replaced dementia with **major neurocognitive disorder** and introduced **mild neurocognitive disorder (mNCD)**, which parallels MCI — cognitive complaint, psychometric impairment and relative preservation of ADLs.

D. EPIDEMIOLOGY AND PROGRESSION

14. Just over 20% of people aged 71 and older in the United States have **cognitive impairment without dementia**.

15. Progression: up to 15–20% of those diagnosed with MCI or CIND convert to dementia over the course of a year. Progression is not inevitable — a proportion remain stable and some revert to normal, especially where depression or drugs were contributory.

16. Subjective cognitive decline (SCD) precedes MCI; cross-sectional studies show SCD does not necessarily correlate with objective impairment, but **longitudinal studies link SCD to future AD or dementia**. A cognitively unimpaired subject with a **positive AD biomarker** is regarded as **at risk of AD or in a preclinical stage**.

E. TREATMENT MODALITIES

17. No intervention has been shown to prevent progression to dementia in classical practice; the therapeutic implications of MCI remain an area of intensive research. **Cholinesterase inhibitors are not licensed for MCI**, and European practice prescribes them less often than American practice.

18. Identify and treat contributory conditions: depression (SSRI such as **citalopram or sertraline**, or **mirtazapine**, all with minimal cognitive side effects), **hypothyroidism, vitamin B12 deficiency, drug side effects, obstructive sleep apnoea and alcohol excess**; and **withdraw anticholinergic drugs**.

19. Vascular risk factor control, especially hypertension, may favourably influence the clinical course of both degenerative and vascular cognitive impairment. **Physical activity and multicomponent exercise** carry the most promising evidence, supported by the **FINGER trial** of multidomain intervention; the **MAPT trial** of omega-3 with or without multidomain intervention was largely negative except in amyloid-positive subgroups.

20. Practical management includes an **informed discussion of diagnosis and prognosis**, arrangements for **ongoing review and support**, cognitive training and stimulation, driving and safety assessment, and advance planning. Most countries, **including India, lack national guidelines on biomarker use in early AD**, which limits harmonisation of practice.

Latest Updates (2023–Present)

- **MCI due to AD is now a treatable diagnosis.** Both **lecanemab (CLARITY-AD)** and **donanemab (TRAILBLAZER-ALZ 2)** are licensed specifically for **MCI due to AD or mild AD dementia with biomarker-confirmed amyloid pathology** — the first time an MCI-stage diagnosis carries a disease-modifying option.
- **Eligibility is biomarker-gated:** amyloid must be confirmed by **amyloid PET, CSF, or now an approved blood test**. Treatment requires **APOE genotyping** (ε4 homozygotes have the highest ARIA risk; excluded in the EU), **baseline and serial MRI**, and caution with anticoagulants and probable cerebral amyloid angiopathy.
- **Plasma biomarkers have reached the MCI clinic.** The **Alzheimer's Association Clinical Practice Guideline (2025)** covers patients **with objective cognitive impairment including MCI**, endorsing **p-tau217, %p-tau217, p-tau181, p-tau231 and Aβ42/Aβ40** with the two accuracy thresholds (**≥90/≥75% for triage; ≥90/≥90% as a substitute for PET or CSF**). The **FDA-cleared Lumipulse G pTau217/Aβ1-42 ratio (May 2025)** is indicated for symptomatic adults ≥55 years — precisely the MCI population.
- **The 2024 Alzheimer's Association revised criteria** stage AD biologically and clinically in parallel, replacing "MCI due to AD" with **clinical Stage 3 (mild cognitive impairment) of the Alzheimer's continuum** in biomarker-positive individuals.
- **Risk reduction is now the mainstay for non-AD MCI:** the **Lancet Commission 2024** framework — hearing aids for hearing loss, cataract surgery and correction of vision loss, LDL and blood pressure control, physical activity, social engagement — carries the strongest population-level evidence, with **US POINTER (2025)** confirming benefit of structured multidomain lifestyle intervention in at-risk older adults.
- **Indian relevance:** biomarker access remains restricted to a few tertiary centres; **MCI detection in India rests on culturally validated cognitive tools** (Hindi Mental State Examination, ACE-III adaptations, LASI-DAD battery, AIIMS Comprehensive Neuropsychological Battery in Hindi) and on the **NPHCE** and **ICOPE** screening platforms rather than on plasma or CSF assays.

Current Practice Update

Aspect	Textbook position	Current evidence and guidelines (2023 onward)
Therapeutic implications	"No intervention has been shown to prevent progression to dementia"	**Anti-amyloid antibodies licensed for MCI due to AD**; modest slowing of decline, not prevention
Biomarker access	Most countries lack national guidelines; unequal access limits practice	**Blood biomarkers (p-tau217) FDA-cleared and guideline-endorsed**, greatly widening access
Terminology	MCI due to AD (2011) / AD with MCI (2018 framework)	**2024 criteria: biologically defined AD, clinical Stage 3**
Conversion risk	15–20% per year	Confirmed, but **biomarker-positive MCI converts far faster than biomarker-negative MCI**, which often remains stable or reverts
Lifestyle intervention	FINGER promising, MAPT largely negative	**US POINTER (2025)** supports structured multidomain lifestyle intervention in at-risk older adults

Exam One-Liners

- MCI = **subjective complaint + objective impairment + preserved ADLs + not demented**.
- Four core clinical criteria: **concern, objective impairment, preserved function, not demented**.
- **No thresholds are specified** for degree of impairment — a common examiner trap.
- **Conversion 15–20% per year**; **20% of those over 71 have CIND**.
- **AT(N)**: A = amyloid, T = tau, **(N) = neurodegeneration, non-specific**.
- IWG-2 prodromal AD = **abnormal CSF Aβ1-42 and tau, or abnormal amyloid PET**.
- DSM-5 equivalent = **mild neurocognitive disorder**.
- **ChEIs are not licensed for MCI.**
- **Lecanemab and donanemab are licensed at the MCI stage** when amyloid is confirmed.
- **FINGER positive, MAPT negative, US POINTER positive** for multidomain lifestyle intervention.

QUESTION 4

Reversible / treatable dementias — investigation and management.

RECURRING TOPIC ALERT — Reversible dementias appear repeatedly in MD Geriatrics papers, usually as a 15-mark long question or as a "how will you investigate a patient with cognitive decline" case. Additional recall scaffolding is given at the end of this answer.

15–20 High-Yield Points

A. DEFINITION AND SCALE OF THE PROBLEM

1. Dementia in older people is grouped into **reversible or partially reversible** and **non-reversible** types. The reversible group is the **clinically indispensable minority**: they are few in number but represent the cases where diagnosis changes outcome.

2. Reversible dementia accounts for probably less than 4% of cases. However, **concurrent medical conditions causing mild cognitive disturbance are much commoner and are potentially treatable** — identifying them avoids unnecessary disability and misdiagnosis even when cognition does not fully normalise.

3. An important caveat: **finding a reversible cause does not guarantee that the dementia will improve once that cause is treated.** Thyroid hormone and vitamin B12 replacement may be important for general health but **have not been shown to reverse established cognitive deficits**.

B. CAUSES — THE CLASSIFIED LIST

4. Neoplasms — primary and secondary intracranial tumours, and paraneoplastic/limbic encephalitis.

5. Metabolic and endocrine disorders — hypothyroidism, hyperparathyroidism, hyponatraemia, hypercalcaemia, hepatic and renal failure, hypoglycaemia.

6. Nutritional disorders — **vitamin B12 deficiency**, folate deficiency, thiamine deficiency (**Wernicke–Korsakoff syndrome**), pellagra.

7. Trauma — **chronic subdural haematoma**, post-traumatic states, dementia pugilistica (the last irreversible).

8. Toxins — **alcoholism**, heavy metals (lead, mercury, arsenic, manganese), organic poisons.

9. Drugs — the single most important reversible cause in practice: **anticholinergics and antihistamines, narcotic and non-narcotic analgesics, NSAIDs, anticonvulsants, antihypertensives, antiparkinsonian drugs, digoxin, antiarrhythmics, H2 receptor antagonists, antianxiety drugs, antidepressants, antipsychotics, sedative-hypnotics, skeletal muscle relaxants, steroids and alcohol**.

10. Infections — **HIV and opportunistic infections**, neurosyphilis, tuberculous meningitis, chronic fungal meningitis, viral encephalitis, Whipple's disease.

11. Autoimmune disorders — **CNS vasculitis, temporal arteritis, systemic lupus erythematosus, multiple sclerosis**, and autoimmune encephalitis.

12. Psychiatric disorders — **depression ("depressive pseudodementia")**.

13. Other — **normal-pressure hydrocephalus**, obstructive sleep apnoea, and severe sensory deprivation from uncorrected hearing and visual loss.

C. DEPRESSIVE PSEUDODEMENTIA — A SPECIAL CASE

14. Depression coexists with dementia in more than one-third of outpatients with dementia and in an even greater proportion in nursing homes. Many patients with early dementia become depressed, and depression may be diagnosed before dementia becomes evident.

15. Clinical pointers to depression as the cause: **prominent complaints of memory loss** (contrast with the concealment typical of AD), **patchy and inconsistent cognitive deficits** on examination, and **frequent "don't know" answers**. **Detailed neuropsychological testing** helps, and where doubt persists, **a careful trial of an antidepressant is justified** both diagnostically and therapeutically.

16. Important prognostic point: **older patients who develop reversible cognitive impairment while depressed are at relatively high risk of developing dementia over the following few years** and need close cognitive follow-up.

D. INVESTIGATION

17. These disorders are detected by careful history, physical examination and selected laboratory studies. The **recommended panel** is: complete blood count, **glucose**, blood **urea nitrogen**, **electrolytes (sodium and potassium**

in mEq/L), **calcium and phosphorus (mg/dL)**, liver function tests, **thyroid-stimulating hormone (µIU/mL)**, **vitamin B12 (pg/mL)**, **serological test for syphilis if suspected**, and **HIV antibodies if suspected**.

18. CT or MRI of the head should be performed to exclude unsuspected correctable structural lesions in patients with **dementia of recent onset in whom no other clinical finding explains the dementia**, and in those with **focal neurological signs or symptoms** — chiefly to exclude **subdural haematoma, tumour and normal-pressure hydrocephalus**. **CT and MRI are roughly equivalent for detecting remediable structural lesions**; MRI shows more lesions in multi-infarct dementia but also white-matter changes of uncertain significance.

19. Neuropsychological testing is valuable when the mental status score is normal but function or behaviour has changed (high baseline intelligence), when the score is low without functional deficit (low educational level), and specifically for **differentiating depression from dementia**.

E. MANAGEMENT

20. Withdraw or substitute every drug that may be worsening cognition, especially those with **strong anticholinergic activity**, and maintain a **high index of suspicion for excessive alcohol intake**, which is easily missed and causes dementia, delirium, depression and falls. **Treat depression energetically** with an SSRI such as **citalopram or sertraline**, or the NaSSA **mirtazapine**, all of which have minimal cognitive side effects. **Correct B12 deficiency, hypothyroidism, hyponatraemia and hypercalcaemia; refer NPH for shunt assessment and chronic subdural haematoma for neurosurgical evaluation; treat neurosyphilis, HIV and tuberculous meningitis specifically; and control vascular risk factors, especially hypertension**, which may favourably influence the course of both degenerative and vascular cognitive impairment.

Latest Updates (2023–Present)

- **Shunting for iNPH now has randomised placebo-controlled proof.** The **PENS trial (NEJM, 2025; 99 patients, 17 centres)** compared open with placebo shunt settings: **gait velocity improved by 0.21 m/s more with an open shunt (p<0.001)**, and **80% of the open-shunt group achieved meaningful improvement versus 24% with placebo**, with better balance and fewer falls. **Cognition and continence did not improve significantly** — an important nuance. This settles the long-standing debate and strengthens the case for shunting the one classically reversible dementia.
- **Autoimmune and antibody-mediated encephalitis** is now firmly established as a treatable cause of subacute cognitive decline in older adults — **LGI1, CASPR2, NMDAR and GAD65 antibodies** should be tested when there is **rapid progression over weeks to months, seizures (especially faciobrachial dystonic seizures with LGI1), hyponatraemia, movement disorder or psychiatric prominence**; immunotherapy can produce dramatic recovery.
- **Rapidly progressive dementia** is a recognised diagnostic emergency: the working rule is that **decline to dementia within 12 months** mandates urgent search for **autoimmune, infective, neoplastic, metabolic and toxic causes** before accepting Creutzfeldt–Jakob disease, using CSF **RT-QuIC**, 14-3-3, autoantibody panels and MRI DWI.
- **Deprescribing has been formalised.** The **AGS Beers Criteria (2023 update)** reinforce avoidance of **strongly anticholinergic drugs, benzodiazepines, Z-drugs and first-generation antihistamines** in older adults, and **anticholinergic burden scales (ACB, ARS)** are now recommended for routine calculation in memory clinics.
- **Obstructive sleep apnoea and untreated hearing and vision loss** have moved from footnote to mainstream: the **Lancet Commission 2024** added **untreated vision loss** as a modifiable risk factor, and **ACHIEVE (2023)** showed hearing aids slowed cognitive decline in older adults at increased risk. Both are practical, high-yield reversible contributors in Indian practice.
- **Indian context: B12 deficiency and hypothyroidism are disproportionately common**, given widespread vegetarianism and iodine-related thyroid disease, making the B12/TSH pair particularly high-yield in Indian memory clinics. **Neurosyphilis, HIV-associated neurocognitive disorder and tuberculous meningitis** remain far commoner reversible causes here than in Western series. **NPHCE district geriatric units and ICOPE screening** are the practical platform for early detection.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
NPH shunting	Surgery, with risk–benefit carefully assessed; efficacy debated	**PENS trial (2025)** — randomised, placebo-controlled proof of **gait** benefit; cognition and continence do not reliably improve
Autoimmune causes	CNS vasculitis, SLE, MS listed	**Antibody-mediated encephalitis (LGI1, CASPR2, NMDAR, GAD65)** now a defined, immunotherapy-responsive category
B12 and thyroid replacement	Not shown to reverse cognitive deficits	Position unchanged; treat for **general health and to prevent further decline**, not with the expectation of cognitive reversal
Sensory impairment	Sensory deprivation noted as contributory	**ACHIEVE (2023)**: hearing aids slow decline in at-risk elders; **vision loss added to Lancet Commission list (2024)**
Drug-induced cognitive impairment	List of offending drug classes	Formalised through **AGS Beers 2023** and routine **anticholinergic burden scoring** with structured deprescribing

Extra Recall Points — Recurring Topic

MNEMONIC FOR REVERSIBLE DEMENTIAS: "DEMENTIA"

Letter	Cause
D	**D**rugs (anticholinergics, sedatives, opioids, steroids) and **D**epression
E	**E**motional (pseudodementia) and **E**ndocrine (hypothyroidism, hyperparathyroidism)
M	**M**etabolic (Na^+, Ca^{2+}, uraemia, hepatic failure)
E	**E**yes and **E**ars — sensory deprivation
N	**N**utritional (**B12**, folate, thiamine) and **N**ormal-pressure hydrocephalus
T	**T**umour, **T**rauma (chronic subdural haematoma)
I	**I**nfection (HIV, syphilis, TB meningitis) and **I**nflammatory/autoimmune
A	**A**lcohol and toxins

NUMERICAL ANCHORS

- Reversible dementia: **<4%** of all dementias
- Depression coexists in **>1/3** of dementia outpatients
- Rapidly progressive dementia = decline to dementia in **<12 months**
- **PENS trial: gait velocity gain 0.21 m/s; 80% vs 24% meaningful improvement**

NAMED ENTITIES TO QUOTE

Clarfield's analyses (small proportion truly reversible) · **Hospital Elder Life Program (HELP)** for delirium prevention overlap · **PENS trial 2025** · **ACHIEVE 2023** · **AGS Beers Criteria 2023** · **Lancet Commission 2024**

COMMON EXAMINER TRAPS

1. Saying reversible dementias are common — they are **<4%**; the value of the search is that the yield, though small, is decisive.
2. Claiming B12 and thyroid replacement reverse dementia — the textbook explicitly states **they have not been shown to do so**.
3. Forgetting that **drugs are the commonest single reversible contributor** and the easiest to correct.
4. Omitting **normal-pressure hydrocephalus and chronic subdural haematoma** — both are surgically treatable.
5. Diagnosing dementia during an episode of delirium — **the diagnosis of dementia must await treatment of all potentially reversible causes of delirium**.
6. Failing to mention that **treating a reversible cause may not restore cognition** but still prevents excess disability.

15-SECOND ANSWER SKELETON

Define → state <4% truly reversible but always worth seeking → classify causes (drugs, depression, metabolic/endocrine, nutritional, structural, infective, autoimmune, NPH) → investigation panel (bloods + TSH + B12 + CT/MRI) → management (deprescribe, treat depression, correct deficiencies, surgical referral for NPH and subdural, control vascular risk) → caveat that reversal is not guaranteed → Indian angle (B12, hypothyroidism, neurosyphilis, HIV, TB meningitis).

Exam One-Liners

- **<4%** of dementias are truly reversible; concurrent treatable conditions are far commoner.
- **Finding the cause does not guarantee reversal.**
- **Drugs** are the commonest reversible contributor — anticholinergics first.
- Depressive pseudodementia: **prominent memory complaints, patchy deficits, "don't know" answers**.
- Depression coexists with dementia in **over one-third** of outpatients.
- Panel: **CBC, glucose, urea, electrolytes, calcium/phosphorus, LFT, TSH, B12, VDRL and HIV if suspected, CT/MRI head**.
- **CT and MRI are equivalent** for detecting remediable structural lesions.
- Structural causes to exclude: **subdural haematoma, tumour, NPH**.
- Treated depression with cognitive impairment → **high risk of later dementia**; follow up closely.
- **PENS 2025**: shunting improves **gait**, not cognition or continence.

QUESTION 5

Behavioural symptoms of dementia.

15–20 High-Yield Points

A. DEFINITION AND TERMINOLOGY
