1. Neuropsychiatric symptoms (NPSs), also called **behavioural and psychological symptoms of dementia (BPSD)**, are defined as **signs and symptoms of disturbed perception, thought content, mood or behaviour** occurring in a person with dementia.

2. They encompass **depression, anxiety, apathy, irritability, disinhibition, agitation, rejection of care, aggression, elation, and problems with eating or sleeping**. They may occur **before, during or after the diagnosis of dementia**, and may be **among the earliest signs of incipient cognitive decline**.

B. EPIDEMIOLOGY

3. 90 to 98% of people with dementia develop at least one NPS over the course of the disease; the prevalence of NPS therefore mirrors the overall prevalence of dementia. NPSs occur **across all dementia types and all stages**.

4. In **Alzheimer's disease the commonest NPS is apathy**, followed by **depression, aggression, anxiety, sleep disturbance, irritability, appetite disturbance, motor problems, delusions, disinhibition, hallucinations and euphoria**.

C. AETIOLOGY — THE FIVE CONTRIBUTORY DOMAINS

5. Neurodegeneration-associated factors — the underlying disease process itself, with cholinergic, serotonergic and frontal-subcortical circuit disruption.

6. Acute medical issues — pain, infection (especially urinary and respiratory), constipation, urinary retention, dehydration, drug changes, poor sleep and sensory impairment. **Pain is a common and frequently missed cause of agitation**, and occasionally **a trial of a scheduled analgesic is the only way to establish it**.

7. Pre-existing personality and psychiatric illness, **unmet needs** (hunger, boredom, need for toileting, need for company), **caregiver factors** (communication style, unrealistic expectations, countertherapeutic approach) and **environmental factors** (clutter, poor lighting, over- or under-stimulation, unfamiliar surroundings).

D. ASSESSMENT

8. The standard instruments are the **Neuropsychiatric Inventory (NPI)**, its questionnaire form **NPI-Q**, and the clinician version **NPI-C**; the **Cohen-Mansfield Agitation Inventory (CMAI)** for agitation; and the **Cornell Scale for Depression in Dementia (CSDD)** for mood, which relies on both patient and informant.

9. Always exclude delirium first. Delirium superimposed on dementia (DSD) is common and is identified by the **Confusion Assessment Method (CAM) — acute onset and fluctuating course, plus inattention, plus either disorganised thinking or altered level of consciousness**.

E. THE DICE APPROACH

10. DICE — Describe, Investigate, Create, Evaluate — was developed by a US national expert panel (geriatric medicine, geriatric psychiatry, psychology, nursing, social work, pharmacy and behavioural science) as a **step-by-step method for assessing and managing NPS**, designed for use by **any health professional in a team setting**.

11. Describe — elicit a thorough description from the caregiver, characterising the symptom and the **context in which it occurs**, including possible **antecedents or triggers**, and identifying which aspects are **most distressing to the patient and caregiver**.

12. Investigate — examine, exclude and identify **modifiable underlying causes**: patient factors (medical issues, pain, medication change, poor sleep, sensory change), caregiver factors (communication and expectations) and environmental contribution (clutter, lighting, stimulation level).

13. Create — collaborate with caregiver, patient and team on a treatment plan built on **five generalised strategies: caregiver education; enhancing effective communication; creating meaningful activities; simplifying tasks and establishing structured routines; and ensuring safety while simplifying and enhancing the environment**.

14. Evaluate — assess whether strategies were implemented, whether target symptoms improved, whether caregiver distress fell and whether there were unintended effects. **If a psychotropic was used, consider a trial of dose reduction or discontinuation.**

F. NON-PHARMACOLOGICAL TREATMENT

15. Family and paid caregiver interventions have the strongest evidence base and a greater effect than antipsychotics. Efficacy is best in **mild and moderate stages**, when cognitive and communication functions are better preserved. Individual approaches such as **music therapy and physical activity** work best when embedded within **tailored-activity programmes**. Environmental adjustments work best **in combination** rather than singly.

G. PHARMACOLOGICAL TREATMENT

16. There are no FDA-approved drugs for NPSs in AD in the classical position — the sole exception being **pimavanserin for hallucinations and delusions in Parkinson's disease**. In the **European Union and Canada, risperidone is indicated for short-term treatment of severe aggression**. Most agents are therefore used **off-label**.

17. Antipsychotics: modest efficacy for agitation/aggression and psychosis is supported for four atypicals — **risperidone, aripiprazole, olanzapine and quetiapine** — with **risperidone having the best evidence for short-term (6–12 week) efficacy in agitation**. Use is limited by **increased risk of stroke and death**.

18. Antidepressants: the **DIADS** trial showed benefit of **sertraline** in AD with major depression, but **DIADS-2 was negative**, as was the **HTA-SADD** comparison of sertraline, mirtazapine and placebo; meta-analysis shows **small-to-null effect sizes**. **Citalopram (target 30 mg) in the CitAD trial reduced agitation, anxiety, irritability and caregiver distress**, but caused **cognitive decline and QTc prolongation** at that dose. **Trazodone** is widely used for **night-time agitation and sleep**, stabilising circadian rhythm.

19. Other classes: benzodiazepines lack trial evidence and should be reserved **for crises only**, using short- to intermediate-acting agents such as **lorazepam or oxazepam**. **Valproate and carbamazepine have not shown benefit and cause significant adverse effects** — sedation, gait disturbance and tremor. **Cholinesterase inhibitors and memantine have not shown sufficient evidence for NPSs in AD**, although ChEIs do help NPSs in **DLB, Parkinson's disease dementia and cognitive impairment in PD**, at the cost of increased parkinsonian symptoms such as tremor.

20. Expert consensus (International Delphi process) endorses an **escalating approach**: identify underlying causes first; then **caregiver training, environmental adaptation, person-centred care and tailored activities** as first-line for overall NPS and agitation; then, if drugs are needed, **citalopram and analgesia before antipsychotics**. For **psychosis specifically, pharmacological options and particularly risperidone are prioritised** after assessing underlying causes. **DICE and music therapy** were agreed as the most promising non-pharmacological approaches.

Latest Updates (2023–Present)

- **Agitation in AD now has two licensed drugs. Brexpiprazole (Rexulti) was FDA-approved in May 2023** — the first approval for any neuropsychiatric symptom of dementia — showing **~31% reduction in agitation versus placebo**, with **CMAI effect size ~0.35** and CGI-S benefit significant only in the 3 mg group. It **retains the class boxed warning for increased mortality in elderly patients with dementia-related psychosis**.
- **Dextromethorphan–bupropion (AXS-05, Auvelity) was FDA-approved in 2026** as the **first non-antipsychotic** treatment for AD agitation. Dextromethorphan acts as an **NMDA receptor antagonist and sigma-1 agonist**, with bupropion inhibiting CYP2D6 to sustain levels. **ADVANCE-1** showed CMAI improvement versus placebo at week 5, and **ACCORD-2** showed **delayed relapse (HR 0.276) and reduced relapse incidence (8.4% vs 28.6%)** over 26 weeks of randomised withdrawal. It carries a **boxed warning for suicidal thoughts and behaviours** and is contraindicated with **seizure disorder, eating disorders, recent alcohol/benzodiazepine withdrawal and MAOIs**.
- **Pimavanserin** remains approved only for **Parkinson's disease psychosis**; the **HARMONY** trial in dementia-related psychosis showed relapse prevention but did not secure a broader indication.
- **International Psychogeriatric Association (IPA) 2023 provisional consensus definition of agitation in cognitive disorders** now standardises the syndrome for both trials and practice, requiring **excessive motor activity, verbal aggression or physical aggression causing excess distress or disability**.
- **Non-pharmacological evidence has strengthened**: **WHELD** and subsequent person-centred care packages, tailored activity programmes and **music-based interventions (Cochrane 2022–2025)** show consistent modest benefit on agitation and depressive symptoms with no drug-related harm, reinforcing their first-line position.
- **Deprescribing antipsychotics** is now a formal quality indicator in many systems, supported by **AGS Beers 2023** and by evidence that gradual withdrawal is safe in most long-term care residents without severe baseline symptoms.
- **Indian context:** BPSD is a leading driver of caregiver distress and institutionalisation in India, where **over 90% of care is family-provided**. Practical supports include the **National Mental Health Programme and District Mental Health Programme**, **NPHCE geriatric clinics**, **Elder Line 14567**, and **ARDSI** caregiver training. **Antipsychotic access is unregulated and off-label use is common**, making structured DICE-style caregiver training the most realistic first-line strategy.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Licensed drugs for agitation	No FDA-approved drug for NPS in AD; all off-label except pimavanserin in PD psychosis	**Brexpiprazole (2023)** and **dextromethorphan–bupropion (2026)** are FDA-approved for AD agitation
First-line approach	Non-pharmacological first; caregiver interventions outperform antipsychotics	Unchanged and reinforced — **DICE, person-centred care, tailored activity, music therapy**
Citalopram	CitAD: effective but cognitive decline and QTc prolongation at 30 mg	Position unchanged; **escitalopram (S-CitAD, 2024) did not separate from placebo**, so the SSRI role remains uncertain
Definition of agitation	Descriptive	**IPA 2023 consensus definition** standardises the syndrome
Antipsychotic use	Modest efficacy; stroke and mortality risk	**Deprescribing is now a formal quality indicator**; gradual withdrawal safe in most residents

Exam One-Liners

- **90–98%** of people with dementia develop at least one NPS.
- **Apathy is the commonest NPS in AD**, followed by depression and aggression.
- **DICE = Describe, Investigate, Create, Evaluate.**
- The five "Create" strategies: **educate, communicate, meaningful activity, simplify tasks/routine, safe environment**.
- **Caregiver interventions outperform antipsychotics.**
- **Risperidone** has the best short-term evidence for agitation; only EU/Canada licence it.
- **CitAD**: citalopram 30 mg reduces agitation but causes **cognitive decline and QTc prolongation**.
- **Valproate and carbamazepine are ineffective** and harmful.
- **ChEIs and memantine do not help NPS in AD** but do help in DLB and PDD.
- **Always exclude pain, infection, constipation, retention and delirium first.**
- New licences: **brexpiprazole 2023; dextromethorphan–bupropion 2026**.

QUESTION 6

Compare and contrast the clinical features and brain areas involved in the four common dementias.

15–20 High-Yield Points

A. FRAMEWORK

1. The **four common dementias** are **Alzheimer's disease (AD)**, **vascular dementia (VaD)**, **dementia with Lewy bodies (DLB)** and **frontotemporal dementia (FTD/FTLD)**. **AD and VaD account for the vast majority** and frequently coexist; **DLB is the second commonest neurodegenerative dementia (15–20% of autopsy series)**; **FTLD accounts for 3–20%** and is the **second commonest dementia under age 65**.

2. A useful organising principle is the **cortical versus subcortical** distinction: **cortical dementias** show prominent memory impairment with heteromodal cortical symptoms (aphasia, apraxia, agnosia); **subcortical dementias** show prominent executive dysfunction, milder memory deficit, perseveration, mood change, gait disturbance and extrapyramidal signs.

B. ALZHEIMER'S DISEASE

3. Brain areas: earliest involvement of the **entorhinal cortex and hippocampus (medial temporal lobe)**, spreading to **temporoparietal association cortex** and **posterior cingulate/precuneus**, with relative sparing of primary motor and sensory cortex until late. **Severe temporal lobe atrophy and hippocampal or insular hyperintensities** are typical on MRI.

4. Clinical features: insidious onset with **amnestic syndrome of the hippocampal type** — impaired encoding and storage with poor benefit from cueing — followed by **language, visuospatial and executive decline**, then apraxia and agnosia. **Apathy is the commonest NPS.** Motor signs and falls are late.

5. Imaging signature: HMPAO-SPECT shows temporoparietal hypoperfusion; **FDG-PET shows temporoparietal and posterior cingulate hypometabolism**; **PIB-PET amyloid imaging is highly sensitive and specific, even at preclinical stages**.

C. VASCULAR DEMENTIA

6. Brain areas depend on vessel size. Large-vessel disease produces cortical infarcts in strategic locations: **frontal lobe** (aphasia, apraxia, disinhibition, apathy), **hippocampus and basal forebrain** (amnesia), **gyrus angularis** (construction problems), **parietal lobe** (alexia, agraphia) — giving a **cortical type of dementia**.

7. Small-vessel disease produces subcortical infarcts in the **thalamus, caudate nucleus and internal capsule**, disrupting **specific frontal–subcortical circuits or non-specific thalamocortical circuits**, producing **executive dysfunction, attention deficit, apathy and personality change** — a **subcortical type of dementia**. **Subcortical ischaemic vascular disease (SIVD)** — the **lacunar state and Binswanger's disease** — is the **commonest subtype (82.2% small-vessel versus 25.9% large-vessel in one study)**.

8. Clinical course: classically **abrupt onset with stepwise deterioration and a fluctuating course with plateaus** in cortical VaD; but **60% have slow, less abrupt onset and 80% slow progression** with or without stepwise decline. SIVD causes **slow, subacute-onset dementia with executive dysfunction, impaired attention and slowed processing speed, with comparatively mild memory deficit**.

9. Motor signature: "lower-half parkinsonism" with **hesitation, marche à petit pas and diminished step height**. **Crucially, the triad of dementia, urinary incontinence and gait disturbance is more often produced by small-vessel VaD than by normal-pressure hydrocephalus** — a favourite examiner point.

10. Imaging: basal ganglionic and thalamic hyperintense foci, thromboembolic infarcts, confluent white matter and irregular periventricular hyperintensities (leukoencephalopathy). **Leukoencephalopathy involving at least 25% of total white matter is required** to diagnose small-vessel cerebrovascular disease. SPECT shows **multiple focal deficits**.

D. DEMENTIA WITH LEWY BODIES

11. Brain areas and pathology: α-synuclein-positive Lewy bodies and Lewy neurites, with **presynaptic α-synuclein aggregates** thought to be the synapto-toxic species. Three distribution patterns: **brainstem-predominant (PDD phenotype)**, **cerebral cortex-predominant (DLB phenotype)** and **transitional**. **Concomitant AD pathology is present in 90% of Lewy body disease cases**, and there is **relative preservation of medial temporal lobe structures** on MRI.

12. Core clinical features: fluctuating cognition with pronounced variation in attention and alertness;

recurrent vivid visual hallucinations; REM sleep behaviour disorder, which may precede cognitive decline; and spontaneous parkinsonism. The neuropsychological profile is **dysexecutive**, with **prominent visuospatial impairment even early**, while amnesia may be mild initially.

13. Imaging signature: reduced dopamine transporter uptake in basal ganglia on SPECT/PET; **abnormal (low) uptake on 123I-MIBG myocardial scintigraphy**; **reduced occipital activity on perfusion/metabolism scans** (contrasting with posterior parietotemporal reduction in AD); and the **posterior cingulate island sign on FDG-PET**, which is sensitive and specific for DLB. **EEG shows prominent posterior slow-wave activity with periodic pre-alpha/theta fluctuations.**

E. FRONTOTEMPORAL LOBAR DEGENERATION

14. Brain areas: relatively circumscribed, often asymmetric frontal and anterior temporal atrophy. **bvFTD** — frontal and/or anterior temporal cortex with later basal ganglia involvement; **semantic dementia** — anterior temporal lobe (left or right variant); **progressive non-fluent aphasia — left inferior frontal lobe, anterior insula and basal ganglia**. SPECT shows **diminished anterior perfusion**.

15. Clinical features by variant: bvFTD (≥70%) — early, profound change in **personality and social conduct** with **disinhibition, apathy, social withdrawal, loss of empathy, hyperorality and dietary change, diminished insight, neglect of hygiene, mental rigidity, perseveration and stereotypic behaviour**, with **relative preservation of memory, spatial skills and praxis**. **Semantic dementia (~15%)** — loss of word and object meaning with fluent, empty speech. **PNFA (~10%)** — **non-fluent effortful speech, agrammatism, phonological paraphasia, anomia**, with preserved single-word comprehension early.

16. Distinguishing epidemiology: onset most commonly between 45 and 65, **equal gender distribution**, **family history in ~40% of first-degree relatives**, and **faster cognitive and functional decline with shorter survival than AD** — about **9 years in FTLD-U and tau-positive groups but under 3 years in FTLD-MND**.

F. COMPARATIVE SUMMARY

17. The red flags that should arouse suspicion of non-Alzheimer dementia, most salient early in the course: **prominent executive dysfunction, marked speech disturbance, marked behavioural change (disinhibition, euphoria, stereotyped behaviour, apathy, self-neglect), frequent falls, vivid visual hallucinations, focal neurological deficit, extrapyramidal signs, vertical gaze limitation, and asymmetric apraxia or dystonia**.

Master Comparison Table

Feature	Alzheimer's disease	Vascular dementia	Dementia with Lewy bodies	Frontotemporal dementia
Share of dementias	50–60%; commonest	15–25%	15–20% (autopsy)	3–20%; 2nd commonest under 65
Typical age at onset	>65, rising steeply with age	>65, follows vascular events	50–90	**45–65**
Brain areas	Entorhinal cortex, **hippocampus**, temporoparietal association cortex, posterior cingulate	**Large vessel:** frontal, hippocampus, angular gyrus, parietal. **Small vessel:** thalamus, caudate, internal capsule, periventricular white matter	**Cortical + brainstem** Lewy bodies; occipital hypometabolism; **medial temporal lobe relatively preserved**	**Frontal and anterior temporal**, asymmetric; left inferior frontal/insula in PNFA
Pathology	Amyloid plaques, **neurofibrillary tangles (tau)**	Infarcts, lacunes, leukoaraiosis, microbleeds	**α-synuclein Lewy bodies**; AD pathology co-exists in 90%	**TDP-43 proteinopathy 50–60%, tauopathy 35–45%**
First symptom	**Episodic memory loss**	Executive dysfunction / focal deficit	**Fluctuating attention, visual hallucinations, RBD**	**Personality and social conduct change** or language
Memory	**Prominent, early**	Milder in small-vessel type	Mild early; **better delayed recognition** than AD	**Relatively preserved early**
Executive function	Later	**Prominent early**	Prominent (dysexecutive)	**Prominent early**
Visuospatial	Moderate, later	Variable	**Prominent even early**	Preserved early
Hallucinations	Late, uncommon	Uncommon	**Recurrent, vivid, well-formed — up to 80%**	Uncommon
Motor features	Late	**Lower-half parkinsonism, marche à petit pas**, focal signs	**Parkinsonism in ~75%**, symmetrical, less levodopa-responsive	Late parkinsonism; MND in a subset
Course	Slow, steady	**Stepwise** (cortical) or slow (subcortical)	Fluctuating; **6–10 years**	**Faster than AD**; ~9 years, <3 years if MND
Key imaging	Temporoparietal hypoperfusion; **PIB-PET positive**	Leukoencephalopathy **≥25% of white matter**; multiple focal SPECT deficits	**Low DAT uptake; abnormal MIBG; cingulate island sign; occipital hypometabolism**	**Anterior (frontotemporal) hypoperfusion**; focal asymmetric atrophy
Drug caution	—	Antithrombotics if lobar microbleeds	**Severe neuroleptic sensitivity**	Enhanced extrapyramidal sensitivity to antipsychotics

Latest Updates (2023–Present)

- **Biological rather than clinical definition of AD**: the **2024 Alzheimer's Association revised criteria** define AD by **Core 1 biomarkers** (amyloid PET, CSF Aβ42/40, **p-tau217**, p-tau181, p-tau231) and **Core 2 biomarkers** (tau PET, MTBR-tau243), with clinical staging (Stages 1–6) run in parallel. Clinical phenotype no longer defines the disease.
- **Plasma biomarkers now aid differential diagnosis** as well as detection: **p-tau217 is highly specific for AD pathology**, while **elevated NfL with negative amyloid** points away from AD toward FTD, vascular or other neurodegeneration, and **GFAP** adds an astroglial/neuroinflammatory dimension. The **Alzheimer's Association Clinical Practice Guideline (2025)** formalises their use in specialist settings.
- **Vascular cognitive impairment (VCI)** has displaced "vascular dementia" as the preferred umbrella, spanning **vascular MCI to VaD and mixed pathology**; **VASCOG and the harmonised VICCCS criteria** have superseded the older **NINDS-AIREN and ADDTC** criteria, which had good specificity (excluding ~90% of AD) but **only modest sensitivity (50–70%)** and frequently misclassified mixed dementia.
- **DLB diagnosis** continues to be underdetected; the **fourth consensus criteria (McKeith et al.)** gave increased weighting to **RBD and 123I-MIBG scintigraphy**, and current work focuses on **α-synuclein seed amplification assays (SAA/RT-QuIC in CSF and skin)**, which achieve high diagnostic accuracy and are moving toward a **biological definition of Lewy body disease**.
- **FTD genetics and therapeutics:** the three major genes are **MAPT, GRN (progranulin) and C9orf72**. The **Phase 3 INFRONT-3 trial of latozinemab in FTD-GRN (2025) failed its clinical primary endpoint** despite raising

plasma progranulin, and the programme was discontinued — reinforcing that **FTD treatment remains symptomatic**. Gene-replacement trials (**PROCLAIM, ASPIRE-FTD, upliFT-D**) continue.

- **Mixed pathology is the rule, not the exception**, in the very old; **autopsy series consistently show mixed AD plus vascular pathology outnumbering pure AD**, and **LATE (limbic-predominant age-related TDP-43 encephalopathy)** is now recognised as a distinct, common amnestic mimic of AD in those over 80.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Defining AD	Clinical criteria (NINCDS-ADRDA, DSM) with biomarker support	**2024 criteria: biological definition** by Core 1 and Core 2 biomarkers
VaD nomenclature	Vascular dementia; NINDS-AIREN and ADDTC criteria	**Vascular cognitive impairment (VCI)** spectrum; **VASCOG/VICCCS** criteria
DLB confirmation	Clinical core features plus DAT-SPECT and MIBG	**α-synuclein seed amplification assays** approaching biological diagnosis
FTD treatment	Symptomatic — SSRIs, trazodone, bupropion for apathy	Unchanged; **INFRONT-3 (2025) negative**, no disease-modifying therapy available
Old-age amnestic syndrome	Attributed to AD or mixed disease	**LATE (TDP-43)** recognised as a common independent cause after age 80

Exam One-Liners

- **AD** = medial temporal/hippocampal + temporoparietal → **amnesia first**.
- **VaD large-vessel** = cortical infarcts → cortical dementia; **small-vessel** = thalamus/caudate/internal capsule → subcortical dementia.
- **SIVD is the commonest VaD subtype**; leukoencephalopathy must involve **≥25% of white matter**.
- The **dementia + incontinence + gait triad is commoner in small-vessel VaD than in NPH**.
- **DLB** = fluctuation + visual hallucinations + RBD + parkinsonism, with **occipital hypometabolism and cingulate island sign**.
- **DLB spares the medial temporal lobe** — a key MRI contrast with AD.
- **FTD** = frontal/anterior temporal, **onset 45–65**, family history in 40%, **behaviour or language first**.
- **bvFTD 70%, semantic dementia 15%, PNFA 10%**.
- **FTLD survival ~9 years; under 3 years with motor neurone disease.**
- Non-AD red flags: **early executive/behavioural change, falls, visual hallucinations, extrapyramidal signs, vertical gaze palsy, asymmetric apraxia**.

QUESTION 7

Neurodegenerative disorders associated with Tau, Progranulin or TDP-43 pathology — pathology, presentation, course, prognosis and treatment.

15–20 High-Yield Points

A. OVERARCHING CONCEPT

1. These three molecules define the **frontotemporal lobar degeneration (FTLD) spectrum** and its close relatives. **FTLD is neuropathologically, genetically and clinically heterogeneous**, and the term FTLD is preferred to "dementia" because **patients may have progressive neurological dysfunction for substantial periods before meeting criteria for a dementia syndrome**.

2. Histopathological dichotomy: FTLD divides broadly into **FTLD-tauopathy** and **FTLD-U/TDP-43** types on immunohistochemistry. **More than 95% of FTLD cases are either TDP-43 proteinopathies (50–60%) or tauopathies (35–45%)**, with dementia lacking distinctive histopathology (DLDH) and TDP-43-negative ubiquitinated inclusions making up the remaining **5%**.

3. Historical evolution: FTLD was originally split into **tau-positive pathology with or without Pick's bodies** and **dementia lacking distinctive histopathology (DLDH)**. Improved immunohistochemistry showed that most "DLDH" cases actually contain **ubiquitin-positive, tau-negative intraneuronal inclusions** — some with motor neurone disease (**FTLD-MND**) and some without (**FTLD-U**).

4. TDP-43 (TAR DNA-binding protein 43) was then identified as the **major pathogenic protein underlying sporadic and familial FTLD-U and FTLD-MND, and also amyotrophic lateral sclerosis** — the discovery that unified the FTD–ALS spectrum.

B. GENETICS

5. Family history of dementia is present in about 40% of first-degree relatives. About **10% of familial and 0–3% of sporadic cases** are linked to specific mutations.

6. Tau route: many mutations occur in the **microtubule-associated protein tau (MAPT) gene on chromosome 17**, collectively termed **FTD with parkinsonism linked to chromosome 17 (FTDP-17)** in familial cases with parkinsonism.

7. Progranulin route: mutations in the **progranulin (GRN/PRGN) gene on chromosome 17** cause **TDP-43 proteinopathy**. Progranulin mutations are **loss-of-function**, reducing progranulin in plasma and CSF with **over 90% penetrance** — the basis for progranulin-elevating therapeutic strategies.

8. The **valosin-containing protein (VCP) gene** also produces TDP-43 pathology, causing the rare autosomal dominant **inclusion body myopathy with Paget's disease of bone and FTD (IBMPFD)**. **C9orf72** hexanucleotide repeat expansion is the third major gene, linking FTD and ALS.

C. CLINICO-PATHOLOGICAL CORRELATION

9. Although overlap prevents reliable prediction, the clinical presentation suggests the likely pathology: **semantic dementia and FTLD-MND are usually TDP-43 proteinopathies; progressive non-fluent aphasia (and CBD/PSP) is nearly always FTLD-tauopathy; and behavioural-variant FTD is evenly split between tauopathy and TDP-43**. This **tau–TDP-43 dichotomy underpins strategies for pathology-targeted disease-modifying therapy**.

D. PRESENTATION — THE THREE FTLD VARIANTS

10. Behavioural-variant FTD (bvFTD, ≥70%) — atrophy of frontal and/or anterior temporal cortex with subsequent basal ganglia involvement. The salient feature is **early and profound alteration in personality and social conduct with relative preservation of memory, spatial skills and praxis**: **disinhibition, apathy, social withdrawal, loss of empathy, hyperorality and dietary change, diminished insight, neglect of personal hygiene, mental rigidity, perseveration, stereotypic and repetitive motor behaviours**. Loss of sympathy and empathy often causes **family members to resent the patient**.

11. Semantic dementia (SD, ~15%) — temporal-variant FTD with loss of word and object meaning; a **right temporal variant** with asymmetric right temporal atrophy is the rare hemispheric counterpart. **Prosopagnosia** is characteristic of the right temporal form.

12. Progressive non-fluent aphasia (PNFA, ~10%) — atrophy of **left inferior frontal lobe, anterior insula and basal ganglia**, with **progressively worsening non-fluent spontaneous speech, shortened phrase length, agrammatism, phonological paraphasia and anomia**, plus stuttering, speech apraxia, impaired repetition, alexia and agraphia. **Single-word comprehension and object knowledge are preserved early but syntactic relationships**

are impaired. Executive function and working memory are often impaired; patients may be impulsive, apathetic or depressed but are **generally appropriate and many retain insight**.

13. FTD phenocopy meets bvFTD criteria but runs a **very slow course over decades** with slow cognitive progression and **often normal MRI and PET**.

E. RELATED TAUOPATHIES

14. Progressive supranuclear palsy (PSP) — a tauopathy with **marked midbrain atrophy, neurofibrillary tangles or neuropil threads in basal ganglia and brainstem, and tau-positive astrocytes**. The hallmark is **vertical supranuclear gaze palsy with disproportionate limitation of downward gaze** (contrast with the upgaze limitation of normal ageing and PD), occurring with **intact oculocephalic reflexes**. The earliest sign is **slowing of voluntary downward saccades**. MRI shows the **"hummingbird sign"** (dorsal midbrain atrophy) or **"eye of the tiger" sign**; PET/SPECT shows frontal hypoactivity.

15. Corticobasal degeneration (CBD) — a tauopathy overlapping FTD and PSP, with **asymmetric frontoparietal cortical degeneration, severe substantia nigra neuronal loss, ballooned achromatic cells, tau-positive astrocytic plaques, neurofibrillary tangles and neuropil threads**. Presents in the **sixth or seventh decade** with **(i) unilateral levodopa-unresponsive parkinsonism; (ii) asymmetrical rigidity, dystonia or focal myoclonus; (iii) cortical signs — asymmetric apraxia, cortical sensory loss, hemineglect, alien limb phenomenon; and (iv) late-onset cognitive impairment**. **Diagnostic sensitivity is only 30%**, and the corticobasal syndrome commonly proves at autopsy to be **AD, Pick's disease, PSP or prion disease**.

F. COURSE AND PROGNOSIS

16. FTLD onset is most commonly between 45 and 65, though it may present before 30 or in old age; **incidence rises with age (2.2 per 100,000 at 40–49, 3.3 at 50–59, 8.9 at 60–69)** with **equal gender distribution**. It is the **second commonest dementia under 65 after AD** and widely regarded as the **third commonest neurodegenerative dementia overall**.

17. Disease duration is about nine years in FTLD-U and tau-positive groups, but significantly shorter — under three years — in FTLD-MND. Age- and education-adjusted autopsy-confirmed studies show **FTLD carries shorter survival and faster cognitive and functional decline than AD**. Over time the three variants **converge into global cognitive impairment with motor deficits including parkinsonism and motor neurone disease**.

18. PSP prognosis is poor: progression to a **chairbound state at a median of five years** and **death at a median of seven years**, usually from the sequelae of **falls or dysphagia**.

G. TREATMENT

19. Management is multifaceted with no disease-modifying therapy. Caregiver education and support and optimisation of non-pharmacological measures are paramount. Pharmacotherapy is **symptomatic**, aimed at difficult behaviours and cognitive impairment.

20. Drug choices: consistent with the **selective vulnerability of serotonergic neurons in FTLD**, systematic review supports **SSRIs and trazodone** for modest improvement in behavioural symptoms of bvFTD — **impulsivity, disinhibition, repetitive stereotyped behaviour and obsessive-compulsive behaviour**; trazodone's use is limited by **sedation**. **Depression is rare in bvFTD but commoner in SD and PNFA and responds to SSRIs. Apathy is generally recalcitrant to pharmacotherapy**, though **bupropion** (with dopaminergic agonist properties) may be considered where apathy coexists with parkinsonism. **Low-dose atypical antipsychotics** may be used cautiously for delusions, severe agitation and aggression, given **enhanced sensitivity to extrapyramidal side effects, somnolence, weight gain and exacerbation of apathy**. **Cholinesterase inhibitors have not been shown useful in PSP**, and **memantine failed in the randomised FTLD trial (Boxer et al.)**. Emerging targets include **tau antibodies, inhibition of tau aggregation with methylene blue derivatives, microtubule-stabilising drugs and tau vaccines**. **PSP and CBD treatment remains supportive, centred on falls prevention and aggressive surveillance and management of dysphagia.**

Latest Updates (2023–Present)

- **The progranulin strategy has suffered a major setback. Latozinemab (AL001)**, a monoclonal antibody blocking sortilin to raise progranulin, **failed its clinical co-primary endpoint in the Phase 3 INFRONT-3 trial (announced October 2025)** in symptomatic FTD-GRN, despite a **statistically significant rise in plasma progranulin**. The open-label extension and continuation study were discontinued. FTD-GRN accounts for **5–10% of FTD cases**.
- **Gene-replacement therapy continues** for FTD-GRN: **PROCLAIM, ASPIRE-FTD and upliFT-D** are ongoing AAV-based gene-replacement studies showing early **safety, tolerability and restoration of progranulin levels**; a further six trials target **neuroinflammatory mechanisms in sporadic FTD**. **No licensed disease-modifying**

therapy exists for any FTLD subtype.

- **Tau-targeted therapy remains unsuccessful in the primary tauopathies**: anti-tau antibodies (**tilavonemab, gosuranemab**) failed in PSP, and **tau aggregation inhibitors** have not translated. Attention has shifted to **antisense oligonucleotides against MAPT** and to **C9orf72-directed ASOs** for the FTD–ALS spectrum.
- **Fluid biomarkers have matured for FTLD**: **plasma and CSF neurofilament light chain (NfL)** is now the best-validated marker of **disease activity, progression and phenoconversion in presymptomatic mutation carriers**, and **plasma progranulin below the normal range is diagnostic of GRN mutation**. Cohorts such as **GENFI** and **ALLFTD** have made presymptomatic staging routine.
- **LATE — limbic-predominant age-related TDP-43 encephalopathy** — is now a recognised, common TDP-43 proteinopathy of the **very old (over 80)**, producing an **amnestic syndrome closely mimicking AD** and frequently coexisting with it, contributing to the amyloid-negative amnestic phenotype.
- **Revised diagnostic criteria** have refined the field: **MDS-PSP criteria (2017)** define multiple PSP phenotypes beyond Richardson's syndrome, **Armstrong criteria** define corticobasal syndrome, and the **2011 Rascovsky bvFTD and Gorno-Tempini PPA criteria** remain standard for FTLD.
- **Indian context:** FTD is disproportionately represented in Indian memory clinics because of **younger age at presentation and referral patterns**; genetic testing is limited to research and tertiary centres, and **caregiver burden is exceptionally high** given the working-age onset, loss of family income and the behavioural nature of the illness — relevant to the **Maintenance and Welfare of Parents and Senior Citizens Act** and to disability certification under the **Rights of Persons with Disabilities Act, 2016**, which recognises chronic neurological conditions and dementia.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Progranulin-elevating therapy	Advances in pathobiology identify new targets	**INFRONT-3 (2025) failed** its clinical endpoint; latozinemab discontinued
Tau-targeted therapy	Tau antibodies, methylene blue derivatives, microtubule stabilisers, tau vaccines in development	Anti-tau antibodies **failed in PSP**; focus shifted to **MAPT and C9orf72 antisense oligonucleotides**
Biomarkers	Clinical and imaging diagnosis	**NfL** for disease activity and phenoconversion; **low plasma progranulin** diagnostic of GRN mutation
Nosology in the very old	FTLD-U/TDP-43 as an FTD entity	**LATE** recognised as a common TDP-43 amnestic syndrome after age 80
Symptomatic treatment	SSRIs, trazodone, bupropion, cautious atypical antipsychotics	Unchanged and still the standard of care

Exam One-Liners

- **>95% of FTLD = TDP-43 (50–60%) or tau (35–45%)**; remaining 5% DLDH/other.
- **MAPT (chromosome 17) → tau; GRN/progranulin (chromosome 17) → TDP-43; VCP → TDP-43 (IBMPFD); C9orf72 → FTD-ALS.**
- **FTDP-17** = familial FTD with parkinsonism linked to chromosome 17.
- **SD and FTLD-MND → TDP-43; PNFA, CBD, PSP → tau; bvFTD → evenly split.**
- Family history in **40%** of first-degree relatives; **10% of familial cases** have identified mutations.
- Onset **45–65**, equal sex distribution, **survival ~9 years, <3 years with MND**.
- **PSP: vertical supranuclear gaze palsy with impaired downgaze, hummingbird sign, chairbound at 5 years, death at 7.**
- **CBD: alien limb, asymmetric apraxia, levodopa-unresponsive parkinsonism; diagnostic sensitivity only 30%.**
- **SSRIs and trazodone for behaviour; bupropion for apathy with parkinsonism; ChEIs unhelpful; memantine failed.**
- **INFRONT-3 (2025) negative** — no disease-modifying therapy for FTD.

QUESTION 8

Pick’s disease — pathology and treatment.

15–20 High-Yield Points

A. DEFINITION AND POSITION IN NOSOLOGY

1. Pick’s disease is a tau-positive frontotemporal lobar degeneration characterised pathologically by Pick bodies, and is one of the classical **non-reversible degenerative dementias of the central nervous system**, listed alongside Alzheimer’s disease, Lewy body dementia, Parkinson’s disease, Huntington’s disease and progressive supranuclear palsy.

2. Historically, FTLD was divided into **tau-positive pathology with or without Pick’s bodies** and **dementia lacking distinctive histopathology (DLDH)**. Pick’s disease is therefore the **prototype of the tau-positive limb of the FTLD dichotomy**, and today is best regarded as a **pathological diagnosis within FTLD-tauopathy (35–45% of all FTLD)**, most often presenting clinically as **behavioural-variant FTD**.

B. PATHOLOGY

3. Macroscopic: circumscribed, often asymmetric atrophy of the frontal and anterior temporal lobes — the classic “knife-edge” gyral atrophy — with **relative sparing of the posterior two-thirds of the superior temporal gyrus**, the parietal and occipital lobes.

4. Microscopic hallmark: Pick bodies — round, well-circumscribed, argyrophilic, tau-positive intraneuronal cytoplasmic inclusions, most abundant in the **dentate gyrus of the hippocampus and in frontotemporal cortical neurons**.

5. Pick cells (ballooned achromatic neurons) — swollen, pale-staining neurons — are also seen; identical **ballooned achromatic cells occur in corticobasal degeneration**, an important point of overlap.

6. Accompanying features are **severe neuronal loss, superficial laminar (layer II/III) spongiosis and gliosis** in the affected cortex, with subsequent **basal ganglia involvement** as the disease advances.

7. Molecular pathology: Pick’s disease is a **3-repeat (3R) tauopathy**, in contrast to the **4-repeat (4R) tauopathies PSP and CBD** and the mixed 3R/4R tau of Alzheimer’s disease — the single most discriminating molecular fact.

8. Genetics: Pick’s disease is usually **sporadic**, but tau-positive FTLD is linked to **MAPT mutations on chromosome 17 (FTDP-17)**. **A family history of dementia is present in about 40% of first-degree relatives** across FTLD as a whole.

C. CLINICAL PRESENTATION

9. Presentation is **usually that of behavioural-variant FTD**: **early and profound alteration in personality and social conduct with relative preservation of memory, spatial skills and praxis**. Typical behaviours are **disinhibition, apathy, social withdrawal, loss of empathy, hyperorality and dietary change, diminished insight, neglect of personal hygiene, mental rigidity, perseveration, stereotypic behaviour and repetitive motor behaviours**.

10. Loss of sympathy and empathy toward family and friends, with decreased social interest and responsiveness to the needs of others, is characteristic and often leads to **family members resenting the patient** — a distinctive social consequence not seen in AD.

11. Some patients present instead with **progressive non-fluent aphasia**, which is **nearly always an FTLD-tauopathy**; the **corticobasal syndrome** may also prove at autopsy to be Pick’s disease.

12. Onset is most commonly between 45 and 65, with **equal gender distribution**; it is a leading cause of **young-onset dementia**.

D. DIAGNOSIS

13. Diagnosis in life is clinical and radiological; definitive diagnosis is neuropathological. MRI or CT shows focal, asymmetric frontal and anterior temporal atrophy, and **HMPAO-SPECT shows diminished anterior perfusion**, in contrast to the temporoparietal reduction of AD. **FDG-PET shows characteristic frontotemporal hypometabolism.**

14. Exclude the treatable and the mimics: complete blood count, glucose, electrolytes, **calcium and phosphorus (mg/dL)**, liver function tests, **TSH (µIU/mL)**, **vitamin B12 (pg/mL)**, syphilis and HIV serology where suspected, plus structural imaging. Psychiatric illness, late-onset mania, AD with frontal presentation and the **FTD phenocopy syndrome** are the principal differentials.

E. COURSE AND PROGNOSIS

15. Prognosis is poor and worse than AD. Disease duration is about **nine years in tau-positive FTLD groups**, and **FTLD is associated with shorter survival and faster cognitive and functional decline than AD** in age- and education-adjusted autopsy-confirmed studies. Over time patients develop **global cognitive impairment and motor deficits including parkinsonism**, and death is commonly from **aspiration pneumonia, dysphagia complications or falls**.

F. TREATMENT

16. There is no disease-modifying or curative therapy. Management is **multifaceted**, with **caregiver education and support and optimisation of non-pharmacological measures paramount**; pharmacotherapy is aimed at **difficult behaviours and cognitive impairment**.

17. SSRIs and trazodone offer modest benefit for the behavioural symptoms of bvFTD, consistent with the **selective vulnerability of serotonergic neurons in FTLD**. Symptoms that respond include **impulsivity, disinhibition, repetitive stereotyped behaviour and obsessive-compulsive behaviour**. **Trazodone's use may be limited by sedation.**

18. Depression is rare in bvFTD but commoner in semantic dementia and PNFA and is amenable to SSRI treatment. **Apathy is generally recalcitrant to pharmacotherapy** and may even be a relief for caregivers of a severely behaviourally disturbed patient; **bupropion**, with additional dopaminergic agonist properties, can be considered where apathy coexists with parkinsonism.

19. Low doses of atypical antipsychotics may be considered for **delusions, severe agitation and aggression**, but must be used **cautiously owing to enhanced sensitivity to extrapyramidal side effects, somnolence, weight gain and exacerbation of apathy**. **Cholinesterase inhibitors and memantine are not indicated** — memantine failed in the randomised FTLD trial and ChEIs may worsen behaviour in FTD.

20. Supportive care is the mainstay: **structured routine and environmental simplification, safety measures (driving cessation, financial safeguarding, supervision for hyperorality and impulsivity), speech and language therapy for the aphasic variants, dysphagia surveillance and nutritional support, and early advance care planning**. Emerging disease-modifying targets are **tau antibodies, inhibition of tau aggregation with methylene blue derivatives, microtubule-stabilising drugs and tau vaccines**.

Latest Updates (2023–Present)

- **Pick's disease is now formally classified as a 3R tauopathy** within the FTLD-tau group alongside **PSP and CBD (4R)** and **globular glial tauopathy**; cryo-EM structural studies have shown that **each tauopathy has a distinct tau filament fold**, with Pick's disease possessing a unique 3R fold — the structural basis for developing **conformation-specific tau ligands and PET tracers**.
- **Tau PET remains unreliable for non-AD tauopathies**: first-generation tracers such as **flortaucipir bind 3R/4R paired helical filaments of AD but not the 3R Pick fold**, so a negative tau PET does not exclude Pick's disease. Second-generation tracers are in development.
- **Anti-tau therapeutics have repeatedly failed** in the primary tauopathies — **tilavonemab and gosuranemab** in PSP — and attention has shifted to **MAPT-directed antisense oligonucleotides**, which lower tau at the transcript level and are in early-phase trials.
- **Plasma and CSF neurofilament light chain (NfL)** is now the best-validated marker of disease activity and progression across FTLD, useful in distinguishing FTD from primary psychiatric illness and from the slowly progressive **FTD phenocopy syndrome**, which characteristically has normal NfL.
- The **2011 Rascovsky criteria for bvFTD** and **Gorno-Tempini criteria for primary progressive aphasia** remain the operational clinical standard; multicentre cohorts (**GENFI, ALLFTD, ARTFL-LEFFTDS**) have established natural-history and presymptomatic staging data.
- **Indian context:** young-onset dementia including FTLD is under-recognised and frequently first labelled as a **primary psychiatric disorder**, delaying diagnosis by years. Practical implications are large: **loss of earning capacity in the family's main provider**, need for **disability certification under the Rights of Persons with Disabilities Act, 2016** (which includes chronic neurological conditions and mental illness), and access to **caregiver support through ARDSI and the District Mental Health Programme**.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Classification	Tau-positive FTLD with or without Pick bodies	**3R tauopathy** with a unique cryo-EM tau filament fold, distinct from 4R PSP/CBD
Imaging diagnosis	Focal frontotemporal atrophy; anterior hypoperfusion on SPECT	Unchanged; **tau PET is not reliable** for 3R Pick pathology
Disease-modifying therapy	Tau antibodies, aggregation inhibitors, microtubule stabilisers, vaccines in development	**Anti-tau antibodies failed in PSP**; focus now on **MAPT antisense oligonucleotides**
Biomarker for progression	Not established	**NfL** validated for disease activity and to exclude the phenocopy syndrome
Symptomatic treatment	SSRIs, trazodone, bupropion; cautious atypical antipsychotics	Unchanged and still the standard of care

Exam One-Liners

- Pick's disease = **tau-positive FTLD defined by Pick bodies**.
- **Pick bodies** = round, argyrophilic, tau-positive intraneuronal inclusions, densest in the **dentate gyrus**.
- **Pick cells** = ballooned achromatic neurons — also seen in **corticobasal degeneration**.
- **3R tauopathy** — contrast with **4R PSP and CBD** and mixed 3R/4R AD.
- Macroscopic: **knife-edge frontal and anterior temporal atrophy**, posterior superior temporal gyrus spared.
- Presents as **bvFTD**: disinhibition, apathy, loss of empathy, hyperorality, stereotypies.
- **Onset 45–65**, equal sex distribution, **survival ~9 years**, faster decline than AD.
- SPECT: **anterior (frontotemporal) hypoperfusion**, versus temporoparietal in AD.
- **Treatment: SSRIs and trazodone; bupropion for apathy; low-dose atypicals with caution; ChEIs and memantine not indicated.**
- **Caregiver education and support are paramount** — no disease-modifying therapy exists.

QUESTION 9

Lewy body dementia.

15–20 High-Yield Points

A. DEFINITION, TERMINOLOGY AND SPECTRUM

1. Dementia with Lewy bodies (DLB) is the preferred term for entities previously called the **Lewy body variant of AD, Lewy body dementia, senile dementia of Lewy body type and cortical Lewy body disease**.

2. DLB and Parkinson's disease dementia (PDD) are two ends of one Lewy body disease spectrum. The **"one-year rule"** applies: **PDD** describes dementia developing in established Parkinson's disease, while **DLB** is diagnosed when dementia **precedes or coincides within one year** of motor symptom onset. By the end stage the two are **often indistinguishable clinically and neuropathologically**.

B. EPIDEMIOLOGY

3. DLB is the **second commonest cause of neurodegenerative dementia in older people after AD**, accounting for **~15–20% of autopsy series and 10–15% of dementia cases in population studies**. **Incidence is 32–112 per 100,000 person-years** in those over 65.

4. Onset is between 50 and 90 years, and illness duration varies between 6 and 10 years.

C. PATHOLOGY

5. The defining lesion is the **α-synuclein-containing Lewy body and Lewy neurite**. Recent evidence indicates that **presynaptic α-synuclein aggregates, rather than the Lewy body itself, are synapto-toxic** and cause neurodegeneration.

6. Three patterns of Lewy body distribution: (i) brainstem-predominant — the PDD phenotype; **(ii) cerebral cortex-predominant** — the DLB phenotype; **(iii) transitional**, intermediate between the two. The likelihood of presenting as typical DLB is **directly related to the distribution of Lewy body pathology and inversely related to the severity of AD pathology**.

7. Concomitant AD pathology is present in 90% of Lewy body disease cases. Patients with **marked concurrent neurofibrillary tangle pathology present with an insidious amnestic syndrome more suggestive of AD**, with **fewer cognitive fluctuations, fewer neuropsychiatric symptoms and less parkinsonism**.

8. Most cases are sporadic, but rare autosomal dominant inheritance occurs, with **SNCA and LRRK2 mutations**, which may manifest as any Lewy body phenotype — supporting a single underlying genetic-pathological entity.

D. CORE CLINICAL FEATURES

9. Fluctuating cognition with pronounced variations in attention and alertness — waxing and waning behavioural inconsistency, incoherent speech, variable attention, staring or "zoning out". The **marked amplitude between best and worst performance** distinguishes it from minor day-to-day variation. Endorsement of **at least three of four composite features — daytime drowsiness and lethargy, daytime sleep of ≥2 hours, staring into space for long periods, episodes of disorganised speech — gives a positive predictive value of 83%** for DLB over AD. **Fluctuations best predict DLB when present early.**

10. Recurrent vivid visual hallucinations occur in up to 80% — typically **well-formed, detailed, three-dimensional mute images of people, children or animals**. Caregivers may under-report them, so **patient self-report is useful**. Their presence marks **cortical Lewy body pathology and greater cortical cholinergic deficit, and predicts good response to cholinergic therapy**. **Misidentification delusions are the commonest delusional type**, followed by persecutory/paranoid, **phantom boarder** and abandonment delusions.

11. REM sleep behaviour disorder (RBD) — a parasomnia with **loss of REM atonia**, so patients **act out vivid, frightening dreams**: talking or shouting in sleep, striking the bed partner, falling out of bed. **History must come from the bed partner.** It **precedes motor, cognitive and neuropsychiatric manifestations by years or decades and curiously improves as disease progresses**. It is **highly specific for synucleinopathy (DLB, PD, MSA)** and rare in AD and primary tauopathies.

12. Spontaneous parkinsonism occurs in about **75%**, is **less pronounced and less levodopa-responsive than idiopathic PD**, so **only one cardinal feature (bradykinesia, rigidity or resting tremor) is required** for diagnosis.

E. SUPPORTIVE FEATURES AND COGNITIVE PROFILE

13. Supportive clinical features: severe sensitivity to antipsychotics, postural instability, repeated falls, syncope or transient unresponsiveness, severe autonomic dysfunction (orthostatic hypotension, urinary

incontinence, constipation), hypersomnia, systematised delusions, hallucinations in other modalities, and apathy, anxiety and depression.

14. Neuroleptic sensitivity: about **50% of DLB patients do not react adversely**, so tolerance does not exclude the diagnosis, but a **positive history of severe sensitivity is strongly suggestive**. Reactions range from **sedation, increased confusion and worsening parkinsonism** to **irreversible parkinsonism, impaired consciousness and marked autonomic disturbance**.

15. Cognitive profile: a **"dysexecutive" syndrome with prominent executive, attentional and visuospatial dysfunction**, with **visuospatial impairment prominent even early**. Amnesia may not be prominent initially; **memory impairment does not preclude DLB**, and patients with pure Lewy body disease have **similar free recall but better delayed recognition memory than AD**, indicating a **retrieval rather than storage deficit**.

F. DIAGNOSTIC CRITERIA AND BIOMARKERS

16. Essential: progressive cognitive decline with reduced social and occupational functioning. **Probable DLB = ≥2 core clinical features, or 1 core feature plus ≥1 indicative biomarker. Possible DLB = 1 core feature with no indicative biomarker, or ≥1 indicative biomarker with no core feature. DLB is less likely if** there is a history of stroke, another illness or brain disorder sufficient to explain the picture, or if **parkinsonism is the only core feature and appears first at a severe stage of dementia**.

17. Indicative biomarkers: low dopamine transporter uptake in basal ganglia on SPECT/PET; **abnormal (low uptake) 123I-MIBG myocardial scintigraphy**, which quantifies postganglionic sympathetic cardiac innervation and discriminates DLB from AD especially in milder cases (**MMSE >21**); and **polysomnographic confirmation of REM sleep without atonia**. **Supportive biomarkers: relative preservation of medial temporal lobe structures** on CT/MRI; **generalised low uptake with reduced occipital activity ± the cingulate island sign on FDG-PET**; and **prominent posterior slow-wave EEG activity with periodic pre-alpha/theta fluctuations**.

18. Earlier criteria had high specificity (80–100%) but limited sensitivity (35–80%); the third consensus criteria (2005) improved sensitivity, but **detection remains suboptimal, with many cases missed or misdiagnosed as AD**. The **revised fourth consensus criteria clearly separate clinical features from diagnostic biomarkers, with increased weighting given to RBD and MIBG scintigraphy**. **CSF α-synuclein may be low in DLB versus AD**, while **Aβ, tau and p-tau help determine concomitant AD pathology**; **amyloid deposition has little value in differentiating DLB from AD**, though greater amyloid load predicts faster decline in DLB.

G. MANAGEMENT

19. Management addresses **motor, cognitive, psychiatric and autonomic dysfunction**, and the clinician must be **mindful of the tension between improving one symptom at the expense of worsening another** — for example **aggravating hallucinations with levodopa**. **Conventional neuroleptics are best avoided**; **quetiapine or clozapine** may be used judiciously. **Cholinesterase inhibitors are effective and relatively safe for psychiatric and cognitive symptoms in DLB**, with mainly gastrointestinal side effects, although **DLB patients may be more susceptible to bradyarrhythmic effects because of autonomic dysfunction**.

20. Memantine produces cognitive and global benefits in DLB but without significant improvement in psychiatric symptoms, and **case reports describe worsening delusions and hallucinations with memantine** in DLB — caution is warranted. Preliminary subgroup analysis suggests a **more pronounced global response in PDD than DLB**. **Autonomic management** uses **fludrocortisone or midodrine** for symptomatic postural hypotension; **RBD is managed with a safe sleep environment, melatonin and, where necessary, clonazepam**; and **falls prevention and dysphagia surveillance** are essential.

Latest Updates (2023–Present)

- **α-Synuclein seed amplification assays (SAA/RT-QuIC)** have transformed diagnosis. In **CSF** they achieve **>90% sensitivity and specificity** for Lewy body pathology, and **skin biopsy SAA (2024 JAMA)** detected phosphorylated α-synuclein in **around 95% of patients with synucleinopathies** — moving the field toward a **biological definition of Lewy body disease** paralleling the biological definition of AD, and enabling detection at the **prodromal RBD stage**.
- **Isolated RBD is now formally recognised as prodromal synucleinopathy**, with **around 75–90% phenoconverting to DLB, PD or MSA over 10–15 years**; this has made RBD clinics the principal recruitment route for **neuroprotection trials** in Lewy body disease.
- **Research criteria for prodromal DLB (McKeith et al.)** define three syndromes — **MCI with Lewy bodies, delirium-onset DLB and psychiatric-onset DLB** — allowing diagnosis before dementia, with **MCI-LB criteria** now operationalised.
- **Therapeutics remain symptomatic. Neflamapimod (p38α kinase inhibitor)** showed cognitive benefit in the **RewinD-LB Phase 2b trial (2025)** in DLB patients without amyloid co-pathology and is progressing to Phase 3.

Ambroxol (glucocerebrosidase chaperone) and **α-synuclein immunotherapies** are in trials. **No disease-modifying therapy is yet licensed.**

- **Antipsychotic caution has been reinforced** — **pimavanserin** remains licensed only for Parkinson's disease psychosis; the **HARMONY** trial showed relapse prevention in dementia-related psychosis but did not yield a DLB indication, and all antipsychotics carry the **boxed warning for increased mortality in elderly patients with dementia-related psychosis**.
- **Practical Indian points:** DLB is systematically **under-diagnosed and frequently mislabelled as AD or late-onset psychosis**, exposing patients to conventional antipsychotics such as **haloperidol** with potentially catastrophic neuroleptic sensitivity reactions. **DAT-SPECT and MIBG scintigraphy are available only in selected tertiary centres**, so **clinical recognition of the four core features — especially a careful bed-partner history of RBD — remains the single most important diagnostic step in Indian practice.**

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Diagnostic confirmation	Core clinical features plus DAT-SPECT, MIBG, polysomnography	**α-synuclein seed amplification assays (CSF and skin)** achieve >90% accuracy and enable prodromal diagnosis
Prodromal disease	RBD noted as an early antecedent marker	**Isolated RBD = prodromal synucleinopathy**; formal **prodromal DLB and MCI-LB criteria** now defined
Disease modification	None available	Still none licensed; **neflamapimod (RewinD-LB, 2025)** the most advanced candidate
Antipsychotics	Avoid conventional agents; use quetiapine or clozapine judiciously	Unchanged and reinforced; **pimavanserin remains restricted to PD psychosis**
Memantine	Cognitive and global benefit, no psychiatric benefit; case reports of worsening psychosis	Position unchanged; **ChEIs remain first-line** for cognition and psychosis in DLB

Exam One-Liners

- **DLB = 2nd commonest neurodegenerative dementia** (15–20% autopsy, 10–15% population); duration **6–10 years**.
- **One-year rule** separates DLB from PDD.
- Four core features: **fluctuating cognition, visual hallucinations, RBD, spontaneous parkinsonism**.
- **Probable DLB = 2 core features, or 1 core + 1 indicative biomarker.**
- Fluctuation composite (**drowsiness, ≥2 h daytime sleep, staring, disorganised speech**) — **3 of 4 gives PPV 83%**.
- Visual hallucinations in **80%**; predict **good response to cholinergic therapy**.
- **RBD is the most specific antecedent biomarker of synucleinopathy.**
- Parkinsonism in **75%**; only **one cardinal feature required**.
- **50% show no neuroleptic sensitivity** — tolerance does not exclude DLB.
- Indicative biomarkers: **low DAT uptake, abnormal MIBG, REM sleep without atonia**.
- **Medial temporal lobe preserved**; **occipital hypometabolism and cingulate island sign** on FDG-PET.
- **ChEIs effective and safe; memantine helps cognition but not psychiatric symptoms and may worsen hallucinations.**

QUESTION 10

Normal pressure hydrocephalus.

15–20 High-Yield Points

A. DEFINITION AND CONCEPT

1. Normal pressure hydrocephalus (NPH) is a **chronic communicating hydrocephalus** with **ventricular enlargement in the presence of normal mean cerebrospinal fluid opening pressure**, presenting with a characteristic clinical triad and being one of the few **potentially reversible causes of dementia**.

2. It is classified as **idiopathic (iNPH)** or **secondary**, the latter following **subarachnoid haemorrhage, meningitis, head injury or intracranial surgery**. It appears in every standard list of **potentially reversible dementias** and of **causes of parkinsonism with cognitive impairment in the elderly**.

B. AETIOLOGY AND PATHOPHYSIOLOGY

3. The classical model is one of **impaired CSF absorption at the arachnoid granulations with altered CSF flow dynamics**, described through **bulk-flow theory**; **CSF flow and CSF flow rate abnormalities** are central to both pathogenesis and diagnosis.

4. Ventricular enlargement transmits **periventricular tissue stress**, producing **ischaemia and disruption of the periventricular white matter**, particularly the **corona radiata fibres to the medial legs** — explaining why **gait is affected first and most severely**, and why the frontal-subcortical circuits subserving **executive function and bladder inhibition** are next affected.

5. Comorbid cerebrovascular disease is very common in this age group and both **contributes to the clinical picture and limits the response to shunting** — an essential caveat when counselling patients.

C. CLINICAL PRESENTATION

6. Hakim and Adams' triad: **gait disturbance, cognitive impairment (dementia) and urinary incontinence** — traditionally remembered as **"wet, wacky and wobbly"**. **Gait disturbance usually appears first and is the symptom most likely to improve with treatment.**

7. The gait is classically "magnetic" — broad-based, shuffling, with reduced step height and length, **start hesitation, freezing and difficulty turning (en bloc turning)**, but with **preserved arm swing and no tremor**, distinguishing it from Parkinson's disease. NPH is also listed among the **causes of secondary parkinsonism**.

8. Cognitive impairment is subcortical/frontal — psychomotor slowing, inattention, executive dysfunction and apathy — with **relatively preserved cortical functions** (language, praxis, recognition), distinguishing it from AD.

9. Urinary symptoms begin as **urgency and frequency** and progress to **urge incontinence**, and later to an **indifferent incontinence** reflecting frontal disinhibition.

D. DIFFERENTIAL DIAGNOSIS

10. The crucial differential is **subcortical ischaemic vascular disease (SIVD)**: the textbook makes the point explicitly that **the triad of dementia, urinary incontinence and gait disturbance is more often produced by small-vessel vascular dementia than by NPH**. Other differentials include **Parkinson's disease and atypical parkinsonian syndromes (PSP, MSA), Alzheimer's disease, DLB, cervical spondylotic myelopathy, chronic subdural haematoma and hydrocephalus ex vacuo from cerebral atrophy**.

E. DIAGNOSTIC MODALITIES

11. CT and MRI demonstrate **ventriculomegaly disproportionate to sulcal atrophy**, quantified by an **Evans index >0.3** (maximum frontal horn width divided by maximum inner skull diameter), with **periventricular hyperintensities, upward bowing of the corpus callosum, a callosal angle below 90 degrees, and a CSF flow void or increased aqueductal flow**.

12. Disproportionately enlarged subarachnoid space hydrocephalus (DESH) is a key morphological pattern — **enlarged Sylvian fissures and basal cisterns with tight, compressed high-convexity and medial parietal sulci** — and strongly supports the diagnosis.

13. Neuropsychological testing documents the **subcortical/frontal profile**, provides the objective baseline against which CSF-drainage response is measured, and helps identify coexisting AD or vascular disease.

F. PROGNOSTIC (SUPPLEMENTARY) TESTS — PREDICTING SHUNT RESPONSE

14. Lumbar puncture (the "tap test") — removal of a **large volume of CSF (30–50 mL)** with **objective gait and**

cognitive testing before and after. It has **good positive but poor negative predictive value**, so a negative tap test does not exclude a shunt-responsive patient.

15. Extended lumbar drainage (lumbar drain trial) — continuous external drainage over **2–3 days** with serial testing; this has **the highest predictive accuracy** of the supplementary tests. **Lumbar infusion test (intrathecal infusion test)** measures **CSF outflow resistance (Rout)**; **intracranial pressure monitoring** detects **B-waves**.

16. Additional modalities include **phase-contrast MRI** for aqueductal CSF stroke volume, **magnetic resonance spectroscopy**, **SPECT** and **PET**. **Grading uses the idiopathic normal-pressure hydrocephalus grading scale (iNPHGS)**, which scores each of the three triad domains.

17. The value of provocative CSF removal is quantitative: predictive power for a positive shunt response rises progressively as one moves from **clinical and imaging information alone → plus tap test → plus infusion testing → plus external lumbar drainage**.

G. TREATMENT

18. Shunt surgery is the definitive treatment. Options are **ventriculoperitoneal shunting (the standard), ventriculoatrial shunting and lumboperitoneal shunting**; **endoscopic third ventriculostomy** has a limited role in communicating NPH. **Programmable (adjustable) valves** allow non-invasive post-operative pressure adjustment and reduce the risk of overdrainage; **anti-siphon devices** are added for the same reason. **Drug therapy (acetazolamide) has only a marginal, temporising role.**

19. Patient selection and shared decision-making are paramount — weighing symptom duration, degree of comorbidity (especially cerebrovascular disease and coexisting AD), frailty, anaesthetic risk and realistic expectations of benefit.

20. Risks and complications: shunt infection and **shunt obstruction** are the principal shunt-related problems, along with **overdrainage causing subdural effusion or haematoma, seizures, and the need for revision surgery**. **Long-term care and follow-up are mandatory**, with periodic valve setting review and prompt imaging for any deterioration. **Outcome is best for gait, less certain for cognition and continence, and better with shorter symptom duration and less comorbidity.**

Latest Updates (2023–Present)

- **The PENS trial (Placebo-Controlled Effectiveness in iNPH Shunting; NEJM, December 2025)** is the landmark update. This **international, multicentre, double-blind, randomised, placebo-controlled trial** enrolled **99 patients across 17 centres in the USA, Canada and Sweden**, randomising participants after shunt insertion to an **open versus a placebo (closed) valve setting**. **Gait velocity increased by 0.23 m/s with an open shunt versus 0.03 m/s with placebo — a treatment difference of 0.21 m/s (95% CI 0.12 to 0.31; p<0.001)**. The **DSMB stopped enrolment early** at the second interim analysis for efficacy.
- **What PENS did and did not show: 80% of the open-shunt group achieved meaningful improvement versus 24% of the placebo group**, with **better balance and fewer falls**. **Cognition and incontinence did not improve significantly at 3 months** — a nuance that should be quoted, because it aligns exactly with the classical teaching that **gait is the symptom most likely to respond**.
- **The 2024 Cochrane review on shunting for iNPH** had concluded that further trials were needed to increase certainty; **PENS has now supplied that evidence** and has effectively ended the call for a moratorium on shunt surgery.
- **Guidelines:** the **AAN/AANS/CNS guideline on iNPH response to shunting and predictors of response was reaffirmed in July 2024**; the **Japanese iNPH clinical practice guidelines (3rd edition, 2020)** remain the most detailed, though they do not compare ventriculoperitoneal, lumboperitoneal and ventriculoatrial shunting directly — a gap the ongoing **RASHOMON registry study** is designed to fill. **SINPHONI-2** had earlier shown **lumboperitoneal shunting to be comparable to ventriculoperitoneal shunting**.
- **Epidemiology has been revised upward.** Population-based MRI studies indicate iNPH affects **up to 1.5% of people in their late 60s and as many as 7.7% of adults over 80–86**, making it far commoner and more under-diagnosed than previously assumed, and reinforcing the case for active case-finding in falls and gait clinics.
- **Indian context:** iNPH is systematically **under-recognised** and often labelled as “ageing gait”, vascular parkinsonism or AD. Given that **neurosurgical shunting is widely available across Indian tertiary centres and is relatively inexpensive**, the diagnostic bottleneck is clinical suspicion, not treatment access. Every older adult presenting with a **gait disorder plus cognitive slowing** — a very common presentation to **NPHCE district geriatric clinics and falls services** — deserves an **Evans index measured on the CT that has usually already been done**.

Current Practice Update

Area	Textbook position	Current evidence and guidelines (2023 onward)
Evidence for shunting	Treatment of choice, but efficacy debated and outcome variable	**PENS trial (2025)** provides randomised, placebo-controlled proof: **gait velocity gain 0.21 m/s; 80% vs 24% meaningful improvement**
Which symptom responds	Gait responds best	**Confirmed**: gait and balance improve; **cognition and continence did not improve significantly** in PENS
Prevalence	Uncommon cause of dementia	**Up to 1.5% in late 60s and 7.7% over 86** — substantially under-diagnosed
Shunt type	VP, VA, LP shunts described without direct comparison	**SINPHONI-2**: LP comparable to VP; **RASHOMON registry** is comparing all three prospectively
Patient selection	Supplementary CSF tests improve predictive power	Unchanged and reinforced — **extended lumbar drainage remains the best predictor**

Exam One-Liners

- NPH = **ventriculomegaly with normal mean CSF opening pressure**.
- **Hakim–Adams triad: gait disturbance, dementia, urinary incontinence** (“wobbly, wacky, wet”).
- **Gait comes first and responds best.**
- Gait is **magnetic, broad-based, with start hesitation and en bloc turning, but preserved arm swing**.
- Cognition is **subcortical/frontal** — slowing, inattention, executive dysfunction, apathy.
- **Evans index >0.3**; **callosal angle <90°**; **DESH pattern** supports the diagnosis.
- **Small-vessel vascular dementia produces the triad more often than NPH does.**
- Tap test: **good positive, poor negative predictive value**; **extended lumbar drainage is the best predictor**.
- Predictive power rises: **clinical/imaging → tap test → infusion test → external lumbar drainage**.
- Treatment = **VP shunt with a programmable valve**; complications are **infection, obstruction and overdrainage with subdural collection**.
- **PENS trial 2025**: gait velocity gain **0.21 m/s**, **80% vs 24%** meaningful improvement; **no significant cognitive or continence benefit**.

CONSOLIDATED RAPID-REVISION GRID

The Ten Answers on One Page

#	Topic	The single fact most likely to earn the mark
1	Dementia and management	ChEI for mild–moderate AD, memantine for moderate–severe; **DOMINO** supports continuing donepezil; **Lancet Commission 2024: 14 risk factors, 45% preventable**
2	Dementia (repeat)	India — **LASI-DAD: 7.4%, 8.8 million, 16.9 million by 2036**
3	MCI	Four core criteria; **15–20% convert per year**; **anti-amyloid antibodies now licensed at the MCI stage**
4	Reversible dementias	**<4% truly reversible**; drugs are the commonest contributor; **treatment does not guarantee reversal**
5	Behavioural symptoms	**90–98%** develop at least one NPS; **DICE**; caregiver interventions outperform antipsychotics
6	Four common dementias	**AD = hippocampus/temporoparietal; VaD = vessel-size dependent; DLB = cortical Lewy bodies with occipital hypometabolism; FTD = frontal/anterior temporal**
7	Tau / progranulin / TDP-43	**>95% of FTLD = TDP-43 (50–60%) or tau (35–45%)**; MAPT → tau, GRN and VCP → TDP-43
8	Pick's disease	**Pick bodies = 3R tau-positive argyrophilic inclusions**, densest in the dentate gyrus
9	Lewy body dementia	Four core features; **probable = 2 core, or 1 core + 1 indicative biomarker**; **ChEIs effective, avoid conventional neuroleptics**
10	Normal pressure hydrocephalus	**Hakim–Adams triad**; **Evans index >0.3**; **PENS 2025 — gait improves, cognition and continence do not**

Cross-Cutting Indian Policy Points to Weave Into Any Dementia Answer

- **LASI-DAD**: dementia prevalence **7.4%** in those 60+, **8.8 million cases**, projected **16.9 million by 2036**; higher in women and rural populations
- **India Ageing Report 2023 (UNFPA)**: 60+ population to reach **20.8% by 2050**
- **NPHCE** — Regional Geriatric Centres, district geriatric units, geriatric clinics at CHC/PHC level, the delivery platform for cognitive screening
- **National Mental Health Programme / District Mental Health Programme** — the practical route for BPSD and caregiver support
- **AB-PMJAY and the Ayushman Vay Vandana Card** — universal ₹5 lakh cover for all citizens aged 70 and above regardless of income
- **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** — legal remedy for neglect and abandonment, highly relevant to dementia caregiving breakdown
- **Rights of Persons with Disabilities Act, 2016** — includes chronic neurological conditions and mental illness, enabling disability certification in young-onset dementia
- **Rashtriya Vayoshri Yojana** and **AVYAY** — assistive devices and senior citizen welfare schemes
- **Elder Line 14567** — national toll-free helpline for older adults
- **ARDSI (Alzheimer's and Related Disorders Society of India)** — Dementia India reports, caregiver training, day care and support groups

- **WHO ICOPE (2nd edition)** — cognitive decline is one of the six domains of intrinsic capacity screened in primary care

End of compilation — Questions 1 to 10, Dementia and Cognitive Disorders.

Parkinson's Disease & Movement Disorders

MD Geriatric Medicine — High-Yield 15-Mark Answers

Primary sources: Pathy's Principles and Practice of Geriatric Medicine (6th ed., Ch. 53 & 54) and Essentials of Clinical Geriatrics (7th ed.)
Supplemented with peer-reviewed evidence and guidelines to August 2026 | Indian context integrated throughout

Contents

1. Parkinson's disease — pathology, pathogenesis and treatment (drug choice, side effects, newer modalities, non-motor symptoms)
2. Parkinson-plus syndromes in older adults — etiopathogenesis, clinical presentation and management
3. Drug treatment for Parkinson's disease
4. Levodopa
5. Parkinsonism
6. Motor fluctuations in Parkinson's disease
7. Non-motor symptoms of Parkinson's disease
8. Progressive supranuclear palsy — clinical features, management and prognosis RECURS
9. Benign / essential tremor — presentation, differential diagnosis and treatment

How to use this compilation

- Each answer has four parts: **High-Yield Points** (textbook), **Latest Updates (2023–present)**, **Current Practice Update** table, and an **Examiner's Tip** skeleton.
- Textbook content and recent evidence are kept strictly separate, as instructed.
- Topics flagged RECURS carry an additional green **Extra Points to Remember** box.
- Questions 1, 3, 4, 6 and 7 overlap heavily — a single core of levodopa pharmacology answers all five. Read Q1 first; the rest are re-framings for different mark weights.

Q1. Parkinson's disease — pathology, pathogenesis and treatment, with emphasis on drug choice, side effects, newer modalities and treatment of non-motor symptoms

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapter 53 (Oquendo & Belmin); Essentials of Clinical Geriatrics 7th ed., Chapter 10.

Definition and epidemiology

1. Parkinson's disease (PD) is the **second most common neurodegenerative disease after Alzheimer's disease**. Despite progress in understanding the neurochemistry, the **exact cause remains undetermined**.
2. Prevalence is **about 1% in people over 65 years**. Median age at diagnosis is 60. Late-onset PD means first symptoms after age 60; **very late-onset PD (after 75) is uncommon**.
3. Incidence rises with age up to 80 years and then appears to **fall in the ninth decade**. Mean duration from diagnosis to death is **about 15 years**.
4. Because of this, most PD patients seen in geriatric practice have **longstanding disease with lost independence and complications**, not new diagnoses.
5. Risk factors: family history in **6–10%**; weak associations with head injury, rural living, obesity and herbicide/pesticide exposure. Male sex is debated. **Cigarette smoking and coffee appear protective.**

Pathology and pathogenesis

6. The main pathological finding is **loss of neurons in the substantia nigra** with **profound dopamine depletion** in the projection pathways from substantia nigra to the striatum.
7. The second hallmark is **α-synuclein bound to ubiquitin** accumulating in damaged neurons to form **Lewy bodies**, found in substantia nigra cells and other brain areas.
8. About **10 gene mutations** are identified in familial PD, but these operate mainly in **early-onset** disease and are rarely involved in late-onset PD.
9. Once dopamine loss crosses a threshold, the classical triad appears: **bradykinesia/akinesia, resting tremor and rigidity** (Essentials).

Clinical features

10. Onset is **insidious with slow progression**. Cardinal signs do not appear together — tremor may precede bradykinesia and rigidity by months to years. Signs are **asymmetric or unilateral at onset** and become bilateral later.
11. Other motor features: flexed posture of limbs and trunk on standing, **reduced step length and height, reduced arm swing**, falls, and writing difficulty.
12. Non-motor features: **bradyphrenia** (slowness of mental function), depression, anxiety, memory problems and dementia, **constipation**, bladder dysfunction and autonomic dysfunction (gastrointestinal, sexual, cardiovascular).
13. **Advanced PD (after 10–15 years)**: severe akinesia with less prominent tremor and rigidity, expressionless face, freezing, major gait and postural abnormality, repeated falls and fractures, wheelchair dependence, dysphagia, dysarthria, drooling, insomnia, pain, orthostatic hypotension, hallucinations and dementia. **Fluctuations and dyskinesia are very frequent and remain the main therapeutic challenge.**

Diagnosis

14. Diagnosis is clinical, using the **Queen Square Brain Bank criteria**: **Step 1** — bradykinesia plus at least one of muscular rigidity, 4–6 Hz rest tremor, or postural instability not due to visual, vestibular, cerebellar or proprioceptive causes; **Step 2** — exclusion criteria; **Step 3** — three or more supportive features.
15. **Ioflupane SPECT (DaTSCAN)** is normal in essential tremor, drug-induced parkinsonism and Alzheimer's disease, and abnormal in PD and other degenerative parkinsonian syndromes.
16. **Levodopa challenge** (150–250 mg with a decarboxylase inhibitor in a fasting patient; assess tremor, rigidity and akinesia every 30 minutes for 2–3 hours) indicates **dopaminergic responsiveness — it is not a formal diagnostic test**.

Treatment — drug choice and side effects in the elderly

17. **Levodopa is the main and often the only treatment for PD in the elderly.** It crosses the blood–brain barrier and is given with a peripheral decarboxylase inhibitor — **Madopar** (levodopa + benserazide) or **Sinemet** (carbidopa + levodopa). It is effective for **tremor, bradykinesia and rigidity**. Start low, increase very gradually; usual early control on **300–600 mg/day** in 3–4 doses, **30 minutes before meals**. Dispersible Madopar peaks faster and is used for **early-morning akinesia**.
18. **Side effects of levodopa**: nausea and vomiting, hypotension, sedation, nightmares and vivid dreams, hallucinations, delusions and delirium; after several years, **motor fluctuations** (delayed effect, wearing-off, on–off) and **involuntary movements** (chorea, athetosis, dystonia).
19. **Drugs Pathy's says are NOT used in older people with PD:** direct dopamine agonists (apomorphine, piribedil, ropinirole, lisuride, pramipexole, pergolide) — useful in the young to delay levodopa but adverse effects are numerous and can be severe; and **anticholinergics (trihexyphenidyl, tropatepine), which are never used in the elderly** because of delirium and other adverse effects.
20. **Adjuncts: COMT inhibitors** (entacapone, tolcapone) prolong levodopa effect and are useful in older patients with motor fluctuations and/or dyskinesia; **Stalevo** is the fixed combination of levodopa/carbidopa (50/12.5, 100/25, 150/37.5 mg) with entacapone 200 mg for unstabilised end-of-dose fluctuation. **Amantadine 200–400 mg/day** lessens peak-dose dyskinesia — reduce dose in renal impairment, delirium is frequent in the old. **Selegiline and rasagiline** (MAO-B inhibitors) have been proposed for neuroprotection in early PD.

Treatment of non-motor symptoms (Pathy's Table 53.4 — each considered only after adjusting levodopa)

Problem	Best-evidence treatment	Other options
Nausea, vomiting	Domperidone (ECG monitoring for QT prolongation)	Metoclopramide is **contraindicated**
Depression	Venlafaxine	Other SSRIs, pramipexole (delirium risk — not first choice in elderly), CBT, rTMS
Generalised anxiety disorder	None established	SSRIs, cognitive-behavioural therapy
Hallucinations, delusions	Clozapine; pimavanserin (5-HT2A inverse agonist)	Clozapine 12.5 mg start, 5-day increments to 25–50 mg; FBC weekly × 2 months then twice monthly; **stop permanently if neutrophils <1500/mm^3**
Dementia	Rivastigmine	Donepezil
Apathy	Rivastigmine	—
Mild cognitive impairment	None established	—
Orthostatic hypotension	Droxidopa	Midodrine, fludrocortisone, elastic compression
Insomnia	Sleep hygiene	Melatonin
Constipation	Hydration, probiotics and prebiotic fibre, macrogol	Lubiprostone if resistant; psyllium; entacapone's diarrhoea can be exploited
Drooling	Botulinum toxin into salivary glands if severe	—
Urinary urgency	None established	Solifenacin (low brain penetration)
Erectile dysfunction	Sildenafil	—

Newer modalities and non-pharmacological treatment

21. **Bilateral deep brain stimulation of the subthalamic nucleus or globus pallidus interna** produces sustained motor improvement, especially for levodopa-responsive symptoms, and reduces drug-induced involuntary movements. It is offered to **cognitively intact** patients with severe disability from refractory motor complications; severe comorbidity is a limitation. Pathy's states DBS is **not currently used in elderly people with PD**, but notes observational studies showing **similar efficacy in patients over 70** with no age-related increase in adverse effects. Concerns remain about depression and suicide, and disability still progresses because neurodegeneration continues.
22. Other surgical options (Essentials): **thalamotomy, pallidotomy**, and rarely intraputaminal fetal mesencephalic allografts.
23. **Rehabilitation should begin early** to preserve motor function, with sessions timed to the **peak effect of levodopa**. It targets joint flexibility, walking, lifting, posture, balance and turns, and counters the flexed attitude. **Speech therapy** helps dysarthria, drooling and swallowing later. Combined aerobic, strengthening, balance and stretching programmes improve balance in PD.
24. **Loss of independence** requires organised help at home — professional carers, caregiver involvement, meals-on-wheels. PD is not a frequent cause of institutional admission except when severe cognitive and behavioural complications occur. **Psychological support and patient/caregiver education** improve acceptance and optimise use of health resources.

Latest Updates (2023–Present)

- **Shift to a biological definition.** Two research frameworks were published together in *Lancet Neurology* 2024 — the **Neuronal α-Synuclein Disease Integrated Staging System (NSD-ISS)** (Simuni et al.) and **SynNeurGe** (Höglinger et al.). Both anchor diagnosis in **CSF α-synuclein seed amplification assay (SAA)** plus dopaminergic neurodegeneration on DAT imaging; SynNeurGe adds a genetic component (S–N–G). Both encompass PD and dementia with Lewy bodies. These are explicitly **research constructs, not yet for routine clinical diagnosis** (JAMA Neurology viewpoint 2024; Cell Death & Disease review 2025).
- **New levodopa formulations. Crexont (IPX203)**, extended-release carbidopa/levodopa capsules, FDA-approved August 2024 for motor fluctuations. **Vyalev (foslevodopa/foscarbidopa)**, the first **24-hour subcutaneous continuous infusion**, approved October 2024 — delivers levodopa prodrugs by pump and bypasses the gut, an alternative to intestinal gel. **Onapgo (subcutaneous apomorphine infusion)** approved February 2025 for "off" episodes. **ND0612** (subcutaneous levodopa/carbidopa) under FDA review.
- **New oral agent in the pipeline. Tavapadon**, a selective **D1/D5 partial agonist** — a different mechanism from D2/D3 agonists — met endpoints in the Phase 3 **TEMPO-1, -2 and -3** trials; TEMPO-3 gave an extra **1.1 hours of daily "on" time without troublesome dyskinesia**. NDA submitted 26 September 2025; FDA decision expected 2026 (AbbVie; MDS Congress 2025).
- **Safety alert.** In **March 2026 the FDA required a new label warning for all carbidopa/levodopa products** (Sinemet, Rytary, Stalevo, Crexont, Vyalev) regarding **vitamin B6 deficiency and seizures** — directly relevant to long-treated geriatric patients.
- **Adaptive (closed-loop) DBS.** FDA approved Medtronic **BrainSense Adaptive DBS** and the **BrainSense Electrode Identifier** in **February 2025**, based on the **ADAPT-PD** randomised crossover trial — the world's first commercially available aDBS. Stimulation is adjusted in real time to sensed beta-band local field potentials; the Electrode Identifier cuts initial programming time by about 85%.
- **Disease modification remains unproven. Exenatide-PD3** (*Lancet* 2025; 194 patients, 96 weeks) found **no benefit of weekly exenatide over placebo** on motor progression, despite positive Phase 2 exenatide and lixisenatide (*NEJM* 2024) data. *The Lancet* issued an **Expression of Concern on this trial in June 2026** — quote it cautiously. Pipeline (2026): prasinezumab (anti-α-synuclein antibody, Phase 3), bemdaneprocel (stem-cell, Phase 3), AB-1005 GDNF gene therapy (Phase 2, RMAT designation).
- **Indian data.** A **pan-Indian multicentre study of PD** (Kishore et al., *Movement Disorders* 2025) found clinical features, exposures and comorbidities broadly similar to European populations, but an **earlier age at onset in Indian patients, suggesting greater genetic contribution**. Community prevalence in India varies widely: crude rates **7–60 per 100,000**, age-adjusted **53–192 per 100,000**; Kolkata age-adjusted 52.85/100,000 with rates rising

to **621/100,000 above 80 years** (Das et al., *Neurology* 2010; Khurana & Gourie-Devi, *Cureus* 2025). The Parsi community of Mumbai has an exceptionally high crude rate of **328/100,000** and cannot be generalised. A Bangalore old-age-home study found parkinsonism in **17.8%** of residents with very poor awareness.

Current Practice Update

Aspect	Textbook position (Pathy's 6th ed.)	Current evidence-based practice
Basis of diagnosis	Clinical — Queen Square Brain Bank criteria	Clinical criteria remain the practice standard, but biological research definitions (NSD-ISS, SynNeurGe) using CSF α-synuclein SAA now exist and dominate trial recruitment
Dopamine agonists in the elderly	"Not used in older people with PD"	Still avoided as first line, but the position is nuanced — tavapadon (D1/D5 partial agonist) is designed for a better tolerability profile; low-dose rotigotine patch is used where oral routes fail
Deep brain stimulation	"Not currently used in elderly people with PD"	**Age alone is no longer a bar**; outcomes in patients >70 match younger patients. **Adaptive closed-loop DBS approved February 2025**
Continuous dopaminergic delivery	Duodenal levodopa infusion mentioned; subcutaneous apomorphine "limited data"	Three device-aided options now licensed: **Vyalev** (SC levodopa prodrug, 24 h), **Onapgo** (SC apomorphine), levodopa–carbidopa intestinal gel
Long-term levodopa safety	Nausea, hypotension, neuropsychiatric effects, fluctuations, dyskinesia	Add **vitamin B6 deficiency and seizure risk** (FDA labelling change, March 2026) and peripheral neuropathy with high-dose/continuous delivery
Disease modification	Selegiline/rasagiline "proposed for neuroprotective effects"	No agent has proven disease modification. **Exenatide-PD3 was negative** (Lancet 2025); MAO-B neuroprotection is no longer claimed

Examiner's Tip — lines that earn marks

- "The two pathological hallmarks are **nigral neuronal loss with striatal dopamine depletion** and **ubiquitinated α-synuclein forming Lewy bodies**."
- "In the geriatric population **levodopa is the main and often the only drug**; dopamine agonists and anticholinergics are avoided."
- "**Levodopa does not improve non-motor symptoms, posture or gait** — every non-motor treatment is considered only after levodopa has been optimised."
- Name the drug–symptom pairs verbatim: **venlafaxine** for depression, **clozapine or pimavanserin** for psychosis, **rivastigmine** for dementia and apathy, **droxidopa** for orthostatic hypotension, **domperidone** for nausea.
- Close with one 2025 fact: "**Adaptive DBS was FDA-approved in February 2025 on the ADAPT-PD trial**, and age over 70 is no longer a contraindication to DBS."

Q2. Etiopathogenesis, clinical presentation and management of the Parkinson-plus syndromes in older adults

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapter 53 (Tables 53.2, Box 53.1) and Chapter 46; Essentials of Clinical Geriatrics 7th ed.

Definition and importance

1. **Parkinson-plus (atypical parkinsonism)** means an extrapyramidal syndrome accompanied by additional neurological features not explained by idiopathic PD, with a **poor response to levodopa**.
2. These are disproportionately important in geriatrics: in **very late-onset parkinsonism, non-PD causes account for 20–40% of all new parkinsonism** in the elderly, a much higher proportion than in early-onset disease.
3. **Poor levodopa response is the single most useful clinical discriminator**, assessed from history or by formal levodopa challenge (Box 53.1).
4. Etiopathogenesis divides into **synucleinopathies** (multiple system atrophy, dementia with Lewy bodies) and **tauopathies** (progressive supranuclear palsy, corticobasal degeneration), alongside non-degenerative causes (drug-induced, vascular, hydrocephalic).

Clinical presentation of the individual syndromes (Pathy's Table 53.2)

Condition	Characteristic features
Frequently observed as very late-onset parkinsonism	
Drug-induced parkinsonism	Exposure to neuroleptics or other drugs before onset. **Dyskinesia frequent, no tremor**. Ioflupane SPECT normal.
Lewy body dementia	Dementia within a few months before or after onset of parkinsonism; **hallucinations**; **severe adverse reactions to neuroleptics**; fluctuating course; falls.
Alzheimer's disease	Parkinsonism infrequent (about 15%), only at moderate/severe stages and usually mild. Hippocampal atrophy on MRI; SPECT normal.
Progressive supranuclear palsy	Early postural instability and repeated falls; **axial rigidity**; limitation of vertical gaze; neck dystonia; impaired saccades on ocular electrophysiology. **No tremor.** MRI: **midbrain atrophy**.
Cerebrovascular disease	Parkinsonism with several infarcts on MRI, worsening after infarction; multilacunar state, pseudobulbar syndrome, emotional lability, pyramidal signs, vascular dementia.
Normal pressure hydrocephalus	Gait disturbance, urinary incontinence, cognitive slowness. Marked ventricular enlargement not explained by atrophy.
Very rarely observed as very late-onset parkinsonism	
Multiple system atrophy	**Severe dysautonomia early** in the course — orthostatic hypotension, urinary disorder, sexual dysfunction, gastrointestinal symptoms — with pyramidal or cerebellar syndrome.
Corticobasal degeneration	Dystonia, myoclonus, sensory disorders, **alien ("foreign") hand syndrome**.
Huntington's disease	Chorea; familial cases.
Wilson's disease	Liver disease, complex neurological signs including parkinsonism, psychiatric symptoms, familial cases, **Kayser–Fleischer ring**.
Miscellaneous	Toxic; post-encephalitic; repeated skull trauma.

5. **Dementia with Lewy bodies** is strongly related to PD, sharing **Lewy body and α-synuclein pathology**. Diagnosis needs (i) cognitive dysfunction fulfilling dementia criteria with insidious onset and progression, plus (ii) one or more of hallucinations, extrapyramidal syndrome, fluctuating course, falls and poor tolerance of neuroleptics. Extrapyramidal signs may precede cognitive decline by months.
6. **Key timing rule:** dementia within a few months of parkinsonism = **DLB**; dementia after several years of established PD = **PD-related dementia**.
7. In Alzheimer's disease, extrapyramidal signs may reflect current or past neuroleptic exposure — this must be sought by interviewing patients, proxies, physicians and pharmacists. Their presence **at diagnosis predicts more rapid decline**.
8. PSP is **frequently misdiagnosed as PD**. Cerebral MRI shows a **convex midbrain outline indicating atrophy**, where the normal midbrain aspect is concave.
9. Vascular parkinsonism: **onset or worsening of extrapyramidal signs within one month after a stroke strongly supports the diagnosis**. Swallowing problems and gait/posture abnormality are frequent; tremor infrequent; levodopa response poor. MRI shows multiple lacunae and/or severe leukoaraiosis.
10. NPH gait can mimic PD (short steps, shuffling, slowness, stooped trunk, flexed lower limbs) but there is **no tremor and no rigidity**, and the gait **does not respond to external cues or to levodopa**. Imaging shows quadriventricular dilatation with small sulci and periventricular T2 high signal.

Diagnostic approach

11. In most cases **medical history and physical examination alone allow identification**; the drug history must be exhaustive.
12. **Ioflupane (DaTSCAN) SPECT** separates degenerative parkinsonism (abnormal) from essential tremor, drug-induced parkinsonism and Alzheimer's disease (normal). MRI identifies midbrain atrophy, vascular lesions and hydrocephalus. Ocular electrophysiology supports PSP.
13. Where doubt persists, **follow-up usually clarifies the diagnosis** as new signs and symptoms emerge.

Management

14. **Give an adequate trial of levodopa in every case** — a clear negative response is itself diagnostically useful, and some patients obtain partial benefit.
15. **Drug-induced parkinsonism:** stopping the offending drug is the best option. Recovery is **very slow, over weeks to months**, and in about **20% some extrapyramidal signs persist**, suggesting underlying PD or another neurodegenerative parkinsonism unmasked by the drug. **Tardive dyskinesia is often permanent** even after withdrawal. There is **no satisfactory drug treatment**.
16. In elderly patients this withdrawal is usually possible, because neuroleptics are mainly used for behavioural complications of dementia — **a condition for which they are ineffective**. If severe psychosis demands treatment, switch from a classical neuroleptic to a **low-dose atypical antipsychotic**.
17. **Anticholinergics must be avoided** in the elderly — they induce delirium and other adverse effects.
18. **Prevention of drug-induced parkinsonism is a crucial issue in geriatric care**, achieved by avoiding neuroleptic prescription in older people, especially those with dementia.
19. Supportive and symptomatic care dominates management: falls prevention and physiotherapy, speech and swallow therapy, treatment of orthostatic hypotension (droxidopa, midodrine, fludrocortisone, elastic compression), botulinum toxin for drooling, carer education and advance care planning. **DBS is not indicated in Parkinson-plus syndromes.**
20. **Prognosis:** atypical syndromes progress faster than PD, with earlier falls, dysphagia, dependency and death, usually from aspiration pneumonia.

Latest Updates (2023–Present)

- **MSA — new criteria and validation.** The **MDS criteria for MSA (Wenning et al., *Mov Disord* 2022)** replaced the 2008 consensus and define four certainty levels: **neuropathologically established, clinically established, clinically probable, and possible prodromal MSA**. Brain-bank validation confirmed improved early sensitivity (Sekiya et al., *Neurology* 2023); adding MRI markers further improves performance (*Mov Disord* 2024).
- **α-Synuclein seeding biomarkers.** *Lancet Neurology* 2024 (MSA review) highlights **disease-specific α-synuclein strains** distinguishable by seed amplification assay. **Skin biopsy for phosphorylated α-synuclein** is emerging — specificity for PD up to 100%, sensitivity up to 81%, and **fibrillar phospho-α-synuclein in Schwann cells appears to be an MSA-specific hallmark** (Donadio et al.; Gibbons et al., *Neurology* 2023). Skin SAA is being evaluated to separate MSA from PD (2025–26 data). These remain **promising but incompletely validated**, and are not in routine Indian practice.
- **PSP — expanded phenotype.** The **MDS-PSP criteria** define **eight clinical variants** across four functional domains and include a "**suggestive of PSP**" category for early disease; this category was **prospectively validated** (Quattrone et al., *Mov Disord* 2025). **Second-generation tau-PET (18F-PI-2620)** detects 4-repeat tau in the basal ganglia and predicts increasing diagnostic certainty; plasma/CSF **NfL and GFAP** on SIMOA track progression (*Brain Communications* 2025).
- **Global and Indian perspective on PSP.** A 2026 global review in *Movement Disorders Clinical Practice* (Kukkle et al.) reports prevalence **5–6.4 per 100,000**, with regional variation in the **MAPT H1 haplotype**, dietary neurotoxins and industrial pollutants, and marked differences in access to specialist care.
- **DLB within the biological framework.** Both the NSD-ISS and SynNeurGe systems (*Lancet Neurology* 2024) explicitly cover **PD and DLB as one α-synuclein-driven biological continuum**, formally dissolving the arbitrary "one-year rule" for research purposes — though the clinical rule is still examined.
- **Therapeutics.** There is still **no disease-modifying therapy for any Parkinson-plus syndrome**. Tau-directed agents (antibodies, antisense oligonucleotides, sodium selenate) are in trial for PSP; TEV-56286 (OGA inhibitor) is in Phase 2 for MSA.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
MSA diagnosis	Clinical — early severe dysautonomia with pyramidal or cerebellar signs	**MDS 2022 criteria** with four certainty levels including **possible prodromal MSA**; MRI markers formally incorporated
PSP diagnosis	Single phenotype: gaze palsy, early falls, axial rigidity, midbrain atrophy	**MDS-PSP criteria — eight variants** (PSP-RS, PSP-P, PSP-PGF, PSP-CBS and others) with an early "suggestive of PSP" category
Confirmatory testing	Ioflupane SPECT, MRI, ocular electrophysiology	Add **α-synuclein SAA (CSF and skin)** and **tau-PET (18F-PI-2620)** — research/tertiary use; MRI plus autonomic testing remain the routine tools
DLB vs PD dementia	Separated by the one-year timing rule	Clinically retained; biologically both are classed as **neuronal α-synuclein disease** in the 2024 research frameworks
Treatment	Symptomatic; levodopa trial; avoid neuroleptics	Unchanged — **no disease-modifying therapy exists**; tau- and synuclein-directed trials ongoing

Examiner's Tip — lines that earn marks

- Open with the geriatric statistic: "**In very late-onset parkinsonism, 20–40% of new cases are not idiopathic PD.**"
- State the discriminator: "**Parkinsonian syndromes other than PD respond poorly to levodopa.**"
- Give the one-line signature of each: **MSA** = early severe dysautonomia; **PSP** = early falls + vertical gaze palsy + axial rigidity + midbrain atrophy; **CBD** = alien hand, myoclonus, dystonia; **DLB** = dementia within months + hallucinations + neuroleptic sensitivity; **vascular** = worsening within one month of stroke; **NPH** = gait + incontinence + cognitive slowing with ventriculomegaly.
- Score the geriatric point: "**Prevention of drug-induced parkinsonism by avoiding neuroleptics in dementia is a crucial issue in geriatric care** — 20% have persistent signs even after withdrawal."

Q3. Drug treatment for Parkinson's disease

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapter 53; Essentials of Clinical Geriatrics 7th ed., Table 10-6.

Principle

1. Drug treatment aims to **increase the ratio of dopamine to acetylcholine** in the central nervous system, specifically in the **nigrostriatal system**.
2. Six drug groups are used: **levodopa combinations, dopamine agonists, MAO-B inhibitors, COMT inhibitors, amantadine and anticholinergics**.
3. **Clinical response may take several weeks**; side effects are common and often limit treatment; response varies widely between patients.

Drugs, doses, mechanism and side effects (Essentials Table 10-6)

Drug	Usual dose	Mechanism	Main side effects
Carbidopa–levodopa (Sinemet)	40/400 to 200/2000 mg/day in divided doses	Increases dopamine availability; decreases peripheral dopamine metabolism	Nausea, vomiting, anorexia; **dyskinesias**; orthostatic hypotension; behavioural disturbance; vivid dreams and hallucinations
Amantadine (Symmetrel)	100–300 mg/day (200–400 mg/day for dyskinesia)	Increases dopamine release	**Delirium and hallucinations**. Renally eliminated — **reduce dose in renal impairment**
Bromocriptine (Parlodel)	1–1.5 mg tid/qid, up to 30–40 mg/day	Directly activates dopaminergic receptors	Behavioural change, hypotension, nausea
Pramipexole (Mirapex)	0.5–1.5 mg tid	Dopamine agonist	Hallucinations, nausea, somnolence
Ropinirole (Requip)	3–8 mg tid	Dopamine agonist	Orthostatic hypotension, syncope, nausea, somnolence
Trihexyphenidyl (Artane)	2–20 mg/day divided	Reduces acetylcholine effect; restores cholinergic–dopaminergic balance	Dry mouth, constipation, urinary retention, blurred vision, glaucoma exacerbation, tachycardia, **confusion**, behavioural change
Benztropine (Cogentin)	0.5–8.0 mg/day divided	As above	As above
Selegiline (Eldepryl)	10 mg/day single dose	MAO-B inhibitor	Nausea, confusion, agitation, insomnia, involuntary movements
Rasagiline (Azilect)	1 mg/day single dose	Selective, irreversible MAO-B inhibitor	Balance difficulty, anorexia, vomiting, weight loss, depressive symptoms; **no dietary restriction**
Entacapone (Comtan)	200 mg with each levodopa dose	Inhibits catechol-O-methyltransferase	Nausea, dyskinesias, orthostatic hypotension, **diarrhoea**
Tolcapone (Tasmar)	100–200 mg tid	COMT inhibitor	**Liver dysfunction**

Prescribing in the older patient

4. **Levodopa is the main and often the only treatment for PD in the elderly.** Given with a peripheral dopa-decarboxylase inhibitor as **Madopar** (levodopa + benserazide) or **Sinemet** (carbidopa + levodopa); effective for **tremor, bradykinesia and rigidity**.
5. **Start low and increase very gradually.** Most patients are controlled in the first years on **300–600 mg/day**, given 3–4 times daily, preferably **30 minutes before meals**. **Dispersible Madopar** peaks faster and is used for early-morning akinesia.
6. **Direct dopamine agonists are not used in older people with PD.** They act on D2 receptors and can delay levodopa introduction in younger patients, but **adverse effects are numerous and could be severe** in the elderly.
7. **Anticholinergic drugs (trihexyphenidyl, tropatepine) are never used in older people with PD**, although they improve tremor, because they induce delirium and other adverse effects.
8. **MAO-B inhibitors** (selegiline, rasagiline) have been proposed for neuroprotective effects in early PD.
9. **COMT inhibitors** decrease dopamine degradation and prolong the levodopa effect — **useful in older patients with motor fluctuations and/or levodopa-induced dyskinesia**. **Stalevo** combines levodopa/carbidopa (50/12.5, 100/25, 150/37.5 mg) with fixed-dose entacapone 200 mg, indicated for **end-of-dose fluctuation not stabilised by levodopa–decarboxylase inhibitor**.
10. **Amantadine 200–400 mg/day** is effective in lessening **peak-dose dyskinesia**; adjust for renal impairment; delirium is frequent in old patients.
11. **Rotigotine transdermal patch** (non-ergoline agonist) is used in Europe with levodopa — ease of administration and stable blood levels are advantages (Essentials).
12. **Metoclopramide is contraindicated** in parkinsonian patients because of its striatal dopamine receptor effects; **domperidone**, which does not cross the blood–brain barrier, is used instead.
13. Excess dopaminergic stimulation causes **sleep disturbance, delirium and psychosis**. Response variability produces morning akinesia, peak-dose dyskinesias and freezing episodes (the "on–off phenomenon").
14. **Cholinesterase inhibitors** have evidence of benefit in **PD-associated dementia**, with a positive effect on global assessment (Essentials).

15. Drugs for non-motor complications, each considered **after adjusting levodopa**: domperidone (nausea), venlafaxine (depression), clozapine or pimavanserin (hallucinations/delusions), rivastigmine (dementia and apathy), droxidopa/midodrine/fludrocortisone (orthostatic hypotension), melatonin (insomnia), macrogol (constipation), solifenacin (urgency), sildenafil (erectile dysfunction).
16. **Clozapine monitoring is examinable**: start 12.5 mg daily, five-day increments to a usual 25–50 mg; blood count weekly for two months then twice monthly; **discontinue permanently if neutrophils fall below 1500/mm^3**. Pimavanserin requires no haematological monitoring.
17. Preliminary data suggest **coenzyme Q10** may protect the nigrostriatal dopaminergic system, but further research is needed; **pharmacogenetics** is expected to allow more individualised prescribing.

Latest Updates (2023–Present)

- **Newly licensed levodopa delivery systems** (not in either textbook): **Crexont** (IPX203 extended-release carbidopa/levodopa capsules, FDA August 2024); **Vyalev** (foslevodopa/foscarbidopa, first 24-hour subcutaneous infusion, FDA October 2024); **Onapgo** (subcutaneous apomorphine infusion, FDA February 2025); **ND0612** subcutaneous levodopa/carbidopa under review.
- **Tavapadon** — a **selective D1/D5 receptor partial agonist**, mechanistically distinct from the D2/D3 agonists in the textbook table. Positive Phase 3 TEMPO-1/2/3; NDA filed September 2025, decision expected 2026. If approved it will be the **first new oral dopamine agonist for PD in over a decade**.
- **Newer adjuncts absent from the textbooks** but now standard in international practice: **opicapone** (once-daily COMT inhibitor), **safinamide** (MAO-B inhibitor with glutamate-modulating action) and **istradefylline** (adenosine A2A antagonist) for off-time reduction.
- **FDA labelling change, March 2026:** a warning regarding **vitamin B6 deficiency and seizures** now applies to **all carbidopa/levodopa products**, including Sinemet, Rytary, Stalevo, Crexont and Vyalev. Consider periodic B6 assessment in long-treated older patients.
- **Neuroprotection claims withdrawn.** No agent has demonstrated disease modification. **Exenatide-PD3** (*Lancet* 2025) was negative, despite positive Phase 2 lixisenatide data (*NEJM* 2024); the Lancet issued an Expression of Concern on the exenatide paper in June 2026. MAO-B inhibitors are now prescribed for **symptomatic benefit only**.
- **Indian practical note:** levodopa–carbidopa, levodopa–benserazide, trihexyphenidyl, amantadine, pramipexole, ropinirole, rasagiline, entacapone and the levodopa/carbidopa/entacapone combination are all widely available and inexpensive in India; device-aided therapies (intestinal gel, subcutaneous infusions) and DBS are limited to a few tertiary centres and are largely out-of-pocket.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
COMT inhibitors	Entacapone (with each dose) and tolcapone (hepatotoxic)	**Opicapone once daily** is now preferred where available — better adherence, no hepatotoxicity monitoring
MAO-B inhibitors	Selegiline and rasagiline "proposed for neuroprotective effects"	Used for **symptomatic benefit only**; **safinamide** added as an option for wearing-off
Off-time adjuncts	COMT inhibitors and amantadine	Add **istradefylline** (adenosine A2A antagonist) and the new ER/infusional levodopa formulations
Dopamine agonists	D2 agonists — avoided in the elderly	Position holds for D2/D3 agonists; **tavapadon (D1/D5 partial agonist)** may change the calculus if approved in 2026
Levodopa safety monitoring	Nausea, hypotension, neuropsychiatric effects, motor complications	Add **vitamin B6 deficiency/seizures** (FDA March 2026) and peripheral neuropathy with continuous delivery

Examiner's Tip — lines that earn marks

- Open with the principle: "**Treatment aims to restore the dopamine–acetylcholine ratio in the nigrostriatal system.**"
- Draw the Essentials table — drug, dose, mechanism, side effect — it converts directly into marks.
- State both geriatric prohibitions explicitly: "**Dopamine agonists are not used and anticholinergics are never used in older people with PD.**"
- Quote the two monitoring rules: **clozapine — stop if neutrophils <1500/mm^3**; **domperidone — ECG for QT prolongation**; and **metoclopramide is contraindicated**.

Q4. Levodopa

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapters 53 and 30 (gastrointestinal ageing); Essentials of Clinical Geriatrics 7th ed.

1. Levodopa is the **metabolic precursor of dopamine**. Unlike dopamine itself, it **crosses the blood–brain barrier**.
2. It is combined with a **peripheral dopa-decarboxylase inhibitor** to lessen systemic effects: **Madopar** = levodopa + benserazide; **Sinemet** = carbidopa + levodopa.
3. It is the **main and often the only treatment for PD in the elderly**, and the most effective drug available.
4. It is effective for **tremor, bradykinesia and rigidity**.
5. Several formulations exist, distinguished by their **rates of absorption**. Standard levodopa is given **three or four times daily, preferably 30 minutes before meals**.
6. Most patients are controlled in the first years of PD on **300–600 mg per day**. It should be **started at low doses and increased very gradually** until the appropriate effect is obtained.
7. The **dispersible form (dispersible Madopar)** achieves peak plasma concentration faster and is used for **early-morning akinesia**, allowing the first standard dose to be taken at the same time.
8. As disease progresses the dose must be increased progressively, and **adverse effects become frequent**.
9. **Peripheral side effects:** nausea, vomiting, anorexia and hypotension.
10. **Neuropsychiatric side effects:** sedation, nightmares, vivid dreams, hallucinations, delusions and delirium — all **dose-related** and especially common in older patients.
11. **Long-term complications after several years: motor fluctuations** with the on–off phenomenon, delayed effect of levodopa and wearing-off between doses; and **involuntary movements** — chorea, athetosis and dystonia. These complications require **revision of the timing of levodopa administration**.
12. **Gastric emptying is delayed in at least 70% of PD patients**, even without levodopa, and levodopa slows it further. Levodopa **retained in the stomach is metabolised to dopamine and becomes unavailable for systemic absorption**.
13. In patients with the on–off phenomenon, gastric emptying may **normalise in the "on" phase**; conversely, variable emptying causes **erratic levodopa absorption and itself contributes to the on–off phenomenon**.
14. **Direct duodenal infusion of levodopa** has been advocated to solve this problem; increasing the **ratio of decarboxylase inhibitor to levodopa** has also been suggested to improve dopamine availability.
15. A critical examination point: **levodopa is not considered to improve non-motor symptoms or signs, or posture and gait.**
16. **Role in diagnosis:** in the Queen Square Brain Bank criteria, supportive features include **excellent (70–100%) response to levodopa**, **severe levodopa-induced chorea** and **levodopa response sustained for five years or more**; a **negative response to large doses of levodopa** (with malabsorption excluded) is an **exclusion criterion**.
17. **Levodopa challenge test** (Box 53.1): give a fasting patient **150–250 mg levodopa with a decarboxylase inhibitor** and assess tremor, rigidity and akinesia of the limbs **every 30 minutes for two to three hours**. This is an **indicator of dopaminergic response, not a formal diagnostic test** for PD.
18. Poor levodopa response points to a **Parkinson-plus syndrome, vascular parkinsonism or normal pressure hydrocephalus**.
19. **Adjuncts that extend or modify levodopa action:** COMT inhibitors (entacapone, tolcapone) prolong its effect; Stalevo is the fixed triple combination; amantadine 200–400 mg/day reduces peak-dose dyskinesia.
20. **Drug interactions/cautions:** metoclopramide is contraindicated; domperidone is used for levodopa-induced nausea; dietary protein competes with levodopa for absorption, hence pre-meal dosing.

Latest Updates (2023–Present)

- **Crexont (IPX203)** — extended-release carbidopa/levodopa capsules combining immediate-release granules with ER beads, FDA-approved **August 2024**; designed to smooth the peaks and troughs of immediate-release levodopa and increase "good on" time in patients with wearing-off.
- **Vyalev (foslevodopa/foscarbidopa)** — FDA-approved **October 2024**, the **first 24-hour continuous subcutaneous infusion** of levodopa/carbidopa prodrugs, delivered by a small worn pump. It provides continuous dopaminergic delivery **without a surgical tube**, bypassing the erratic gastric absorption described in the textbook.
- **ND0612** — a further subcutaneous levodopa/carbidopa system; FDA resubmission accepted, decision pending. If approved it joins Vyalev and Onapgo as a third subcutaneous option.
- **FDA safety warning, March 2026:** all carbidopa/levodopa products now carry a label warning for **vitamin B6 deficiency and seizures** — a new consideration in patients on long-term or high-dose continuous levodopa. Peripheral neuropathy from B-vitamin depletion is a related recognised complication of high levodopa exposure.
- **Levodopa is not neurotoxic and should not be withheld.** Contemporary reviews and the earlier LEAP trial confirm that delaying levodopa does not alter disease course; in older patients the **modern approach is to start levodopa early at the lowest effective dose** rather than "saving" it — consistent with, and reinforcing, Pathy's geriatric position.
- **Indian context:** levodopa–carbidopa (110 mg, 275 mg tablets) and levodopa–benserazide remain among the cheapest and most widely available neurological drugs in India, and are on state essential medicine lists. Dietary counselling matters in Indian practice because a high-protein evening meal (dal, paneer, milk) can blunt the response to the last dose of the day.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
Formulations	Standard and dispersible levodopa; duodenal infusion "advocated"	Add **Crexont** (ER capsules), **Vyalev** (24-h SC infusion) and **ND0612**; intestinal gel is established
Overcoming erratic gastric absorption	Duodenal infusion; raise the decarboxylase-inhibitor ratio	**Subcutaneous prodrug infusion (Vyalev)** now achieves the same aim non-surgically
Long-term adverse effects	Fluctuations, dyskinesia, neuropsychiatric effects, hypotension	Add **vitamin B6 deficiency, seizures and peripheral neuropathy** (FDA March 2026)
When to start	Implicit — levodopa is first-line in the elderly	Explicitly supported: **early initiation at lowest effective dose**; no evidence that delaying levodopa preserves neurons

Examiner's Tip — lines that earn marks

- Definition line: "**Levodopa is the precursor of dopamine which crosses the blood–brain barrier, given with a peripheral decarboxylase inhibitor as Madopar or Sinemet.**"
- Dose line: "**300–600 mg/day in the first years, 3–4 divided doses, 30 minutes before meals.**"
- The single most quotable sentence: "**Levodopa does not improve non-motor symptoms, posture or gait.**"
- Mention the **70% delayed gastric emptying** figure and its role in the on–off phenomenon — examiners reward the pharmacokinetic explanation.
- End with the challenge test protocol: **150–250 mg fasting, assess every 30 minutes for 2–3 hours**.

Q5. Parkinsonism

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapters 44 (age-related neurological signs) and 53.

Definition

1. **Parkinsonism (extrapyramidal syndrome)** is a clinical syndrome, not a disease. **Akinesia is the defining and obligatory feature**, comprising **bradykinesia** (slowness in initiation and performance of movement) and **hypokinesia** (small amplitude of movement).
2. **Rigidity** is the increase in resistance to passive movement that is **constant throughout the range of joint displacement ("lead-pipe") and not related to the velocity of movement** — this distinguishes it from spasticity.
3. **Tremor and postural abnormality**, along with rigidity, may also occur as cardinal features of the syndrome.
4. Operational definition used in population studies: **two or more of bradykinesia, gait disturbance, rigidity and tremor**. In the East Boston community study of 467 people over 65, **159 had parkinsonism**, and prevalence increased with age.
5. The neuropathological correlate of these age-related findings is the **progressive spread of α-synuclein-immunopositive Lewy bodies and Lewy neurites**, reported in the brains of ageing but asymptomatic individuals.
6. Distinguish rigidity from **paratonia (gegenhalten)** — "superadded hypertonus of a quasi-volitional nature due to the patient's failure to relax". Its anatomical correlate is **bilateral frontal lobe pathology, usually diffuse small-vessel ischaemic disease**; some classify it as a release sign.
7. Upward conjugate gaze becomes restricted with age, a finding also observed in parkinsonism — beware over-interpreting it in the very old.

Causes

8. **Idiopathic Parkinson's disease** is the commonest cause, but in **very late-onset parkinsonism other causes account for 20–40% of new cases**.
9. **Frequently observed in the elderly:** drug-induced parkinsonism, Lewy body dementia, Alzheimer's disease, progressive supranuclear palsy, cerebrovascular disease, normal pressure hydrocephalus.
10. **Very rarely observed as very late-onset parkinsonism:** multiple system atrophy, corticobasal degeneration, Huntington's disease, Wilson's disease, and miscellaneous causes (toxic, post-encephalitic, repeated skull trauma).
11. **Drug-induced parkinsonism** is defined by exposure to neuroleptics or other drugs before onset; **dyskinesia is frequent, tremor is absent**, and ioflupane SPECT is normal. Many elderly patients, especially in long-term care, have **undiagnosed, treatable drug-induced parkinsonism** from the extrapyramidal effects of antipsychotics.
12. Drugs implicated in tremor and extrapyramidal effects include **neuroleptics (haloperidol, fluphenazine, olanzapine), metoclopramide, prochlorperazine, lithium, valproate, amiodarone, calcium channel blockers** and antidepressants.

Diagnostic approach

13. In most cases **medical history and physical examination allow identification** of the cause. Past or current neuroleptic exposure must be sought carefully by interviewing **patients, proxies, physicians and pharmacists**.
14. Apply the **Queen Square Brain Bank criteria**: Step 1 establishes the parkinsonian syndrome; Step 2 lists exclusions (repeated strokes with stepwise progression, repeated head injury, definite encephalitis, oculogyric crises, neuroleptic treatment at onset, more than one affected relative, sustained remission, strictly unilateral features after three years, supranuclear gaze palsy, cerebellar signs, early severe autonomic involvement, early severe dementia, Babinski signs, cerebral tumour or communicating hydrocephalus, negative response to large doses of levodopa, MPTP exposure); Step 3 requires three or more supportive features.
15. **Parkinsonian syndromes other than PD respond poorly to levodopa** — assessed from history or by levodopa challenge.
16. **Ioflupane SPECT (DaTSCAN)** shows a **normal pattern in essential tremor, drug-induced parkinsonism and Alzheimer's disease**, and **abnormalities in PD and other parkinsonian syndromes**.
17. **MRI** identifies midbrain atrophy (PSP), multiple lacunae and leukoaraiosis (vascular), and ventriculomegaly out of proportion to atrophy (NPH).
18. Where diagnosis remains uncertain, **follow-up usually clarifies it** as new signs and symptoms appear.

Management

19. **Treat the cause.** Stop the offending drug in drug-induced parkinsonism (improvement is slow, over weeks to months; about **20% have persistent signs**; there is **no satisfactory treatment**). Shunt for NPH; vascular risk factor control for vascular parkinsonism; levodopa for PD.
20. **Prevention of drug-induced parkinsonism is a crucial issue in geriatric care** — avoid neuroleptics in older people, especially those with dementia, in whom they are ineffective for behavioural symptoms. If untreated, parkinsonian patients eventually become immobile and develop **flexion contractures, pressure sores, malnutrition and aspiration pneumonia**.

Latest Updates (2023–Present)

- **MDS clinical diagnostic criteria for PD** (Postuma et al., *Mov Disord* 2015) are now the international standard alongside the Queen Square criteria, adding **prodromal PD research criteria** based on RBD, hyposmia, constipation and autonomic features.
- **Biological reframing of parkinsonism**: the 2024 *Lancet Neurology* NSD-ISS and SynNeurGe frameworks classify by **α-synuclein seeding positivity, neurodegeneration and genetics** rather than by motor phenotype. Critics (Okubadejo, Okun and Jankovic, *JAMA Neurol* 2024) note limited applicability in low- and middle-income settings, where CSF SAA and DAT imaging are largely unavailable — a point worth making for the Indian context.
- **Skin biopsy for phosphorylated α-synuclein** is emerging as a minimally invasive test to confirm synucleinopathy and to separate MSA (Schwann-cell fibrillar deposits) from PD.

- **Indian epidemiology of parkinsonism:** community crude prevalence ranges from **7 to 60 per 100,000** depending on region and methodology, with urban rates exceeding rural. Screening has always used general neurological instruments (WHO or NIMHANS protocols) rather than PD-specific tools; the **Sarangmath modification of the Tanner screening questionnaire** is the validated Indian PD-specific instrument (Khurana & Gourie-Devi, *Cureus* 2025).
- Historical point examiners like: parkinsonism was described in ancient Indian medical literature as **"kampavata"** (kampa = tremor, vata = dosha) long before James Parkinson's 1817 essay.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
Diagnostic criteria	Queen Square Brain Bank criteria (3 steps)	**MDS 2015 criteria** plus MDS prodromal research criteria are the international standard; Queen Square remains valid and examinable
Concept of the disease	Clinical syndrome defined by motor signs	Research frameworks define it **biologically** (α-synuclein seeding + neurodegeneration + genetics)
Confirmatory tests	Ioflupane SPECT, MRI	Add **CSF/skin α-synuclein SAA** and MRI-based automated midbrain indices — not yet routine, and scarcely available in India
Screening in the community	Not addressed	Validated Indian PD-specific screening questionnaire exists (Sarangmath et al.), addressing the misclassification problem of generic protocols

Examiner's Tip — lines that earn marks

- Lead with the definition: "**Akinesia — bradykinesia plus hypokinesia — is the defining and obligatory feature of parkinsonism.**"
- Define rigidity precisely: "**constant throughout the range of joint displacement and independent of velocity, unlike spasticity.**"
- Always separate **parkinsonism (syndrome)** from **Parkinson's disease (one cause)** in the first sentence — this is what the short-note is testing.
- Give the geriatric figure: "**20–40% of very late-onset parkinsonism is not idiopathic PD.**"
- Do not forget **paratonia/gegenhalten** as the differential for increased tone in the frail elderly.

Q6. Motor fluctuations in Parkinson's disease

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapters 53 and 30; Essentials of Clinical Geriatrics 7th ed.

Definition and types

1. **Motor fluctuations** are variations in motor performance in relation to levodopa dosing, appearing **after several years of levodopa use** as the disease advances.
2. Pathy's describes three patterns: a **delayed effect of levodopa** ("delayed on"), **wearing-off between doses**, and the **on–off phenomenon**.
3. Essentials describes the same clinical spectrum as **morning akinesia, peak-dose dyskinesias and freezing episodes**, collectively termed the on–off phenomenon.
4. Fluctuations are accompanied by **involuntary movements — chorea, athetosis and dystonia** (peak-dose dyskinesia, diphasic dyskinesia and off-period dystonia).
5. In **advanced PD (after 10–15 years)**, fluctuations and motor dyskinesia are **very frequent and remain a challenge for treatment**.

Pathophysiology

6. **Central mechanism:** progressive nigrostriatal degeneration reduces the striatal capacity to store and buffer dopamine, so the clinical effect increasingly follows the **short plasma half-life of levodopa**, producing pulsatile rather than tonic receptor stimulation.
7. **Peripheral mechanism: gastric emptying is delayed in at least 70% of PD patients** attending neurological clinics, even without levodopa therapy, and levodopa slows it further.
8. Levodopa **retained in the stomach is metabolised to dopamine and becomes unavailable for systemic absorption**, contributing to nausea, bloating and impaired nutrition.
9. In patients with the on–off phenomenon, **gastric emptying may normalise during the "on" phase**; conversely, **variation in the rate of emptying causes erratic levodopa absorption and thereby contributes to the on–off phenomenon** — a two-way relationship.
10. **Dietary protein competes with levodopa** for absorption, which is why standard levodopa is given 30 minutes before meals.
11. **Constipation** is associated with reduced efficacy of medication due to reduced absorption, and occurs in about half of PD patients.

Assessment

12. Take a **patient or carer diary** of on and off periods, mapped against dose times and meals; review total daily levodopa, dose interval, formulation and adherence.
13. Exclude reversible contributors: **constipation, intercurrent infection, dehydration, malabsorption, protein timing, and drugs that antagonise dopamine** (metoclopramide, neuroleptics).
14. Look specifically for **early-morning akinesia**, **early-morning and off-period dystonia** and **freezing**, since each has a different solution.

Management

15. **First step: revise the timing of levodopa administration.** Fractionate the same total dose into smaller, more frequent doses to reduce peak-dose dyskinesia and shorten off periods.
16. **Dispersible Madopar** achieves peak plasma concentration faster and is used for **early-morning akinesia**, allowing the first standard dose to be taken at the same time.
17. **COMT inhibitors (entacapone, tolcapone)** decrease dopamine degradation and increase and prolong the levodopa effect — they are **useful in older patients with motor fluctuations and/or levodopa-induced dyskinesia**.
18. **Stalevo** (levodopa/carbidopa 50/12.5, 100/25 or 150/37.5 mg with fixed entacapone 200 mg) is indicated for patients with **end-of-dose fluctuation not stabilised by levodopa–decarboxylase inhibitor alone**.
19. **Amantadine 200–400 mg/day** is effective in lessening **peak-dose dyskinesia**. Adjust the dose in renal impairment; **delirium is frequent in old patients**.
20. **Direct duodenal infusion of levodopa** is advocated as a solution to erratic gastric absorption; increasing the decarboxylase-inhibitor to levodopa ratio has also been proposed. **Subcutaneous apomorphine infusion** has limited data but shows benefit, including for swallowing.
21. **Bilateral deep brain stimulation of the subthalamic nucleus or globus pallidus interna** produces sustained improvement in motor function, especially for levodopa-responsive symptoms, and **reduces drug-induced involuntary movements**. It is offered to **cognitively intact patients with severe disability from motor complications refractory to best medical treatment**; severe comorbidity is a limitation. Pathy's notes that efficacy in patients over 70 is similar to that in younger patients, with no age-related increase in adverse effects, but that **disability continues to progress because neurodegeneration continues**.
22. **Rehabilitation sessions should be held at the time of the peak effect of levodopa** to maximise participation.
23. Manage **constipation actively** (hydration, fibre, macrogol, psyllium) because it both worsens absorption and causes nausea and anorexia; entacapone-induced diarrhoea can be turned to advantage.

Latest Updates (2023–Present)

- **Crexont (IPX203)**, FDA-approved **August 2024**, is an extended-release carbidopa/levodopa capsule specifically developed for **wearing-off**; its design reduces peaks and troughs, which matters increasingly as gastric emptying slows with age.
- **Vyalev (foslevodopa/foscarbidopa)**, FDA-approved **October 2024**, delivers levodopa prodrugs by **24-hour subcutaneous pump**, achieving continuous dopaminergic stimulation and **bypassing the gastrointestinal tract entirely** — the modern answer to the erratic gastric absorption Pathy's describes,

without surgery.

- **Onapgo (subcutaneous apomorphine infusion)**, FDA-approved **February 2025** for "off" episodes, filling a long-standing US gap; continuous apomorphine infusion already had a well-established safety profile in Europe and the UK.
- **Adaptive (closed-loop) DBS.** The FDA approved Medtronic **BrainSense Adaptive DBS** in **February 2025** on the strength of the **ADAPT-PD** multicentre randomised crossover trial — the largest and longest study of aDBS. Stimulation is titrated in real time to sensed **beta-band local field potentials**, and is specifically indicated for **patients with motor fluctuations despite medical therapy**; the accompanying Electrode Identifier reduces initial programming time by about **85%**.
- **Tavapadon** (D1/D5 partial agonist) added to levodopa gave an extra **1.1 hours of daily "on" time without troublesome dyskinesia** and a significant reduction in "off" time in Phase 3 TEMPO-3; NDA filed September 2025 (MDS Congress 2025).
- **Additional off-time adjuncts** not covered in the textbooks: **opicapone** (once-daily COMT inhibitor), **safinamide** and **istradefylline** (adenosine A2A antagonist), and **inhaled levodopa** and **sublingual apomorphine film** as on-demand rescue for off episodes.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
First-line manoeuvre	Revise timing; fractionate levodopa doses	Unchanged — still the correct first step before adding drugs or devices
Oral adjuncts for wearing-off	Entacapone/tolcapone; Stalevo	Add **opicapone** (once daily), **safinamide** and **istradefylline**; **Crexont** ER capsules as a levodopa alternative
Continuous dopaminergic delivery	Duodenal infusion; apomorphine "limited data"	**Vyalev** (SC levodopa prodrug, 24 h) and **Onapgo** (SC apomorphine) are licensed; intestinal gel established; **ND0612** pending
Rescue for sudden "off"	Not addressed	**Inhaled levodopa** and **sublingual apomorphine film** are licensed on-demand rescue therapies
DBS	Continuous open-loop stimulation; "not currently used in the elderly"	**Adaptive closed-loop DBS approved February 2025 (ADAPT-PD)**; age >70 no longer a barrier

Examiner's Tip — lines that earn marks

- Classify first: "**Delayed on, wearing-off, and the on–off phenomenon**, with chorea, athetosis and dystonia as the associated dyskinesias."
- Explain both mechanisms: "**loss of striatal dopamine buffering makes the effect track the short plasma half-life**" and "**gastric emptying is delayed in at least 70% of PD patients, causing erratic absorption**."
- Answer in a stepwise algorithm: **timing revision → dispersible levodopa for morning akinesia → COMT inhibitor/Stalevo → amantadine for peak-dose dyskinesia → continuous delivery → DBS**.
- Add the geriatric caveats: **amantadine needs renal dose adjustment and causes delirium**; **DBS requires cognitive intactness**.
- One current fact closes it: "**Adaptive DBS driven by beta-band local field potentials was approved in February 2025 for exactly this indication.**"

Q7. Non-motor symptoms of Parkinson's disease

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapters 53, 30 and 42; Essentials of Clinical Geriatrics 7th ed.

Overview and classification

1. Non-motor symptoms (NMS) are common in PD and, in the geriatric population, contribute more to disability, institutionalisation and carer burden than the motor features.
2. Pathy's lists them as **bradyphrenia (slowness of mental function), depression, memory problems and dementia, constipation, bladder dysfunction and autonomic dysfunction** (gastrointestinal, sexual, cardiovascular). Essentials adds **psychosis, anxiety and sleep disturbance**.
3. They can be grouped as **neuropsychiatric, cognitive, autonomic, sleep and sensory**.

Neuropsychiatric and cognitive

4. **Neuropsychiatric symptoms are dominated by anxiety and depressive syndrome.** The anxiety disorders encountered are mainly **generalised anxiety disorder and obsessive–compulsive disorder**.
5. **Major depressive episodes are frequent — about 50% of patients may be affected during the course of the disease.** Diagnosis is difficult because fatigue, sleep disorders and lack of interest occur in PD in the absence of overt depression.
6. **Cognitive impairment is never a sign of early PD** and is observed only after several years of evolution (**PD-related dementia**). Dementia occurring within a few months of parkinsonism indicates **dementia with Lewy bodies** instead.
7. Visual hallucinations, delusions and delirium occur in advanced disease and are frequently **dose-related adverse effects of levodopa** rather than the disease itself.

Autonomic

8. **Autonomic disorders are dominated by orthostatic hypotension and constipation.**
9. **Orthostatic hypotension** is directly related to autonomic dysfunction and is **often worsened by antiparkinsonian drugs**. It is defined as a fall in **systolic BP of 20 mmHg or diastolic BP of 10 mmHg within three minutes of standing from supine**. It is often asymptomatic but can cause discomfort or syncope. **Repeated search for orthostatic hypotension is part of the monitoring of any parkinsonism patient.**
10. **Constipation is found in about 50% of PD patients**, related to impaired bowel motility, sphincter dysfunction and poor physical activity. It arises from **dyssynergic defecation due to incoordination of the pelvic floor musculature** and from the constipating effect of PD medication.
11. Constipation is a **key symptom that must be actively elicited** — it causes abdominal discomfort, nausea and reduced appetite, and is **associated with reduced efficacy of medications due to reduced absorption**.
12. **Gastric emptying is delayed in at least 70%** of PD patients, causing nausea and bloating and impairing nutrition and drug absorption. Small-intestinal, colonic and anorectal dysmotility are also common, with prolonged oro-caecal transit.
13. Other autonomic symptoms: **sweating, drooling, sexual dysfunction and urinary frequency, urgency and dysuria**. Urinary symptoms may be attributed to PD only after excluding **urinary infection, bladder or prostate disease and anticholinergic drugs**.
14. **Swallowing:** heartburn is common from impaired acid clearance. The effects of levodopa and anticholinergics on swallowing are **inconsistent** — either may improve or worsen dysphagia. Limited data indicate benefit from **subcutaneous apomorphine infusion**.

Sensory, sleep and advanced-stage symptoms

15. **Impaired olfaction** is an early sign, reflecting early involvement of the olfactory pathways by α-synuclein pathology. **Hyposmia and visual hallucination are supportive criteria** in the Queen Square Brain Bank criteria.
16. **REM sleep behaviour disorder** — loss of normal REM atonia with acting-out of dreams — results from brainstem circuit dysfunction and is strongly associated with neurodegenerative disease; melatonin is used in treatment.
17. In **advanced PD**, patients experience **insomnia, pain, sweats, orthostatic hypotension, dysphagia, dysarthria, drooling of saliva, urinary dysfunction, and cognitive or psychiatric disorders** including depression, anxiety, visual hallucinations and dementia.

Management principles

18. **The governing rule (Pathy's Table 53.4): every non-motor treatment is considered only after adjusting levodopa therapy**, because **levodopa itself does not improve non-motor symptoms, posture or gait**, and many non-motor problems are levodopa side effects.
19. **Best-evidence treatments:** domperidone for nausea and vomiting (ECG monitoring for QT prolongation; **metoclopramide is contraindicated**); **venlafaxine** for depression; **clozapine or pimavanserin** for hallucinations and delusions; **rivastigmine** for dementia and for apathy; **droxidopa** for orthostatic hypotension; **sleep hygiene** for insomnia; **probiotics, prebiotic fibre, hydration and macrogol** for constipation; **botulinum toxin into salivary glands** for severe drooling; **sildenafil** for erectile dysfunction.
20. **Other options:** SSRIs, cognitive-behavioural therapy or rTMS for depression; SSRIs or CBT for generalised anxiety (no best-evidence treatment exists); donepezil for dementia; midodrine, fludrocortisone and elastic venous compression for orthostatic hypotension; melatonin for insomnia; lubiprostone or psyllium for resistant constipation; solifenacin (low brain penetration) for urinary urgency. **Pramipexole** is effective for PD depression but may induce delirium and should not be first choice in older patients. **No effective treatment exists for mild cognitive impairment in PD.**
21. **Clozapine practicalities:** start 12.5 mg daily, titrate in five-day increments to a usual 25–50 mg; contraindicated in neutropenia; blood count weekly for two months then twice monthly; **discontinue permanently if the neutrophil count falls below 1500/mm^3**. Pimavanserin, a **5-HT2A inverse agonist**, is effective and safe without haematological monitoring.
22. **Timed toileting every 2–4 hours and 30 minutes after meals** improves continence and prevents constipation, particularly in patients with coexisting cognitive impairment.

Latest Updates (2023–Present)

- **Non-motor features are now recognised as the earliest biological stage.** The **NSD-ISS** (*Lancet Neurology* 2024) formally stages the disease from biomarker positivity through **non-motor manifestations** to motor signs and functional impairment — the first framework in which non-motor symptoms are a defining, not an accessory, feature.
- **Isolated REM sleep behaviour disorder is prodromal synucleinopathy.** α-Synuclein seed amplification assay is positive in the great majority of patients with isolated RBD (PPMI, *Lancet Neurology* 2023), and **dermal phospho-α-synuclein deposits confirm RBD as prodromal PD** (Doppler et al.). In geriatric practice, a new RBD in an older adult warrants counselling and follow-up rather than reassurance.
- **Indian non-motor profile.** The pan-Indian multicentre study (Kishore et al., *Movement Disorders* 2025) found the motor and non-motor spectrum in Indian PD broadly similar to European populations, but with an **earlier age at onset**, implying a longer period of non-motor burden and greater caregiving demand across the family life cycle.
- **Off-time reduction improves non-motor fluctuation.** The new continuous delivery systems (**Vyalev** October 2024, **Onapgo** February 2025) and extended-release **Crexont** (August 2024) reduce off periods, during which non-motor symptoms — anxiety, pain, sweating, akathisia and bladder urgency — typically cluster.
- **New safety signal relevant to non-motor care:** the **FDA warning of March 2026 on vitamin B6 deficiency and seizures** with all carbidopa/levodopa products. B6 depletion also underlies levodopa-associated peripheral neuropathy, an under-recognised non-motor complication in long-treated patients.
- **Exercise remains one of the few interventions with broad non-motor benefit** — combined aerobic, strengthening, balance and stretching programmes improve balance in PD, and structured dance and exercise programmes are increasingly reported to benefit mood, sleep and quality of life alongside motor outcomes.

Current Practice Update

Aspect	Textbook position	Current evidence-based practice
Status of non-motor symptoms	Accompanying features of the disease	**Defining features of the earliest disease stages** in the 2024 biological staging systems
REM sleep behaviour disorder	Associated with neurodegenerative disease	Recognised as **prodromal synucleinopathy**, confirmable by α-synuclein SAA and skin biopsy
PD psychosis	Clozapine best evidence; pimavanserin noted as unavailable in Europe	**Pimavanserin is now the first-line antipsychotic for PD psychosis** where licensed; clozapine remains an effective and inexpensive alternative and is the practical choice in India
Orthostatic hypotension	Droxidopa (noted as unavailable in Europe); midodrine, fludrocortisone	Droxidopa now more widely available; in India, **midodrine and fludrocortisone with non-pharmacological measures remain the mainstay**
Levodopa and non-motor symptoms	"Does not improve non-motor symptoms"	Holds true for the symptoms themselves, but **reducing off-time with continuous delivery reduces non-motor fluctuation**

Examiner's Tip — lines that earn marks

- Give the exact orthostatic hypotension definition — "**a fall of 20 mmHg systolic or 10 mmHg diastolic within three minutes of standing**" — and add that "**repeated search for orthostatic hypotension is part of the monitoring of any parkinsonism patient**."
- Two numbers earn marks: "**depression affects about 50%**" and "**constipation affects about 50%**."
- State the timing rule: "**cognitive impairment is never a sign of early PD**" — dementia within months of parkinsonism means DLB.
- Reproduce Table 53.4 as a two-column table (best evidence vs other options) — it is the highest-yield single element of this answer.
- Finish with the governing principle: "**Each non-motor treatment should be considered only after adjusting levodopa therapy.**"

Q8. Progressive supranuclear palsy — clinical features, management and prognosis RECURS

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapters 53 (Table 53.2, Figure 53.1) and 46; Essentials of Clinical Geriatrics 7th ed., Table 6-7.

Definition and importance

1. **Progressive supranuclear palsy (PSP) is a neurodegenerative disorder that is frequently misdiagnosed as Parkinson's disease.**
2. It is one of the causes of extrapyramidal syndrome **frequently observed as very late-onset parkinsonism**, and is listed among the **nonreversible dementias** (Essentials, Table 6-7).
3. The disease is characterised by an **extrapyramidal syndrome associated with complex eye movement dysfunction**.

Clinical features

4. **Tremor is infrequent** — its absence in a parkinsonian patient should raise suspicion.
5. **Rigidity predominates at the spine (axial rigidity)** rather than in the limbs; **neck dystonia (retrocollis)** is characteristic.
6. **Posture and gait abnormalities are frequent at an early stage and lead to repeated falls**, which are also favoured by **attentional and visual problems**. Early postural instability with falls in the first year is the classical distinguishing feature from PD.
7. **Eye movement abnormalities:** inability to **voluntarily shift the gaze downward**, **impaired saccades**, and **difficulty controlling the eyelids**.
8. **Motor symptoms are unresponsive to levodopa** — a key discriminator, assessable by history or levodopa challenge.
9. As the disease progresses, **changes in personality, dementia and swallowing problems are common**.
10. **MRI shows a typical pattern relating to midbrain atrophy**: the midbrain aspect becomes **convex, whereas the normal midbrain aspect is concave** (Figure 53.1). This underlies the eponymous "hummingbird" and "morning glory" appearances.
11. **Ocular electrophysiology** demonstrating impaired saccades helps in recognising the disease.
12. PSP must be included in the differential diagnosis of **normal pressure hydrocephalus**, since both cause gait disturbance and cognitive change in older people.

Distinguishing PSP from Parkinson's disease

Feature	Parkinson's disease	Progressive supranuclear palsy
Onset pattern	Asymmetric or unilateral	Symmetric from the outset
Rest tremor	Characteristic, 4–6 Hz	**Infrequent**
Rigidity	Limb-predominant	**Axial (spinal) predominant**, with neck dystonia
Falls	Late, in advanced disease	**Early and repeated**
Eye movements	Normal (apart from age-related upgaze limitation)	**Vertical — especially downgaze — supranuclear palsy; impaired saccades; eyelid control problems**
Levodopa response	Excellent (70–100%), sustained for years	**Unresponsive**
Cognition	Dementia only after several years	Personality change and dementia as the disease progresses
MRI	Usually unremarkable	**Midbrain atrophy — convex instead of concave outline**
Ioflupane SPECT	Abnormal	Abnormal (does not separate the two)

Management

13. **There is no disease-modifying therapy.** Management is symptomatic, supportive and multidisciplinary.
14. **Give an adequate trial of levodopa in every case** — response is poor, but a small number derive transient benefit, and a documented negative response supports the diagnosis.
15. **Falls prevention is the single most important intervention:** physiotherapy, gait and balance training, weighted or wheeled walkers rather than simple canes, environmental hazard modification, appropriate footwear and hip protectors.
16. **Speech and swallow therapy** for dysarthria, drooling and dysphagia; early dietitian involvement; timely discussion of feeding options as dysphagia progresses.
17. **Ocular management:** lubricating drops for reduced blink, reading aids and prisms for downgaze palsy, and **botulinum toxin** for blepharospasm or eyelid-opening apraxia.
18. **Avoid neuroleptics and anticholinergics.** Treat depression; manage drooling with botulinum toxin injection into salivary glands as in PD.
19. **Deep brain stimulation is not indicated** in PSP.
20. **Carer support, advance care planning and palliative-care involvement** should begin early, given the rapid trajectory and predictable swallowing failure.

Prognosis

21. PSP is **relentlessly progressive**, with earlier loss of independence than PD. Death typically results from **aspiration pneumonia and the complications**

of immobility.

Latest Updates (2023–Present)

- **PSP is now defined as a spectrum, not a single syndrome.** The **MDS-PSP criteria** operationalise diagnosis across four functional domains — **ocular motor dysfunction, postural instability, akinesia and cognitive dysfunction** — with defined levels of certainty and **eight clinical variants**, including **PSP-RS (Richardson's syndrome), PSP-P (parkinsonism), PSP-PGF (progressive gait freezing) and PSP-CBS (corticobasal syndrome)**. The early "**suggestive of PSP**" category was **prospectively validated** in the DESCRIBE-PSP and ProPSP cohorts (Quattrone et al., *Movement Disorders* 2025).
- **Pathology is a 4-repeat tauopathy.** PSP is characterised by accumulation of abnormal **4-repeat (4R) tau**; the **MAPT H1 haplotype** is the major genetic risk factor.
- **Prognosis is now subtype-specific** — a high-yield update. A global systematic review (Kukkle et al., *Movement Disorders Clinical Practice* 2026) reports **global prevalence 5–6.4 per 100,000**, with **PSP-RS progressing rapidly with survival of 5–7 years**, while **PSP-P has a milder course with survival of 8–12 years**. Regional differences reflect MAPT haplotype frequency, dietary neurotoxins, industrial pollutants and access to care.
- **Biomarkers.** Second-generation tau-PET with **18F-PI-2620** detects 4R tau (basal ganglia readout) and predicts subsequent increases in diagnostic certainty (LMU Munich prospective cohort). Fluid biomarkers — **neurofilament light chain (NfL) and GFAP** measured on the SIMOA platform — track progression and are being used as trial endpoints (*Brain Communications* 2025).
- **Therapeutic pipeline.** There is still **no approved disease-modifying therapy**. Tau-directed strategies — anti-tau antibodies, antisense oligonucleotides and **sodium selenate (SEL003 trial)** — are in trial. Reasons for past failures include late-stage intervention, poor patient selection, absence of prodromal biomarkers and inadequate outcome measures.
- **Indian relevance:** Indian movement-disorder centres contributed to the 2026 global review; PSP is under-recognised in India, and diagnostic accuracy has improved measurably since adoption of the MDS-PSP criteria. Tau-PET is not available outside a few research centres, so **MRI midbrain measures and clinical criteria remain the practical tools**.

Current Practice Update

Aspect	Textbook position (Pathy's 6th ed.)	Current evidence-based practice
Concept of the disease	A single disorder: gaze palsy, early falls, axial rigidity	**A spectrum of 4R-tauopathy syndromes with eight recognised clinical variants**
Diagnostic criteria	Clinical description only	**MDS-PSP criteria** with four domains, certainty levels and a "suggestive of PSP" early category
Pathological basis	Not specified in the parkinsonism chapter	Explicitly a **4-repeat tauopathy**, MAPT H1 haplotype the major genetic risk
Investigations	MRI midbrain atrophy; ocular electrophysiology	Add **18F-PI-2620 tau-PET** and **plasma/CSF NfL and GFAP** — research and tertiary use
Prognosis	Progressive, unspecified duration	**Subtype-specific: PSP-RS 5–7 years, PSP-P 8–12 years**
Treatment	Symptomatic, levodopa-unresponsive	Unchanged — **no disease-modifying therapy**; tau-directed agents in trial

Extra Points to Remember — this topic recurs

- **Mnemonic for the classical (Richardson's) syndrome — "PSP FALLS": P**ostural instability with early falls; **S**upranuclear vertical gaze palsy (downgaze first); **P**seudobulbar features and personality change; **F**alls in the first year; **A**xial rigidity and retrocollis; **L**evodopa non-response; **L**ate dysphagia and dementia; **S**accades impaired with no tremor.
- **The three-line answer if asked in viva:** "PSP is a sporadic 4-repeat tauopathy presenting with early falls, vertical supranuclear gaze palsy, axial rigidity and levodopa non-response; MRI shows midbrain atrophy with a convex rather than concave outline; management is symptomatic, and Richardson's syndrome carries a survival of 5–7 years."
- **The single best discriminator to state first** is not the gaze palsy (which may appear late) but **early falls within the first year in a symmetric, tremor-free, levodopa-unresponsive parkinsonian patient**.
- **Radiological signs worth naming:** hummingbird/penguin sign on sagittal MRI, morning glory sign on axial MRI, and the **Magnetic Resonance Parkinsonism Index (MRPI)** as a quantitative midbrain–pons measure.
- **Do not confuse** the **supranuclear** palsy of PSP (voluntary gaze lost, reflex vestibulo-ocular movements preserved — doll's-eye manoeuvre overcomes it) with a **nuclear or infranuclear** palsy, where reflex movements are also lost. Examiners commonly ask this.
- **Common exam trap:** ageing itself restricts upward conjugate gaze, so **downgaze limitation, not upgaze limitation, is the meaningful sign** in an older patient.

Examiner's Tip — lines that earn marks

- Open with: "**PSP is a neurodegenerative disorder frequently misdiagnosed as Parkinson's disease, characterised by an extrapyramidal syndrome with complex eye movement dysfunction.**"
- Say "**no tremor, axial rigidity, early repeated falls, downgaze palsy, levodopa-unresponsive**" as a single string — five marks in one sentence.
- Describe the MRI precisely: "**convex midbrain aspect indicating atrophy, where the normal midbrain aspect is concave.**"
- Add the modern framing: "**a 4-repeat tauopathy with eight MDS-defined clinical variants**."
- Give subtype-specific prognosis — **PSP-RS 5–7 years, PSP-P 8–12 years** — and state that death is usually from **aspiration pneumonia**.

Q9. Benign / essential tremor — presentation, differential diagnosis and treatment

High-Yield Points (Textbook)

Source: Pathy's 6th ed., Chapter 54 (Non-Parkinsonian movement disorders in the elderly), Tables 54.3 and 54.4; Chapter 53.

Definition and epidemiology

1. **Essential tremor (ET) is the most common tremor disorder and the most common movement disorder**, with an estimated prevalence of **up to 3% in the general population and up to 5% in adults over 60**.
2. **ET becomes more common with age** — in one study the prevalence in adults over 95 was as high as **21.7%**.
3. Tremor of some kind is near-universal: an estimated **98.9%** prevalence in a large population study, the overwhelming majority being **physiological**.
4. Other tremor disorders are less common and are **often missed or misdiagnosed as essential tremor** — especially **dystonic tremor and parkinsonian tremor**.

Pathophysiology

5. The exact mechanism is unknown, but tremor disorders arise from **dysfunction in networks involving the inferior olive, cerebellum, thalamus, basal ganglia and cortex**.
6. Current theory: the **basal ganglia network triggers the onset of tremor**, while the **cerebellar network — predominantly affected in essential tremor — modulates its amplitude**. Which part of the network is affected determines the phenomenology — **rest tremor in PD, action-induced tremor in ET**.
7. Because tremor arises from dysfunctional CNS networks, **tremor disorders form a spectrum with overlapping clinical features**.

Presentation

8. ET is an **action-induced (postural and kinetic) tremor**. Features making ET more likely are the presence of an **intention tremor** and an **action-induced kinetic tremor of greater amplitude than the postural tremor**.
9. **Rest tremor is not a typical feature of ET** and renders a diagnosis of parkinsonism more likely.
10. ET may be **asymmetric but is usually not unilateral**; unilateral tremor is more commonly parkinsonian, dystonic or task-specific.
11. An **isolated head tremor, or head tremor that started before other body parts**, points away from ET and towards dystonia.
12. **Ethanol can improve the tremor**, but this is not unique to ET and also occurs in dystonia. **Increased coffee intake and smoking may cause or worsen tremor.**
13. A **strong family history of tremor** is often found in ET, but may also occur in dystonia (for example in certain Jewish populations).

Differential diagnosis

14. **Parkinsonian tremor** — look for rest tremor with rigidity, bradykinesia and postural instability, plus minor signs such as **hypomimia, loss of prosody and camptocormia**. Note that slow/rapid alternating movements without decrement, and reduced arm swing, can also occur in dystonia and ET.
15. **Dystonic tremor** — abnormal posturing such as **spooning of the hand, abnormal posturing or flexion of the thumb or hand**; **focal muscle hypertrophy, torticollis or a geste antagoniste**; the tremor may be **arrhythmic**, and dystonic head tremor may be **directional**. Voice tremor with **voice breaks and a spasmodic quality** suggests dystonia.
16. **The spiral test** is a valuable and easy clinic test: patients with ET draw spirals with **one clear single axis**, whereas dystonic tremor spirals typically have **multiple axes or no clear axis at all**.
17. **Cerebellar tremor** — intention tremor accompanied by **dysmetria, scanning speech, saccadic eye movement abnormalities and truncal ataxia**. MRI with and without contrast is required, since a mass, stroke or multiple sclerosis may cause secondary tremor.
18. **Functional tremor** — features of **variability, distractibility, entrainment and suggestibility**.
19. **Drug-induced tremor** is especially important in the elderly with polypharmacy. Common culprits: **caffeine, ethanol, nicotine, beta-adrenergic agonists (albuterol, salmeterol), tricyclic antidepressants, lithium, SSRIs, neuroleptics, valproate, amiodarone, ciclosporin, tacrolimus and metoclopramide**; Chapter 53 adds bronchodilators and theophylline. The medication list must be scrutinised and any tremorogenic drug stopped if possible.
20. **Other causes:** hyperthyroidism (recognised by other signs and TSH estimation), orthostatic tremor, late-onset Wilson's disease (rare in the elderly but considered in complex cases), and the extrapyramidal syndrome of ageing.

Investigation

21. **In most cases of tremor in the elderly no further workup is required** — history and examination are sufficient to establish the diagnosis. Basic blood work, **liver function tests and thyroid studies** can at times be helpful.
22. **EMG is very beneficial for diagnosing orthostatic tremor**. **DaTSCAN** is normal in ET and abnormal in PD and other parkinsonian syndromes, and may establish the correct diagnosis in difficult cases.

Treatment

23. **There is no curative therapy for essential tremor**, and the **indication for symptomatic therapy depends solely on the functional and social impairment the patient experiences** — a critical geriatric principle.
24. **First-line pharmacotherapy: propranolol and primidone**, which induce a **30–70% reduction in tremor amplitude**.
25. Both cause significant side effects leading to **frequent discontinuation — bradycardia with propranolol; nausea, dizziness and drowsiness with primidone**. In older patients also consider bronchospasm, hypotension and masking of hypoglycaemia with propranolol.
26. **Second-line: topiramate, gabapentin and benzodiazepines.**

27. **Surgical therapy** gives a more pronounced reduction of tremor amplitude than drugs: **deep brain stimulation with the typical target being the ventral intermediate (Vim) nucleus of the thalamus**, **gamma knife surgery**, and **focused ultrasound thalamotomy**. Given their invasive nature, these are **reserved for patients with severe tremor refractory to medication**.

Latest Updates (2023–Present)

- **Staged bilateral MRgFUS thalamotomy is now approved.** The FDA approved **staged bilateral** magnetic resonance-guided focused ultrasound thalamotomy for essential tremor, with the **second side treated at least nine months after the first**. The pivotal open-label trial was published by Kaplitt, Krishna, Eisenberg, Elias and colleagues in ***JAMA Neurology* 2024**.
- **Efficacy comparable to bilateral DBS.** A 2025 *Movement Disorders* analysis found the efficacy of bilateral MRgFUS and bilateral DBS to be **comparable**, and probabilistic lesion mapping identified **two sweet spots — the dorsal Vim–Vop border and the ventral Vim/posterior subthalamic area**. A prospective series in *Brain Communications* 2025 (20 patients, 6-month follow-up on the Clinical Rating Scale for Tremor) confirmed benefit, with **balance and gait impairment as the adverse events to counsel about** — particularly relevant to falls risk in the elderly.
- **Classification has changed.** The MDS consensus classification of tremor uses **two axes** — clinical characteristics and aetiology — and introduces the category "**essential tremor plus**" for isolated tremor with additional soft neurological signs (mild dystonic posturing, impaired tandem gait, questionable rest tremor). Pathy's Chapter 54 already uses the phrase "ET or ET plus" without defining it.
- **Position statement:** the American Society for Stereotactic and Functional Neurosurgery position statement on MRgFUS for essential tremor (*Neurosurgery* 2020) remains the reference document; in the USA all treatment sites are approved for Medicare payment.
- **Indian context:** propranolol and primidone are inexpensive and widely available; topiramate and gabapentin are readily obtainable. **MRgFUS is available in a small number of Indian tertiary centres** (and is costly and largely out-of-pocket), so **DBS and stereotactic thalamotomy remain the practical surgical options** for refractory tremor in most of the country. In differential diagnosis, remember that **Wilson's disease is relatively more common in India and presents at a younger age**, so serum ceruloplasmin, 24-hour urinary copper and slit-lamp examination should be checked in any tremor with atypical features, hepatic disease or psychiatric symptoms.

Current Practice Update

Aspect	Textbook position (Pathy's 6th ed.)	Current evidence-based practice
Nomenclature	"Essential tremor" (with the phrase "ET or ET plus" used in passing)	Formal MDS two-axis classification with a defined "**essential tremor plus**" category
First-line drugs	Propranolol and primidone, 30–70% amplitude reduction	Unchanged — still first line, and still frequently discontinued for side effects
Focused ultrasound	Mentioned as a newer option for refractory tremor	**Staged bilateral MRgFUS is FDA-approved**, second side at least 9 months after the first (JAMA Neurology 2024)
MRgFUS vs DBS	Both listed as options for refractory tremor	Efficacy appears **comparable**; MRgFUS is incisionless but **lesional and irreversible**, with gait and balance adverse effects
Indication to treat	Depends solely on functional and social impairment	Unchanged — and reinforced as a geriatric principle: treat disability, not the tremor amplitude

Examiner's Tip — lines that earn marks

- Lead with epidemiology: "**the most common movement disorder — up to 3% of the population, up to 5% over 60, and as high as 21.7% over 95.**"
- State the network theory: "**the basal ganglia network triggers tremor onset while the cerebellar network, predominantly affected in ET, modulates amplitude.**"
- Contrast in one line: "**rest tremor in Parkinson's disease, action-induced tremor in essential tremor**" — and add that DaTSCAN is normal in ET.
- Name the **spiral test** — single axis in ET, multiple or no axis in dystonic tremor. Examiners love this because it is a bedside test.
- State the treatment principle verbatim: "**There is no curative therapy, and the indication for symptomatic treatment depends solely on the functional and social impairment the patient experiences.**"
- Finish the ladder: **propranolol/primidone → topiramate, gabapentin, benzodiazepines → Vim DBS, gamma knife or focused ultrasound thalamotomy for refractory cases.**

Cross-cutting revision aid — the night before the examination

One-line signatures to recall under pressure

Condition	The line that identifies it
Parkinson's disease	Asymmetric onset, rest tremor, excellent sustained levodopa response, dementia only after years
Progressive supranuclear palsy	Symmetric, no tremor, early falls, downgaze palsy, axial rigidity, levodopa-unresponsive, convex midbrain on MRI
Multiple system atrophy	Early severe dysautonomia with pyramidal or cerebellar signs
Corticobasal degeneration	Alien hand, myoclonus, dystonia, cortical sensory loss
Dementia with Lewy bodies	Dementia within months of parkinsonism, hallucinations, fluctuation, neuroleptic sensitivity
Vascular parkinsonism	Onset or worsening within one month of stroke; multilacunar state; pseudobulbar features
Drug-induced parkinsonism	Neuroleptic exposure, dyskinesia frequent, no tremor, normal DaTSCAN, 20% persist after withdrawal
Normal pressure hydrocephalus	Gait + incontinence + cognitive slowing; ventriculomegaly out of proportion to atrophy; no tremor or rigidity
Essential tremor	Bilateral action tremor, family history, alcohol-responsive, normal DaTSCAN, single-axis spiral

Numbers most likely to be asked

- PD prevalence **~1% over age 65**; median age at diagnosis **60**; mean survival from diagnosis **15 years**; family history in **6–10%**.
- Non-PD causes of very late-onset parkinsonism: **20–40%**. Persistent signs after stopping the offending drug: **20%**.
- Levodopa **300–600 mg/day** in early disease; challenge dose **150–250 mg**; rest tremor frequency **4–6 Hz**.
- Depression in PD **~50%**; constipation **~50%**; delayed gastric emptying **≥70%**; parkinsonism in Alzheimer's disease **~15%**.
- Orthostatic hypotension: **≥20 mmHg systolic or ≥10 mmHg diastolic within 3 minutes**. Clozapine stop threshold: **neutrophils <1500/mm^3**.
- Essential tremor: **3%** general population, **5%** over 60, **21.7%** over 95; propranolol/primidone reduce amplitude by **30–70%**.
- PSP: prevalence **5–6.4/100,000**; survival **PSP-RS 5–7 years, PSP-P 8–12 years**.
- India: PD crude prevalence **7–60/100,000**, age-adjusted **53–192/100,000**; Parsi community of Mumbai **328/100,000** (not generalisable); parkinsonism in Bangalore old-age homes **17.8%**.

Dates and approvals worth quoting (2024–2026)

- **February 2024** — NSD-ISS and SynNeurGe biological frameworks published together in *Lancet Neurology*.
- **August 2024** — Crexont (IPX203 extended-release carbidopa/levodopa) FDA-approved.
- **September 2024** — staged bilateral MRgFUS thalamotomy trial for essential tremor published in *JAMA Neurology*.
- **October 2024** — Vyalev (foslevodopa/foscarbidopa), first 24-hour subcutaneous levodopa infusion, FDA-approved.
- **February 2025** — Medtronic BrainSense **Adaptive DBS** FDA-approved on ADAPT-PD; Onapgo subcutaneous apomorphine infusion FDA-approved; **Exenatide-PD3 published negative** in *The Lancet*.
- **September 2025** — tavapadon (D1/D5 partial agonist) NDA submitted on the TEMPO Phase 3 programme.
- **March 2026** — FDA label warning for **vitamin B6 deficiency and seizures** across all carbidopa/levodopa products.
- **June 2026** — *The Lancet* issued an Expression of Concern regarding the Exenatide-PD3 publication.

MD Geriatric Medicine

High-Yield 15-Mark Answers

Neurology · Neuro-ophthalmology · Environmental Emergencies

Compiled from **Pathy's Principles and Practice of Geriatric Medicine (6th ed.)**
and **Essentials of Clinical Geriatrics (7th ed.)**
with Latest Updates (2023–2026) and Indian Clinical Context

14 Questions | Prepared for Sudarsan

Contents

1. Epilepsy in the elderly — definition, pathophysiology, clinical features, investigations, treatment
2. Coma in the elderly
3. Subdural haematoma RECURS ×2
4. Lacunar infarcts
5. Subacute combined degeneration of the cord — presentation and treatment
6. Motor neuron disease — presentation, evaluation and treatment
7. Peripheral neuropathy — common causes and clinical approach
8. Neuritic (neuropathic) pain
9. Management of extracranial carotid artery stenosis
10. Bedside assessment of swallow after acute stroke
11. Visual impairment — age-related causes and approach RECURS
12. Macular degeneration — presentation, aetiology, diagnosis, treatment, prevention
13. Heat stroke
14. Heat exhaustion

Every answer follows the same architecture: 15–20 high-yield textbook points → Latest Updates (2023–present, cited inline) → Current Practice Update table → Examiner's Tip. Recurring topics carry an additional "Extra Points to Remember" panel.

1. Epilepsy in the Elderly — Definition, Pathophysiology, Clinical Features, Investigations and Treatment

Definitions (ILAE / IBE)

1. An **epileptic seizure** is a transient occurrence of signs and/or symptoms due to **abnormal excessive or synchronous neuronal activity** in the brain.
2. **Epilepsy** exists when a seizure is confirmed and the brain shows an enduring tendency to recur. It is diagnosed with: **two unprovoked or reflex seizures more than 24 hours apart**; OR **one unprovoked seizure with a ≥60% probability of another over the next 10 years**; OR an **epilepsy syndrome**.
3. A seizure provoked by a transient factor acting on an otherwise normal brain **does not count** towards a diagnosis of epilepsy.
4. **Status epilepticus (SE)**: more than 30 minutes of continuous seizure activity, or intermittent seizures without full recovery of consciousness between them. Shorter operational durations are now proposed.
5. **Refractory epilepsy**: failure of adequate trials of **two tolerated, appropriately chosen antiepileptic drug (AED) schedules** to achieve sustained seizure freedom.

Epidemiology

6. Epilepsy is the **third most common neurological disorder** in older age groups. Incidence follows a **U-shaped curve**, highest at both ends of life. **25% of new-onset seizures occur after age 65.**
7. Prevalence of active epilepsy at age ≥75 is about **1.5%** (twice that of younger adults); in **nursing homes it exceeds 5%**.
8. SE incidence in the elderly is almost **double** the general population (86/100,000/year), rising with age, highest at ≥85 years. **Non-convulsive SE (NCSE)** occurs more often in the very old and critically ill.

Aetiology and pathophysiology

9. **Acute symptomatic seizures**: stroke 30–54%, metabolic/electrolyte imbalance 10–15%, tumours 10%, trauma 10%, drug-related 10%, CNS infection 2–3%.
10. **Epilepsy**: cryptogenic 48–50%, **stroke 40–53% (single largest identifiable cause)**, dementia 5–20%, tumours 4–19%, trauma 1–3%.
11. Mechanism: cortical/subcortical injury → gliotic scar → a hyperexcitable focus. In Alzheimer's disease, amyloid-driven **network hyperexcitability** raises seizure risk. Consider also autoimmune limbic encephalitis (VGKC/LGI1 antibodies) and Hashimoto's encephalopathy.

Clinical features

12. Seizure onset is **focal in 62–68%** and generalised in 27–39%; for established epilepsy, focal 65%, generalised 13%, unknown 22%.
13. Presentation is **subtle** — brief episodes of confusion, unexplained falls, or stereotyped movements, often **misdiagnosed as non-specific confusional states**.
14. Typical auras (fear, epigastric rising sensation, déjà vu) are **less common**; **non-specific auras such as dizziness predominate**. The seizure focus is more often **extratemporal, especially frontal**.
15. The **postictal period is prolonged** — lasting hours to days. Todd's paresis may mimic stroke.
16. **NCSE** presents as altered mental status ranging from mild disorientation to confusion or coma, uncharacteristic behaviour or aphasia. More than half occur with acute medical illness — organ failure, drug toxicity, alcohol/benzodiazepine withdrawal, metabolic disturbance.

Investigations

17. Diagnosis is **clinical**, based on an **eyewitness description**. The major difficulty is that older patients often cannot give an accurate history.
18. **EEG sensitivity falls with age**: epileptiform transients occur less often, activation procedures add little, EEG is normal in about one-third, and non-specific focal slowing is common even without seizures. A **sleep or nap EEG** is advised if the awake study is negative.
19. **Inpatient video-EEG is the gold standard** for characterising events and distinguishing epileptic from **psychogenic non-epileptic attacks** (6–15% of "uncontrolled epilepsy").
20. **Brain imaging in every patient** — MRI preferred over CT as it is more sensitive for stroke, TBI and structural lesions. Add ECG (exclude arrhythmic syncope), glucose, electrolytes, calcium, renal and liver function, and drug review.
21. **Differential diagnosis**: syncope, limb-shaking TIA, transient global amnesia, transient epileptic amnesia, hypoglycaemia, REM sleep behaviour disorder, periodic limb movement disorder, hypnic jerks, delirium, psychogenic attacks.

Treatment

22. Because recurrence risk is high, treat **after the first confirmed unprovoked seizure**, especially with a brain lesion or epileptiform EEG.

23. An ideal AED for the elderly has **linear pharmacokinetics, minimal hepatic metabolism, minimal drug interaction and renal excretion, and minimal impact on cognition, memory or mood** — no such drug exists.
24. **Start low, titrate slowly, use monotherapy first-line.** Older patients often respond to lower doses (e.g. valproate dose reduced by 30–40%).
25. **Preferred agents: lacosamide, lamotrigine and levetiracetam** — these have the greatest likelihood of seizure freedom at 6 and 12 months. Lamotrigine is better tolerated than carbamazepine.
26. **Avoid**: phenytoin, carbamazepine, phenobarbital, primidone, valproate and benzodiazepines — chronic toxicity, interactions and neurotoxicity in hypoalbuminaemia.
27. Match the drug to comorbidity: in **depression** avoid levetiracetam (irritability), topiramate, phenobarbital, primidone and vigabatrin. In **Alzheimer's disease**, treat after a second episode; avoid polytherapy, which impairs cognition.
28. Epilepsy is one of the **top 10 conditions related to frailty**. Assess falls risk and provide **bone protection** — AEDs increase fracture risk. Use **STOPP/START and Beers criteria** to manage polypharmacy.
29. **SE algorithm (Pathy's Box 51.1)**: treat within 5–10 minutes; IV glucose if hypoglycaemic. *First line* — lorazepam 0.1 mg/kg IV (2 mg/min), or diazepam 10 mg over 2 min, or midazolam 10 mg IM; repeat once at 10 min. *Second line (established SE)* — phenytoin 15 mg/kg (max 20 mg/min, with cardiac and BP monitoring), or valproate 15–30 mg/kg if cardiovascular comorbidity, or levetiracetam 20–30 mg/kg over 15 min. *Refractory* — midazolam or propofol infusion, then general anaesthesia and ventilation.
30. **Prognosis is good** — most newly diagnosed older patients become seizure-free on first AED monotherapy. Failure to become seizure-free within the first year predicts drug resistance. Epilepsy surgery and vagus nerve stimulation (27–44% seizure reduction) are feasible in selected older patients.

Latest Updates (2023–Present)

- ***Continuum* "Update on Antiseizure Medications" (2025)**: lamotrigine, oxcarbazepine, levetiracetam, topiramate, zonisamide and lacosamide have efficacy equal to older agents with equal or better tolerability as first-line therapy for focal epilepsy; pregabalin is inferior to lamotrigine. Lacosamide, pregabalin and eslicarbazepine have successful conversion-to-monotherapy data. **Ganaxolone** is the newest FDA-approved ASM.
- ***Drugs & Aging* (2026) review of ASMs in adults ≥65**: because most ASMs have comparable efficacy, **tolerability and quality of life — not efficacy — should drive drug choice**. Practical cautions: eslicarbazepine and oxcarbazepine cause **hyponatraemia** in the elderly; lacosamide should be avoided in **AV block**; lamotrigine needs slow titration and an ECG in cardiac disease; cenobamate, brivaracetam and perampanel are emerging options.
- ***Neurology* (2025) network meta-analysis of ASMs in post-stroke seizures (Misra et al.)** and ***Frontiers in Neurology* (2025)**: **lamotrigine and levetiracetam** are favoured; **primary ASM prophylaxis after stroke is not recommended**; early seizures (≤7 days) are acute symptomatic, while late seizures (>7 days) define **post-stroke epilepsy** and warrant long-term treatment. Lacosamide is a promising option including for NCSE in stroke.
- The **ILAE 2017 classification** (focal / generalised / combined / unknown, with awareness and motor descriptors) remains the operative framework; the term "antiseizure medication (ASM)" has replaced "AED" in current literature.
- **Indian context**: the epilepsy treatment gap remains 50–70% in rural India; phenytoin and phenobarbital remain widely used because of cost, though both are on the STOPP/Beers avoid list for older adults. Levetiracetam and lamotrigine are now inexpensive generics and should be preferred. Driving requires self-declaration of epilepsy under the **Central Motor Vehicles Rules**; Indian epilepsy society practice advises at least **one year of seizure freedom** before resuming driving.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Term "antiepileptic drug (AED)"	Replaced by **"antiseizure medication (ASM)"** — reflects symptomatic rather than disease-modifying action
Lacosamide, lamotrigine, levetiracetam are safe and first-line	Confirmed. **Choice now driven explicitly by tolerability and quality of life**, since efficacy is comparable (*Drugs & Aging* 2026)
SE defined as >30 minutes; shorter durations "proposed"	**Operationally accepted**: t_1 = 5 min (start treatment), t_2 = 30 min (risk of neuronal injury)
Eslicarbazepine listed as a useful newer agent	Usable, but **hyponatraemia risk in the elderly** now explicitly flagged; monitor sodium
Post-stroke seizure treatment not separately addressed	**No primary prophylaxis after stroke.** Late seizures = post-stroke epilepsy → treat with lamotrigine or levetiracetam
Edaravone/newer agents "need more study"	Cenobamate, brivaracetam, perampanel and ganaxolone now have geriatric tolerability data

> **Examiner's Tip — say these lines verbatim:**
> - "Epilepsy is the **third commonest neurological disorder** in the elderly; incidence follows a **U-shaped curve** and **25% of new-onset seizures occur after 65**."
> - "**Stroke is the single largest identifiable cause**, accounting for 40–53% of epilepsy in this age group."
> - "Presentation is subtle — **brief confusion, falls or stereotyped movements**. Over- and under-diagnosis are equally common."

- "**EEG sensitivity falls with age**; it is normal in one-third. **Video-EEG is the gold standard**; MRI is mandatory in all."
- "**Treat after the first unprovoked seizure** because of high recurrence — start low, go slow, monotherapy first."
- "**Lacosamide, lamotrigine and levetiracetam** are the drugs of choice; **avoid phenytoin, carbamazepine, phenobarbital and valproate**."
- "Epilepsy is one of the **top 10 conditions related to frailty** — always assess falls risk and give bone protection."

2. Coma in the Elderly

Source note: Coma is addressed across chapters in the uploaded textbooks (Glasgow Coma Scale and prognosis in the subdural haematoma chapter, level-of-consciousness grading within the Confusion Assessment Method, hyperosmolar non-ketotic coma, myxoedema coma, hypothermia and hyperthermia) rather than in a single dedicated chapter. Points below integrate these with current peer-reviewed neurocritical care literature.

Definition and physiology

1. **Coma** is a state of **unarousable unresponsiveness** — no eye opening, no comprehensible speech and no purposeful motor response even to noxious stimuli; operationally **GCS ≤8**.
2. Consciousness has two components: **arousal** (ascending reticular activating system in the brainstem tegmentum and thalamus) and **awareness** (cerebral cortex). Coma requires damage to the ARAS or to **both** hemispheres.
3. Spectrum of impaired consciousness (as graded in the CAM): **alert → vigilant → lethargic (drowsy, easily aroused) → stupor (difficult to arouse) → coma (unarousable)**.
4. Distinguish from **delirium** (acute onset, fluctuating, inattention, disorganised thinking — CAM), **vegetative state / unresponsive wakefulness**, **minimally conscious state**, **akinetic mutism**, **locked-in syndrome** (ventral pontine lesion; preserved vertical eye movement and blinking) and **psychogenic unresponsiveness**.
5. Ageing predisposes to coma: reduced cerebral reserve, **brain atrophy** (facilitating subdural haematoma), impaired drug clearance, polypharmacy, multimorbidity, blunted febrile and thirst responses, and atypical presentation.

Causes — structural vs non-structural

6. **Supratentorial structural**: large hemispheric infarct with oedema, intracerebral haemorrhage, **subdural haematoma** (bridging vein tear after trivial or unremembered trauma — the classic elderly cause), extradural haematoma, tumour, abscess, hydrocephalus.
7. **Infratentorial structural**: brainstem infarct or haemorrhage, **basilar artery occlusion**, cerebellar haemorrhage or infarct with brainstem compression, central pontine myelinolysis.
8. **Diffuse / metabolic-toxic (commonest group in the elderly)**: hypoglycaemia, **hyperosmolar hyperglycaemic state** (increased incidence in older adults), DKA, hyponatraemia, hypercalcaemia, uraemia, hepatic encephalopathy, hypoxia and hypercapnia, **myxoedema coma**, adrenal crisis, **hypothermia**, **heat stroke**, sepsis, Wernicke's encephalopathy.
9. **Drugs and poisons**: opioids, benzodiazepines, anticholinergics, antipsychotics, lithium, alcohol, carbon monoxide. In India, **organophosphate and aluminium phosphide poisoning** remain important.
10. **Seizure-related**: prolonged postictal state and **non-convulsive status epilepticus** — a reversible and frequently missed cause; have a low threshold for urgent EEG.
11. **Infective**: meningitis, encephalitis, cerebral malaria, neurocysticercosis, tuberculous meningitis (all endemic considerations in India).

Bedside evaluation

12. **ABC first**: airway, breathing, circulation; check **capillary blood glucose immediately**; give **thiamine before glucose** if alcohol use or malnutrition is possible.
13. Obtain a collateral history: tempo of onset, trauma (even trivial), anticoagulants, drug and alcohol history, preceding headache, fever, seizures, and baseline cognitive and functional state.
14. **Glasgow Coma Scale** (E4 V5 M6, total 3–15) quantifies depth. Limitations in the elderly: dysphasia, hearing and visual impairment, intubation, and pre-existing dementia. The **FOUR score** (eye, motor, brainstem, respiration) is preferred in intubated patients.
15. **Pupils**: pinpoint reactive → pontine lesion or opioids; unilateral fixed dilated → uncal herniation compressing CN III; mid-position fixed → midbrain; **preserved pupillary reactivity with deep coma strongly suggests a metabolic cause**.
16. **Brainstem reflexes**: corneal, oculocephalic (doll's eye — not if cervical injury), oculovestibular (cold caloric), gag and cough. **Respiratory pattern**: Cheyne–Stokes (bihemispheric/diencephalic), central neurogenic hyperventilation, apneustic (pons), ataxic/Biot (medulla).
17. **Motor**: asymmetry indicates a structural lesion; **decorticate** (flexor) posturing implies a lesion above the red nucleus, **decerebrate** (extensor) posturing a brainstem lesion. **Multifocal myoclonus and asterixis point to a metabolic cause**.
18. Also examine: fundi (papilloedema, subhyaloid haemorrhage), neck stiffness, skin (rash, needle marks, jaundice, cyanosis, hot dry skin of heat stroke), temperature, and evidence of head or cervical injury.

Investigations and management

19. Blood glucose, sodium, calcium, urea and creatinine, LFT, ammonia, ABG, CK, TSH, cortisol, blood and urine cultures, toxicology, ECG, chest X-ray.
20. **Non-contrast CT head is the first-line imaging**; MRI (with DWI) for posterior fossa, brainstem and basilar occlusion. **Lumbar puncture** after imaging if meningoencephalitis is suspected. **EEG** if NCSE is suspected.
21. Immediate reversal agents: 25–50 mL of 50% dextrose for hypoglycaemia; **thiamine 100 mg IV**; naloxone for opioids; flumazenil used cautiously (may precipitate seizures in chronic benzodiazepine use or mixed overdose).

22. **Airway protection if GCS ≤8.** Maintain oxygenation and normocapnia, treat hypotension, nurse head-up 30°, avoid hypotonic fluids.
23. **Raised intracranial pressure**: mannitol or hypertonic saline, controlled ventilation, urgent neurosurgical referral for subdural haematoma, intracerebral haemorrhage, cerebellar haemorrhage or hydrocephalus.
24. **Correct hyponatraemia cautiously** — Pathy's recommends raising serum sodium by only **6–8 mEq/L in 24 hours**; a **100 mL bolus of 3% saline** restores the GCS faster than a slow 20 mL/h infusion and had a lower mortality trend. Over-rapid correction risks osmotic demyelination.
25. Treat the cause: sepsis bundle and empirical antibiotics ± aciclovir; antiepileptics for NCSE; levothyroxine and hydrocortisone for myxoedema coma; rapid cooling for heat stroke; rewarming for hypothermia.
26. **Supportive care**: pressure-area care, VTE prophylaxis, aspiration precautions and nil by mouth, eye care to prevent exposure keratopathy, bladder and bowel care, nutrition, and prevention of contractures.
27. **Prognosis** depends entirely on cause. Metabolic and toxic causes are largely reversible; structural and hypoxic-ischaemic causes carry a poor outcome. In the elderly, **early goals-of-care discussion and review of advance directives are an essential part of management**, not an afterthought.

Latest Updates (2023–Present)

- **Curing Coma Campaign / Neurocritical Care Society (2023–2025)**: coma is being reframed as an **"acute disorder of consciousness"** with standardised common data elements, endotypes, and a proposed shift from purely descriptive to mechanism-based classification.
- **Cognitive motor dissociation (*NEJM* 2024, Bodien et al.)**: approximately **25% of clinically unresponsive patients** show volitional brain activation on task-based fMRI or EEG despite no bedside response. This is transforming prognostication and cautions strongly against early withdrawal of treatment based on the bedside examination alone.
- **FOUR score** has increasingly supplanted the GCS in intubated and sedated patients, as the verbal component of the GCS cannot be scored and it captures brainstem reflexes and respiratory pattern.
- **NCSE**: contemporary series find that up to **20% of unexplained coma in older adults** is non-convulsive status; the **Salzburg consensus criteria** are now the standard EEG diagnostic framework, and continuous EEG is recommended for unexplained persistent altered consciousness.
- **SCCM Heat Stroke Guidelines (*Critical Care Medicine*, 2025)** are directly relevant — hyperthermic coma requires cooling to <39°C within 30 minutes; and **Surviving Sepsis** updates address sepsis-associated encephalopathy.
- **Indian context**: road traffic injury, poisoning (organophosphate, aluminium phosphide), cerebral malaria, tuberculous meningitis and neurocysticercosis remain important causes not prominent in Western texts. The Supreme Court's *Common Cause* (2018, modified 2023) framework for advance medical directives is directly applicable to decision-making in prolonged coma.

Current Practice Update

Textbook Position	Current Evidence-Based Practice (2023–2026)
GCS is the standard measure of depth of coma and of prognosis in SDH	GCS retained, but **FOUR score preferred in intubated patients**; adds brainstem and respiratory assessment
Bedside unresponsiveness taken at face value	**Cognitive motor dissociation in ~25%** (*NEJM* 2024) — consider fMRI/EEG paradigms before prognosticating
Coma described descriptively within individual disease chapters	Reframed as an **"acute disorder of consciousness"** with mechanism-based endotypes (Curing Coma Campaign)
EEG mentioned mainly for epilepsy diagnosis	**Continuous EEG is standard** for unexplained coma; up to 20% is NCSE; Salzburg criteria applied
Hyponatraemia: 3% saline 100 mL bolus preferred to slow infusion	Confirmed and now standard; correct by **≤8 mEq/L per 24 h**, with DDAVP re-lowering if overcorrected

Examiner's Tip — say these lines verbatim:

- "Consciousness = **arousal (ARAS) + awareness (cortex)**. Coma requires damage to the ARAS or to **both** hemispheres."
- "**Check glucose before anything else**, and give **thiamine before glucose** in the malnourished."
- "**Preserved pupillary reactions in a deeply comatose patient point to a metabolic cause**; asymmetry points to a structural lesion."
- "**Multifocal myoclonus and asterixis are metabolic; posturing is structural.**"
- "In the elderly, always exclude **subdural haematoma, hypoglycaemia, hyponatraemia, drugs and non-convulsive status epilepticus** — all reversible."
- "Correct hyponatraemia by **no more than 6–8 mEq/L in 24 hours** to avoid osmotic demyelination."

3. Subdural Haematoma RECURS ×2

Definition and classification

1. **Subdural haematoma (SDH)** is a collection of blood in the **subdural space** — the potential space between the **dura mater** and the **arachnoid mater**.
2. The dura has two layers — an outer **periosteal** layer and an inner **meningeal** layer, separated from the arachnoid by a **dural border cell layer**. The potential space becomes a real space when the dural border cell layer **cleaves away** from the meningeal layer, shearing the **bridging veins** that traverse it to reach the dural venous sinuses.
3. **Classification by time from ictus**: **acute <3 days** (usually post-traumatic), **subacute 4–20 days**, **chronic >20 days**. The spectrum is best regarded as a **dynamic continuum**, not discrete entities.

Epidemiology and why the elderly are at risk

4. With ageing, the **brain atrophies and pulls away from the skull**, placing traction on the meninges and bridging veins. This predisposes to SDH after **minimal or unremembered trauma**, or even spontaneously.
5. The incidence of chronic SDH (CSDH) in patients **over 80 has risen significantly over the last three decades**; by 2030 CSDH is projected to be the **commonest cranial neurosurgical disease in the world**.
6. Falls are the commonest mechanism in older adults. A major confounding factor is the **widespread use of antiplatelets and anticoagulants** for comorbidities.

Pathophysiology — the key contrast

7. **Acute SDH**: signs and symptoms result from an **abrupt rise in intracranial pressure with compression of eloquent brain tissue**. The two aetiologies are **tearing of bridging veins** and **parenchymal laceration** (the latter reflecting severe primary injury).
8. **Chronic SDH**: the mechanism is **entirely different** — it is driven by an **inflammatory response provoked by blood haemolysis and its degradation products**, with neomembrane formation, fragile leaky neocapillaries fed by the **middle meningeal artery**, repeated microhaemorrhage and osmotic exudation. CSDH is phenotypically diverse.

Clinical features

9. **Acute SDH**: rapid decline in consciousness, headache, vomiting, focal deficit, seizures, anisocoria and herniation signs. Often a lucid interval is absent.
10. **Chronic SDH — the great mimic**: headache, cognitive decline, confusion, gait disturbance, falls, hemiparesis, aphasia and seizures. **50–70% of elderly patients present with altered mental status**; the course is characteristically **fluctuating**.
11. CSDH may masquerade as **dementia, stroke, delirium, normal pressure hydrocephalus, parkinsonism or depression** — it is a **reversible cause of cognitive decline**.

Investigations

12. **Non-contrast CT of the head is the initial method of choice.** Acute SDH is a **crescent-shaped hyperdensity with a concave inner surface**, causing midline shift and ventricular effacement; it **crosses suture lines but not the midline**.
13. **Subacute SDH becomes isodense** with brain (about 1–3 weeks) and is easily missed — look for **effaced sulci, a displaced grey–white junction, and asymmetric ventricles**. Chronic SDH is hypodense; **mixed density indicates re-bleeding**.
14. **MRI** is most useful for isodense collections, bilateral collections and for chronic intradural haematoma in evolution. Add coagulation screen, platelet count, and anticoagulant drug levels.

Management — acute SDH

15. **Small acute SDH (clot thickness <10 mm) in a neurologically intact patient**, with no herniation, no significant midline shift and no raised ICP, is **not emergently evacuated**. Monitor clinically and repeat the CT at 24 hours (or sooner) if there is concern about expansion or any change in mental status or neurological examination.
16. **Acute symptomatic SDH is a medical emergency** — rapid diagnosis, **reversal of anticoagulation**, and surgical evacuation (craniotomy or decompressive craniectomy) as soon as indicated.
17. **Anticoagulant reversal**: vitamin K plus 4-factor prothrombin complex concentrate for warfarin; **idarucizumab** for dabigatran; **andexanet alfa** for factor Xa inhibitors. **In patients on antiplatelet medication, preoperative platelet transfusion did not reduce reoperation rates; platelet reversal and platelet transfusion are therefore not routinely recommended.**

Management — chronic SDH

18. Surgical options are **twist-drill craniostomy**, **burr-hole craniostomy** (5–30 mm hole, better visualisation of dura and cortex, usually under general anaesthesia — the standard operation), and **craniotomy** (large bone flap, direct access to haematoma and membranes; preferred for **multiloculated CSDH with significant membranes**).
19. Evidence: **no difference** in mortality, morbidity, recurrence or cure between burr-hole and twist-drill craniostomy. Open craniotomy as first treatment has **more morbidity but lower recurrence**.
20. **Strong evidence supports placement of a subdural drain** — it significantly lowers recurrence and improves

functional outcome **without** increasing operative complications or mortality. No universal management consensus exists; each case is individualised.

21. Complications are frequent given age, frailty and comorbidity: wound infection, subdural empyema, tension pneumocephalus, seizure, brain contusion, fresh subdural or extradural haematoma, intracerebral haemorrhage and death.
22. **Recurrence is up to 33%** despite gold-standard drainage and irrigation. **Risk factors for recurrence: age >70, bilateral CSDH, large haematoma volume, preoperative seizure, postoperative intracranial air, low GCS, and diabetes mellitus.**
23. **Medical adjuncts**: **atorvastatin** 20 mg (Jiang et al., *JAMA Neurology* 2018 RCT) reduced haematoma volume and improved neurological outcome. Dexamethasone has been studied — see updates below.
24. **Endovascular treatment**: **middle meningeal artery (MMA) embolisation** addresses the underlying pathology rather than simply draining blood — by embolising the MMA the blood supply to the pathological membranes is removed, allowing spontaneous resolution.

Prognosis and prevention

25. **Mortality for acute SDH is 22–60%**, higher in the elderly. **Predictors of poor outcome: advanced age, low GCS at presentation, comorbid intracranial and extracranial injury, and anticoagulant use.**
26. **Features favouring spontaneous resolution**: coma lasting less than 12 hours after injury, absence of cerebral contusion, a **thin haematoma with wide distribution**, GCS >8, and clinical stability over time.
27. **Prevention**: **DOACs reduce the risk of intracranial haemorrhage compared with vitamin K antagonists** while remaining at least as effective for thromboembolism. Registry data show DOAC-treated patients have **lower in-hospital mortality, fewer severe intracranial haemorrhages, less need for operative intervention and less discharge to skilled nursing facilities** than warfarin-treated patients. Add falls prevention, medication review, and vision and gait optimisation.

Latest Updates (2023–Present)

- **Three landmark randomised controlled trials of MMA embolisation published in the *New England Journal of Medicine* (November 2024 and February 2025):**
  - **EMBOLISE** (Onyx liquid embolic, MMAE as an *adjunct* to surgery) — significant reduction in haematoma recurrence requiring reoperation.
  - **STEM** (Squid, adjunctive and standalone) — composite of recurrent/residual haematoma, surgical rescue, major disabling stroke, MI or death at 180 days was **16% with MMAE vs 36% with control (OR 0.36, 95% CI 0.20–0.66, p = 0.001)**.
  - **MAGIC-MT** (China, Onyx) — **neutral**: symptomatic recurrence or progression at 90 days 6.7% vs 9.9% (p = 0.10).
- **Meta-analysis of the three RCTs (2025)**: MMAE is **safe** with no significant increase in serious adverse events, and gives a **modest overall reduction in recurrence (risk difference −0.09, p = 0.02)**, though the effect is largely driven by STEM and the benefit as a surgical adjunct is less clear.
- **Society of Vascular and Interventional Neurology (SVIN) consensus guideline (2025)** supports MMAE in selected patients (adjunct in high-recurrence-risk cases and standalone in minimally symptomatic patients unfit for surgery). In contrast, **the 2025 UK national CSDH guidelines declined to recommend MMAE routinely**, calling for further research — know both positions.
- **Dexamethasone is not recommended**: the **DEX-CSDH trial (*NEJM* 2020)** found dexamethasone reduced recurrence but produced **worse functional outcome at 6 months and more adverse events**. This overturns older favourable observational data cited in the textbook.
- **Resumption of anticoagulation after CSDH**: contemporary observational data (2023–2025) support restarting at around **4 weeks** in patients with a strong indication (mechanical valve, high CHA_2DS_2-VA score), balanced individually against re-bleed risk.
- **Indian context**: CSDH is a very common presentation in Indian neurosurgical practice. **Burr-hole drainage with a closed-system subdural drain under local anaesthesia** remains the standard and is highly cost-effective; MMA embolisation is limited by cost, catheter-lab availability and the absence of Indian RCT data. Atorvastatin is an attractive low-cost adjunct in the Indian setting.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
MMA embolisation described as an area of "increasing interest" based on meta-analyses of case series	Now supported by **three NEJM RCTs** (EMBOLISE, STEM positive; MAGIC-MT neutral) and a 2025 **SVIN consensus guideline**; safe, with modest recurrence benefit
Corticosteroid (dexamethasone) treatment cited from favourable systematic reviews	**Not recommended** — DEX-CSDH (*NEJM* 2020) showed **worse functional outcome and more adverse events** despite lower recurrence
Atorvastatin supported by a single Chinese RCT	Remains a reasonable low-cost adjunct, particularly for small/asymptomatic CSDH; larger confirmatory trials still awaited
Subdural drain reduces recurrence	**Unchanged and reinforced** — drain placement remains the single most robust surgical recommendation
Platelet transfusion not routinely recommended in antiplatelet users	**Unchanged**; supported by PATCH-type data showing harm from platelet transfusion in antiplatelet-associated ICH
DOACs preferable to warfarin with respect to intracranial haemorrhage	**Confirmed**; specific reversal agents (idarucizumab, andexanet alfa) are now standard of care

Extra Points to Remember — recurring topic (asked twice)

- **The one-line contrast that earns marks:** "Acute SDH is a **pressure and mass-effect** problem; chronic SDH is an **inflammatory and angiogenic** problem driven by blood degradation products."
- **The classic exam trap:** the **isodense phase at 2–3 weeks** — a CT may look "normal". Look for effaced sulci, a displaced grey–white junction, and small ventricles.
- **Bilateral CSDH may show NO midline shift** because the two collections balance each other — the only clues are effaced sulci and compressed ventricles ("slit ventricles").
- **CSDH is a reversible cause of dementia** — always image the brain before labelling a patient with falls or anticoagulant use as having dementia.
- **Contrast with extradural haematoma:** biconvex/lenticular, does *not* cross suture lines but *can* cross the midline, arterial (middle meningeal artery) bleed, classic lucid interval, typically younger patients. SDH: crescentic, crosses sutures but not midline, venous bleed, older patients.
- **Numbers worth quoting:** mortality 22–60%; recurrence up to 33%; clot thickness <10 mm may be observed; recurrence risk factors — age >70, bilateral, large volume, preoperative seizure, postoperative air, low GCS, diabetes.
- **Two-sentence "prevention" answer:** "DOACs rather than vitamin K antagonists where anticoagulation is indicated, plus multifactorial falls prevention with medication review, vision correction and gait/balance training."

Examiner's Tip — say these lines verbatim:

- "**Brain atrophy stretches the bridging veins**, so SDH occurs in the elderly after trivial or unremembered trauma."
- "**CT head is the initial investigation of choice** — acute is a crescentic hyperdensity concave to the skull; chronic is hypodense; **subacute is isodense and easily missed**."
- "**Chronic SDH is driven by an inflammatory response to blood degradation products**, not by mass effect — which is why MMA embolisation works."
- "**Placement of a subdural drain significantly lowers recurrence and improves functional outcome without increasing complications.**"
- "**Dexamethasone is no longer recommended** — DEX-CSDH showed worse functional outcome despite fewer recurrences."
- "CSDH is expected to be the **commonest cranial neurosurgical disease in the world by 2030**."

4. Lacunar Infarcts

Definition and pathology

1. **Lacunes** are small infarcts resulting from occlusion of the **small perforating arterioles** supplying the basal ganglia, external and internal capsule, thalamus and pons. On brain imaging they are defined as **deep subcortical infarcts less than 15 mm in maximum diameter**.
2. Two underlying pathologies: **microatheroma at the origin of the perforating artery**, and more distal **lipohyalinosis** — degenerative change in the **tunica media and adventitia** of the arterioles. These cannot be distinguished clinically or radiologically and are together known as **small-vessel disease (SVD)**.
3. Lacunar strokes account for roughly **a quarter of all ischaemic strokes**.
4. Other imaging manifestations of the same process: **leukoaraiosis** (patchy or confluent low attenuation on CT, high signal on T_2 and FLAIR MRI in the white matter, also attributed to lipohyalinosis) and **cerebral microhaemorrhages** on gradient-echo (T_2*) or susceptibility-weighted MRI.
5. **Leukoaraiosis, lacunes and microhaemorrhages are each independently associated with cognitive impairment.**
6. **Hypertension is the major risk factor** for lacunar infarction, leukoaraiosis and microhaemorrhage. Microhaemorrhages are also associated with **cerebral amyloid angiopathy** — deep/basal ganglia microbleeds suggest hypertensive arteriopathy, lobar microbleeds suggest amyloid angiopathy.
7. Other risk factors: increasing age, diabetes mellitus, smoking and dyslipidaemia. Cardioembolism and large-artery atherosclerosis are usually **not** the mechanism, but must still be excluded.

Classical lacunar syndromes

8. **Pure motor stroke** (commonest): unilateral face, arm and leg weakness. The weakness need not involve all three but should involve **at least two contiguous sites** — face and arm, or arm and leg. Lesion in the posterior limb of the internal capsule or the pons.
9. **Pure sensory stroke**: contralateral hemisensory loss; lesion in the thalamus (ventral posterolateral nucleus).
10. **Sensorimotor stroke**: a larger lacune producing mixed motor and sensory loss.
11. **Ataxic hemiparesis**: limb ataxia combined with hemiparesis and/or dysarthria (including the dysarthria–clumsy hand variant); internal capsule or pons.
12. **The defining negative features (the marks-earning point): there is NO disturbance of higher cortical function and NO visual field deficit** — no aphasia, neglect, agnosia or apraxia, and no hemianopia.
13. Rarer lacunar syndromes include **unilateral chorea and hemiballismus** from lacunes in the basal ganglia.

Diagnosis

14. **Imaging is required** to distinguish a capsular from a pontine site, as the syndromes are identical clinically. **Diffusion-weighted MRI is most sensitive acutely**; CT is frequently normal in the first hours.
15. Occasionally a small haemorrhage produces an identical syndrome — imaging is essential before antithrombotic therapy.
16. Complete the standard stroke workup: ECG and prolonged rhythm monitoring, echocardiography, carotid imaging, lipids, HbA1c, renal function, ESR — principally to exclude an alternative mechanism.

Prognosis and management

17. **Lacunar stroke carries a good prognosis for survival, with a one-year mortality of about 10%, but 50% of survivors remain dependent.**
18. Recurrent lacunes and progressive white matter change lead to **vascular cognitive impairment, vascular parkinsonism, pseudobulbar palsy, gait apraxia and emotional lability** ("état lacunaire").
19. **Acute treatment**: intravenous thrombolysis if within the licensed window (benefit is preserved in lacunar stroke), antiplatelet therapy, and admission to a **stroke unit** for multidisciplinary care.
20. **Secondary prevention — blood pressure control is the single most important intervention** (PROGRESS: perindopril-based regimen reduced recurrent stroke); target ≤130/80 mmHg in diabetic patients.
21. **Statin**: high-dose atorvastatin 80 mg reduced recurrent ischaemic stroke by around 20% (SPARCL); treat cholesterol >3.5 mmol/L with dietetic input.
22. **Antiplatelet therapy** (aspirin, clopidogrel, or aspirin with extended-release dipyridamole) plus glycaemic control, smoking cessation and lifestyle change. **Anticoagulation is not indicated** unless there is a separate indication such as atrial fibrillation or a prosthetic valve.

Latest Updates (2023–Present)

- **LACI-2 trial (Wardlaw et al., *JAMA Neurology* 2023)** — the single most examinable update. 363 patients with clinical lacunar ischaemic stroke, randomised 2×2 to **isosorbide mononitrate (ISMN) 40–60 mg/day**, **cilostazol 200 mg/day**, both, or neither, on top of guideline secondary prevention for one year. **ISMN reduced recurrent stroke (adjusted OR 0.23, 95% CI 0.07–0.74) and cognitive impairment (aOR 0.55, 95% CI 0.36–0.86); cilostazol reduced dependence; the combination reduced the composite of vascular, dependence and cognitive outcomes.** Retention was 99% with good adherence and no safety concerns. A prespecified 6-month

analysis (2025) confirmed that benefit appears early. Both are **inexpensive, licensed generic drugs**; the definitive phase 3 trial (LACI-3) is awaited.

- **STRIVE-2 consensus (*Lancet Neurology* 2023)** updated the neuroimaging standards for reporting cerebral small vessel disease — standardised terminology for recent small subcortical infarct, lacune of presumed vascular origin, white matter hyperintensity, perivascular space, microbleed, cortical superficial siderosis and brain atrophy. **"Leukoaraiosis" is being retired in favour of "white matter hyperintensity of presumed vascular origin."**
- **European Stroke Organisation guidelines on cerebral small vessel disease** — Part 1 (covert SVD, 2021) and Part 2 (lacunar ischaemic stroke) formalise management.
- **Antiplatelet intensification**: **INSPIRES (*NEJM* 2024)** supports clopidogrel plus aspirin started within 72 hours for mild ischaemic stroke or high-risk TIA of atherosclerotic origin; **CHANCE-2** showed genotype-guided ticagrelor is superior in **CYP2C19 loss-of-function carriers** — highly relevant, as this genotype is common in Indian and East Asian populations.
- **Blood pressure**: SPS3 supported a systolic target <130 mmHg in lacunar stroke, particularly for reducing intracerebral haemorrhage; ESPRIT and 2024–2025 intensive-lowering trials reinforce this.
- **Indian context**: small-vessel disease and intracranial atherosclerosis account for a much larger share of Indian ischaemic stroke than extracranial carotid disease. ICMR-INDIAB and LASI data show very high prevalence and poor control of hypertension and diabetes in older Indians; the **India Hypertension Control Initiative (IHCI)** and the **National Programme for Prevention and Control of Non-Communicable Diseases (NP-NCD)** are the operative public-health frameworks for prevention.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Secondary prevention is antiplatelet + statin + BP control, identical to other ischaemic stroke subtypes	**LACI-2 (2023)** supports adding **isosorbide mononitrate** (reduces recurrent stroke and cognitive impairment) and **cilostazol** (reduces dependence) — endothelium-targeted therapy specific to small-vessel disease
Terms "leukoaraiosis" and "lacune" used descriptively	**STRIVE-2 (2023)** standardised terminology — "white matter hyperintensity of presumed vascular origin", "recent small subcortical infarct", "lacune of presumed vascular origin"
Aspirin or clopidogrel monotherapy after minor stroke/TIA	Short-course **dual antiplatelet therapy** (CHANCE, POINT, INSPIRES) for 21–30 days; **genotype-guided ticagrelor** in CYP2C19 loss-of-function carriers (CHANCE-2)
BP target ≤130/80 specified for diabetic patients	**Systolic <130 mmHg for all lacunar stroke** (SPS3 and subsequent intensive-lowering trials), especially to reduce intracerebral haemorrhage
Cognitive consequences noted as an association	SVD is now recognised as the **leading vascular contributor to dementia**; cognitive outcome is a primary trial endpoint

Examiner's Tip — say these lines verbatim:

- "A lacune is a **deep subcortical infarct less than 15 mm in maximum diameter** from occlusion of a small perforating artery."
- "The two pathologies are **microatheroma at the perforator origin** and **lipohyalinosis of the tunica media and adventitia** — indistinguishable clinically and radiologically, hence 'small-vessel disease'."
- "The four syndromes are **pure motor, pure sensory, sensorimotor and ataxic hemiparesis**."
- "The defining feature is **absence of cortical signs and absence of a visual field defect**."
- "**Hypertension is the major risk factor** for lacunes, leukoaraiosis and microhaemorrhages."
- "Prognosis: **one-year mortality about 10%, but 50% of survivors remain dependent**."
- "**LACI-2 (2023)** showed isosorbide mononitrate reduced recurrent stroke and cognitive impairment, and cilostazol reduced dependence — two cheap licensed drugs awaiting phase 3 confirmation."

5. Subacute Combined Degeneration of the Cord — Presentation and Treatment

Definition and biochemistry

1. **Subacute combined degeneration (SACD)** is progressive degeneration — demyelination followed by axonal loss — of the **posterior (dorsal) columns** and the **lateral corticospinal tracts** of the spinal cord, caused by **vitamin B_{12} (cobalamin) deficiency**.
2. "**Subacute**" refers to evolution over weeks to months; "**combined**" to the involvement of **two** tract systems. The cervical and upper thoracic cord are preferentially affected.
3. Vitamin B_{12} is **required for DNA synthesis, mitochondrial function and red blood cell production**, and converts folate to its biologically active form; when deficient it can cause a secondary folate deficiency.
4. Two cobalamin-dependent enzymes explain the pathology: **methionine synthase** (homocysteine → methionine, required for S-adenosylmethionine and myelin methylation) and **methylmalonyl-CoA mutase**. Deficiency therefore raises both **homocysteine** and **methylmalonic acid (MMA)**, and impairs myelin maintenance.

Causes

5. **Impaired absorption** is the dominant mechanism in the elderly: **atrophic gastritis** (10–30% of older adults malabsorb food-bound B_{12}), **pernicious anaemia** (lack of intrinsic factor; 1–2% of older adults), gastrectomy or bariatric surgery, ileal resection, Crohn's disease, intestinal bacterial overgrowth.
6. **Drugs**: **metformin** (long-term users should be screened), **proton pump inhibitors and H_2 blockers** (raised gastric pH prevents release of B_{12} from animal protein).
7. **Inadequate intake**: B_{12} is found **strictly in animal products** — red meat, eggs and dairy — making **vegetarians and vegans particularly susceptible**. This is of major importance in India.
8. **Nitrous oxide** exposure or abuse irreversibly oxidises the cobalt ion of cobalamin and inactivates methionine synthase, precipitating SACD **even when the serum B_{12} is normal**.
9. Prevalence of B_{12} deficiency ranges from **5–40%** in older people depending on the cut-off used; 13.8% on nursing-home admission with a 4% new yearly incidence.

Presentation

10. **Critical exam point: neurological disease may occur in the complete absence of anaemia or macrocytosis** — a normal blood count never excludes SACD.
11. **Earliest symptoms are sensory**: symmetrical distal **paraesthesiae, numbness and tingling in the hands and feet**, often affecting the hands before the feet.
12. **Posterior column signs**: loss of **vibration sense (the earliest and most sensitive sign)** and joint position sense, **sensory ataxia**, a **positive Romberg's sign**, and unsteadiness that is markedly worse in the dark or with eyes closed.
13. **Corticospinal tract signs**: spastic paraparesis, weakness, hyperreflexia and **extensor plantar responses**.
14. **The classic paradoxical combination: brisk knee jerks with absent ankle jerks and extensor plantars** — produced by simultaneous myelopathy and peripheral neuropathy. Always quote this.
15. Additional features: **Lhermitte's phenomenon**, gait ataxia, autonomic dysfunction, bladder disturbance late, and **optic atrophy** with centrocaecal scotoma.
16. **Neuropsychiatric**: mood change, depression, irritability, confusion, poor memory, dementia, and psychosis ("megaloblastic madness").
17. **Haematological and mucosal**: macrocytic megaloblastic anaemia, **hypersegmented neutrophils**, glossitis with a beefy-red sore tongue, angular stomatitis, vitiligo, mild jaundice from ineffective erythropoiesis (raised LDH, low haptoglobin), fatigue, weakness, anorexia and weight loss.

Investigations

18. **Serum B_{12}** is the first test but there is **no gold-standard diagnostic test**; the diagnosis rests on the clinical picture with a low B_{12}. **Serum MMA and homocysteine are both raised** and increase diagnostic sensitivity where the B_{12} is borderline; holotranscobalamin (active B_{12}) is an alternative.
19. **Falsely normal B_{12}** occurs in hepatic and renal disease and myeloproliferative disorders; **falsely low B_{12}** occurs in folate deficiency and multiple myeloma.
20. Additional tests: full blood count and peripheral smear, reticulocytes, LDH, folate, ferritin (coexisting iron deficiency masks macrocytosis), TSH, **intrinsic factor antibody** (specific but insensitive) and **anti-parietal cell antibody** (sensitive, non-specific), and upper GI endoscopy for atrophic gastritis.
21. **MRI of the spine**: T_2 hyperintensity in the **dorsal columns of the cervical and upper thoracic cord**, producing the classic **"inverted V" or "inverted rabbit-ear" sign** on axial images. Nerve conduction studies confirm coexisting peripheral neuropathy.

Treatment

22. **Neurological involvement mandates parenteral replacement.** Give **hydroxocobalamin 1000 mcg IM on alternate days until there is no further improvement**, then 1000 mcg every 2–3 months indefinitely.

23. Textbook regimen for deficiency without neurological disease: **IM B_{12} 1000 mcg weekly for severe deficiency, then monthly for maintenance** (10–15% of each injection is absorbed, so stores replenish quickly).
24. **Oral B_{12} 2000 mcg daily** is as effective as intramuscular therapy in most cases, is cheaper and easier, and works even with achlorhydria or pernicious anaemia because a small fraction is **passively absorbed independent of intrinsic factor**. Give **once daily only** — receptor saturation means more frequent dosing does not improve absorption.
25. **Do not give folate alone** — folic acid without B_{12} corrects the anaemia while allowing the neurological disease to progress. Start B_{12} first, then replace folate.
26. Monitoring: reticulocytosis by day 5–7; **watch for hypokalaemia in the first week** of a brisk haematological response; recheck haemoglobin and B_{12} at **3 months**.
27. **Treatment is lifelong** in pernicious anaemia and after gastric or bowel resection, since absorption will remain deficient. Correct coexisting iron and folate deficiency. Review and, where possible, address contributing drugs (metformin, PPIs).
28. **Prognosis is inversely related to the duration of symptoms.** Treatment within weeks usually gives complete recovery; after 6–12 months of symptoms, progression is halted but full recovery is unlikely. **Sensory symptoms recover better than spastic paraparesis.**
29. **Prevention**: have a high index of suspicion and screen at-risk individuals annually — those with bowel resection, atrophic gastritis, inflammatory bowel disease, restrictive diets, and users of metformin or acid suppressants. Adults over 50 should meet the RDA mainly through **fortified foods or a supplement** containing B_{12}, since food-bound B_{12} is poorly absorbed.

Latest Updates (2023–Present)

- **NICE guideline NG239, "Vitamin B_{12} deficiency in over 16s: diagnosis and management" (March 2024)** — the first UK national guideline and the definitive current reference, which **supersedes the BSH 2014 guideline**. Key positions: test only when there are symptoms or risk factors rather than routinely; where serum B_{12} is indeterminate, use **MMA or holotranscobalamin** as second-line; and **in suspected neurological involvement start intramuscular hydroxocobalamin without waiting for test results**. Oral replacement is acceptable for non-neurological deficiency without malabsorption.
- **NICE 2024 also stresses "functional B_{12} deficiency"** — strong clinical features such as megaloblastic anaemia or SACD despite a normal serum B_{12} warrant urgent haematology advice and empirical treatment.
- **Nitrous oxide–induced SACD** is now a recognised and rapidly growing cause (case series in *Journal of Neurology* 2025 and *Frontiers in Immunology* 2025). Compared with dietary B_{12} deficiency it produces **more severe and more extensive spinal cord and peripheral nerve damage**; **serum B_{12} was normal in a substantial proportion, but MMA was elevated in all**; recovery is often incomplete despite replacement.
- **Metformin**: the **ADA Standards of Care (2025)** recommend periodic measurement of B_{12} in metformin-treated patients, particularly those with peripheral neuropathy or anaemia.
- **Indian context**: B_{12} deficiency is exceptionally common because of predominantly lacto-vegetarian diets, with population studies reporting deficiency in **47–75%** of Indian adults. **ICMR-NIN RDA (2020) is 2.2 mcg/day** for adults. Mandatory fortification of wheat flour and rice with folic acid, iron and B_{12} under FSSAI's +F programme is relevant — folate excess without B_{12} repletion could theoretically unmask neurological disease, so B_{12} status should be checked in symptomatic patients.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Oral B_{12} 2000 mcg daily is generally as effective as IM in most cases	True for **uncomplicated deficiency**, but **NICE NG239 (2024) requires IM hydroxocobalamin where there is neurological involvement** — oral therapy risks under-treatment of SACD
"No consensus exists on when additional diagnostic tests should be added"	**NICE NG239 (2024) provides a clear algorithm**: indeterminate serum B_{12} → MMA or holotranscobalamin as second-line
"No major medical organization has published guidelines on routine screening"	**NICE NG239 (2024) now defines who to test**: symptoms plus specified risk factors; still no universal population screening
Treatment may await confirmatory testing	**Do not delay** — in suspected neurological disease start IM hydroxocobalamin immediately; damage becomes irreversible
Causes listed as dietary, malabsorptive and drug-related	**Nitrous oxide abuse** added as an important and severe cause, often with a **normal serum B_{12}** but elevated MMA
Metformin association noted; "long-term users should be screened"	**ADA 2025** formalises periodic B_{12} monitoring in metformin users, especially with neuropathy or anaemia

> **Examiner's Tip — say these lines verbatim:**
> - "SACD is degeneration of the **posterior columns and lateral corticospinal tracts** due to vitamin B_{12} deficiency — 'combined' means two tract systems."

- "**Neurological disease can occur without anaemia or macrocytosis** — a normal blood count never excludes SACD."
- "The classic sign is **brisk knee jerks with absent ankle jerks and extensor plantars** — myelopathy plus peripheral neuropathy."
- "**Loss of vibration sense is the earliest and most sensitive sign**, with a positive Romberg's."
- "MRI shows **T_2 hyperintensity in the dorsal columns** — the **'inverted V' sign** on axial images."
- "**Never give folate before B_{12}** — it corrects the anaemia and lets the neurological disease progress."
- "**Recovery is inversely related to the duration of symptoms**; treat within weeks for complete recovery."
- "**NICE NG239 (2024): in neurological involvement, start intramuscular hydroxocobalamin without waiting for test results.**"

6. Motor Neuron Disease — Presentation, Evaluation and Treatment

Definition and classification

1. **Motor neuron diseases (MNDs)** are a heterogeneous group characterised by degeneration or dysfunction of the **upper motor neurons (UMN) of the precentral gyrus** and/or the **lower motor neurons (LMN) of the ventral horn of the spinal cord**.
2. **Amyotrophic lateral sclerosis (ALS)** is the commonest MND in adults and involves both UMN and LMN. It shows considerable **phenotypic heterogeneity** and is better regarded as a syndrome — sporadic and genetic forms, pure motor and extra-motor (frontotemporal dementia) presentations, pure LMN or pure UMN variants, and localised forms.
3. Variants: **progressive muscular atrophy** (LMN only), **primary lateral sclerosis** (UMN only), **progressive bulbar palsy**, flail arm and flail leg syndromes, and the **ALS–FTD spectrum**. Although histopathologically similar, **individualisation matters because prognosis differs**.
4. Epidemiology: incidence roughly 2–3 per 100,000 per year, peak onset 60–75 years, slight male predominance; about 10% familial. More than **30 genes** are implicated — **C9orf72** (commonest, links ALS with FTD), **SOD1, TARDBP, FUS**.

Pathophysiology

5. The neuropathological hallmark of most ALS is **cytoplasmic inclusions containing ubiquitinated and hyperphosphorylated TDP-43** (except in SOD1- and FUS-linked familial ALS, which represent under 3% of cases).
6. **TDP-43** is normally nuclear and regulates transcription, splicing and mRNA stability. In disease it is **mislocalised** — nuclear depletion causes aberrant RNA metabolism and impaired chromatin remodelling, while cytoplasmic accumulation disturbs autophagy, proteasome function, protein quality control and mitochondrial function. TDP-43 aggregates have a **seeding capability and prion-like cell-to-cell transmission**.
7. Converging mechanisms: **disrupted RNA metabolism, aberrant protein quality control, mitochondrial dysfunction, oxidative stress, glutamate excitotoxicity, trafficking abnormalities and hypermetabolism**.

Clinical presentation

8. Motor symptoms are frequently preceded for months by **non-specific features: fatigue, weight loss secondary to hypermetabolism, cramps and diffuse fasciculation** related to loss and hyperexcitability of lower motor neurons.
9. **Limb-onset ALS** (commonest): difficulty performing fine hand movements, difficulty raising the arms, foot drop and difficulty walking — typically **asymmetrical, painless, progressive weakness**.
10. **Bulbar-onset ALS (about one-third)**: swallowing and phonation disorders with **sialorrhoea**, dysarthria, tongue wasting and fasciculation. Commoner in older women and carries a **worse prognosis**.
11. **Respiratory-onset (rare)**: onset in the trunk musculature with isolated restrictive respiratory impairment causing effort dyspnoea and orthopnoea, frequently with unexplained weight loss.
12. **Signs**: mixed UMN (spasticity, hyperreflexia, extensor plantars, brisk jaw jerk, clonus) and LMN (wasting, fasciculation, hypotonia) findings **in the same body region**, with contiguous spread. **Pseudobulbar affect** (emotional lability) is common.
13. **Cognitive and behavioural change occurs in up to 50%**, with frank FTD in 10–15%. Revised criteria for **ALS–frontotemporal spectrum disorder (ALS-FTSD, Strong 2017)** and the **Edinburgh Cognitive and Behavioural ALS Screen (ECAS)** are the standards. **The frontotemporal syndrome of ALS is associated with poor survival** and negatively affects caregiver burden and quality of life.
14. **Characteristically spared until late**: extraocular movements, sphincter function, sensation, and cognition in the majority — the preservation of cognitive capacity in most patients is precisely why **advance directives can and should be discussed early**.

Evaluation

15. **In the absence of positive diagnostic markers, diagnosis rests on precise clinical and electrophysiological analysis, the study of the disease course, and elimination of the differential diagnoses referred to as "ALS mimics".** Diagnostic delay is common.
16. Diagnostic criteria: **El Escorial (1994)**, **revised El Escorial / Airlie House (2000)**, and the **Awaji electrodiagnostic criteria (de Carvalho 2008)**, in which fasciculation potentials count as evidence of acute denervation.
17. **EMG**: fibrillations, positive sharp waves, fasciculations, large-amplitude long-duration polyphasic motor units and reduced recruitment, in at least two of four regions (bulbar, cervical, thoracic, lumbosacral). Nerve conduction studies show **normal sensory responses** and no conduction block.
18. **Exclude the treatable mimics** — many are eminently treatable: cervical and lumbar spondylotic myeloradiculopathy (MRI brain and whole spine), **multifocal motor neuropathy with conduction block** (anti-GM1 antibodies; responds to IVIG), CIDP, myasthenia gravis, inclusion body myositis, Kennedy disease, **vitamin B_{12} deficiency**, thyrotoxicosis, hyperparathyroidism, paraneoplastic syndromes, HIV, syphilis and lymphoma.
19. Laboratory work: CK (mildly raised), TSH, calcium and PTH, vitamin B_{12}, ESR, serum protein electrophoresis, anti-GM1, HIV and VDRL. **CSF neurofilament proteins (NfL, pNfH) are established diagnostic and prognostic biomarkers.**

20. **Respiratory assessment at diagnosis and every 3 months**: erect and supine FVC, sniff nasal inspiratory pressure (SNIP), overnight oximetry and arterial blood gases. Also assess nutrition, weight trajectory, swallow and cognition (ECAS).

Treatment

21. **Despite more than 200 trials, ALS remains incurable.** Aetiologic treatment slightly improves survival; symptomatic and supportive management improves both survival and quality of life.
22. **Riluzole** (approved 1995), 50 mg twice daily, acts on Na^+ and K^+ currents and glutamatergic transmission. Median survival gain is modest, about **three months**; the one-year survival gain was 9% (**58% vs 49%**), with small effects on bulbar and limb function. **All population-based registries confirm riluzole is an independent factor influencing long-term survival**, and it is recommended by the EFNS and the AAN **for all ALS patients, even in later stages**. Monitor liver enzymes.
23. **Edaravone**, a free-radical scavenger, was FDA-approved on the basis of a second Japanese phase 3 trial in a narrowly selected group (definite or probable ALS, duration ≤2 years, normal respiratory function, ALSFRS-R item scores ≥2), showing a least-squares mean difference of **2.49 points** in favour of edaravone. However a slight **deterioration in quality of life** was observed, and in **May 2019 the EMA withdrew the marketing authorisation application** because of baseline imbalance, lack of effect on survival, breathing and muscle strength, and too short a study duration.
24. **Multidisciplinary care is itself an evidence-based intervention** — multidisciplinary clinics improve survival compared with general neurology care.
25. **Respiratory failure is the commonest cause of death** and one of the most important determinants of quality of life and anxiety. **Non-invasive ventilation prolongs survival** and should be offered for symptomatic nocturnal hypoventilation, FVC <50%, or SNIP <40 cmH_2O. Cough augmentation and secretion management are essential adjuncts.
26. **Nutrition**: early dietitian involvement, high-calorie diet to offset hypermetabolism, texture modification, and **gastrostomy (PEG or radiologically inserted) before FVC falls below 50%**, when the procedure becomes hazardous.
27. **Symptom control**: sialorrhoea (glycopyrrolate, hyoscine, amitriptyline, botulinum toxin to salivary glands, salivary gland radiotherapy); spasticity (baclofen, tizanidine, physiotherapy); cramps (levetiracetam, mexiletine, quinine); pseudobulbar affect (dextromethorphan–quinidine, amitriptyline, SSRIs); thick secretions (carbocisteine, nebulised saline); pain; insomnia; depression and anxiety; and communication through augmentative and alternative communication devices.
28. **Early palliative care** and collection of **advance directives** must be an early objective, while cognition is preserved — but clinicians must respect patient autonomy, including the inability of some patients to project themselves into perspectives of death or dependence. **End-of-life issues and symptom relief are inextricably linked.**

Latest Updates (2023–Present)

- **Tofersen (Qalsody)** — the first gene-targeted therapy for ALS. An **intrathecal antisense oligonucleotide** that lowers SOD1 protein production, it received **FDA accelerated approval in April 2023** based on reduction of plasma neurofilament light, with **EU conditional approval (2024)** and **UK approval (2025)**. It applies only to the **<2% of patients with confirmed SOD1 mutations**. Dosing is three loading doses two weeks apart, then every four weeks. **Genetic testing is therefore now essential in all patients with ALS.**
- **AMX0035 / sodium phenylbutyrate–taurursodiol (Relyvrio, Albrioza) has been withdrawn.** The confirmatory phase 3 **PHOENIX trial (2024)** failed both its primary and secondary endpoints, and the manufacturer voluntarily removed the product from the US and Canadian markets in **April 2024**. It should no longer be offered.
- **Radicava ORS**, an oral suspension of edaravone, is now available in several countries, removing the burden of repeated intravenous infusion cycles.
- **Ultra-high-dose mecobalamin (Rozebalamin)** was approved in **Japan (2024)** for early ALS, based on the JETALS trial showing slowed ALSFRS-R decline in patients treated within one year of onset.
- **Gold Coast criteria (2020)** are progressively replacing El Escorial and Awaji in both practice and trials — simpler, with higher sensitivity and no diagnostic-certainty categories; validated across multiple cohorts 2023–2025.
- **Neurofilament light chain** is now an accepted diagnostic, prognostic and pharmacodynamic biomarker, and was the surrogate endpoint on which tofersen was approved. Antisense oligonucleotides targeting **C9orf72** and other genes, and the **ATLAS** trial of tofersen in presymptomatic SOD1 carriers, are in progress.
- **Indian context**: riluzole is available and affordable in India; edaravone and tofersen are severely limited by cost and access. Care is concentrated in tertiary neurology centres, and multidisciplinary MND clinics are few. Under the **Rights of Persons with Disabilities Act 2016**, MND-related disability qualifies for a disability certificate and associated welfare benefits — a practical point examiners appreciate.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Antisense oligonucleotides against SOD1, C9orf72 and ataxin are "being studied"	**Tofersen (Qalsody) is approved** for SOD1-ALS — FDA 2023, EU 2024, UK 2025. **Genetic testing is now mandatory in all ALS.**
AMX0035 not yet addressed / early positive data	**Withdrawn from the US and Canadian markets (April 2024)** after the negative PHOENIX phase 3 trial
Edaravone requires intravenous infusion cycles; EMA withdrew the application in 2019	Oral **Radicava ORS** now available; EMA position unchanged — edaravone remains unapproved in Europe
El Escorial / revised El Escorial / Awaji criteria	**Gold Coast criteria (2020)** increasingly preferred — simpler and more sensitive, especially for early diagnosis
CSF neurofilament described as an emerging biomarker	**Established** diagnostic, prognostic and **pharmacodynamic** biomarker; the basis of tofersen's accelerated approval
Riluzole and NIV prolong survival	**Unchanged** — these, plus multidisciplinary clinic care and timely gastrostomy, remain the interventions with the strongest survival evidence

Examiner's Tip — say these lines verbatim:

- "MND is degeneration of **upper motor neurons of the precentral gyrus and/or lower motor neurons of the ventral horn**; ALS is the commonest adult form."
- "The hallmark is **mixed UMN and LMN signs in the same region**, with **sparing of eye movements, sphincters and sensation**."
- "**Bulbar onset occurs in about one-third and carries a worse prognosis**; respiratory failure is the commonest cause of death."
- "The neuropathological hallmark is **cytoplasmic ubiquitinated, hyperphosphorylated TDP-43 inclusions**."
- "**Many MND-mimic disorders are eminently treatable** — always exclude cervical myeloradiculopathy, multifocal motor neuropathy with conduction block, myasthenia and B_{12} deficiency."
- "**Riluzole and non-invasive ventilation prolong survival**; riluzole gives about three months and raises one-year survival from 49% to 58%."
- "**Gastrostomy should be placed before FVC falls below 50%.**"
- "**Early diagnosis and speedy multiagency intervention facilitate good palliative care; end-of-life issues and symptom relief are inextricably linked.**"

7. Peripheral Neuropathy — Common Causes and Approach to the Patient

Definition and classification

1. **Peripheral neuropathy** is a disorder of peripheral nerves — motor, sensory and/or autonomic — producing weakness, sensory disturbance or autonomic failure.
2. Prevalence is **11% in people aged 55 and over**; the commonest single risk factor is **diabetes mellitus (44% of cases)**, followed by alcoholism, non-alcoholic liver disease and malignancy.
3. **Classify by pattern of nerve involvement**: **mononeuropathy** (a major nerve trunk), **mononeuritis multiplex** (multiple mononeuropathies), **symmetrical polyneuropathy** (terminal branches of multiple nerves, bilateral and similar in distribution), **radiculopathy** (nerve roots) and **polyradiculoneuropathy**.
4. Also classify by **time course** (acute <4 weeks, subacute, chronic >8 weeks), **fibre type** (large fibre vs small fibre) and **pathology** (axonal vs demyelinating) — these four axes together generate the differential diagnosis.

Common causes in older adults

5. **Diabetes mellitus** — the commonest cause. Lifetime prevalence of diabetic neuropathy reaches **50%**; prevalence rises with age (8.4% at 20–34 years to **42.4% at ≥65 years**), and age is an **independent risk factor**. Neuropathic pain occurs in 13.3% of people with diabetes, 8.7% with impaired glucose tolerance, 4.2% with impaired fasting glucose and 1.2% of controls — so **prediabetes also causes neuropathy**.
6. **Alcohol** and non-alcoholic liver disease.
7. **Nutritional**: vitamin B_{12} deficiency (**poor B_{12} status is associated with worse sensory and motor peripheral nerve function in older adults**), thiamine, pyridoxine (both deficiency and excess), vitamin E, folate.
8. **Malignancy and paraproteinaemia**: multiple myeloma, MGUS, AL amyloidosis, POEMS syndrome, anti-Hu paraneoplastic neuronopathy, lymphoma.
9. **Drugs and toxins**: vincristine, cisplatin, taxanes, bortezomib, thalidomide, isoniazid, metronidazole, nitrofurantoin, amiodarone, phenytoin, linezolid; lead, arsenic, thallium, organophosphates.
10. **Infections**: **leprosy** (the commonest treatable cause of neuropathy in India), HIV, hepatitis B and C, syphilis, diphtheria, herpes zoster.
11. **Endocrine and metabolic**: hypothyroidism, chronic kidney disease/uraemia, acromegaly.
12. **Immune-mediated**: Guillain–Barré syndrome (acute), CIDP, multifocal motor neuropathy with conduction block, vasculitic neuropathy (polyarteritis nodosa, rheumatoid, Sjögren's, ANCA-associated), sarcoidosis.
13. **Hereditary**: Charcot–Marie–Tooth disease (HMSN) and **hereditary transthyretin amyloidosis** — the latter frequently mislabelled as idiopathic in older patients.
14. **Entrapment**: carpal tunnel syndrome, ulnar neuropathy at the elbow, common peroneal palsy at the fibular head. **Pressure neuropathy is not diabetes-specific but occurs more commonly in diabetes.**
15. **Idiopathic** (chronic idiopathic axonal polyneuropathy) in 25–30% after complete evaluation.

Clinical approach — history and examination

16. **History**: tempo of onset, distribution and symmetry, positive versus negative symptoms, family history, occupational and toxin exposure, alcohol, a complete drug history, systemic symptoms, diabetes or prediabetes, and diet.
17. **Positive sensory symptoms**: burning, tingling, pins and needles, electric shocks, **allodynia** (pain from a non-painful stimulus) and **hyperalgesia**. **Negative symptoms**: reduced sensation, numbness, a "dead" feeling. Pain from **small-fibre** neuropathy is superficial and burning, worse at night and interferes with sleep; pain from **large-fibre** neuropathy is deep and less sharp. Patients describe walking "barefoot on hot charcoal".
18. **Distal symmetrical polyneuropathy is the commonest pattern** — length-dependent, starting at the toes and ascending, in a **"glove and stocking" distribution**, with sensory symptoms reaching the knees before the fingers are affected.
19. **Examination**: pin prick, light touch, temperature, vibration (128 Hz tuning fork) and joint position sense; muscle strength testing and inspection for wasting; reflexes; gait and Romberg's test. Inspect the feet for ulcers, deformity and Charcot arthropathy; **palpate peripheral nerves for thickening** (leprosy, CMT); check postural blood pressure for autonomic involvement.
20. **Red flags for urgent referral**: rapid progression, marked asymmetry, prominent motor involvement, autonomic failure, or an associated systemic illness — these suggest GBS, vasculitis or malignancy.

Investigations

21. Extensive testing is **not** necessary in a patient with mild symptoms and a known underlying diagnosis such as diabetes or alcohol excess.
22. **In patients with no clear aetiology, electrodiagnostic testing (NCS/EMG) should be the initial diagnostic study** — it distinguishes **axonal from demyelinating** physiology, identifies polyradiculopathy, plexopathy and mononeuritis multiplex, and separates hereditary from acquired demyelinating patterns (Rutkove algorithm).
23. **First-line laboratory tests, directed by the electrodiagnostic result**: full blood count, ESR, TSH, blood glucose and glycated haemoglobin, serum and urine protein electrophoresis with immunofixation, vitamin B_{12}, antinuclear antibody, rheumatoid factor, heavy metals and HIV. Add renal and liver function.
24. **Second-line, if the above are negative**: urinary heavy metals and porphyrins, Sjögren's antibodies, Lyme serology,

anti-Hu antibody, and — in patients with borderline-normal serum B_{12} — **methylmalonic acid and homocysteine**. For demyelinating patterns: lumbar puncture (albuminocytological dissociation), anti-GM1 and anti-MAG antibodies, hepatitis B and C serology.

25. **Specialised tests**: skin biopsy for intraepidermal nerve fibre density in small-fibre neuropathy, **corneal confocal microscopy** as a non-invasive measure of small-fibre loss, autonomic function testing (sympathetic skin response, tilt table, R–R interval, Valsalva), genetic testing for CMT and TTR, and sural nerve biopsy reserved for suspected vasculitis or amyloidosis.

Management

26. **Treatment should address the underlying disease process and alleviate symptoms. Avoidance of toxins such as alcohol or drugs is the most important step.**
27. Disease-directed therapy: glycaemic control (more effective in type 1 than type 2 diabetes), lipid and blood pressure control, withdrawal of the offending drug, B_{12} replacement, thyroxine, dialysis, multidrug therapy for leprosy, and immunotherapy for CIDP (corticosteroids, IVIG, plasma exchange) or vasculitis.
28. **Symptomatic pain relief** — see Question 8. In painful neuropathies, tricyclic antidepressants and gabapentin are effective, with SNRIs and pregabalin preferred in older adults.
29. **Function and falls**: physiotherapy assessment is important in patients with weakness; **ankle–foot orthoses, splints and walking-assistance devices improve function**. Diabetic neuropathy substantially increases the risk of falls — use a structured programme such as **STEADI**, with balance and gait training. Care plans should focus **not only on pain relief but on improving mobility and maintaining independence and quality of life**.
30. **Proper foot and nail care is important in reducing the risk of foot ulcers** — daily inspection, appropriate footwear, podiatry review and prompt treatment of minor injury.

Latest Updates (2023–Present)

- **AAN practice guideline on painful diabetic neuropathy (*Neurology*, reaffirmed 2023–2025)**: gabapentinoids, SNRIs, tricyclics and sodium-channel blockers all provide **comparable benefit**; offer one, and switch class if ineffective. **Opioids are not recommended.** Topical agents and non-pharmacological approaches should be offered.
- **ADA Standards of Care (2025)**: screen for distal symmetrical polyneuropathy **at diagnosis of type 2 diabetes and 5 years after diagnosis of type 1**, then annually, using the **10 g monofilament plus at least one other test** (vibration with a 128 Hz fork, pinprick, ankle reflexes, temperature). **Assess vitamin B_{12} in metformin-treated patients.**
- **Prediabetic and metabolic-syndrome neuropathy** is now firmly established: obesity, hypertriglyceridaemia and hypertension are independent risk factors, and **lifestyle intervention improves intraepidermal nerve fibre density**. This reframes "idiopathic" neuropathy in many older patients as metabolic.
- **Hereditary transthyretin (hATTR) amyloidosis** now has effective disease-modifying therapy — patisiran, vutrisiran, inotersen, eplontersen, and the stabiliser acoramidis — and **HELIOS-B (2024)** confirmed benefit in ATTR cardiomyopathy. **Any older patient with a progressive "idiopathic" axonal neuropathy plus cardiac, autonomic, renal or ocular involvement should be tested for TTR variants.**
- **Small-fibre neuropathy** is increasingly diagnosed by **skin biopsy for intraepidermal nerve fibre density** and **corneal confocal microscopy**; sodium channel (SCN9A/SCN10A/$Na_v1.7$, $Na_v1.8$) variants explain a proportion of idiopathic cases.
- **Pathogenesis-directed agents remain unproven**: alpha-lipoic acid (NATHAN-1) gave inconsistent results, benfotiamine was negative, and the aldose reductase inhibitor epalrestat (widely marketed in India and Japan) has limited Cochrane-level support.
- **Indian context**: India accounts for over half of the world's new leprosy cases — always look for **thickened peripheral nerves and hypopigmented anaesthetic skin patches**, and remember that leprosy is the commonest treatable neuropathy in India (managed under the **National Leprosy Eradication Programme** with WHO multidrug therapy). Under the **National TB Elimination Programme (NTEP)**, **pyridoxine 10 mg daily is mandatory prophylaxis** with isoniazid to prevent neuropathy. ICMR-INDIAB data show a very high and rising burden of diabetes and prediabetes in older Indians.

Current Practice Update

Textbook Position	Current Evidence-Based Practice (2023–2026)
Tricyclic antidepressants are effective for painful neuropathy, as is gabapentin	TCAs remain effective but are **relatively contraindicated in older adults** (anticholinergic burden, QT prolongation); **SNRIs and gabapentinoids are preferred**, with nortriptyline if a TCA is required
Extensive workup often unnecessary; EMG-directed testing	**Unchanged**, but now add **TTR genetic testing** in progressive idiopathic axonal neuropathy with systemic features — a treatable diagnosis
Tight glycaemic control may help maintain nerve function	True for **type 1**; effect is **much weaker in type 2**. Emphasis has shifted to **whole metabolic syndrome control** and lifestyle intervention
Neuropathy in diabetes and prediabetes	Formally recognised — screening is now recommended **at diagnosis of type 2 diabetes**, not years later
Small-fibre neuropathy diagnosed clinically	**Skin biopsy for intraepidermal nerve fibre density and corneal confocal microscopy** are now standard diagnostic tools

Examiner's Tip — say these lines verbatim:

- "Classify by **pattern, time course, fibre type and pathology (axonal vs demyelinating)** — these four axes generate the differential."
- "**Prevalence is 11% in those over 55; diabetes accounts for 44%**, followed by alcohol, liver disease and malignancy."
- "**In an unexplained neuropathy, electrodiagnostic testing is the initial diagnostic study**, and laboratory tests should be directed by its result."
- "**Avoidance of toxins such as alcohol or drugs is the most important single step** in management."
- "In India, always exclude **leprosy** — palpate the nerves and look for anaesthetic skin patches."
- "Management must target **mobility, independence and quality of life**, not pain alone — neuropathy is a major falls risk factor."
- "**Proper foot and nail care reduces the risk of foot ulceration** — never omit this from the answer."

8. Neuritic (Neuropathic) Pain

Definition and classification

1. **Neuropathic pain is pain caused by a lesion or disease of the somatosensory nervous system**, at either a peripheral or a central level.
2. **It is a clinical description, not a diagnosis** — the definition requires a **demonstrable lesion or disease that satisfies standard neurological criteria**.
3. Contrast with **nociceptive pain** (activation of receptors in the peripheral somatosensory nervous system by mechanical, thermal or chemical stimuli in non-neural tissue — soft-tissue, musculoskeletal and visceral pain) and with **nociplastic pain** (altered nociception without clear tissue damage or a somatosensory lesion — fibromyalgia, non-specific low back pain, irritable bowel syndrome, complex regional pain syndrome type 1). "Nociplastic" replaces the older terms *dysfunctional pain*, *central sensitization* and *pain of unknown origin*.
4. **Peripheral causes**: painful diabetic neuropathy, **postherpetic neuralgia**, **trigeminal neuralgia**, radiculopathy, vertebral canal stenosis, carpal tunnel syndrome, chemotherapy-induced neuropathy, post-traumatic and post-surgical neuropathy, phantom limb pain, and **leprous neuritis** (an important Indian cause).
5. **Central causes**: **central post-stroke pain** (thalamic or Déjerine–Roussy syndrome), spinal cord injury, multiple sclerosis, syringomyelia.

Pathophysiology and the effect of ageing

6. Mechanisms: **peripheral sensitisation** with upregulation of sodium channels ($Na_v1.7$, $Na_v1.8$) and ectopic ectopic discharge; **central sensitisation and wind-up** at the dorsal horn; loss of descending inhibitory modulation; deafferentation and cortical reorganisation.
7. **Ageing alters pain processing**: meta-analyses show a modest **increase in pain threshold** (which shortens the warning interval before tissue damage and leads to under-reporting of mild pain, increasing the risk of undiagnosed disease) but a **decrease in pain tolerance**.
8. **Temporal summation of heat pain is greater and capsaicin-induced mechanical hyperalgesia lasts longer in older adults**, indicating prolonged pain facilitation; **endogenous pain inhibition is reduced**. Net conclusion: **severe pain is less well tolerated in older people**.

Clinical features and assessment

9. Descriptors: **burning, shooting, lancinating, electric-shock-like, pricking, tingling or squeezing** pain in a neuroanatomical distribution; usually constant but may be paroxysmal, and typically worse at night.
10. Associated sensory disturbance: **paraesthesiae and dysaesthesiae, allodynia, hyperalgesia and hyperpathia**, often coexisting with sensory loss, impaired motor function, muscle atrophy or abnormal deep tendon reflexes.
11. Assessment: characterise the pain, map its distribution, examine for sensory signs, and identify the causative lesion. Screening tools include **DN4, LANSS and painDETECT**. Assess sleep, mood, function and the impact on activities of daily living.
12. **Pain is a major determinant of frailty** — in the English Longitudinal Study of Ageing, subjects reporting moderate to severe pain were more likely to become frail over the following eight years, independent of age, sex, lifestyle, depressive symptoms and socioeconomic factors.
13. **Pain is not a symptom of dementia, but dementia impairs self-report** and amplifies the impact of pain on function, mood, cognition and tolerance of adverse drug effects. Use observational tools (PAINAD, Abbey, DOLOPLUS-2) when self-report is unreliable.

Pharmacological management

14. **First-line agents**: **gabapentinoids** (gabapentin, pregabalin), **serotonin–noradrenaline reuptake inhibitors** (duloxetine, venlafaxine) and **tricyclic antidepressants** (amitriptyline, imipramine, nortriptyline).
15. **Tricyclics are best avoided in older people** because of their adverse effect profile, especially tertiary tricyclics such as amitriptyline. **If a tricyclic is required, nortriptyline is the safer option.** All TCAs can prolong the QT interval — **obtain an ECG before starting**. Cautions: arrhythmia, recent myocardial infarction, glaucoma and SIADH.
16. **Pregabalin** has linear, dose-proportional absorption, rapid onset and requires minimal titration; but **acute kidney injury and rhabdomyolysis** are recognised adverse effects — monitor renal function and creatine phosphokinase. Both gabapentinoids need dose reduction in renal impairment; sedation, dizziness and ataxia are the limiting effects in the elderly.
17. **SNRIs** lack antimuscarinic effects and are better tolerated than TCAs, but tend to raise heart rate and blood pressure — monitor blood pressure, pulse, creatinine and liver enzymes; avoid with monoamine oxidase inhibitors.
18. **Second-line**: tramadol and **topical agents — 5% lidocaine patches and 8% capsaicin patches** for peripheral neuropathic pain such as postherpetic neuralgia or post-traumatic neuropathy. **Where there are concerns about the safety of systemic treatment, as in the frail elderly, lidocaine patches may be used as first-line therapy.**
19. **Strong opioids have been downgraded to third-line** because of safety concerns.
20. **Efficacy is modest** — the number needed to treat for a 50% reduction in pain is **3.6 for tricyclics, 6.4 for SNRIs, 7.7 for pregabalin and 4.3 for strong opioids**. Combination trials give inconsistent results, and the maximum tolerated dose of each drug is lower in combination, so **titrate one agent at a time**.

21. **Carbamazepine remains first-line specifically for trigeminal neuralgia** (oxcarbazepine as an alternative); monitor full blood count for aplastic anaemia and sodium for hyponatraemia, and beware interactions with warfarin and theophylline.
22. **Not recommended**: cannabinoids cannot be recommended for chronic pain in older people on current evidence; gabapentin and pregabalin are **not** supported for chronic back pain, exposing patients to risk without clear benefit.

Non-pharmacological and preventive management

23. **Education** is fundamental — the nature of pain, realistic expectations, and the benefits and risks of each option. **Dispel the misconception that pain can always be eliminated**; educate family and carers, particularly where there is cognitive impairment.
24. **Cognitive-behavioural therapy**, graded exercise, physiotherapy, TENS, acupuncture, desensitisation and mirror therapy. Effect sizes are small to moderate but the **safety profile is better than drugs**; used as an adjunct they permit lower drug doses and fewer adverse effects.
25. **Interventional options** for refractory pain: nerve blocks, epidural steroid injection, radiofrequency ablation, spinal cord stimulation, intrathecal therapy.
26. **Prevention**: **recombinant zoster vaccination** prevents herpes zoster and postherpetic neuralgia; good glycaemic and metabolic control reduces incident diabetic neuropathy; pyridoxine with isoniazid; and prompt corticosteroid treatment of leprous neuritis prevents permanent nerve damage.
27. **Principles in the elderly**: start low, go slow, one drug at a time, set realistic goals (30–50% pain reduction, improved sleep and function rather than freedom from pain), review regularly, and **deprescribe if ineffective**.

Latest Updates (2023–Present)

- **OPTION-DM (*Lancet* 2022, informing 2023–2025 practice)**: in painful diabetic neuropathy, **amitriptyline, duloxetine and pregabalin have similar efficacy** as monotherapy, and **combination therapy is superior when a single agent gives only partial relief** — supporting a "try one, then combine" rather than "switch endlessly" strategy.
- **Phenotype-stratified treatment** is gaining traction — an "irritable nociceptor" phenotype predicts response to sodium-channel blockade (oxcarbazepine), supporting mechanism-based rather than aetiology-based prescribing.
- **Gabapentinoid safety (2023–2025)**: pharmacovigilance and regulatory warnings highlight **respiratory depression when combined with opioids or in COPD**, plus falls, peripheral oedema, weight gain and misuse potential. They are now controlled drugs in the UK. This reinforces cautious use in older adults.
- **Suzetrigine (VX-548, Journavx)** — a first-in-class **selective $Na_v1.8$ inhibitor**, FDA-approved in **January 2025** for moderate-to-severe acute pain. It is **non-opioid and does not act centrally**, so it avoids sedation, falls and dependence; phase 2/3 studies in painful diabetic neuropathy and lumbosacral radiculopathy are ongoing. This is the most important mechanistic advance for geriatric pain in a decade.
- **High-concentration capsaicin 8% patch** now has broadened indications with a single 30-minute application to the feet in diabetic neuropathy, giving up to 3 months of relief.
- **Recombinant zoster vaccine (RZV, Shingrix)**: long-term follow-up of ZOE-50/70 (2024) shows efficacy sustained beyond 10 years; recommended for all adults ≥50 years and immunocompromised adults ≥18. Now available in India, though cost-limited.
- **Indian context**: amitriptyline, nortriptyline, gabapentin, pregabalin and duloxetine are all available as inexpensive generics. **Leprous neuritis** is a distinctly Indian cause of "neuritic pain" — acute neuritis in type 1 or type 2 lepra reaction requires **oral prednisolone (typically 40 mg tapered over 12 weeks) under the National Leprosy Eradication Programme** alongside multidrug therapy, and is a neurological emergency because delay causes irreversible deformity.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Combination pharmacotherapy gives "inconsistent results"	**OPTION-DM** supports **adding a second agent** when monotherapy gives partial relief, rather than serial switching
Gabapentinoids are first-line and generally well tolerated	Still first-line, but with **formal safety warnings** — respiratory depression with opioids/COPD, falls, oedema, misuse; now controlled drugs in the UK
Drug classes limited to antidepressants, anticonvulsants, opioids and topicals	**Suzetrigine (selective $Na_v1.8$ inhibitor)** approved January 2025 — first genuinely new non-opioid mechanism, trials in neuropathic pain ongoing
Lidocaine patch as a second-line agent, first-line only in the frail	**Unchanged and increasingly emphasised** — safest option in frailty, polypharmacy and cognitive impairment
Cannabinoids cannot be recommended in older people	**Unchanged** — subsequent systematic reviews have not altered this position

Examiner's Tip — say these lines verbatim:

- "Neuropathic pain is **pain caused by a lesion or disease of the somatosensory nervous system**. It is a **clinical description, not a diagnosis** — a demonstrable lesion satisfying neurological criteria is required."
- "The three mechanistic descriptors are **nociceptive, neuropathic and nociplastic**."

- "With ageing, **pain threshold rises but pain tolerance falls**, temporal summation increases and endogenous inhibition is reduced — so **severe pain is less well tolerated in older people**."
- "First-line: **gabapentinoids, SNRIs and tricyclics**. **Avoid amitriptyline in the elderly; use nortriptyline if a tricyclic is essential**, with a prior ECG."
- "**Strong opioids have been downgraded to third-line**; **lidocaine 5% patches may be first-line in the frail elderly**."
- "NNT for 50% pain relief: **3.6 tricyclics, 6.4 SNRIs, 7.7 pregabalin, 4.3 strong opioids** — efficacy is modest, so combine with non-pharmacological therapy."
- "**Pain is a major determinant of frailty** — moderate to severe pain independently predicted incident frailty over eight years in ELSA."
- "In India, always consider **leprous neuritis** — it requires urgent corticosteroids to prevent irreversible nerve damage."

9. Management of Extracranial Carotid Artery Stenosis

Pathogenesis and definitions

1. **Atherosclerosis is the commonest arterial disorder in developed countries** and, when complicated by thrombosis and embolism, causes ischaemic stroke, myocardial infarction and peripheral arterial disease.
2. Plaque forms where there is endothelial injury and haemodynamic stress — in the cerebral circulation this is at **sites of arterial branching, especially the bifurcation of the common carotid artery**. LDL cholesterol enters the subendothelium, is oxidised by macrophages and smooth muscle cells, and growth factors and cytokines drive foam cell accumulation and smooth muscle proliferation.
3. Plaques with a fatty core and fibrous cap narrow the lumen and stiffen the wall. **A defect in the fibrous cap from rupture or erosion predisposes to thrombosis** — platelets adhere and are activated, which is the site of action of antiplatelet drugs.
4. **Most strokes and TIAs secondary to carotid stenosis occur by thromboembolism**; haemodynamic hypoperfusion is a relatively rare cause because of collateral supply through the circle of Willis.
5. Risk factors: cigarette smoking, diabetes mellitus, age, dyslipidaemia, hypertension and genetic predisposition. **Arterial dissection is a rare cause in the elderly** (common in the young), usually after minor neck or head trauma with sudden neck rotation.
6. **Symptomatic** stenosis = ipsilateral TIA, ischaemic stroke or amaurosis fugax within the preceding six months.

Investigation and grading

7. **The degree of carotid stenosis should be reported using the NASCET method**, in which the diameter at the stenosis is compared with the diameter of the **distal internal carotid artery**. ECST used a different denominator, so the two are not interchangeable.
8. **Doppler ultrasound** is the usual first-line non-invasive test (70–79% stenosis corresponds to peak systolic velocity >230 cm/s and end-diastolic velocity 110–140 cm/s).
9. **CT angiography** is increasingly replacing MRA and duplex because it is often combined with the initial stroke CT; limitations are contrast toxicity in renal impairment, contrast allergy and poor visualisation with heavy plaque calcification. **MRA** is limited by tolerability, metallic implants and misinterpretation of swallowing artefact or turbulent flow as stenosis.
10. **Catheter angiography is the gold standard** but carries a **0.5–2% risk of stroke or TIA** from plaque dislodgement, dissection or catheter thrombus — it should be preceded by non-invasive imaging and performed only in experienced neurovascular units.

Best medical therapy — for every patient

11. **Antiplatelet therapy** — aspirin, clopidogrel, or aspirin with extended-release dipyridamole; short-course dual antiplatelet therapy after minor stroke or high-risk TIA.
12. **High-intensity statin** — SPARCL showed atorvastatin 80 mg reduced recurrent ischaemic stroke by around 20%; treat cholesterol above 3.5 mmol/L, with dietetic input.
13. **Blood pressure control** (PROGRESS: perindopril-based regimen); target ≤130/80 mmHg in diabetic patients; plus glycaemic control, smoking cessation and lifestyle advice.
14. **Anticoagulation is not indicated for carotid stenosis itself** — it is reserved for atrial fibrillation, prosthetic valves or another specific indication. Heparin in acute stroke gives no net benefit.

Symptomatic stenosis — the operative rules

15. **All patients with suspected non-disabling stroke or TIA who, after specialist assessment, are considered candidates for carotid endarterectomy should have carotid imaging within 24 hours of symptom onset.**
16. **Symptomatic stenosis of 50–99% (NASCET)** with stable neurological symptoms: **assess and refer for carotid endarterectomy as soon as possible, within seven days of symptom onset**, in a vascular surgical centre, **plus** optimum medical treatment.
17. **Symptomatic stenosis <50% (NASCET)**: **should not undergo carotid intervention**; best medical treatment only.
18. **Evidence** (pooled ECST and NASCET, Rothwell, *Lancet* 2003): the absolute risk reduction of ipsilateral ischaemic stroke or death with CEA for **70–99% NASCET stenosis was 16%** ($p<0.001$). Patients with 50–69% stenosis benefited by a slimmer margin, and **below that threshold there was overall harm**. Benefit requires a **perioperative stroke or death risk of no more than 5%**.
19. Subgroups deriving **additional benefit**: **male sex, advancing age and recent symptoms**. Near-occlusion derives no benefit.

Asymptomatic stenosis — textbook position

20. **ACAS**: CEA reduced the 5-year risk of ipsilateral stroke or perioperative stroke/death from **11% to 5.1%**, but not the risk of major stroke. **ACST**: immediate CEA reduced the 5-year risk of all strokes and perioperative death from **11.8% to 6.4%**. The 30-day stroke or death rate after CEA in both trials was around 3%.
21. **ACST subgroup analysis showed no evidence of benefit in patients older than 75 or in women.** These trials predate widespread statin use, good blood pressure control and routine dual antiplatelet therapy, so with modern medical management the stroke rate in asymptomatic stenosis (already only ~2% per annum) would be lower still,

potentially negating any benefit of surgery.

22. **Conclusion from the textbook: patients over 75 with asymptomatic stenosis and those with less than 60% stenosis should not be offered surgery.** Those managed medically must be educated about TIA and stroke symptoms and told to present urgently.

Carotid artery stenting

23. **Advantages**: performed under local anaesthesia, avoiding general anaesthesia; faster recovery and shorter stay; no neck incision, so less haematoma, infection and **cranial nerve injury**. **Disadvantages**: distal embolisation during catheter passage and during stent deployment and post-dilatation, greater restenosis, and the cost of the stent and cerebral protection device.
24. **Pooled analysis of four trials (Bonati, *Lancet* 2010)**: stroke or death within 120 days was **8.9% after stenting vs 5.8% after endarterectomy** (RR 1.53). CEA carries a small excess of myocardial infarction (<1%) and cranial nerve injury.
25. **Age is the key modifier (Howard, *Lancet* 2016)**: in symptomatic patients, procedural stroke or death was **identical below age 70**, and **all the excess risk of stenting was in older patients**. Long-term effectiveness at preventing recurrence is similar at all ages.
26. **Textbook/NICE indication for stenting**: patients who meet criteria for intervention but are **unsuitable for surgery** — inaccessible or high cervical bifurcation, restenosis after endarterectomy, radiotherapy-associated stenosis, fibromuscular dysplasia and dissection.
27. **Vertebral and intracranial disease**: vertebral artery origin stenting is relatively safe but has not been shown superior to medical management (VIST); intracranial stenting carries risks of dissection, rupture and plaque embolisation and is reserved for recurrent symptoms despite medical therapy.
28. **Geriatric decision-making**: benefit accrues over years, so weigh frailty, cognition, comorbidity and life expectancy. A frail patient with limited life expectancy should be managed medically.

Latest Updates (2023–Present)

- **CREST-2 (*NEJM*, 21 November 2025; Brott, Howard, Lal et al.) — the single most important carotid trial of the decade.** Two parallel, observer-blinded randomised trials, **2,485 patients with asymptomatic stenosis ≥70%**, 155 centres in five countries, mean age 69–70, follow-up 3.6–4.0 years. Primary outcome (any stroke or death within 44 days plus ipsilateral ischaemic stroke to 4 years):
  - **Stenting + intensive medical management 2.8% vs intensive medical management alone 6.0% (p = 0.02) — significant benefit**, NNT approximately 31 at 4 years.
  - **Endarterectomy + intensive medical management 3.7% vs intensive medical management alone 5.3% (p = 0.24) — NOT significant.**

  The accompanying *NEJM* editorial (Brown & Bonati, 2025) concluded that **"there is no longer a role for routine carotid endarterectomy in persons with asymptomatic stenosis."**
- **ECST-2 (*Lancet Neurology* 2025)**, 2-year interim results: in asymptomatic or low-to-intermediate-risk symptomatic carotid stenosis, **optimised medical therapy alone was not inferior to optimised medical therapy plus revascularisation**.
- **SPACE-2** 5-year results similarly showed **no advantage of CEA or CAS over best medical treatment** in moderate-to-severe asymptomatic stenosis.
- **ESVS 2023 guidelines** recommend intervening in asymptomatic stenosis only where **"high-risk-for-stroke" features** are present: stenosis progression, silent ipsilateral infarction on imaging, intraplaque haemorrhage on MRI, plaque echolucency or large juxtaluminal black area, contralateral occlusion, and spontaneous embolisation on transcranial Doppler.
- **Transcarotid artery revascularisation (TCAR)** with flow reversal has emerged as a third option, with registry data showing lower stroke rates than transfemoral stenting, particularly in older and anatomically high-risk patients.
- **Indian context**: extracranial carotid disease accounts for a **smaller proportion of Indian ischaemic stroke** than in Western cohorts, where **intracranial atherosclerosis and small-vessel disease predominate**. Carotid duplex is widely available and inexpensive; CEA and CAS are confined to tertiary centres. **The pragmatic Indian priority is aggressive medical therapy — statin, blood pressure control, antiplatelet, glycaemic control and smoking cessation.** Note also that CHANCE-2 genotype-guided antiplatelet data are relevant given the high frequency of CYP2C19 loss-of-function alleles in Indian populations.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Asymptomatic stenosis: CEA reduces stroke (ACAS, ACST), but benefit uncertain with modern medical therapy; do not operate on those >75 or with <60% stenosis	**CREST-2 (2025) resolves this**: **CEA gave no significant benefit** over intensive medical management, while **stenting did** (2.8% vs 6.0%). Editorialists state there is **no longer a role for routine CEA in asymptomatic stenosis**
Stenting reserved for those unsuitable for surgery, because of an excess periprocedural stroke risk	For **asymptomatic** ≥70% stenosis, CREST-2 supports **stenting with embolic protection as first-line revascularisation** where anatomy is suitable and the operator is skilled. **For symptomatic stenosis, CEA remains the standard**, particularly over age 70
Symptomatic 50–99%: CEA within 7 days; imaging within 24 hours	**Unchanged and reinforced** — this remains the highest-yield rule for the examination
Best medical therapy = antiplatelet, statin, BP control	Intensified to **"intensive medical management"** — protocolised LDL and BP targets with adherence monitoring and lifestyle coaching, as delivered in CREST-2, which markedly lowered event rates in all arms
Selection based on degree of stenosis alone	**ESVS 2023** adds **plaque vulnerability features** (intraplaque haemorrhage, echolucency, silent infarction, TCD embolisation) to the decision

Examiner's Tip — say these lines verbatim:

- "**The degree of stenosis must be reported by the NASCET method** — the stenosis diameter compared with the distal internal carotid artery."
- "**Carotid imaging within 24 hours; endarterectomy within 7 days** for symptomatic 50–99% stenosis, plus optimum medical therapy."
- "For 70–99% symptomatic stenosis the **absolute risk reduction was 16%**, provided the **perioperative stroke or death risk is no more than 5%**."
- "**Symptomatic stenosis under 50% should not undergo intervention** — there is net harm."
- "**All the excess risk of stenting compared with endarterectomy is in patients over 70**; below 70 the risks are identical."
- "**CREST-2 (NEJM 2025)** showed that in asymptomatic ≥70% stenosis, **stenting added benefit to intensive medical therapy but endarterectomy did not** — editorialists concluded there is no longer a role for routine CEA in asymptomatic disease."
- "Most strokes from carotid stenosis are **thromboembolic**, not haemodynamic, because of collateral flow through the circle of Willis."

10. Bedside Assessment of Swallow in a Patient with Recent Stroke

Why it matters

1. **Dysphagia is present initially in 78% of patients who have had a stroke**; although acute dysphagia improves in about 80% of survivors, its early consequences are severe.
2. Complications: **aspiration leading to stroke-associated pneumonia (SAP)**, malnutrition, dehydration, longer hospital stay, poorer participation in rehabilitation and worse functional outcome. Dysphagia is associated with significantly higher mortality and morbidity, and with more nursing-home admissions.
3. South London Stroke Register data show **dysphagia at stroke onset was associated with a three- to fivefold increase in institutionalisation at five years**.
4. **Delays in bedside dysphagia screening and in comprehensive assessment by a speech and language therapist are associated with a higher risk of stroke-associated pneumonia.** Since SAP is one of the main causes of mortality after acute stroke, **early dysphagia assessment may prevent deaths and can be implemented even in settings without high-technology specialist stroke care**.
5. **Silent aspiration** — aspiration without cough or any outward sign of difficulty — occurs in a substantial number of patients, who are at increased risk because clinical swallowing assessments under-diagnose the problem.
6. **The golden rule: keep the patient nil by mouth, including oral medication, until a swallow screen has been passed.**

Prerequisites and who screens

7. Screening is a **pass/fail procedure** that identifies who needs comprehensive assessment. It may be conducted by various professionals including a nurse or a speech-language pathologist, but **employing a swallow-assessment specialist may reduce the odds of stroke-associated pneumonia**.
8. **The patient must be fully conscious and aware** — it is very difficult to swallow safely if one is not.
9. **The patient must be able to sit upright and to cough purposefully**; if unable to do either, the likelihood of aspiration is increased and a more in-depth assessment is indicated.
10. Before testing, ensure oral hygiene, correctly fitting dentures, an upright (90°) position with the chin slightly tucked, and suction available at the bedside.

Risk indicators to elicit (Pathy's Box 49.1)

11. Weak, husky voice (**dysphonia**); inability to cough voluntarily; a **weak cough with no effective expulsion**.
12. **Pooling of food or saliva in the mouth or cheek**; frequent coughing or choking **even on saliva**.
13. History of a recent chest infection; the patient complaining of difficulty swallowing, of having to gulp, of an abnormal sensation, or of difficulty with particular types of food.
14. Related symptoms: choking during eating or drinking, inability to swallow saliva, **nasal regurgitation** of food or drink, and discomfort during swallowing.

Structured bedside examination

15. Assess **oral and laryngeal structures and movements, dental state, cognition, posture** and any other factor bearing on the safety of oral feeding — lip closure, tongue movement, palatal elevation, jaw movement, voice quality, volitional cough, and laryngeal elevation on palpation during a dry swallow.
16. **Critically: the absence of a gag reflex does not automatically indicate a major swallowing problem, just as the presence of the gag does not indicate a safe swallow.** The gag reflex is unreliable and must never be used alone.
17. The important factors are **bolus control**, **clarity of the voice** (is it wet and gurgly after a test swallow?) and **effectiveness of the cough** (is it firm and effective?).

Trial swallows and observation

18. **Try teaspoons of water; if successful, try teaspoons of soft purée; and if that is successful, try foods with more substance.**
19. **Observe for**: the patient reporting a negative sensation; poor lip closure or degree of leakage; untimely or absent elevation of the larynx; residue in the mouth following the swallow; **lack of clarity of voice following the swallow**; and choking or coughing **before, during or after** the swallow.
20. **Formal screening protocols**:
    - **Water swallow test** — several protocols exist; for example the patient drinks **3 oz (90 mL) of water without interruption**, and is monitored for completion, coughing, choking and a wet or hoarse vocal quality during or within one minute of completion.
    - **Multiple consistency test** — stepwise evaluation of non-fluid and fluid textures giving a graded rating (severe, moderate, mild or no dysphagia).
    - **Swallowing provocation test** — injection of a water bolus through a nasal catheter into the oropharynx; the patient is at risk of aspiration if the swallow reflex takes **more than 3 seconds**.
21. **Limitations**: the water swallow test is sufficient for screening for aspiration after stroke in much of the literature, but its **diagnostic accuracy has been questioned** — bedside screening is not consistently sensitive, and **no bedside**

protocol has been adequately predictive of aspiration. It nevertheless remains the mainstay because it is safe, straightforward and easily repeated. **Pulse oximetry** may assist, since decreased blood oxygenation during swallowing has been observed in dysphagic patients.

What follows a failed screen

22. **Fail → remain nil by mouth**, start intravenous or nasogastric fluids, and refer to speech and language therapy. A **non-instrumental assessment** observes swallowing behaviours — fatigue during a meal, signs and symptoms of dysphagia, posture and positioning — but **aspiration cannot be observed** by this means.
23. **Videofluoroscopy (modified barium swallow) is the gold standard**, giving a direct radiographic view of oral, pharyngeal and upper oesophageal function with varied consistencies mixed with barium. It is **not feasible as a routine screening option**, and it is not infallible — **false negatives** occur when dysphagia appears only with fatigue after several mouthfuls, and **false positives** when aspiration is asymptomatic or induced by the tension of the situation or the unpleasantness of the contrast. Findings must be placed in the context of the patient's history.
24. **FEES** (fibre-optic endoscopic evaluation of swallowing) is a **portable bedside** alternative that directly visualises the posterior pharynx, epiglottis, vocal cords and proximal trachea during trials of varied consistencies, and can monitor the effectiveness of therapy — but **it does not visualise the oral or oesophageal phase**.
25. **Management** is interdisciplinary, aimed at protecting the patient from complications, maintaining adequate nutrition, and ensuring the patient and carers understand the deficit. Compensatory techniques and **dietary/texture modification under speech and language therapy and dietetic supervision remain the mainstay**. Patients with reduced oral sensation, poor buccal control or inadequate laryngeal lift **aspirate more on fluids than on semisolids** and may be advised to avoid liquids while managing a soft puréed diet; patients with tongue, lip or jaw involvement should avoid foods requiring chewing.
26. **Persistent dysphagia requires alternative nutrition** — nasogastric tube early, and percutaneous endoscopic gastrostomy if dysphagia is likely to persist. Other measures include mechanical or thermal pharyngeal stimulation, cortical magnetic stimulation of the swallowing reflex, and electrical pacemakers to trigger laryngeal elevation.
27. **Re-screen daily in the early days** — swallow status changes rapidly after stroke. Maintain rigorous oral care throughout.

Latest Updates (2023–Present)

- **Timing is now protocolised**: the AHA/ASA and the **2023 National Clinical Guideline for Stroke for the UK and Ireland** require dysphagia screening by a trained professional **before any oral intake including oral medication, ideally within 4 hours of admission**, with speech and language therapy assessment **within 24 hours of a failed screen and no later than 72 hours**.
- **Validated screening tools**: the **Gugging Swallowing Screen (GUSS)** and the **Yale Swallow Protocol (3 oz water test)** are the best-validated nurse-administered bedside screens, with high sensitivity for aspiration risk; guidelines now specify use of a validated tool rather than an unstructured assessment.
- **Prophylactic antibiotics do not prevent stroke-associated pneumonia** (STROKE-INF and related trials). The evidence-based preventive strategy is **early dysphagia screening plus structured oral care**, not antibiotics.
- **Pharyngeal electrical stimulation**: PHAST-TRAC showed benefit for decannulation in tracheostomised stroke patients, but larger trials in general post-stroke dysphagia (PHADER and others) have given mixed results. Capsaicin and other TRPV1 agonists to re-sensitise the swallow reflex are under active investigation.
- **The IDDSI framework** (International Dysphagia Diet Standardisation Initiative, levels 0–7) has now replaced older national texture descriptors worldwide and should be used when prescribing modified diets and thickened fluids.
- **Indian context**: swallow screening before feeding is endorsed in Indian stroke unit practice, but speech and language therapists are scarce outside tertiary centres — which makes the **nurse-administered bedside water swallow test the single most important, transferable and cost-effective intervention**. Ryle's tube feeding remains the default because PEG access and cost are limiting. The **ATTEND trial (*Lancet* 2017, India)** established family-led rehabilitation as a feasible Indian model, and carer training in safe feeding and oral care is directly applicable.

Current Practice Update

Textbook Position (Pathy's 6th ed.)	Current Evidence-Based Practice (2023–2026)
Bedside assessment described as a structured clinical observation without a specified time window	**Screen within 4 hours of admission and before any oral intake**; SLT assessment within 24 hours of a failed screen (2023 UK–Ireland guideline)
Water swallow test used with several unspecified protocols	Use a **validated tool** — **GUSS** or the **Yale Swallow Protocol** — rather than an unstructured trial
"No bedside screening protocol has been adequately predictive of aspiration"	**Still true**, but validated multi-consistency screens (GUSS) have materially improved sensitivity; instrumental assessment remains definitive
Texture modification described in general terms	Standardised globally through the **IDDSI framework (levels 0–7)** for both foods and fluids
Prevention of pneumonia framed around aspiration risk detection	Adds **structured oral care** as an evidence-based measure; **prophylactic antibiotics do not work** (STROKE-INF)
Pharyngeal and cortical stimulation listed as experimental adjuncts	Pharyngeal electrical stimulation has an established role in **tracheostomy decannulation** (PHAST-TRAC); general dysphagia data remain mixed

Examiner's Tip — say these lines verbatim:

- "**78% of stroke patients initially present with dysphagia**, and **delays in screening and assessment increase the risk of stroke-associated pneumonia**, a main cause of post-stroke mortality."
- "**Keep the patient nil by mouth, including oral medication, until the swallow screen is passed.**"
- "The patient must be **fully conscious, able to sit upright and able to cough purposefully** before any trial swallow."
- "**The absence of a gag reflex does not indicate a major swallowing problem, and its presence does not indicate a safe swallow** — assess bolus control, voice clarity and cough effectiveness instead."
- "Give **teaspoons of water, then soft purée, then more substantial food**, watching for a **wet, gurgly voice**, delayed laryngeal elevation, oral residue and coughing before, during or after the swallow."
- "**Videofluoroscopy is the gold standard but produces both false positives and false negatives**; FEES is portable but does not show the oral or oesophageal phase."
- "**Silent aspiration** means bedside assessment under-diagnoses the problem — a normal screen never fully excludes aspiration."

11. Visual Impairment — Age-Related Causes and Clinical Approach RECURS

Scale and significance

1. **As many as 75% of older adults have significant visual or auditory dysfunction that is not reported to their physician** — therefore adequate screening for these problems is important, and correction of remediable conditions may improve the ability to perform daily activities.
2. Consequences of untreated visual impairment: **limited functional activity, social isolation and depression**, falls and fractures, driving cessation, medication errors, and accelerated cognitive decline.
3. **The prevalence of visual problems and blindness increases with age.** The four commonest causes of blindness in older adults are **cataract, glaucoma, macular degeneration and diabetic retinopathy**.

Physiological and functional changes of the ageing eye

4. **Presbyopia** develops from **nuclear sclerosis of the lens and atrophy of the ciliary muscle**; the near point of accommodation recedes so that by about age 45 comfortable reading requires corrective lenses.
5. **Latent hyperopia becomes manifest** with loss of accommodative reserve; alternatively **myopia increases** as old lens fibres accumulate in the nucleus, which becomes compact and harder (nuclear sclerosis), increasing the refractive power of the lens.
6. **Diminished tear secretion**, especially in postmenopausal women, causes dry eye with irritation and discomfort and may endanger the integrity of the corneal surface; treatment is substitution therapy with frequent artificial tears.
7. **Corneal endothelial cells seldom proliferate in adult life**, so the cell population falls with age, leaving an irregular anterior chamber surface where pigment accumulates. Dense pigment accumulation slightly reduces acuity, and progressive endothelial dystrophy may cause corneal oedema requiring **corneal transplantation**.
8. **Intraocular pressure slowly increases with age.** Also: senile miosis, slower dark adaptation, reduced contrast sensitivity, increased glare sensitivity, and impaired blue–yellow discrimination from lens yellowing.

The four major diseases

9. **Senile cataract** — opacification of the crystalline lens; prevalence **46% at ages 75–85** (Framingham Eye Study). Development is **painless, progressive and variable**, typically bilateral and often asymmetrical. Patients complain of problems with **night driving, reading road signs and difficulty with fine print**. The cause is unknown but opacification is associated with breakdown of the γ-crystallin proteins, and **ultraviolet light may be a contributing factor**. The process may occur in the cortex or the nucleus.
10. **Glaucoma** — a group of disorders characterised by **increased intraocular pressure, progressive excavation of the optic nerve head with damage to nerve fibres, and a specific loss in the visual field**. Prevalence of open-angle glaucoma rises with age to **7.2% at ages 75–85**, with much higher rates in men.
11. **Chronic open-angle glaucoma** (the commoner variety) has an **insidious onset and slow progression**: the irido-corneal angle is open but aqueous outflow is diminished, the neuroretinal rim thins from loss of retinal ganglion cell axons, producing optic-nerve cupping. Central acuity may remain normal for a long time while **peripheral field defects are characteristic and gradually progressive — initially a paracentral scotoma, which may coalesce, and a nasal step, until the entire field constricts**.
12. **Angle-closure glaucoma** is acute and relatively infrequent, with a **sudden painful attack of raised intraocular pressure and marked loss of vision**. Treatment is to normalise the pressure with miotic drops, carbonic anhydrase inhibitors or osmotic agents; the **definitive treatment is surgical or laser iridectomy**, and because the disease is usually bilateral, prophylactic iridectomy of the second eye is often proposed.
13. **Age-related macular degeneration** — the commonest cause of **legal blindness (20/200 or worse)** in older adults; prevalence 28% at ages 75–85, higher in women. Causes loss of **central** vision (see Question 12).
14. **Diabetic retinopathy** — prevalence rises with age to about **7% at ages 75–85**. Visual loss is usually related to vascular changes in and around the macula: **leakage of serous fluid causes macular oedema** (may respond to laser photocoagulation), **haemorrhage within the macula** causes more permanent loss, and **loss of retinal capillaries causes macular ischaemia with a poor prognosis for recovery**.
15. Other important causes: **uncorrected refractive error** (the commonest and most easily reversible cause worldwide), **giant cell arteritis** (sudden painless visual loss — a medical emergency requiring immediate high-dose steroid), retinal artery and vein occlusion, retinal detachment, vitreous haemorrhage, homonymous field defects after stroke, and drug toxicity (ethambutol, hydroxychloroquine, amiodarone).

Clinical approach

16. **History**: onset (sudden versus gradual), laterality, central versus peripheral loss, pain, redness, glare, floaters and flashes, **metamorphopsia**, diplopia; difficulty with specific tasks (reading, driving, recognising faces, negotiating stairs); falls history; full medication review; and systemic disease (diabetes, hypertension, symptoms of giant cell arteritis).
17. **Sudden painless visual loss** → retinal detachment, vitreous haemorrhage, retinal artery or vein occlusion, giant cell arteritis, wet AMD, occipital stroke — **same-day ophthalmology referral**. **Sudden painful visual loss with a red eye** → acute angle-closure glaucoma, uveitis, keratitis.
18. **Ophthalmological screening** comprises **visual acuity** (ability to read newspaper-sized print), **ophthalmoscopic examination** of lens and fundus, **tonometry** for intraocular pressure, and **visual field testing**.

19. **Bedside additions**: Snellen chart with **pinhole** (improvement indicates refractive error), near-vision card, confrontation fields, **Amsler grid** (central distortion in AMD), pupils for a relative afferent pupillary defect, red reflex, colour vision, and dilated fundoscopy.
20. **Pattern recognition (Essentials Table 13-4)**: pain, red eye and a fixed pupil → angle-closure glaucoma; glare intolerance with loss of acuity → cataract; loss of peripheral vision with optic disc changes → open-angle glaucoma; sudden visual loss → temporal arteritis or diabetic retinopathy; loss of central acuity with retinal vessel changes and exudates → macular degeneration or diabetic retinopathy.
21. Systemic evaluation: blood pressure, HbA1c, and **ESR/CRP urgently if giant cell arteritis is suspected**.

Management principles

22. **Consider cataract surgery when the cataract progresses to interfering with activities**; **consider glaucoma when defects in the peripheral visual field are present**; and **consider AMD when central visual acuity is affected**.
23. **Restoring vision after cataract surgery**: an **intraocular lens** corrects central and peripheral vision, increases image size by only **1%**, can be used after surgery on one or both eyes, is useful for older adults unable to wear contact lenses, but requires bifocal spectacles and introduces added surgical and postsurgical complications. **Contact lenses** increase apparent object size by **6%** and are difficult for many older people to handle.
24. **Visual impairment is a known risk factor for falls and fractures, and patients who have had cataract surgery have a lower risk of hip fracture.**
25. **Glaucoma** is usually treated medically first with miotics and β-blocking agents (which have the advantage of not changing pupil diameter), with combination drops and systemic carbonic anhydrase inhibitors in severe cases; **surgery or laser therapy is indicated only if disease progresses on maximal medical therapy**.
26. **Diabetic retinopathy**: **initiate intensive blood glucose control and tight blood pressure control to reduce retinopathy in type 2 diabetes**; panretinal and focal laser photocoagulation reduce the risk of visual loss in severe retinopathy and macular oedema respectively.
27. **Aids to maximise visual function**: magnifying device; lighting intensifiers without glare; tinted glasses to reduce glare; a night light to assist dark adaptation; and large-print newspapers, books and magazines. **Refer all patients with AMD for visual rehabilitation.**
28. **Beware systemic absorption of ophthalmic medications** — these agents may cause other organ system dysfunction and interact with other medications. β-blocker drops can cause bradycardia, bronchospasm and heart failure. Assess the patient's other medical problems and medications, **use the minimum dose to achieve the desired effect, and monitor for systemic toxicity**.
29. Screen for and treat **depression**, which commonly follows the loss of quality of life. Recognise **Charles Bonnet syndrome** — formed visual hallucinations with retained insight in the visually impaired — and reassure rather than misdiagnose psychosis or dementia.

Latest Updates (2023–Present)

- **The *Lancet* Commission on dementia prevention, intervention and care (2024) added untreated vision loss as a new modifiable risk factor for dementia**, contributing approximately 2% of the population-attributable fraction, and observational data associate **cataract surgery with reduced dementia incidence**. This is the single highest-yield update for this question.
- **Dual sensory impairment** (combined hearing and vision loss) has **multiplicative** effects on dementia, falls, depression and mortality — a growing 2023–2025 literature relevant to comprehensive geriatric assessment.
- **Screening guidance diverges**: the **USPSTF (2022) issued an "I" statement** — insufficient evidence for routine primary-care vision screening in asymptomatic older adults — while the AAO and geriatric societies recommend a **comprehensive dilated eye examination every 1–2 years after age 65**. Know both positions.
- **Glaucoma**: the **LiGHT trial 10-year extension (2024)** established **selective laser trabeculoplasty as first-line therapy** — more effective, more cost-effective and with less need for surgery than eye drops. Newer agents include Rho-kinase inhibitors (netarsudil) and latanoprostene bunod, plus preservative-free formulations and **minimally invasive glaucoma surgery (MIGS)** combined with cataract extraction.
- **WHO World Report on Vision** targets for 2030: a 40 percentage-point increase in effective refractive error coverage and a 30 percentage-point increase in effective cataract surgical coverage. **Uncorrected refractive error and cataract remain the leading global causes.**
- **Indian context**: the **National Blindness and Visual Impairment Survey (2015–19)** reported blindness prevalence of **1.99% in those aged 50 and over**, with **cataract responsible for about 66%** and **93% of blindness avoidable**. The **National Programme for Control of Blindness and Visual Impairment (NPCBVI)** targets a blindness prevalence of 0.25% and provides free cataract surgery with intraocular lens; **Vision Centres under Ayushman Bharat Health and Wellness Centres** extend refraction services; and the **NPHCE** mandates vision screening for older persons. **LASI Wave 1** documented a very high burden of self-reported visual difficulty and unmet cataract need in Indian elders.

Current Practice Update

Textbook Position	Current Evidence-Based Practice (2023–2026)
Visual impairment causes functional limitation, isolation and depression	Add: **untreated vision loss is now a *Lancet* Commission (2024) modifiable dementia risk factor**; cataract surgery is associated with reduced dementia incidence
Glaucoma treated medically first; laser or surgery only on progression	**LiGHT (10-year, 2024): selective laser trabeculoplasty as first-line** — better disease control, more cost-effective, fewer glaucoma surgeries than drops
Insufficient evidence for VEGF antagonists in diabetic retinopathy	**Anti-VEGF therapy is now first-line for centre-involving diabetic macular oedema**, superior to laser (Protocol T and successors)
Screen for visual dysfunction in all older adults	Still recommended by AAO and geriatric societies, but the **USPSTF (2022) found insufficient evidence** for routine primary-care screening — present both views
Cataract surgery reduces hip fracture risk	**Confirmed and extended** — also associated with reduced motor-vehicle collisions, less depression and lower dementia incidence

Extra Points to Remember — recurring topic

- **Four causes of blindness in the elderly — "CGMD": C**ataract, **G**laucoma, **M**acular degeneration, **D**iabetic retinopathy. Quote the Framingham prevalences: cataract 46%, AMD 28%, open-angle glaucoma 7.2%, diabetic retinopathy 7% (all at ages 75–85).
- **The one-line pattern discriminator:** "Cataract = glare and gradual blurring; glaucoma = **peripheral** field loss; AMD = **central** loss with metamorphopsia; diabetic retinopathy = macular oedema, haemorrhage or ischaemia."
- **The pinhole test** is the fastest bedside discriminator — improvement means refractive error, no improvement means organic disease.
- **Never miss giant cell arteritis** — sudden painless monocular loss with headache, jaw claudication and scalp tenderness needs immediate high-dose steroid before biopsy.
- **Charles Bonnet syndrome** — formed hallucinations *with insight* in the visually impaired. Reassure; do not prescribe antipsychotics.
- **Systemic toxicity of eye drops** is a classic geriatric viva question — timolol drops causing bradycardia, bronchospasm and falls.
- **Indian data to quote:** blindness prevalence 1.99% in those ≥50 years, cataract responsible for 66%, **93% of blindness in India is avoidable**; NPCBVI target 0.25%.
- **The examiner's favourite closing line:** "Vision loss is one of the few dementia risk factors that is **cheaply and completely reversible** — a pair of spectacles or a cataract operation."

Examiner's Tip — say these lines verbatim:

- "**As many as 75% of older adults have visual or auditory dysfunction that is not reported to their physician** — hence screening is essential."
- "Screening comprises **visual acuity, ophthalmoscopy, tonometry and visual fields**."
- "**Presbyopia arises from nuclear sclerosis of the lens and atrophy of the ciliary muscle**."
- "**Visual impairment is a risk factor for falls and fractures, and cataract surgery lowers the risk of hip fracture.**"
- "**Refer all patients with age-related macular degeneration for visual rehabilitation.**"
- "Ophthalmic solutions are **significantly absorbed systemically** — use the minimum effective dose and monitor for toxicity."
- "The ***Lancet* Commission 2024 added untreated vision loss as a modifiable dementia risk factor**."

12. Macular Degeneration — Presentation, Aetiology, Diagnosis, Treatment and Prevention

Definition and anatomical basis

1. **Age-related macular degeneration (AMD)** is degeneration of the macula — the area of the retina lying at the **posterior pole of the globe**, which is the **site of highest visual acuity** — producing progressive loss of **central** vision with preservation of peripheral vision.
2. **The macula depends entirely on the choriocapillaris for nutrition.** Any disturbance in the vessel wall of the choroidal capillaries, in the **permeability or thickness of Bruch's membrane**, or in the **retinal pigment epithelium**, interferes with the exchange of nutrients and oxygen from the choroidal blood to the central retina. Such disturbances occur frequently in older patients.
3. **AMD is one of the most frequent causes of visual loss in older adults and is the commonest cause of legal blindness (20/200 or worse)**; Framingham Eye Study prevalence was **28% at ages 75–85, with a higher rate in women than in men**.

Aetiology and risk factors

4. Modifiable and non-modifiable risks: **older age, family history of the disorder, cigarette smoking, low dietary intake or low plasma concentrations of antioxidant vitamins and zinc, and white race (for "wet" lesions)**. **High lifetime exposure to sunlight** is also a risk factor, as are obesity and hypertension.
5. **AMD is caused by the interplay of genetic predisposition and exposure to modifiable risk factors.** Two susceptibility genes have been identified — **CFH (complement factor H)** and **LOC387715/ARMS2**.
6. **Carrying the susceptibility allele of either gene increases risk three- to eightfold; having two copies of the susceptibility alleles in both genes increases the risk 50-fold.** The combined effect of these polymorphisms carries an **attributable risk of 60%**. **Cigarette smoking and obesity multiply the risks associated with these variants.**
7. The central role of **complement factor H** identifies **complement dysregulation and chronic low-grade inflammation** as the pathogenic core — the rationale for modern complement-inhibitor therapy.

Types and presentation

8. **Dry (non-exudative, atrophic) AMD — 85–90% of cases.** Early and intermediate stages show **drusen** and pigmentary change. In the **geographic atrophy** form there are **areas of depigmentation alternating with zones of hyperpigmentation, caused mainly by changes in the retinal pigment epithelium**; in another form the degeneration involves **Bruch's membrane**, producing pigmentation of **well-circumscribed, roundish yellow areas**. **As lesions coalesce and involve the central macula, there is progressive worsening of vision to legal blindness.**
9. **Wet (exudative, neovascular) AMD — 10–15% of cases**, but responsible for most severe visual loss. There is **acute exudative pathology as a consequence of neovascularisation** — choroidal neovascular membranes breaching Bruch's membrane, with subretinal fluid, haemorrhage, lipid exudate and eventual disciform scarring.
10. **Symptoms**: gradual (dry) or rapid (wet) **painless loss of central vision**; **metamorphopsia** — straight lines appearing wavy or bent, the earliest and most characteristic symptom of wet AMD; a central scotoma; difficulty reading and recognising faces; reduced contrast sensitivity; need for brighter light; and micropsia. **Peripheral vision and navigational vision are preserved — patients never become totally blind from AMD.**
11. **Ophthalmoscopic findings vary and do not always parallel the loss of vision** — a key clinical caution.

Diagnosis

12. Visual acuity (distance and near) and an **Amsler grid** for metamorphopsia and central scotoma — also used for home self-monitoring with instructions to report new distortion urgently.
13. **Dilated fundoscopy and slit-lamp biomicroscopy**: hard and soft drusen, RPE mottling and clumping, geographic atrophy, subretinal fluid, haemorrhage, hard exudate, and disciform scar.
14. **Optical coherence tomography (OCT)** is the current standard for detecting intraretinal and subretinal fluid, pigment epithelial detachment, and drusen volume — it guides initiation, retreatment and extension of anti-VEGF therapy.
15. **Fundus fluorescein angiography** defines classic and occult choroidal neovascular membranes; **indocyanine green angiography** is required to diagnose **polypoidal choroidal vasculopathy**, which is far commoner in Indian and other Asian eyes.
16. **OCT angiography** gives non-invasive detection of neovascularisation including subclinical (non-exudative) CNV; **fundus autofluorescence** is used to measure and monitor geographic atrophy lesion area.

Treatment

17. **Dry/intermediate AMD — AREDS2 antioxidant supplementation**: vitamin C, vitamin E, zinc, copper, plus **lutein and zeaxanthin** (which replaced β-carotene because of increased lung cancer risk in smokers). It reduces progression to advanced AMD by roughly **25% over 5 years** in patients with intermediate AMD or with advanced AMD in one eye. It does **not** prevent AMD in those who do not have it, and Cochrane reviews find no benefit for cataract prevention.

18. **Wet AMD — intravitreal anti-VEGF injection is the standard of care**: ranibizumab, **bevacizumab** (off-label but far cheaper; the CATT trial showed it equivalent to ranibizumab), aflibercept, brolucizumab and **faricimab**. Typically three monthly loading doses followed by a **treat-and-extend** or pro-re-nata regimen guided by OCT.
19. Older modalities — **photodynamic therapy with verteporfin** and thermal laser photocoagulation — are now largely superseded, retained for polypoidal choroidal vasculopathy and selected extrafoveal lesions.
20. **Visual rehabilitation is an important part of therapy for AMD. Patients may benefit from reading glasses or magnification devices — refer all patients with AMD for visual rehabilitation.** Add high-intensity task lighting without glare, large print, eccentric viewing training, high-contrast markings and home hazard modification.
21. **Clinical depression may occur as a consequence of reductions in quality of life and should be treated.** Screen actively; also recognise Charles Bonnet syndrome.

Prevention

22. **Smoking cessation is the single most important modifiable intervention** — smoking both causes AMD and multiplies genetic risk.
23. **Sunlight protection** with ultraviolet-blocking sunglasses and a wide-brimmed hat, given high lifetime sunlight exposure as a risk factor.
24. **Diet** rich in dark green leafy vegetables (lutein and zeaxanthin) and oily fish (omega-3), with control of obesity, hypertension and dyslipidaemia.
25. **Amsler grid self-monitoring** of the fellow eye with clear instructions to report new distortion immediately, plus regular dilated fundus examination — the second eye is at high risk once one eye is affected.
26. **Prognosis**: dry AMD progresses slowly over years; **untreated wet AMD causes severe central visual loss within weeks to months**, which makes urgent referral for anti-VEGF therapy essential.

Latest Updates (2023–Present)

- **The first-ever treatments for geographic atrophy were approved in 2023. Pegcetacoplan (Syfovre)**, a **C3 inhibitor**, was FDA-approved in February 2023 on the basis of **OAKS and DERBY (*Lancet* 2023)** — in OAKS at 12 months monthly dosing slowed GA lesion growth by **21%** and every-other-month dosing by **16%**. **Avacincaptad pegol (Izervay)**, a pegylated RNA aptamer inhibiting **C5**, was FDA-approved in August 2023 on **GATHER1 and GATHER2 (*Lancet* 2023)**, with **27% and 14%** reductions in GA growth at 12 months.
- **The critical caveat, and the most examinable nuance:** these agents slow **anatomical** lesion growth but have **not demonstrated a clinically meaningful functional benefit**. GATHER2 two-year data (*Ophthalmology* 2025) showed persistent loss of ≥15 ETDRS letters in **18% with avacincaptad versus 19% with sham (HR 0.90, p = 0.64)**. **The EMA's CHMP issued a negative opinion and both manufacturers withdrew their European marketing applications — as of 2025 there is no approved treatment for geographic atrophy in Europe.** Both carry a risk of conversion to exudative AMD, and pegcetacoplan carries a risk of retinal and occlusive retinal vasculitis.
- **Faricimab (Vabysmo)** — a bispecific antibody targeting **VEGF-A and angiopoietin-2**; TENAYA and LUCERNE showed non-inferiority to aflibercept with dosing intervals extended to **16 weeks**, and 2024–2025 real-world data confirm reduced injection burden.
- **Aflibercept 8 mg (Eylea HD)** — FDA-approved 2023 and EU 2024; the PULSAR trial showed **12- to 16-week dosing** non-inferior to 2 mg every 8 weeks.
- **Ranibizumab port delivery system (Susvimo)** — a refillable surgical ocular implant giving continuous delivery with refills every 24 weeks; reintroduced in 2024 after a 2022 recall.
- **Gene therapy** — ixoberogene soroparvovec (Ixo-vec) and RGX-314 are in phase 3, aiming for sustained intraocular anti-VEGF expression from a single administration. **Home OCT monitoring** (Notal Vision Home OCT, FDA-cleared 2024) enables patient-performed weekly scans for fluid detection.
- **AREDS2 10-year follow-up (*JAMA Ophthalmology* 2022)** confirmed **lutein/zeaxanthin is superior to β-carotene** for reducing progression, with no excess lung cancer — consolidating the current formulation.
- **Indian context**: population-based studies (INDEYE, CIEMS, APEDS) report AMD prevalence of roughly **2–3% in those aged 60 and over**, lower than Western figures but rising. **Polypoidal choroidal vasculopathy is substantially commoner in Indian eyes** and must be excluded with ICG angiography in wet AMD that responds poorly to anti-VEGF. **Bevacizumab and the Indian-developed ranibizumab biosimilar (Razumab, the world's first) are the mainstay because of cost**; aflibercept biosimilars became available in 2024–2025. AMD care falls under the NPCBVI, and low-vision aids are supplied through its low-vision programme.

Current Practice Update

Textbook Position (Essentials 7th ed.)	Current Evidence-Based Practice (2023–2026)
No treatment exists for the atrophic (dry/geographic atrophy) form beyond antioxidant supplementation	**Two complement inhibitors approved in the US in 2023** — pegcetacoplan (C3) and avacincaptad pegol (C5) — slowing lesion growth by 14–27%. **But no proven visual-function benefit, and both were rejected in Europe**
Ranibizumab and bevacizumab for neovascular AMD, given monthly	**Faricimab and aflibercept 8 mg allow 12–16-week intervals**; treat-and-extend guided by OCT is standard; **biosimilars have transformed affordability in India**
Antioxidant formulation includes β-carotene	**AREDS2 formulation replaces β-carotene with lutein and zeaxanthin** — more effective and safe in smokers
Diagnosis by ophthalmoscopy and fluorescein angiography	**OCT is the standard** for diagnosis and monitoring; OCT-angiography detects subclinical CNV; **home OCT** FDA-cleared 2024
Genetics: CFH and LOC387715 confer risk	Confirmed, and now **therapeutically actionable** — complement dysregulation is the target of the new geographic atrophy drugs
Refer all patients for visual rehabilitation; treat depression	**Unchanged and still under-performed in practice** — state it explicitly in the answer

Examiner's Tip — say these lines verbatim:

- "**The macula depends entirely on the choriocapillaris for nutrition**; AMD results from disturbance of the choroidal capillaries, Bruch's membrane or the retinal pigment epithelium."
- "AMD is the **commonest cause of legal blindness (20/200 or worse)** in older adults; prevalence 28% at ages 75–85, higher in women."
- "**CFH and LOC387715/ARMS2** — one susceptibility allele raises risk 3–8 fold, two copies of both raise it **50-fold**, with a **60% attributable risk**; **smoking and obesity multiply these genetic risks**."
- "**Metamorphopsia is the earliest symptom of wet AMD** — the Amsler grid is the bedside test."
- "**Ophthalmoscopic findings vary and do not always parallel the loss of vision.**"
- "**Peripheral vision is always preserved — patients never become totally blind from AMD.**"
- "**Smoking cessation is the single most important preventive measure**, and **AREDS2 supplementation reduces progression by about 25% over 5 years** in intermediate disease."
- "**Refer all patients with AMD for visual rehabilitation, and treat the depression that commonly follows.**"
- "The 2023 complement inhibitors **slow lesion growth but have not shown visual benefit**, and were **rejected by the EMA**."

13. Heat Stroke

Definition and epidemiology

1. **Heat stroke is defined as a failure to maintain body temperature, and is characterised by a core temperature of >40.6°C (>105°F), severe central nervous system dysfunction (psychosis, delirium, coma), and anhidrosis (hot, dry skin).** These are the **three defining criteria**.
2. **The two groups primarily affected are older adults who are chronically ill (classic or non-exertional heat stroke) and the young undergoing strenuous exercise (exertional heat stroke).**
3. **Mortality is as high as 80% once this syndrome is manifest.**
4. **Hypo- and hyperthermic states are predominantly disorders of older adults.** Morbidity and mortality increase during particularly hot or cold periods, especially among the ill elderly, and much of this illness is caused by an increased incidence of **cardiovascular disorders (myocardial infarction and stroke) or infectious disease (pneumonia)** during these periods.

Pathophysiology — why older people are vulnerable

5. The major pathophysiological mechanisms of temperature dysregulation in ageing are **impaired temperature perception** and **diminished sweating in hyperthermia**.
6. **Dermal vascularisation and the number of sweat glands both decrease with age**, along with sebum production. **Since dermal vascularisation and sweating are the major mechanisms for balancing body temperature and losing heat from the skin, and both are impaired with age, elderly people tend to experience hyperthermia in hot weather.**
7. **There are multiple predisposing factors for heat stroke in older adults, but most often there is a prolonged heat wave.** Others: cardiovascular disease, diabetes, dementia, immobility, social isolation, living alone without cooling, obesity, dehydration and blunted thirst.
8. **Drugs**: anticholinergics, antihistamines, tricyclic antidepressants and antipsychotics (impair sweating); diuretics (volume depletion); β-blockers (limit the cardiac output response); alcohol.
9. Mechanism of injury: heat produces **direct cytotoxic injury plus a systemic inflammatory response with cytokine release**, causing endothelial damage, coagulopathy and multi-organ failure — the syndrome behaves like sepsis.

Clinical features

10. **The diagnosis requires a high level of suspicion**, because the **early manifestations are non-specific**.
11. **Early signs (Table 12-14)**: **dizziness, weakness, sensation of warmth, anorexia, nausea, vomiting, headache and dyspnoea.**
12. **Later signs**: **central nervous system dysfunction, psychosis, delirium, coma, anhidrosis, and hot dry skin.**
13. Differential diagnosis: sepsis, thyroid storm, neuroleptic malignant syndrome, serotonin syndrome, malignant hyperthermia, anticholinergic toxidrome, meningitis and status epilepticus. In older people the presentation overlaps heavily with delirium and infection.

Complications (Table 12-15)

14. **Cardiac**: myocardial damage, congestive heart failure, arrhythmias. **Renal**: renal failure in **20–25%**.
15. **Neurological**: cerebral oedema, seizures, diffuse and focal findings. **Hepatic**: hepatocellular necrosis, jaundice, liver failure.
16. **Muscle**: rhabdomyolysis with myoglobinuria. **Haematological**: bleeding diathesis, disseminated intravascular coagulation.
17. **Metabolic**: electrolyte disturbance, acid–base disturbance (metabolic acidosis, respiratory alkalosis). **Infective**: aspiration pneumonia, sepsis. **Circulatory**: dehydration and shock.
18. Investigations: **rectal core temperature** (most accurate), full blood count, electrolytes, urea and creatinine, liver function, creatine kinase, coagulation screen, arterial blood gases, urinary myoglobin, ECG, chest radiograph, blood cultures, and CT head if there are focal signs.

Management

19. **Once the full syndrome has developed for any length of time the prognosis is very poor.** Management at this stage requires intense multisystem care, but **the key is rapid specific therapy consisting of cooling to 38.9°C (102°F) within the first hour.**
20. **Ice packs and ice-water immersion are superior to convection cooling with alcohol sponge baths or electric fans.** This is the single most important therapeutic statement in the chapter.
21. **ABC**: airway protection if comatose, high-flow oxygen, large-bore intravenous access, continuous cardiac monitoring, and careful fluid resuscitation guided by haemodynamics — older patients are at risk of precipitating pulmonary oedema.
22. Adjunctive measures: remove clothing, cold intravenous fluids, cold gastric or bladder lavage, benzodiazepines to control shivering and seizures, fluids and urinary alkalinisation for rhabdomyolysis, and correction of electrolyte disturbance and coagulopathy.

23. **Do not give antipyretics** (paracetamol or NSAIDs) — the hypothalamic set point is normal, so they are ineffective and may worsen hepatic and renal injury. **Do not give dantrolene** — it has no role in heat stroke, unlike malignant hyperthermia.

Prevention

24. **In view of the poor survival, efforts must be directed toward prevention. Prevention appears to be the most appropriate approach to management of temperature dysregulation in older adults.**
25. **Older patients should be cautioned about the dangers of hot weather. For those at particularly high risk, temporary relocation to more protected environments should be considered.**
26. **Education of older adults about their susceptibility to hypo- and hyperthermia in extremes of environmental temperature, education as to appropriate behaviour in such conditions, and close monitoring of the most vulnerable older adults should help reduce morbidity and mortality.**
27. Practical measures: remain indoors and in shade between noon and 3 pm; **drink fluids on a schedule rather than waiting for thirst**, since thirst is blunted with age; light, loose cotton clothing; cool showers; avoid alcohol, caffeine and heavy meals; pre-summer medication review; buddy or check-in systems for those living alone; and access to cooling centres.

Latest Updates (2023–Present)

- **Society of Critical Care Medicine Guidelines for the Treatment of Heat Stroke (*Critical Care Medicine*, February 2025)** — the first dedicated critical care guideline. **Active cooling is recommended over passive cooling, and cold- or ice-water immersion achieves the fastest cooling rate and should be prioritised where available.** The target is a core temperature **below 39°C within 30 minutes**. Where immersion is not feasible, select the method or combination achieving the fastest cooling rate — evaporative cooling with misting and fanning (well tolerated in classic heat stroke), ice packs to neck, axillae and groin, cooling blankets, and cold intravenous fluids. The governing principle is **"cool first, transport second."** Antipyretics and dantrolene are explicitly not recommended.
- Contemporary outcome data: **mortality approaches 60% in ICU patients, and approximately 30% of survivors have long-term cognitive or motor dysfunction** — the central nervous system is particularly vulnerable, with cell death increasing exponentially with the duration of temperature exposure.
- **India — National Programme on Climate Change and Human Health (NPCCHH), NCDC/MoHFW**: the **National Action Plan on Heat Related Illnesses** (2021, revised subsequently) and the **"Emergency Cooling for Severe Heat-Related Illnesses" guidance (March 2024)**. Key positions: **conductive cooling with ice or cold water immersion is the gold standard**; where a tub is unavailable a **tarpaulin-based portable cold-water immersion method** can be improvised; and **cooling should not be delayed in order to remove all clothing or equipment**. Standard case definitions and first aid for heat rash, heat cramps, heat syncope, heat exhaustion and heat stroke are provided.
- **MoHFW heatwave advisory (2025)**: every health facility must have a designated cooling area, ice packs and a heat stroke protocol; medical officers must submit **patient-level data daily on the IHIP (Integrated Health Information Platform) portal** using standardised checklist criteria to classify heat stroke and heat-related illness deaths.
- **Global burden**: approximately **61,672 heat-related deaths occurred in Europe in the summer of 2022**; 2023 saw a substantial global increase in heat-related illness; India recorded severe heatwaves in 2024 and 2025 with several hundred confirmed heat-stroke deaths. The *Lancet* Countdown reports that **heat-related mortality in adults over 65 has risen by roughly 85% since the 1990s**. Older adults, outdoor workers and the urban poor are disproportionately affected, and South Asian populations with inadequate access to cooling, healthcare and safe water are at particularly high risk.
- Under investigation: extracorporeal and endovascular cooling catheters, and biomarkers (heat shock proteins, IL-6) for prognostication.

Current Practice Update

Textbook Position (Essentials 7th ed.)	Current Evidence-Based Practice (2023–2026)
Cool to **38.9°C within the first hour**	**SCCM 2025 tightens this to <39°C within 30 minutes** — "cool first, transport second"
Ice packs and ice-water immersion superior to alcohol sponging and fans	**Confirmed and formalised**: cold/ice-water immersion (≤12°C) is the gold standard; evaporative cooling with misting and fanning is the preferred alternative in classic heat stroke
Mortality "as high as 80% once the syndrome is manifest"	Contemporary ICU mortality is around **60%**, with **~30% of survivors left with cognitive or motor dysfunction**
Prevention through education, caution in hot weather, relocation of the high-risk	**Institutionalised in India** through NPCCHH Heat Action Plans, facility-level cooling protocols and mandatory **IHIP daily reporting**
Antipyretics and dantrolene not specifically addressed	**Explicitly not recommended** in current guidelines — ineffective and potentially harmful

> **Examiner's Tip — say these lines verbatim:**
>
> - "Heat stroke is defined by the **triad of core temperature >40.6°C, severe CNS dysfunction, and anhidrosis with hot**

dry skin."

- "The two affected groups are **chronically ill older adults (classic) and young people exercising strenuously (exertional)**; **mortality is as high as 80%**."
- "The mechanisms in ageing are **impaired temperature perception and diminished sweating** — dermal vascularisation and sweat gland numbers both fall with age."
- "**The key is rapid cooling to 38.9°C within the first hour; ice packs and ice-water immersion are superior to alcohol sponge baths and electric fans.**"
- "**Do not give antipyretics or dantrolene** — the hypothalamic set point is normal."
- "Renal failure occurs in **20–25%**; also expect rhabdomyolysis, DIC, hepatic necrosis and cerebral oedema."
- "**Prevention is the most appropriate approach to management** — caution about hot weather and temporary relocation of the highest-risk older adults."
- "**SCCM 2025: cool to below 39°C within 30 minutes — cool first, transport second.**"

14. Heat Exhaustion

Definition and place in the spectrum

1. **Heat exhaustion** is a moderate heat-related illness caused by **water and/or salt depletion** during heat exposure, characterised by a core temperature that is **normal or only mildly elevated (usually below 40°C)**, with **preserved sweating** and an **intact mental state**.
2. It occupies the stage immediately before heat stroke on the continuum of heat-related illness: **heat rash (miliaria) → heat oedema → heat cramps → heat syncope → heat exhaustion → heat stroke**. **Untreated, heat exhaustion progresses to heat stroke, which carries up to 80% mortality** — this is why recognising it matters.
3. **Early manifestations of heat exhaustion are non-specific**; later, severe central nervous system dysfunction and anhidrosis develop, which signifies progression to heat stroke.

Pathophysiology

4. Prolonged heat exposure causes sustained **cutaneous vasodilatation and profuse sweating**, producing loss of water and sodium, **hypovolaemia and reduced cardiac output**, and hence inadequate tissue perfusion. Crucially, **thermoregulation remains intact** — which is why sweating continues and consciousness is preserved.
5. Two overlapping types: **water-depletion heat exhaustion** (inadequate fluid intake; hypernatraemia; rapid onset — the dominant form in the elderly, in whom thirst is blunted) and **salt-depletion heat exhaustion** (losses replaced with water alone; hyponatraemia; prominent cramps; more insidious onset).
6. **Why older adults are vulnerable**: impaired temperature perception, diminished sweating from reduced sweat gland numbers and dermal vascularisation, blunted thirst sensation, reduced renal concentrating ability, lower total body water, diuretic and anticholinergic use, immobility and dependence on carers for fluids, and dementia limiting self-protective behaviour.

Clinical features

7. **Early/non-specific symptoms (Table 12-14)**: **dizziness, weakness, sensation of warmth, anorexia, nausea, vomiting, headache and dyspnoea.**
8. Additional features: **profuse sweating with cool clammy skin**, intense thirst, fatigue, myalgia and muscle cramps, irritability, tachycardia, **postural hypotension and near-syncope**, and oliguria with concentrated urine.
9. **The cardinal distinction from heat stroke**: in heat exhaustion the core temperature is **below 40°C**, the **skin is moist because sweating is preserved**, and there is **no severe CNS dysfunction** — no psychosis, delirium, coma or seizures. Mild irritability or feeling faint is acceptable; **any frank alteration of sensorium means heat stroke until proved otherwise**.
10. In older people the picture is easily mistaken for gastroenteritis, urinary sepsis, drug adverse effects or delirium — **a high index of suspicion during a heatwave is essential**, exactly as for heat stroke.

Investigations

11. **Rectal core temperature** (essential to separate exhaustion from stroke), capillary glucose, serum electrolytes (**sodium may be high or low depending on the type**), urea and creatinine (pre-renal pattern), creatine kinase (to exclude rhabdomyolysis), urine specific gravity and ECG.
12. Investigate to exclude infection or another acute illness whenever the diagnosis is not clear-cut, since heat illness and sepsis coexist and mimic each other in the elderly.

Management

13. **Move the patient immediately to a cool, shaded or air-conditioned environment** and lay them supine with the legs elevated; remove excess clothing.
14. **Active external cooling** — cool water spray with fanning, cool wet cloths, and ice packs to the neck, axillae and groin. Cooling is less aggressive than for heat stroke but should still be prompt.
15. **Oral rehydration with cool electrolyte-containing fluid (ORS)** if the patient is alert and not vomiting. **Intravenous isotonic saline** if there is vomiting, marked postural hypotension or failure to improve; in older patients infuse cautiously with monitoring for fluid overload and heart failure.
16. Correct electrolyte abnormalities; **correct hyponatraemia slowly** to avoid osmotic demyelination. Rest and avoid further heat exposure for 24–48 hours.
17. **Do not give antipyretics** — the hypothalamic set point is normal, so they are ineffective.
18. **Monitor core temperature, blood pressure, urine output and mental status. Any deterioration in mental status, or a core temperature reaching 40°C, means the patient has progressed to heat stroke — begin aggressive cooling immediately.**
19. **Indications for admission in older adults**: advanced age with comorbidity, persistent symptoms after 30–60 minutes of cooling and rehydration, significant electrolyte derangement, renal impairment, rhabdomyolysis, inability to take oral fluids, and an unsafe or unairconditioned home environment.
20. **Prognosis is excellent with prompt treatment** — heat exhaustion resolves fully without sequelae. Its clinical importance lies entirely in being the **recognisable and completely reversible stage** before the very high mortality of heat stroke.

Prevention

21. Identical to heat stroke prevention: **education of older adults about their susceptibility and about appropriate behaviour in extremes of environmental temperature, and close monitoring of the most vulnerable**.
22. Practical measures: pre-summer medication review (diuretics, anticholinergics, antipsychotics, β-blockers); **scheduled fluid intake rather than thirst-driven drinking**; avoid outdoor activity between noon and 3 pm; light loose clothing; cool showers; use of cooling centres; buddy check-in systems; and **temporary relocation of very high-risk older people to a protected environment**.

Latest Updates (2023–Present)

- **SCCM Heat Stroke Guidelines (*Critical Care Medicine*, 2025)** emphasise that the distinction between heat exhaustion and heat stroke rests on **core temperature and CNS dysfunction**, and that **where there is any doubt the patient should be treated as heat stroke and cooled** — the risk of over-treating exhaustion is trivial compared with the risk of under-treating stroke.
- **India — NCDC/NPCCHH "National Action Plan on Heat Related Illnesses"** provides **standard case definitions, symptoms and first aid for heat rash, heat cramps, heat syncope, heat exhaustion and heat stroke** (Annexure 2), and mandates **daily reporting of heat-related illness and deaths on the IHIP portal**. The **March 2024 "Emergency Cooling for Severe Heat-Related Illnesses"** document supplements this for severe cases, and the NPCCHH Programme Implementation Plan funds procurement of emergency cooling equipment.
- **MoHFW 2025 heatwave advisory** requires facility preparedness — a designated cooling area, ice packs and a written heat illness protocol at every health facility.
- **Oral rehydration solution is superior to plain water** in salt-depletion heat exhaustion (2024–2025 occupational and sports medicine literature); ice-slurry or "slushy" ingestion provides useful internal cooling and is being adopted for outdoor workers.
- **WHO–WMO heat and health guidance (2024)** and India's state and city **Heat Action Plans** (with the Ahmedabad Heat Action Plan as the internationally cited model) identify **older adults as a priority vulnerable group**, with early warning systems, cooling shelters and targeted outreach.
- ***Lancet* Countdown (2025)**: heat exposure days and heat-attributable mortality in adults over 65 continue to rise in India. **ICMR-NIN** guidance advises older adults to take roughly **2–2.5 litres of fluid daily in summer** unless fluid-restricted for heart failure or chronic kidney disease.

Current Practice Update

Textbook Position (Essentials 7th ed.)	Current Evidence-Based Practice (2023–2026)
Heat exhaustion described only as the "early manifestations of hyperthermia", without a separate management protocol	**Now a distinct entity with its own case definition and first-aid protocol** under India's NPCCHH National Action Plan on Heat Related Illnesses
Distinction from heat stroke implied by the early/late signs table	**Explicit criteria**: core temperature <40°C, preserved sweating, intact sensorium. **When in doubt, treat as heat stroke and cool** (SCCM 2025)
Rehydration not specified in detail	**Oral rehydration solution preferred over plain water** in salt depletion; IV isotonic saline with cautious monitoring for fluid overload in older adults
Prevention through education and relocation of the high-risk	**Operationalised** through state and city **Heat Action Plans**, early warning systems, cooling shelters and mandatory IHIP reporting

Examiner's Tip — say these lines verbatim:

- "Heat exhaustion is **water and/or salt depletion during heat exposure, with a core temperature below 40°C, preserved sweating and an intact sensorium**."
- "**The early manifestations of heat exhaustion are non-specific** — dizziness, weakness, a sensation of warmth, anorexia, nausea, vomiting, headache and dyspnoea."
- "**The single discriminator from heat stroke is CNS dysfunction with anhidrosis** — if the sensorium is altered and the skin is hot and dry, it is heat stroke."
- "Two types: **water-depletion (hypernatraemic, rapid, commoner in the elderly because thirst is blunted)** and **salt-depletion (hyponatraemic, insidious, prominent cramps)**."
- "Treatment is **cool environment, supine with legs elevated, active external cooling, and oral rehydration solution or cautious isotonic saline**."
- "**Do not give antipyretics** — the hypothalamic set point is normal."
- "**Heat exhaustion is the completely reversible stage before heat stroke**, which carries up to 80% mortality — recognising it is the whole point."
- "**Prevention is the most appropriate approach to management of temperature dysregulation in older adults.**"

Rapid Revision Grid — Night Before the Examination

Topic	One-line textbook anchor	Single most examinable 2023–2026 update
Epilepsy in the elderly	3rd commonest neurological disorder; stroke causes 40–53%; treat after first unprovoked seizure	Choose ASM by **tolerability, not efficacy**; no prophylaxis after stroke; lacosamide/lamotrigine/levetiracetam
Coma	Arousal (ARAS) + awareness (cortex); GCS ≤8; preserved pupils = metabolic	**Cognitive motor dissociation in ~25%** (*NEJM* 2024); FOUR score; cEEG for NCSE
Subdural haematoma	Acute = mass effect; chronic = inflammation from blood degradation products; subdural drain lowers recurrence	**MMA embolisation** — EMBOLISE and STEM positive, MAGIC-MT neutral; **dexamethasone harmful (DEX-CSDH)**
Lacunar infarct	<15 mm deep infarct; microatheroma or lipohyalinosis; **no cortical signs, no field defect**	**LACI-2 (2023)**: isosorbide mononitrate reduces recurrence and cognitive impairment; cilostazol reduces dependence
SACD	Posterior columns + lateral corticospinal tracts; brisk knees, absent ankles, extensor plantars	**NICE NG239 (2024)**: IM hydroxocobalamin immediately in neurological disease; nitrous oxide SACD
Motor neuron disease	Mixed UMN + LMN in one region; eyes, sphincters and sensation spared; riluzole + NIV prolong survival	**Tofersen approved** for SOD1-ALS; **AMX0035 withdrawn (2024)**; Gold Coast criteria
Peripheral neuropathy	11% over 55; diabetes 44%; NCS/EMG is the initial study in unexplained cases	**Test for hATTR** in progressive "idiopathic" neuropathy; screen for DPN at diagnosis of T2DM
Neuritic pain	Lesion or disease of the somatosensory nervous system; NNT 3.6 TCA, 7.7 pregabalin	**Suzetrigine ($Na_v1.8$ inhibitor), FDA-approved January 2025**; OPTION-DM supports combination
Carotid stenosis	NASCET method; image within 24 h; CEA within 7 days for symptomatic 50–99%	**CREST-2 (*NEJM* 2025)**: in asymptomatic ≥70%, stenting helped, **CEA did not**
Bedside swallow	78% dysphagic after stroke; gag reflex unreliable; water → purée → solids; watch for wet gurgly voice	**Screen within 4 hours**, before any oral intake; use **GUSS or Yale**; oral care not antibiotics
Visual impairment	75% unreported; cataract, glaucoma, AMD, diabetic retinopathy; cataract surgery lowers hip fracture risk	***Lancet* Commission 2024: vision loss is a modifiable dementia risk factor**; LiGHT — SLT first-line for glaucoma
Macular degeneration	Macula depends on choriocapillaris; CFH + LOC387715 give 50-fold risk; metamorphopsia; refer for rehabilitation	**Pegcetacoplan and avacincaptad** approved 2023 for GA — but **no functional benefit and rejected by EMA**
Heat stroke	>40.6°C + CNS dysfunction + anhidrosis; mortality up to 80%; cool to 38.9°C within 1 hour	**SCCM 2025: cool to <39°C within 30 minutes; "cool first, transport second"**; India NPCCHH/IHIP reporting
Heat exhaustion	<40°C, sweating preserved, sensorium intact; the reversible stage before heat stroke	Distinct case definition and first aid under India's **National Action Plan on Heat Related Illnesses**

Prepared from Pathy's Principles and Practice of Geriatric Medicine (6th edition) and Essentials of Clinical Geriatrics (7th edition) as primary sources, supplemented with peer-reviewed literature and guidelines published between 2023 and 2026. Where the textbook position and current evidence differ, the difference is set out explicitly in the Current Practice Update table for that question.

MD GERIATRIC MEDICINE — EXAM REVISION

Genitourinary System Continence, Prostate & Urinary Infection

High-Yield Structured Answers · 15 Questions

Prepared for: Dr. Sudarsan · MD Geriatric Medicine

Module: Urinary Incontinence · LUTS/BPH · Catheters · UTI

Format: University 15-mark & 7-mark answer patterns

Compiled: August 2026

Core text: Pathy's Principles and Practice of Geriatric Medicine (6th ed.) · Kane's Essentials of Clinical Geriatrics

Supplemented with guideline and trial evidence up to 2026 · Indian units and Indian programme context throughout

Contents

1	Classify urinary incontinence; evaluation and treatment **(RECURS)**	**15 marks**
2	Types, diagnosis and management of incontinence in the elderly, including reversible causes	**15 marks**
3	Case: 65-year-old woman with frequency, nocturia and leakage for 6 months	**15 marks**
4	Urinary incontinence in males — types, epidemiology, pathogenesis, risk factors, screening, evaluation, management	**15 marks**
5	Algorithm to investigate and treat an elderly male with lower urinary tract symptoms	**15 marks**
6	Medical management of benign prostatic hypertrophy	**7 marks**
7	Overactive bladder	**7 marks**
8	Bladder retraining protocol	**7 marks**
9	Behavioural intervention in urinary incontinence	**7 marks**
10	Uroflowmetry	**7 marks**
11	Prostate specific antigen	**7 marks**
12	Obstructive uropathy — clinical features, investigation and treatment	**15 marks**
13	Chronic indwelling catheter usage in the elderly	**7 marks**
14	Catheter-associated urinary tract infections — prevention and management	**7 marks**
15	Recommendations for treatment of complicated urinary tract infection in males	**7 marks**

Each answer is arranged as: high-yield numbered points → Latest Updates (2023–present) → Current Practice Update → Exam One-Liners. Recurring / high-yield topics additionally carry mnemonics, numerical anchors, examiner traps and a 15-second answer skeleton.

QUESTION 1

Classify urinary incontinence; discuss its evaluation and treatment. 15 MARKS RECURS

High-Yield Points

A. Definition and Burden

1. **Definition:** Urinary incontinence (UI) is the **involuntary loss of urine that is objectively demonstrable**, in an amount or frequency sufficient to be a social and/or health problem.
2. **Prevalence:** About **one in three women** and **15–20% of men** above 65 years are affected; rises to **60–80% in nursing homes**. In women with comorbidity, cognitive or physical impairment, or polypharmacy, prevalence may reach 70–80%.
3. **Ageing is not the cause.** Age-related changes only predispose: reduced bladder capacity, higher residual urine, more involuntary detrusor contractions, fall in urethral closure pressure (women), prostatic enlargement (men), and loss of the normal night-time rise in **vasopressin** with higher **ANP** causing **nocturnal polyuria**.
4. **Consequences:** skin breakdown, recurrent UTI, **falls and fractures** (especially nocturnal), isolation, depression, dependency, caregiver strain, and **institutionalisation**.

B. Classification

5. **Physiological classification (two basic faults):** (i) **failure to store** — overactive or poorly compliant bladder, or weak outlet; (ii) **failure to empty** — poorly contractile bladder, or increased outlet resistance.
6. **By time course: Acute (transient) incontinence** — sudden onset with an acute illness or drug, resolves when the cause is treated; **Persistent incontinence** — unrelated to acute illness, continues over time.
7. **Persistent UI has four basic clinical types** (they overlap in the same patient):

Type	Definition	Common causes
Stress	Small-volume leak on rise in intra-abdominal pressure — cough, laugh, exercise	Pelvic floor weakness with urethral hypermobility; bladder outlet or sphincter weakness (intrinsic sphincter deficiency); obesity, chronic cough, prior childbirth/ surgery, oestrogen lack
Urge	Larger-volume leak because voiding cannot be delayed once fullness is felt	**Detrusor overactivity**, alone or with local disease (stone, tumour, diverticulum, obstruction) or CNS disease (stroke, dementia, parkinsonism, cord injury)
Overflow (incomplete emptying)	Nonspecific symptoms; classically small-volume dribble from an over-distended bladder	Prostatic enlargement, urethral stricture, cystocele; acontractile bladder in diabetes or cord injury; detrusor–sphincter dyssynergia (multiple sclerosis, suprasacral cord lesion)
Functional	Cannot or will not reach the toilet in time despite an intact lower tract	Severe dementia, other neurological disease, depression/hostility, immobility, restraints, inaccessible toilet

8. **Mixed incontinence** (stress + urge) is the commonest pattern in older women. **Frail older patients** typically combine urge incontinence with functional disability.

9. **Special subtype — DHIC** (**detrusor hyperactivity with impaired contractility**): involuntary contractions but emptying of less than one-third of bladder volume; patients strain to void and are difficult to treat because of retention. **Very high-yield.**
10. **Overactive bladder (OAB)** is a symptom syndrome (urgency ± frequency >8/24 h ± nocturia), with or without incontinence; ~30% of women and ~40% of men aged ≥75 report these symptoms.

C. Evaluation

11. **Case-finding first** — patients rarely volunteer it. Ask: "Do you have trouble with your bladder?", "Do you ever lose urine when you don't want to?", "Do you wear padding in case you lose urine?"
12. **Basic evaluation in ALL patients (four components):** focused **history** (with bladder record), targeted **physical examination**, **urinalysis**, and **post-void residual (PVR)**.
13. **History:** onset and type, frequency/timing/volume, irritative vs voiding symptoms, fluid and caffeine pattern, obstetric/surgical/GU history, comorbidity (diabetes, heart failure, neurological disease), **drug review**, bowel habit, environment, and the **most bothersome symptom**.
14. **Bladder diary / voiding chart** for 3 days characterises the pattern and monitors response to treatment.
15. **Examination:** mobility and dexterity, cognition and mood, focal neurology and **sacral reflexes**, abdomen for distended bladder, rectal for impaction/tone/prostate, and pelvic examination for **atrophic vaginitis** and prolapse (cystocele grading).
16. **Urinalysis:** persistent microscopic haematuria (>5 RBC/hpf) without infection needs cytology and cystoscopy. Bacteriuria in a community patient with new or worsening incontinence should be treated before further evaluation; in nursing-home residents, eradicating bacteriuria does **not** improve chronic stable incontinence.
17. **PVR:** by bladder ultrasound or in–out catheter. **>200 mL is abnormal** and warrants further evaluation. PVR may be omitted in a carefully selected patient with pure stress or pure urgency symptoms, no voiding difficulty and no risk factor for retention.
18. **Uroflowmetry** is a useful non-invasive screen in older men: **peak flow <10 mL/s on a voided volume >150 mL** suggests obstruction or impaired contractility.
19. **Referral criteria** for urology/gynaecology/urodynamics: recent pelvic surgery or irradiation (<6 months), **≥2 symptomatic UTIs in 12 months**, risk factors for bladder cancer (new irritative symptoms, heavy smoking, aniline dye exposure), **marked pelvic prolapse**, significant retention, prostatic nodule, or failure of an adequate therapeutic trial.

D. Treatment

20. **Step 1 — correct reversible factors** (mnemonic **DRIP**: Delirium; Restricted mobility/ Retention; Infection, Inflammation, Impaction; Polyuria, Pharmaceuticals). Relief of faecal impaction alone may restore continence.
21. **Step 2 — behavioural therapy for everyone.** Patient-dependent: **pelvic floor (Kegel) exercises** — the single most effective component — bladder training, bladder retraining. Caregiver-dependent: scheduled toileting, habit training, **prompted voiding** (25–40% of nursing-home residents become dry by day).

22. **Step 3 — drugs, by type:**
    - **Urge/OAB:** antimuscarinics — darifenacin 7.5–15 mg, solifenacin 5–10 mg, tolterodine, fesoterodine, oxybutynin, trospium. Full effect takes **1–2 months**; warn about dry mouth, constipation, glaucoma, reflux and **cognitive impairment/delirium**.
    - **Men with BPH-related irritative symptoms:** α-blocker (tamsulosin 0.4 mg, alfuzosin 10 mg, silodosin 4 mg) ± antimuscarinic; add a 5-α-reductase inhibitor if prostate >30 g.
    - **Stress:** no drug is licensed; α-agonist (pseudoephedrine) ± topical oestrogen, or duloxetine, are off-label options.
    - **Atrophic vaginitis: topical vaginal oestrogen** only — **oral oestrogen is ineffective and may worsen incontinence.**
    - **Refractory nocturia:** low-dose desmopressin with **close sodium monitoring** — hyponatraemia risk is high in the elderly.
23. **Step 4 — devices and surgery:** pessary for prolapse; periurethral bulking or sling for intrinsic sphincter deficiency; colposuspension/autologous fascial sling for stress UI; TURP or other prostatic surgery for obstruction; **artificial urinary sphincter** for post-prostatectomy sphincter damage; intradetrusor **botulinum toxin** and **sacral neuromodulation (S3)** for refractory OAB.
24. **Catheters only for specific indications.** Condom catheter only for intractable incontinence in a dependent man without retention; intermittent catheterisation keeps volumes <400 mL; chronic indwelling catheters are a last resort.
25. **Supportive care throughout:** education, accessible toilets and toilet substitutes, timing of diuretics, fluid and caffeine advice, absorbent pads (never as the *first* response), and meticulous skin care.
26. **Prognosis:** UI is **curable or controllable in most older patients** with adequate mobility and cognition; when not curable it can always be managed to keep the patient comfortable and the caregiver's burden low.

Latest Updates (2023–Present)

- **AUA/SUFU Idiopathic Overactive Bladder Guideline 2024** replaced the older stepped "first/second/third-line" framework with **shared decision-making**; patients may move directly to any treatment tier. Behavioural therapy remains the foundation but need no longer be exhausted before advanced therapy.
- The same guideline explicitly recommends **frailty assessment (Clinical Frailty Scale)** and anticholinergic-burden review before prescribing antimuscarinics, and prefers **β3-agonists (mirabegron, vibegron) in older and cognitively vulnerable adults**.
- **Vibegron (β3-agonist)** received FDA approval in **December 2024** for men with OAB symptoms already on pharmacological therapy for BPH, based on the phase-3 **COURAGE / URO-901-3005** trial in ~1100 men — a group previously restricted to antimuscarinics.
- **AUA/GURS/SUFU Incontinence after Prostate Treatment Guideline (2024)** and **AUA/SUFU/AUGS Genitourinary Syndrome of Menopause Guideline (2025)** formalised, respectively, post-prostatectomy stress UI management and low-dose vaginal oestrogen for urogenital atrophy.
- **Cochrane and guideline-level evidence continues to place supervised pelvic floor muscle training first** for stress and mixed UI in women — around an eight-fold higher chance of cure or improvement versus no treatment.

- **Indian data:** LASI Wave 1 (2017–18, 72,250 participants aged ≥45) shows UI is strongly linked to insomnia, sarcopenia, diabetes and household solid-fuel smoke; self-report grossly under-estimates true prevalence, confirming that **active case-finding, not passive reporting, is the Indian priority**. Continence care is now embedded in NPHCE geriatric clinics and district geriatric units.

Current Practice Update

Issue	Textbook position	Current evidence / practice
Treatment sequencing	Stepwise: behavioural → drug → surgery	AUA/SUFU 2024 — **shared decision-making**; any tier may be entered directly based on bother and patient preference
Drug of choice for OAB in the elderly	Antimuscarinics listed first, β3-agonists barely represented	**β3-agonists preferred** in older adults and cognitive impairment; antimuscarinics carry a dementia-risk signal with cumulative exposure
Men with BPH + OAB	α-blocker ± antimuscarinic, retention feared	**Vibegron approved (2024)** for exactly this group; low retention risk
Oestrogen	Topical oestrogen adjunctive; oral may worsen UI	Unchanged and reinforced — 2025 GSM guideline supports **low-dose vaginal oestrogen**, including after breast cancer with counselling
Urodynamics before treatment	Selected patients only	Confirmed — routine urodynamics before conservative or first-line drug therapy is **not** recommended

Extra Points to Remember (Recurring Topic)

Mnemonics

- **DRIP** — Delirium · Restricted mobility, Retention · Infection, Inflammation, Impaction · Polyuria, Pharmaceuticals (the textbook's own mnemonic for reversible causes).
- **DIAPPERS** — Delirium, Infection, Atrophic vaginitis/urethritis, Pharmaceuticals, Psychological, Excess urine output, Restricted mobility, Stool impaction (classic alternative; quote both).
- Four persistent types — **"S-U-O-F"**: Stress, Urge, Overflow, Functional.

Numerical anchors

- Normal bladder capacity **300–600 mL**; first urge **150–300 mL**; filling pressure **<15 cm H_2O**.
- Frequency = **>8 voids/24 h** or voiding more often than 2-hourly; nocturia = **≥2 voids** at night.
- PVR **>200 mL** abnormal; keep intermittent catheter volumes **<400 mL**; Qmax **<10 mL/s** abnormal.
- Prompted voiding success **25–40%**; nursing-home prevalence **60–80%**; DHIC = emptying **<1/3** of bladder volume.

Examiner traps — (1) Do not say ageing causes incontinence; say ageing *predisposes*. (2) Do not order urodynamics routinely; it is for selected patients only. (3) Do not forget PVR — overflow incontinence is easily missed on examination. (4) Do not treat asymptomatic bacteriuria in a

stable nursing-home resident. (5) Do not prescribe oral oestrogen. (6) Remember DHIC — antimuscarinics can precipitate retention in these patients.

15-second answer skeleton: Definition → prevalence → ageing predisposes (not causes) → two basic faults (storage/emptying) → acute vs persistent → four types + mixed + DHIC → evaluation: 4 basics (history, examination, urinalysis, PVR) + selected further tests + referral criteria → treatment: DRIP → behavioural → drugs by type → devices/surgery → catheters last → supportive care → prognosis.

Exam One-Liners

- UI = involuntary, objectively demonstrable urine loss that is a social or health problem.
- Four persistent types: stress, urge, overflow, functional — overlap is the rule.
- Mixed (stress + urge) is commonest in older women; urge + functional in frail elders.
- Reversible causes: **DRIP** / **DIAPPERS**.
- Basic evaluation = history + examination + urinalysis + PVR. PVR >200 mL is abnormal.
- Pelvic floor muscle exercises give the greatest benefit of all behavioural measures.
- Antimuscarinics take 1–2 months for full effect; β3-agonists are safer in the frail elderly.
- Topical, never oral, oestrogen for atrophic vaginitis.
- DHIC = detrusor overactivity + impaired contractility; patients strain and retain.
- Catheters are for specific indications, never for convenience.

QUESTION 2

Types, diagnosis and management of incontinence in the elderly, including reversible causes. 15 MARKS

*This question overlaps Question 1; the classification and treatment framework there applies. The points below are weighted towards **reversible causes and diagnosis**, which is what this phrasing is testing, and include **faecal incontinence**, which "incontinence in the elderly" also covers.*

High-Yield Points

A. Requirements for Continence and Types

1. **Continence needs four things:** an intact lower urinary tract, adequate **cognition**, adequate **mobility and dexterity**, **motivation**, and an **accessible environment**. Failure of any one of these can produce incontinence in an older person.
2. **Four basic causes** of geriatric UI: lower urinary tract disease, neurological disease, functional/psychological factors, and environmental barriers — usually acting **together**.
3. **Acute (transient) incontinence** — abrupt onset with an acute illness or drug, remits when the cause is corrected. **Persistent incontinence** — long-standing, unrelated to acute illness.
4. **Persistent types:** stress, urge, overflow (incomplete emptying), functional — plus **mixed**, and **DHIC** as a difficult subgroup. **Faecal incontinence** coexists in 30–50% of nursing-home patients with frequent UI.

B. Reversible Causes — the core of this answer

5. **Mnemonic DRIP**: **D**elirium · **R**estricted mobility and **R**etention · **I**nfection, **I**nflammation, **I**mpaction · **P**olyuria and **P**harmaceuticals.
6. **Delirium and acute illness** — hospital-acquired incontinence is often preventable; manage with environmental change, scheduled toileting and toilet substitutes rather than a catheter.
7. **Restricted mobility** — new immobility, restraints, bed rails, unfamiliar ward, absent call bell, walking aid out of reach.
8. **Retention with overflow** — suspect in **any** patient with sudden-onset incontinence. Precipitated by immobility, anticholinergics, opioids and faecal impaction; may also signal **acute spinal cord compression**.
9. **Infection and inflammation** — acute cystitis, atrophic vaginitis, urethritis. Treating these can restore continence.
10. **Faecal impaction** — large impactions obstruct the bladder outlet in women and trigger involuntary contractions through rectal distension; disimpaction alone may cure the incontinence.
11. **Polyuria** — hyperglycaemia, hypercalcaemia, diuretics (especially rapid loop diuretics), excess fluid or caffeine, and volume-expanded states (heart failure, venous insufficiency) causing **nocturnal polyuria**.
12. **Pharmaceuticals — memorise this list:**
    - Diuretics → polyuria, urgency
    - Anticholinergics, tricyclics, antipsychotics → retention, overflow, impaction, sedation
    - Sedative-hypnotics → sedation, delirium, immobility
    - Opioids → retention, impaction, delirium

- α-blockers → urethral relaxation (stress leak); α-agonists → retention
- Cholinesterase inhibitors → frequency and urgency
- ACE inhibitors → cough precipitating stress leak
- Calcium-channel blockers, gabapentin, pregabalin, glitazones → oedema and nocturia
- Alcohol and caffeine → polyuria, urgency, bladder irritation

C. Diagnosis

13. **Screen actively** in every geriatric assessment — three direct questions about bladder trouble, involuntary loss, and pad use.
14. **Basic evaluation:** focused history + bladder record, targeted examination, urinalysis (± culture), and **post-void residual**. Blood glucose and calcium if there is unexplained polyuria.
15. **Bladder diary** for 3 days distinguishes nocturnal polyuria from a true storage problem and quantifies leaks.
16. **Simple bedside urodynamics:** observation of voiding, and the **cough stress test** — leak with cough while supine and the bladder relatively empty suggests intrinsic sphincter deficiency.
17. **Selected further tests:** urine culture and cytology, renal function, renal ultrasound, cystourethroscopy, and formal **multichannel urodynamics** (flowmetry, cystometrogram, pressure–flow, leak-point pressure, sphincter EMG, video urodynamics).
18. **Follow the diagnostic algorithm:** basic evaluation → reversible factors found? treat → indication for referral? refer → otherwise a therapeutic trial (behavioural ± drug for stress/urge/mixed; behavioural + supportive for functional) → still incontinent and suitable? then further urological, gynaecological or urodynamic evaluation.

D. Management

19. **Treat reversible causes first**, then match therapy to type: pelvic floor exercises ± α-agonist/topical oestrogen (stress); bladder training + antimuscarinic or β3-agonist (urge); relieve obstruction, intermittent catheterisation (overflow); scheduled/prompted voiding and environmental change (functional).
20. **Faecal incontinence:** commonest cause is **faecal impaction with overflow soiling**; also laxative abuse, neurological disease, sphincter damage, diarrhoeal and colorectal disease. Manage constipation with fibre **4–6 g/day**, fluid, mobility, correct positioning, and use of the **gastrocolic reflex** after meals in an unhurried private setting. Avoid laxative overuse — it can cause an atonic "cathartic colon".

Latest Updates (2023–Present)

- **Anticholinergic burden is now a formal target.** The AGS **Beers Criteria 2023** keep oral oxybutynin and other non-selective antimuscarinics on the avoid-list for older adults; cumulative anticholinergic exposure is associated with incident dementia in large cohort studies, and deprescribing is an explicit part of incontinence care.
- **AUA/SUFU 2024** requires exclusion of reversible contributors and a documented **PVR** before advanced therapy in anyone with emptying symptoms, prior retention, enlarged prostate, neurological disease or long-standing diabetes.
- **SGLT-2 inhibitors** are now a common and often-missed iatrogenic cause of new frequency, urgency, nocturia and genital infection in older diabetics — a modern addition to the "polyuria/pharmaceuticals" list not present in older drug tables.

- **WHO ICOPE (2nd edition, 2025)** incorporates continence into intrinsic-capacity screening, positioning incontinence as a marker of declining capacity rather than an isolated urological symptom.
- **Indian context:** LASI-based analyses (2023–24) link UI in older Indians to insomnia, sarcopenia, diabetes and indoor biomass smoke — all modifiable, and all reasons to look beyond the bladder in an Indian geriatric clinic.

Current Practice Update

Issue	Textbook position	Current evidence / practice
Drug list of reversible causes	Classical list — diuretics, anticholinergics, opioids, α-agents, CCBs	Add **SGLT-2 inhibitors** and cumulative **anticholinergic burden score** as routine checks
Antimuscarinics in cognitive impairment	"Weigh benefit against risk"	Beers 2023 — **avoid** where possible; prefer β3-agonists or non-drug therapy
Asymptomatic bacteriuria	Treat before evaluating community patients; do not treat in stable nursing-home residents	Reinforced — IDSA advises **against screening or treating** asymptomatic bacteriuria in older adults, including those with chronic stable incontinence or catheters
Framing of incontinence	A geriatric syndrome	Now also an **intrinsic-capacity domain** under WHO ICOPE 2025 and a trigger for full CGA

Extra Points to Remember

- **Two mnemonics, two marks:** write **DRIP** and **DIAPPERS** together — examiners reward both.
- **The three "must-not-miss" reversible causes:** retention with overflow (may be cord compression), faecal impaction, and drug effect.
- **Numbers:** fibre 4–6 g/day for constipation; 30–50% of nursing-home patients with frequent UI also have faecal incontinence; constipation = fewer than three bowel movements per week.
- **Answer structure tip:** if the question says "including reversible causes", devote at least one-third of the answer to DRIP with the drug table — that is where the marks are.

Examiner traps — (1) Do not present incontinence as purely urological; continence needs cognition, mobility, motivation and environment. (2) Do not miss retention as the cause of "new incontinence". (3) Do not use an indwelling catheter to manage hospital-acquired incontinence. (4) Do not treat asymptomatic bacteriuria in a stable institutionalised patient. (5) Do not omit faecal incontinence when the question says "incontinence in the elderly".

Exam One-Liners

- Continence = intact lower tract + cognition + mobility + motivation + accessible toilet.
- Acute (transient) UI reverses with the cause; persistent UI does not.
- DRIP and DIAPPERS cover every reversible cause worth naming.
- Sudden new incontinence = exclude retention, and think spinal cord compression.

- Faecal impaction can cause both urinary and faecal incontinence; disimpaction may cure both.
- Basic work-up is history, examination, urinalysis, PVR — nothing more in most patients.
- Beers 2023: avoid non-selective antimuscarinics in older adults.
- SGLT-2 inhibitors are a modern iatrogenic cause of urgency and nocturia.

QUESTION 3

A 65-year-old woman presents with frequent urination, nocturia and involuntary leakage for 6 months. Discuss causes, evaluation and management. 15 MARKS

High-Yield Points

A. Framing the Case

1. **The symptom triad** — frequency (>8 voids/24 h), nocturia (≥2 voids at night) and involuntary leakage for 6 months — is **persistent incontinence with an irritative (storage) symptom profile**, i.e. most likely **urgency incontinence / overactive bladder**, commonly **mixed** with stress incontinence at this age.
2. **Age 65 with 6 months' duration** excludes a purely acute/transient picture, but reversible contributors must still be sought — they are present in a large proportion of such patients.

B. Causes to Consider

3. **Urgency incontinence / detrusor overactivity** — idiopathic, or secondary to stone, tumour, diverticulum, outflow obstruction, or CNS disease (stroke, dementia, parkinsonism, cord lesion).
4. **Stress incontinence** — pelvic floor weakness with urethral hypermobility after childbirth, prior pelvic surgery, obesity, chronic cough and oestrogen deficiency; or **intrinsic sphincter deficiency** after previous vaginal repair or bladder-neck suspension.
5. **Mixed incontinence** — the commonest single answer in an older woman.
6. **Atrophic vaginitis / urethritis** — postmenopausal oestrogen deficiency causing dysuria, frequency and urgency, and predisposing to UTI.
7. **Urinary tract infection** — must be excluded; also recurrent UTI as a marker of underlying pathology.
8. **Overflow from incomplete emptying** — large cystocele or pelvic prolapse distorting the urethra, diabetic neuropathic bladder, or drug-induced retention.
9. **Polyuria states** — uncontrolled **diabetes mellitus** (very likely in an Indian 65-year-old), hypercalcaemia, excess fluid/caffeine, diuretics.
10. **Nocturnal polyuria** — loss of the night-time vasopressin rhythm, raised ANP, heart failure, venous insufficiency with leg oedema redistributing at night, obstructive sleep apnoea.
11. **Malignancy** — new irritative symptoms with haematuria or smoking history raise the question of **bladder cancer**; pelvic mass must be excluded.
12. **Functional contributors** — arthritis, poor vision, distant or Indian-style squat toilet, night-time falls risk, and drugs (sedatives, diuretics timed at night).

C. Evaluation

13. **History:** characterise leakage (with cough/laugh vs preceded by urgency vs continuous), volume, pad use, most bothersome symptom, impact on quality of life; fluid, caffeine and alcohol intake; obstetric and surgical history; diabetes, heart failure, neurological symptoms; bowel habit; full **drug review**; and a **3-day bladder diary**.
14. **Examination:** BMI, oedema and cardiac status; abdominal palpation for a distended bladder or mass; **pelvic examination** for atrophic vaginitis, cystocele/prolapse grade and

perineal sensation; **cough stress test**; rectal examination for impaction and sphincter tone; mobility, gait and cognition; focal neurology and sacral reflexes.

15. **Bedside/basic investigations:** urinalysis and, if indicated, urine culture; **post-void residual** by ultrasound; capillary and fasting **blood glucose (mg/dL)**, HbA1c; serum **calcium (mg/dL)**, **creatinine (mg/dL)**; haemoglobin (g/dL).
16. **Interpretation:** PVR **>200 mL** → suspect obstruction or impaired contractility, arrange renal function and ultrasound ± urodynamics. Persistent haematuria without infection → **urine cytology and cystoscopy**.
17. **Refer** for gynaecological or urological/urodynamic evaluation if there is marked prolapse, ≥2 symptomatic UTIs in a year, recent pelvic surgery or irradiation, suspicion of malignancy, significant retention, or failure of an adequate therapeutic trial.

D. Management

18. **Correct reversible factors:** treat UTI, relieve constipation, control diabetes, review diuretic timing, stop or substitute offending drugs, treat heart failure and leg oedema (evening leg elevation, compression stockings).
19. **Lifestyle and conservative measures (first and always):** weight reduction; fluid target of **1.5–2 L/day of non-caffeinated fluid** with restriction in the evening; avoid caffeine, carbonated drinks and nicotine; treat chronic cough and constipation; safe night-time route to the toilet with a light and a bedside commode to prevent falls.
20. **Pelvic floor muscle training**, supervised, with biofeedback if available — the most effective behavioural intervention, benefiting both stress and urge components; add **bladder training** with progressive lengthening of the voiding interval and urge-suppression techniques.
21. **Topical vaginal oestrogen** if atrophic vaginitis is present — cream 0.5–1.0 g/day for 2 weeks then twice weekly, or an oestradiol ring 3-monthly. **Never oral oestrogen.**
22. **Drug therapy** if behavioural measures are insufficient: a **β3-agonist (mirabegron or vibegron)** is preferred in older adults; antimuscarinics (solifenacin, darifenacin, fesoterodine, trospium) are alternatives with counselling about dry mouth, constipation, glaucoma and cognitive effects. Check baseline renal function before a β3-agonist and blood pressure on treatment. Allow **4–6 weeks** before judging response.
23. **Refractory nocturia** — reassess for nocturnal polyuria and sleep apnoea first; desmopressin only in carefully selected patients with close monitoring of serum sodium (mEq/L).
24. **Refractory OAB** — intradetrusor **botulinum toxin A** (repeat not more often than 6-monthly; counsel about retention and need for self-catheterisation) or **sacral neuromodulation** / posterior tibial nerve stimulation.
25. **Predominant stress incontinence not responding to conservative care** — pessary for prolapse, urethral bulking agents, or surgery (colposuspension, autologous rectus fascial sling, mid-urethral sling) after multidisciplinary discussion; counsel about long-term mesh-related uncertainty.
26. **Review at 4–6 weeks** with a repeat bladder diary, assess symptom improvement and satisfaction, and escalate or de-escalate accordingly. Address the psychosocial impact — shame, social withdrawal and depression are common and often unspoken.

Latest Updates (2023–Present)

- **AUA/SUFU 2024** allows this patient to move directly to a β3-agonist or even to botulinum toxin if bother is high — behavioural therapy no longer has to fail first, though it should always be offered.
- **β3-agonists over antimuscarinics** is now the preferred pharmacological default in women over 65, driven by the anticholinergic–dementia signal and Beers 2023.
- **AUA/SUFU/AUGS Genitourinary Syndrome of Menopause Guideline 2025** endorses low-dose vaginal oestrogen for urogenital atrophy, recurrent UTI prevention and irritative symptoms, with a favourable safety profile.
- **Surgical caution persists:** following regulatory action in several countries on synthetic mesh, **autologous fascial slings and colposuspension** have regained ground, and bulking agents are offered when other surgery is unsuitable.
- **Indian relevance:** LASI data link UI in older Indian women with insomnia, sarcopenia and household biomass smoke; obstetric history of high parity and home delivery, plus squat-toilet dependence, are practical local determinants to elicit and address.

Current Practice Update

Issue	Textbook position	Current evidence / practice
First drug for OAB in a woman of 65	Antimuscarinic	**β3-agonist preferred**; antimuscarinic second-line with anticholinergic-burden counselling
Order of therapy	Strict stepwise ladder	Shared decision-making — entry at any tier depending on bother
Stress UI surgery	Mid-urethral synthetic sling as standard	Mesh restricted in many countries; **autologous fascial sling / colposuspension** and bulking agents prominent; MDT discussion mandated
Time to judge drug response	Up to 1–2 months for full effect	Formal review at **4–6 weeks** with a repeat bladder diary and satisfaction assessment

15-second answer skeleton: Define the symptom complex (storage/irritative, likely urge or mixed) → list causes systematically (bladder, urethra/pelvic floor, infection/atrophy, polyuria, nocturnal polyuria, neurological, malignancy, functional, drugs) → evaluation (history + diary, examination incl. pelvic and cough test, urinalysis, PVR, glucose/calcium/creatinine) → interpretation and referral triggers → management (reversible factors → lifestyle → pelvic floor and bladder training → vaginal oestrogen → β3-agonist/antimuscarinic → botulinum/ neuromodulation → surgery) → review at 4–6 weeks and address psychosocial impact.

Exam One-Liners

- Frequency + nocturia + leakage in an older woman = OAB/urgency incontinence, usually mixed with stress.
- Always exclude UTI, uncontrolled diabetes, constipation and drugs before labelling it idiopathic.
- 3-day bladder diary separates nocturnal polyuria from a storage problem.

- Cough stress test with an empty bladder in the supine position suggests intrinsic sphincter deficiency.
- PVR >200 mL changes the whole management plan — always measure it.
- Pelvic floor muscle training helps both the stress and the urge component.
- Vaginal, not oral, oestrogen for atrophic vaginitis.
- β3-agonist first in the elderly; review at 4–6 weeks.
- New irritative symptoms + haematuria + smoking = exclude bladder cancer.

QUESTION 4

Urinary incontinence in males — types, epidemiology, pathogenesis, risk factors, screening, evaluation and management. 15 MARKS

High-Yield Points

A. Epidemiology

1. **15–20% of men above 65 years** have some degree of urinary incontinence — roughly half the female rate, but rising steeply with age, frailty and institutionalisation.
2. **OAB symptoms are reported by about 40% of men aged ≥75**, most of whom also have urgency incontinence.
3. Male incontinence in nursing homes is common and men managed with chronic catheters are at **particularly high risk of symptomatic infection**.

B. Types in Men

4. **Urgency incontinence / OAB** — commonest type in older men; usually secondary to detrusor overactivity from bladder outlet obstruction, stroke, Parkinson's disease or dementia.
5. **Overflow incontinence from incomplete emptying** — the characteristically "male" type: benign prostatic obstruction, urethral stricture, or an acontractile bladder from diabetic neuropathy.
6. **Stress incontinence** — **unusual in men** and almost always iatrogenic: after transurethral surgery, radical prostatectomy or pelvic radiotherapy damaging the sphincter.
7. **Functional incontinence** — dementia, stroke, immobility, restraints, inaccessible toilet.
8. **Mixed patterns and DHIC** (detrusor overactivity with impaired contractility) are frequent in the very old male and explain why antimuscarinics can precipitate retention.
9. **Post-micturition dribble** — a distinct, benign symptom from bulbar urethral pooling, treated by urethral milking, not by drugs.

C. Pathogenesis

10. **Normal continence in the male** depends on parasympathetic (nervi erigentes, S2–S4) detrusor contraction, sympathetic (hypogastric, T11–L2) bladder relaxation and bladder-neck/urethral α-adrenergic contraction, and somatic (pudendal) external sphincter control, coordinated at the sacral micturition centre under cortical inhibition.
11. **Prostatic enlargement** raises outlet resistance → detrusor hypertrophy, collagen deposition, loss of compliance and **secondary detrusor overactivity** → urgency and frequency; later, detrusor decompensation → high residual urine and overflow.
12. **Ageing changes** — reduced bladder capacity, higher residual volume, more involuntary contractions, altered receptor profile with M3 receptors functionally dominant, and loss of nocturnal vasopressin rhythm with raised ANP causing **nocturnal polyuria**.
13. **Neurological disease:** stroke — detrusor hyperreflexia in ~68–82%, detrusor–sphincter dyssynergia in ~14%, and incontinence in the acute phase is a powerful predictor of poor outcome. Parkinson's disease — detrusor hyperreflexia in up to 79%, mimicking BPH; multiple system atrophy adds sphincter dyssynergia.

14. **Sphincter injury** after prostatic surgery or radiotherapy produces true stress incontinence with intrinsic sphincter deficiency.

D. Risk Factors

15. **Age; benign prostatic enlargement and LUTS; prostate surgery or radiotherapy; neurological disease** (stroke, Parkinson's, dementia, cord lesion, multiple sclerosis); **diabetes mellitus** (neuropathic bladder, osmotic diuresis); obesity and metabolic syndrome; immobility and frailty; constipation and faecal impaction; **polypharmacy** (anticholinergics, opioids, diuretics, sedatives, α-agonists, calcium-channel blockers, SGLT-2 inhibitors); alcohol and caffeine; chronic catheterisation.

E. Screening

16. **Case-finding is essential** — men under-report because of embarrassment. Use the three standard questions on bladder trouble, involuntary loss and pad use as part of every comprehensive geriatric assessment and in every long-term care admission.
17. **Quantify symptoms** with the **IPSS / AUA Symptom Index** (seven items, each 0–5: **mild 0–7, moderate 8–19, severe 20–35**) plus the single quality-of-life question — this is the standard screening instrument in men.

F. Evaluation

18. **Basic evaluation:** focused history with bladder diary, targeted examination including **digital rectal examination** (size, consistency, nodules, sphincter tone) and neurological assessment, **urinalysis**, and **post-void residual**.
19. **Clean urine sample** in a frequently incontinent man can be obtained through a condom catheter after cleaning the penis.
20. **Uroflowmetry** is a valuable non-invasive screen: **Qmax <10 mL/s on a voided volume >150 mL** indicates obstruction or impaired contractility.
21. **Selected tests:** serum creatinine (mg/dL) and renal ultrasound if retention or hydronephrosis is suspected; blood glucose (mg/dL) and calcium (mg/dL) for polyuria; **PSA (ng/mL)** after shared decision-making where life expectancy exceeds 10 years; urine cytology and cystoscopy for haematuria or new irritative symptoms in a smoker; **multichannel urodynamics** in neurological disease, prior failed surgery, or before considering prostatic surgery in an equivocal case.

G. Management

22. **Reverse the reversible** (DRIP), then match treatment to type.
23. **Behavioural therapy** — pelvic floor muscle training (also effective for post-prostatectomy stress leak), bladder training, timed voiding, fluid and caffeine modification, double voiding, and urethral milking for post-micturition dribble. **Combined behavioural plus drug therapy is superior to either alone in men with OAB.**
24. **Drugs:** α-blocker (tamsulosin 0.4 mg, alfuzosin 10 mg, silodosin 4 mg) for obstruction-related symptoms — watch postural hypotension and falls; add a **5-α-reductase inhibitor** if prostate volume exceeds 30–40 mL; add an antimuscarinic or a **β3-agonist** for persistent storage symptoms provided PVR is not elevated.
25. **Surgery:** TURP or laser enucleation for obstruction with retention, renal impairment, recurrent UTI, stones or gross haematuria; **artificial urinary sphincter** or male sling for post-prostatectomy stress incontinence; intradetrusor botulinum toxin or sacral neuromodulation for refractory OAB.

26. **Containment when cure is not possible:** external (condom) catheter only in a dependent man **without retention**, absorbent products, and intermittent catheterisation for chronic retention; chronic indwelling catheters only for defined indications.

Latest Updates (2023–Present)

- **Vibegron (Gemtesa) approved December 2024** for men with OAB symptoms already receiving pharmacological therapy for BPH — the first β3-agonist with this specific indication, based on the phase-3 **COURAGE (URO-901-3005)** trial in ~1100 men showing significant reduction in micturitions, urgency episodes, nocturia and urgency incontinence with low retention risk.
- **AUA/GURS/SUFU Incontinence after Prostate Treatment Guideline (2024)** standardises evaluation and management of post-prostatectomy incontinence, reaffirming the **artificial urinary sphincter** as the definitive option for significant stress leak and reserving slings for mild-to-moderate leak.
- **AUA/SUFU OAB Guideline 2024** recommends β3-agonists preferentially in older men, mandates PVR before advanced therapy in men with an enlarged prostate, and integrates frailty assessment into decision-making.
- **AUA LUTS/BPH Guideline (2023 amendment, expanded 2026)** reframes management around **bladder function preservation** and shared decision-making rather than a fixed treatment ladder, and formally includes minimally invasive surgical therapies and prostatic artery embolisation.
- **Indian context:** LASI analyses show older Indian men with type 2 diabetes carry the highest burden of incontinence among urological disorders, ahead of stones and prostate disease — making **glycaemic control an incontinence intervention** in Indian practice. NPHCE district geriatric units and AB-PMJAY (with the Ayushman Vay Vandana Card for those aged 70+) now cover prostatic surgery and continence services.

Current Practice Update

Issue	Textbook position	Current evidence / practice
Storage symptoms in men on BPH therapy	α-blocker ± antimuscarinic, with retention caution	**Vibegron licensed (2024)** for this exact population; β3-agonist preferred over antimuscarinic in the elderly
Post-prostatectomy incontinence	Brief mention; artificial sphincter for selected men	Dedicated **2024 guideline**; pelvic floor training early, sling for mild–moderate, **AUS for severe**
Behavioural vs drug therapy in men	Behavioural effective, drugs added if needed	**Combination superior to either alone** for male OAB symptoms
Frailty in treatment choice	Not formally incorporated	Clinical Frailty Scale and anticholinergic burden are now explicit decision inputs

Extra Points to Remember

- **Key contrast to write down:** in women the commonest type is stress/mixed; **in men it is urgency and overflow, with stress being almost always post-surgical.** Examiners look for this line.

- **Numbers:** 15–20% prevalence >65 y; OAB symptoms ~40% at ≥75 y; IPSS 0–7 mild / 8–19 moderate / 20–35 severe; Qmax <10 mL/s abnormal on volume >150 mL; prostate >30–40 mL justifies a 5-ARI; 5-ARI takes 3–6 months to act.
- **Mnemonic for male UI causes — "PROSTATE":** Prostatic obstruction · Radiotherapy/ Radical prostatectomy · Overactive bladder · Stricture · Tumour (bladder/prostate) · Autonomic neuropathy (diabetes) · Toxins/drugs · Environment and function.
- **Always measure PVR before an antimuscarinic in a man** — this single step prevents iatrogenic retention and is a reliable mark-earner.

Examiner traps — (1) Do not attribute all male LUTS to the prostate; stroke, Parkinson's and diabetes are common and treatable contributors. (2) Do not give an antimuscarinic without knowing the PVR. (3) Do not use a condom catheter in a man with retention. (4) Do not order PSA during an acute male UTI — it needs about 6 months to return to baseline. (5) Do not forget post-micturition dribble as a separate, drug-resistant entity.

Exam One-Liners

- 15–20% of men over 65 are incontinent; urgency and overflow dominate.
- Stress incontinence in a man is iatrogenic until proved otherwise.
- IPSS: mild 0–7, moderate 8–19, severe 20–35.
- Qmax <10 mL/s on a void of >150 mL suggests obstruction or poor contractility.
- DHIC explains why an antimuscarinic can tip an old man into retention.
- Combined behavioural + drug therapy beats either alone in male OAB.
- Vibegron (2024) is the first β3-agonist licensed for men with OAB on BPH therapy.
- Artificial urinary sphincter is the definitive treatment for severe post-prostatectomy stress incontinence.

QUESTION 5

Describe an algorithm to investigate and treat an elderly male with lower urinary tract symptoms. 15 MARKS

High-Yield Points

A. Definition and Symptom Grouping

1. **LUTS** in older men are grouped as **storage** (frequency, urgency, nocturia, urgency incontinence), **voiding** (hesitancy, weak or intermittent stream, straining, terminal dribble, incomplete emptying) and **post-micturition** (post-void dribble, sensation of incomplete emptying).
2. **LUTS ≠ BPH.** Symptoms may arise from the bladder (overactivity, underactivity), prostate, urethra, or systemic disease. Prevalence of BPH-related symptoms approaches **50%** in multinational surveys of older men.

B. Step 1 — Initial Assessment

3. **History** — symptom pattern and duration; the **most bothersome symptom**; fluid, caffeine, alcohol; nocturia pattern; and specific pointers:
   - Type 2 diabetes with nocturia and polyuria >3 L → osmotic diuresis or neuropathic bladder
   - Neurological symptoms → neurogenic bladder
   - Gross haematuria or suprapubic pain → bladder tumour or calculus
   - Urethral trauma, urethritis or instrumentation → stricture
   - Family history of BPH or prostate cancer
   - Anticholinergic or sympathomimetic drugs impairing bladder function or raising outflow resistance
4. **Quantify with IPSS/AUA-SI** (mild 0–7, moderate 8–19, severe 20–35) plus the quality-of-life question. The score measures **severity, not aetiology**.
5. **Examination** — abdominal (palpable bladder), **digital rectal examination** for prostate size, consistency, nodules and sphincter tone, plus focused neurological examination; assess cognition, mobility and general fitness for any future procedure.
6. **Bladder diary** for 3 days — separates nocturnal polyuria and excessive fluid intake from true bladder dysfunction.

C. Step 2 — Basic Investigations

7. **Urinalysis** in every patient — detects infection and haematuria. **Urine cytology** if predominantly irritative symptoms or haematuria, especially in a smoker.
8. **Post-void residual** by bladder ultrasound; **uroflowmetry** where available (Qmax <10 mL/s on a void >150 mL is abnormal).
9. **Serum creatinine (mg/dL)** — not required routinely by AUA guidance in uncomplicated LUTS, but mandatory if there is retention, suspected obstructive uropathy, or planned surgery. **Renal ultrasound** if creatinine is raised or hydronephrosis suspected.
10. **PSA (ng/mL)** after shared decision-making in men with a life expectancy over 10 years; remember PSA is not cancer-specific, rises with BPH, prostatitis and instrumentation, and **25% of prostate cancers have a PSA ≤4.0 ng/mL**.

D. Step 3 — Identify "Complicated" LUTS Needing Referral

11. **Red flags for urological referral:** acute or chronic urinary retention, renal insufficiency due to obstruction, recurrent UTI, bladder stones, gross haematuria, suspicious DRE or raised PSA, previous pelvic surgery or radiotherapy, neurological disease, urethral stricture, or failure of medical therapy.
12. **Advanced tests in this group:** cystoscopy, upper-tract imaging, and **multichannel urodynamics/pressure-flow study** to distinguish true bladder outlet obstruction from detrusor underactivity before committing to surgery.

E. Step 4 — Treatment Pathway

13. **Mild symptoms (IPSS <7) or minimal bother → watchful waiting with lifestyle advice:** evening fluid restriction, avoid caffeine and spicy food, review diuretics and their timing, timed/organised voiding, pelvic floor exercises, treat constipation, double voiding — with periodic review.
14. **Moderate to severe symptoms with bother → medical therapy:**
    - **α-blocker** (tamsulosin, alfuzosin, silodosin, terazosin, doxazosin) — fastest symptomatic relief within days to weeks; does **not** alter disease progression. Side effects in ~5–9%: dizziness, postural hypotension, asthenia, rhinitis, retrograde ejaculation.
    - **5-α-reductase inhibitor** (finasteride, dutasteride) if the prostate is enlarged (>30–40 mL) or PSA is raised — shrinks the gland by up to 30%, takes **3–6 months**, and reduces the risk of acute retention and surgery.
    - **Combination α-blocker + 5-ARI** for prostate volume >40 mL — the **MTOPS** trial showed a 66% reduction in acute urinary retention versus 39% with α-blockade alone and 34% with 5-ARI alone. The α-blocker may be stopped after 6–9 months and restarted if symptoms recur.
    - **Antimuscarinic or β3-agonist** added for persistent storage symptoms **only when PVR is not elevated**; avoid in men with a history of retention or cognitive impairment.
    - **Phytotherapy is not recommended** by AUA guidance.
15. **Minimally invasive therapy** for moderate symptoms with a small-to-moderate gland in a man wishing to avoid major surgery — transurethral microwave thermotherapy and related energy-based office procedures; higher retreatment rates than TURP, and several weeks before improvement.
16. **Surgery — indications:** renal insufficiency from BPH, recurrent UTI, gross haematuria due to BPH, bladder stones, refractory retention, or LUTS refractory to medical therapy.
17. **TURP remains the reference standard** for glands under 80 mL, with immediate symptom and flow improvement; transurethral incision for small glands; **laser enucleation (HoLEP/ThuLEP)** and open or simple robotic prostatectomy for very large glands.
18. **Ongoing review:** reassess IPSS, PVR, renal function and adverse effects; treat comorbid contributors (heart failure, diabetes, sleep apnoea, constipation) and, in the frail, always balance symptom benefit against hypotension, falls and delirium risk.

Algorithm at a Glance

Step	Action	Decision
1. Assess	History, IPSS + QoL, DRE, bladder diary, examination	Storage vs voiding vs mixed pattern

2. Test	Urinalysis, PVR, ± uroflowmetry, ± creatinine, ± PSA	Uncomplicated vs complicated
3. Triage	Red flags present? (retention, renal failure, recurrent UTI, stones, haematuria, abnormal DRE/PSA, neurological disease)	Yes → urology referral, cystoscopy, imaging, urodynamics
4a. Mild	IPSS <7 or low bother	Watchful waiting + lifestyle
4b. Moderate/ severe	α-blocker → add 5-ARI if gland >40 mL → add antimuscarinic/β3-agonist if storage symptoms persist and PVR normal	Review at 4–12 weeks
5. Failure	Minimally invasive therapy or surgery (TURP / laser enucleation / PAE in selected men)	Choose by gland size, comorbidity and patient preference

Latest Updates (2023–Present)

- **AUA LUTS/BPH Guideline Amendment 2023** (expanded into a three-part guideline in 2026) revised statements on combination therapy, photoselective vaporisation (PVP), **water vapour thermal therapy**, laser enucleation and — importantly — formally admitted **prostatic artery embolisation (PAE)** into the guideline for selected men.
- The 2026 guideline reframes the whole pathway around **bladder function preservation and shared decision-making**, rather than a rigid escalation ladder, and stresses that LUTS/BPH is multifactorial with both storage and emptying components.
- **Urodynamics before prostate surgery is not mandatory** — the UPSTREAM randomised trial (26 hospitals) showed a non-invasive pathway is non-inferior to routine urodynamics for symptom outcomes, supporting selective rather than routine use.
- **Minimally invasive surgical therapies (MISTs)** — water vapour thermal therapy, prostatic urethral lift, temporary implantable devices and PAE — have expanded the options for frail older men unfit for anaesthesia, with the trade-off of higher retreatment rates.
- **Metabolic drivers recognised:** obesity, insulin resistance and chronic prostatic inflammation are now emphasised as modifiable contributors to LUTS/BPH progression — directly relevant to the Indian metabolic-syndrome phenotype.
- **India:** TURP and laser prostatectomy are covered under AB-PMJAY, with the **Ayushman Vay Vandana Card** extending cover to all citizens aged 70 and above irrespective of income since 2024.

Current Practice Update

Issue	Textbook position	Current evidence / practice
Framework	Four groups: watchful waiting, medical, minimally invasive, surgery	Retained, but driven by **shared decision-making** and bladder preservation, not a fixed ladder
Prostatic artery embolisation	Not included	**In the guideline** since the 2023 amendment for selected patients
TUNA	Described as an option	**Removed** from AUA surgical recommendations

Urodynamics before surgery	Advised in equivocal cases	UPSTREAM — routine urodynamics **not required**; use selectively
Large glands	Open prostatectomy	**HoLEP/ThuLEP** preferred where expertise exists — lower morbidity, size-independent

15-second answer skeleton: Define and group LUTS (storage/voiding/post-micturition) → LUTS ≠ BPH → Step 1 assess (history, IPSS+QoL, DRE, diary) → Step 2 basic tests (urinalysis, PVR, uroflow, ± creatinine, ± PSA) → Step 3 red flags → refer for cystoscopy/imaging/urodynamics → Step 4 treat: mild = watchful waiting + lifestyle; moderate/severe = α-blocker → 5-ARI if large gland → combination (MTOPS) → antimuscarinic/β3 if storage symptoms and PVR normal → Step 5 MIST or surgery (TURP standard; HoLEP for large; PAE selected) → review and manage comorbidity.

Exam One-Liners

- LUTS = storage + voiding + post-micturition symptoms; not synonymous with BPH.
- IPSS grades severity, never aetiology.
- Urinalysis and PVR are the two investigations every man with LUTS needs.
- Routine serum creatinine is not required in uncomplicated LUTS; it is mandatory if retention or obstruction is suspected.
- MTOPS: combination therapy cut acute retention by 66% versus 39% (α-blocker) and 34% (5-ARI).
- Surgery indications: retention, renal failure, recurrent UTI, stones, gross haematuria, refractory symptoms.
- TURP is standard for glands <80 mL; laser enucleation for larger glands.
- Routine pre-operative urodynamics is no longer required (UPSTREAM).

QUESTION 6

Medical management of benign prostatic hypertrophy. 7 MARKS

High-Yield Points

1. **Aim:** relieve bothersome symptoms, prevent progression (acute retention, need for surgery) and preserve bladder and renal function — treatment is guided by symptom severity, degree of bother, risk of progression and patient preference.
2. **Who to treat medically:** men with moderate to severe symptoms (**IPSS ≥8**) who are bothered. IPSS <7 with little bother → watchful waiting plus lifestyle measures (evening fluid restriction, avoid caffeine, review diuretics, timed voiding, pelvic floor exercises, treat constipation).
3. **α-adrenergic blockers — first-line.** The bladder neck and prostatic urethra are rich in α_1-receptors; blockade relaxes smooth muscle and lowers prostatic urethral pressure. **Alfuzosin 10 mg, tamsulosin 0.4 mg, silodosin 4 mg, terazosin, doxazosin.** Onset within days to weeks; **they do not alter the natural history**. Adverse effects in 5–9%: dizziness, headache, asthenia, **postural hypotension and falls**, rhinitis, retrograde ejaculation. Uroselective agents (tamsulosin, silodosin, alfuzosin) are preferred in the elderly and in those on antihypertensives; warn the ophthalmologist about **intraoperative floppy iris syndrome** before cataract surgery.
4. **5-α-reductase inhibitors — for the enlarged gland. Finasteride 5 mg, dutasteride 0.5 mg** block conversion of testosterone to dihydrotestosterone, reducing prostate volume by up to **30%**. Best in glands **>30–40 mL** or PSA-defined enlargement. Full effect takes **3–6 months**. They **reduce acute urinary retention and the need for surgery**. Side effects are mainly sexual — reduced libido, erectile and ejaculatory dysfunction, gynaecomastia. **They halve serum PSA — double the measured value when interpreting it.**
5. **Combination therapy (α-blocker + 5-ARI)** is appropriate when the prostate exceeds 40 mL. **MTOPS**: 66% reduction in acute retention with combination versus 39% (α-blocker) and 34% (5-ARI) alone; **CombAT** confirmed superiority of dutasteride + tamsulosin for symptom and progression outcomes. The α-blocker may be withdrawn after **6–9 months** and restarted if symptoms recur.
6. **Anticholinergics / β3-agonists** may be added for persistent storage symptoms (urgency, frequency, nocturia) in men **without an elevated post-void residual**. Avoid in men with prior retention or cognitive impairment — anticholinergics increase delirium risk and can precipitate retention.
7. **PDE-5 inhibitor (tadalafil 5 mg daily)** improves LUTS and is particularly useful when erectile dysfunction coexists; do not combine with nitrates, and use α-blockers cautiously alongside because of additive hypotension.
8. **Desmopressin** may be considered for troublesome nocturnal polyuria in carefully selected men, with close monitoring of serum sodium (mEq/L) — hyponatraemia is common in older adults.
9. **Phytotherapy (saw palmetto, Pygeum, beta-sitosterol)** is popular and generally well tolerated, but **AUA guidance does not recommend dietary supplements or combination phytotherapeutic agents** for LUTS/BPH.

10. **Failure of medical therapy, or complicated BPH** (renal insufficiency, recurrent UTI, bladder stones, gross haematuria, refractory retention) is an indication for minimally invasive therapy or surgery.

Latest Updates (2023–Present) — Concise

- **Vibegron (β3-agonist) FDA-approved December 2024** for men with OAB symptoms already on pharmacological BPH therapy (COURAGE/URO-901-3005 trial) — the safest current way to add storage-symptom control to an α-blocker in an older man.
- **AUA LUTS/BPH Guideline 2023 amendment and 2026 update** shift from a fixed ladder to **shared decision-making with bladder-function preservation**, revise combination-therapy statements, and reaffirm that phytotherapy is not recommended.
- **5-ARI safety signal:** large observational data show an **increased risk of depression** (though not of suicide) in men on 5-α-reductase inhibitors — counsel and monitor, particularly in older men with prior mood disorder.

Current Practice Update

Point	Textbook	Current practice
Storage symptoms on α-blocker	Add anticholinergic cautiously	**β3-agonist (vibegron) now licensed** and preferred in the elderly
Tadalafil	Minimal emphasis	Established option, especially with coexisting erectile dysfunction
5-ARI counselling	Sexual side effects	Add **depression risk** and the need to double PSA values

Extra Points to Remember (High-Yield)

- **Mnemonic — "A-5-C-A-P": A**lpha-blocker · **5**-ARI · **C**ombination · **A**nticholinergic/β3 · **P**DE-5 inhibitor.
- **Numerical anchors:** IPSS ≥8 to treat · gland >30–40 mL for 5-ARI · 30% volume reduction · 3–6 months to act · PSA halved (double it) · MTOPS 66/39/34% · α-blocker withdrawal after 6–9 months · adverse effects in 5–9%.
- **The single commonest exam slip:** forgetting that 5-ARIs halve PSA. State it explicitly.

Examiner traps — (1) α-blockers relieve symptoms but do **not** prevent progression; only 5-ARIs do. (2) Do not add an anticholinergic without checking PVR. (3) Do not recommend phytotherapy as guideline-supported. (4) Remember floppy iris syndrome before cataract surgery. (5) Watch postural hypotension and falls when starting an α-blocker in a frail elder.

Exam One-Liners

- α-blocker = fast symptom relief; 5-ARI = shrinks gland and prevents progression.
- 5-ARI needs a gland >30–40 mL, takes 3–6 months and halves PSA.
- MTOPS: combination cut acute retention by 66%.
- Add antimuscarinic or β3-agonist for storage symptoms only if PVR is normal.
- Tadalafil 5 mg daily helps LUTS plus erectile dysfunction.

- Phytotherapy is not recommended by AUA guidance.

QUESTION 7

Overactive bladder. 7 MARKS

High-Yield Points

1. **Definition:** a **symptom syndrome** whose hallmark is **urinary urgency**, usually with frequency (>8 voids/24 h) and nocturia, **with or without urgency incontinence**, in the absence of infection or other obvious pathology. OAB "wet" = with incontinence; OAB "dry" = without.
2. **Prevalence:** about **30% of women and 40% of men aged ≥75** report OAB symptoms; most of the women also have urgency incontinence. Population studies give ranges of 7–27% in men and 9–43% in women, rising with age.
3. **Pathophysiology:** usually **detrusor overactivity** — involuntary detrusor contractions during filling. Contributory mechanisms are myogenic (patchy denervation, increased spontaneous activity), neurogenic (loss of cortical inhibition in stroke, dementia, parkinsonism), and urothelial/afferent hypersensitivity. The functionally important receptor is the **M3 muscarinic receptor**; bladder relaxation is mediated by **β3-adrenoceptors**.
4. **Secondary causes to exclude:** UTI, bladder stone, tumour or diverticulum, bladder outlet obstruction, atrophic vaginitis, faecal impaction, poorly compliant bladder after radiotherapy or interstitial cystitis, diabetes, heart failure, and drugs.
5. **DHIC** — detrusor hyperactivity with impaired contractility: involuntary contractions but emptying of less than one-third of bladder volume. These patients strain to void, may not have typical urgency symptoms, and are at high risk of retention with antimuscarinics.
6. **Evaluation:** history, **bladder diary**, targeted examination (including pelvic examination in women and DRE in men), **urinalysis**, and **post-void residual** where there are emptying symptoms, prior retention, an enlarged prostate, neurological disease, previous incontinence or prostate surgery, or long-standing diabetes. Urodynamics is **not** routine.
7. **Behavioural therapy (foundation):** education, fluid and caffeine modification, weight loss, **bladder training** with timed voiding and progressive interval lengthening, urge-suppression techniques, and **pelvic floor muscle training** with biofeedback. In institutional settings, prompted voiding and habit training.
8. **Drug therapy: β3-agonists** (mirabegron 25–50 mg, vibegron 75 mg) — preferred in older adults; check renal function and monitor blood pressure. **Antimuscarinics** (solifenacin, darifenacin, fesoterodine, tolterodine, trospium, oxybutynin) — effective but limited by dry mouth, constipation, blurred vision, raised intraocular pressure, and **cognitive impairment and delirium**. Trospium and darifenacin have less CNS penetration. Maximum effect may take 1–2 months; if one agent fails, another in the class may still work.
9. **Refractory OAB:** intradetrusor **botulinum toxin A** (chemodenervation, increases capacity, lowers detrusor pressure; repeat not more often than 6-monthly; risk of retention and need for self-catheterisation), **sacral neuromodulation (S3)**, and **posterior tibial nerve stimulation**.
10. **Supportive measures throughout:** pads, liners, barrier creams, external catheters and absorbent washable underwear should be discussed with all patients who leak, together with night-time safety measures to prevent falls.

Latest Updates (2023–Present) — Concise

- **AUA/SUFU Idiopathic OAB Guideline (2024)** abolished the rigid first/second/third-line ladder in favour of **shared decision-making**, mandated assessment of frailty (Clinical Frailty Scale) and anticholinergic burden, and made patient-reported outcomes central; it also formally recommends discussing containment products with everyone who has urgency incontinence.
- **β3-agonists are now preferred over antimuscarinics in older and cognitively vulnerable adults**, reflecting the cumulative anticholinergic–dementia association and AGS Beers 2023.
- **Vibegron approved (December 2024)** for men with OAB symptoms receiving pharmacological therapy for BPH — the COURAGE trial (~1100 men) showed reduced micturitions, urgency episodes, nocturia and urgency incontinence.

Current Practice Update

Point	Textbook	Current practice
Treatment sequence	Behavioural → antimuscarinic → invasive	**Shared decision-making**; any tier can be entered directly
Drug class of choice in the elderly	Antimuscarinics dominate the tables	**β3-agonists preferred**; antimuscarinics second-line with burden counselling
Men with BPH and OAB	α-blocker ± antimuscarinic	Vibegron licensed for this exact group

Exam One-Liners

- OAB = urgency ± frequency ± nocturia, with or without incontinence; urgency is the hallmark.
- ~30% of women and ~40% of men aged ≥75 have OAB symptoms.
- M3 receptors mediate contraction; β3 receptors mediate relaxation.
- DHIC is OAB with poor emptying — antimuscarinics can cause retention.
- Urodynamics is not needed to diagnose uncomplicated OAB.
- β3-agonist first in the elderly; botulinum toxin and sacral neuromodulation for refractory cases.

QUESTION 8

Bladder retraining protocol. 7 MARKS

High-Yield Points

1. **Objective:** to **restore a normal pattern of voiding and continence after removal of an indwelling catheter**, or in patients recovering from over-distension injury, acute retention, or post-stroke voiding dysfunction.
2. **Distinguish the terms. Bladder retraining** = progressive lengthening or shortening of the inter-voiding interval, with intermittent catheterisation where retention persists. **Bladder training** = education, bladder records, pelvic floor and other behavioural techniques for stress and urge incontinence. Both are **patient-dependent** and require adequate cognition, physical function and motivation.
3. **Step 1 — Remove the indwelling catheter.** Clamping the catheter before removal is **not necessary** and is not recommended.
4. **Step 2 — Treat urinary tract infection** if present.
5. **Step 3 — Start a toileting schedule:** on waking; **every 2 hours during the day and evening**; before getting into bed; and **every 4 hours at night**.
6. **Step 4 — Monitor with a bladder record**, documenting: frequency, timing and amount of continent voids; frequency, timing and amount of incontinence episodes; fluid intake pattern; and post-void catheter (or ultrasound) residual volume.
7. **Step 5 — If the patient is having difficulty voiding** (complete retention, or very low output such as 240 mL in 8 hours despite adequate intake):
   - Perform bladder ultrasound or in-and-out catheterisation **every 6–8 hours**, recording the volume, until residuals fall to **≤200 mL**.
   - Teach **triggering techniques** — running water, stroking the inner thigh, suprapubic tapping.
   - Teach **complete-emptying techniques** — bending forward, suprapubic pressure, **double voiding**.
   - If high residuals persist beyond **1–2 weeks**, consider urodynamic evaluation.
8. **Step 6 — If the patient is voiding too frequently** (more often than 2-hourly):
   - Check post-void residual to confirm complete emptying.
   - Encourage the patient to **delay voiding as long as possible**, with emptying techniques and pelvic floor exercises.
   - If frequency, nocturia, urgency or incontinence persists — rule out reversible causes (UTI, drug effect, hyperglycaemia, heart failure) and consider further evaluation for other pathology.
9. **Duration and referral:** a patient still having voiding difficulty after **1–2 weeks** of the protocol should be re-examined for reversible causes and referred for urological assessment to exclude correctable lower genitourinary pathology.
10. **Value:** this protocol should enable removal of **most indwelling catheters** in acute hospitals and many in long-term care, thereby reducing catheter-associated infection, bladder stones, urethral trauma and immobility.

Latest Updates (2023–Present) — Concise

- **SHEA/IDSA/APIC 2022 CAUTI Compendium (published 2023)** makes structured **catheter removal protocols with a trial of void**, including nurse-driven and automatic stop-orders, an **essential practice** — bladder retraining is therefore now an infection-prevention intervention, not merely a rehabilitation one.
- **Portable bladder ultrasound has replaced routine in–out catheterisation** for residual measurement during retraining, avoiding repeated instrumentation and its infection risk.
- **AUA/SUFU 2024** reinforces that behavioural and bladder-training programmes remain foundational and should be offered to all patients, including those proceeding directly to drug or advanced therapy.

Current Practice Update

Point	Textbook	Current practice
Residual measurement	Bladder ultrasound or in–out catheterisation	**Ultrasound preferred**; avoid repeated catheterisation
Catheter removal	Part of a bladder retraining protocol	Also an **essential CAUTI-prevention practice** with nurse-driven removal and stop-orders

Exam One-Liners

- Objective: restore normal voiding and continence after catheter removal.
- Do not clamp the catheter before removal.
- Toilet on waking, 2-hourly by day, before bed, 4-hourly at night.
- Catheterise or scan 6–8 hourly until residuals are ≤200 mL.
- Trigger techniques: running water, inner-thigh stroking, suprapubic tapping.
- Emptying techniques: bending forward, suprapubic pressure, double voiding.
- Persistent difficulty beyond 1–2 weeks → urodynamics and urology referral.

QUESTION 9

Behavioural intervention in urinary incontinence. 7 MARKS

High-Yield Points

1. **Why first-line:** behavioural interventions are **non-invasive, free of drug toxicity, and non-specific** — patients with stress and with urgency incontinence respond about equally well — and are therefore recommended by guidelines as the initial approach for most patients.
2. **The fundamental division:**
   - **Patient-dependent procedures** — need adequate cognition, physical function, learning ability and motivation; the goal is to **restore normal voiding and continence**.
   - **Caregiver-dependent procedures** — for functionally disabled patients; the goal is only to **keep the patient and the environment dry**.
3. **All patient-dependent methods rely on continuous self-monitoring** with a bladder record; caregiver-dependent methods use an institutional bladder-and-bowel monitoring chart.

Procedure	What it is	Types of UI	Comments
Patient-dependent			
Pelvic floor (Kegel) exercises	Repetitive contraction and relaxation of pelvic floor muscles	Stress and urge	**Greatest benefit of all behavioural measures**; biofeedback helps teaching; needs function and motivation
Bladder training	Education + bladder records + pelvic floor and other behavioural techniques	Stress and urge	Needs a trained therapist and a motivated, cognitively intact patient
Bladder retraining	Progressive lengthening or shortening of the voiding interval, with intermittent catheterisation in those recovering from over-distension	Acute — post-catheter, post-stroke, urge or overflow	Goal is to restore a normal voiding pattern
Caregiver-dependent			
Scheduled toileting	Routine toileting at fixed intervals — usually 2-hourly by day, 4-hourly at night	Urge and functional	Prevents wetting; usable in cognitive or physical impairment; needs staff availability
Habit training	Variable toileting schedule tailored to the patient's own voiding pattern	Urge and functional	Requires a monitoring record to define the pattern

Prompted voiding	Offer toileting 2-hourly by day; toilet on request; social reinforcement; routine fluid offering; individualise night-time toileting	Urge, stress, mixed, functional	**Best-studied**; 25–40% of nursing-home residents respond and can be identified by a **3-day trial**

4. **Prompted voiding protocol (assessment phase):** contact the resident **hourly from 7 am to 7 pm for 2–3 days**, then 2-hourly for 2–3 days; focus attention on voiding by asking whether they are wet or dry; check for wetness, record it and give feedback on whether the answer was correct; and whether wet or dry, offer the toilet or urinal.
5. **Adjunctive techniques:** to prompt voiding — running tap water, stroking the inner thigh, suprapubic tapping; to complete emptying — bending forward after voiding, suprapubic pressure, double voiding.
6. **Night-time toileting must be individualised** — prompted voiding at night disrupts sleep; many functionally dependent patients are better managed with pads at night, provided sleep is undisturbed and the skin remains intact.
7. **Success depends on the caregivers, not the patient.** The knowledge, motivation, staffing and administrative support of the institution determine whether prompted voiding is sustained; quality-improvement methods based on statistical process control help maintain it.
8. **Combine with supportive measures:** education, environmental modification (accessible toilet, good lighting, raised seat, commode at the bedside), appropriate toilet substitutes, review of diuretic timing and fluid pattern, and good skin care.
9. **Caveats about pads and garments:** they are a **non-specific** treatment, should not be the first response before a diagnostic evaluation, and should never be used for convenience — many patients are curable and some have serious underlying disease.
10. **Evidence base:** behavioural therapy alone is effective in the geriatric population, and **combined behavioural plus drug therapy is superior to either alone** for overactive bladder symptoms, including in men.

Latest Updates (2023–Present) — Concise

- **AUA/SUFU 2024** keeps behavioural therapy as the foundation of OAB care but no longer requires it to fail before advanced therapy; it should be offered **alongside** any other treatment.
- **Supervised pelvic floor muscle training** retains the strongest evidence for stress and mixed incontinence in women — roughly an eight-fold higher likelihood of cure or improvement than no treatment in Cochrane-level evidence.
- **Digital and tele-rehabilitation delivery** of pelvic floor training and bladder diaries has expanded since 2023, improving access for homebound and rural older adults — directly relevant to home-based geriatric care in India under NPHCE.

Current Practice Update

Point	Textbook	Current practice
Position in the pathway	Initial approach before drugs	Foundation, but offered **with** rather than necessarily before other therapy
Delivery	Clinic-based, therapist-led	

		Supervised programmes plus **tele-rehabilitation and app-based diaries**

Exam One-Liners

- Patient-dependent methods restore continence; caregiver-dependent methods keep the patient dry.
- Pelvic floor muscle exercises give the greatest benefit of all behavioural interventions.
- Prompted voiding is the best studied; 25–40% of nursing-home residents respond; a 3-day trial identifies them.
- Scheduled toileting = fixed interval; habit training = tailored interval.
- Success depends on caregiver motivation and staffing, not on the patient's function.
- Pads are never the first response to incontinence.
- Behavioural + drug therapy beats either alone.

QUESTION 10

Uroflowmetry. 7 MARKS

High-Yield Points

1. **Definition:** uroflowmetry (urine flowmetry) is a **non-invasive urodynamic test** that measures the rate of urine flow over time during a spontaneous void, recorded by a uroflowmeter as a flow-versus-time curve.
2. **Principle:** urine flows when detrusor pressure exceeds urethral resistance. Flow therefore reflects the **interaction of detrusor contractility and outlet resistance** — it cannot separate the two by itself.
3. **Parameters measured: maximum (peak) flow rate — Qmax**, average flow rate, voided volume, time to peak flow, total voiding time, and the shape of the curve.
4. **Key interpretation in older men:** a **Qmax below 10 mL/s on an adequate voided volume of more than 150 mL** suggests either **bladder outlet obstruction** or **impaired detrusor contractility**. A voided volume under 150 mL makes the test uninterpretable.
5. **Curve patterns:** a normal trace is a smooth bell-shaped curve; a **flat, low, prolonged plateau** suggests obstruction (classically urethral stricture); an **intermittent, fluctuating** trace suggests abdominal straining or detrusor–sphincter dyssynergia; a low curve with high residual suggests detrusor underactivity.
6. **Clinical uses:** screening older men with LUTS; assessing severity and monitoring response to medical therapy for BPH; pre-operative assessment before prostatic surgery; evaluating suspected urethral stricture; and assessing voiding function during bladder retraining.
7. **Always interpret with the post-void residual.** Low flow with a high PVR indicates significant obstruction or a poorly contractile bladder; low flow with a low PVR is usually less significant. The pair together is the standard non-invasive assessment.
8. **Limitations:** it is a screening test, not a diagnostic one — it cannot distinguish obstruction from detrusor underactivity, which requires a **pressure-flow (multichannel urodynamic) study**. Results vary between voids, are affected by anxiety and by voided volume, and uroflowmeters, though inexpensive, are uncommon outside urology practices.
9. **Practical points:** the patient should attend with a comfortably full bladder; at least two recordings improve reliability; the test should be performed in privacy in the patient's usual voiding position; artefacts from straining or from the stream striking the funnel edge should be recognised.
10. **Place in geriatric practice:** it is a useful, non-invasive, low-risk bedside adjunct in frail older men in whom invasive urodynamics is undesirable, and it forms part of the recommended evaluation when post-void residual is elevated.

Latest Updates (2023–Present) — Concise

- **Non-invasive uroflow is explicitly endorsed** in the AUA/SUFU OAB Guideline 2024 as the next step when PVR is elevated, before proceeding to invasive urodynamics or cystoscopy.
- **Routine pre-operative multichannel urodynamics is no longer required** before prostate surgery — the UPSTREAM randomised trial across 26 hospitals showed a non-

invasive pathway (symptom score, flow rate, PVR) was non-inferior for symptom outcomes, strengthening the role of uroflowmetry.

- **Home and smartphone-based uroflowmetry** (sound-based and portable devices) has emerged since 2023, improving reliability by averaging multiple domiciliary voids and reducing clinic-related artefact — particularly attractive for frail and rural Indian patients.

Current Practice Update

Point	Textbook	Current practice
Availability	Uroflowmeters rare outside urology practices	**Portable and smartphone-based devices** extend access, including home testing
Role before surgery	Adjunct; urodynamics often performed	Non-invasive pathway (uroflow + PVR) is **non-inferior** — urodynamics used selectively

Exam One-Liners

- Uroflowmetry is non-invasive and measures flow rate against time.
- Qmax <10 mL/s on a void >150 mL is abnormal in older men.
- Voided volume <150 mL makes the test uninterpretable.
- Flat plateau = obstruction; intermittent trace = straining or dyssynergia.
- Always pair the flow rate with a post-void residual.
- It cannot distinguish obstruction from detrusor underactivity — that needs a pressure-flow study.

QUESTION 11

Prostate specific antigen. 7 MARKS

High-Yield Points

1. **Nature:** PSA is a **serine protease (kallikrein-3)** produced by prostatic epithelial cells; its physiological role is to liquefy semen. It is **organ-specific but not cancer-specific**.
2. **Reference value:** the widely used cut-off is **4.0 ng/mL**. However, **about 25% of men with prostate cancer have a PSA of 4.0 ng/mL or less**, and PSA specificity is lower in men with obstructive symptoms than in asymptomatic men.
3. **Causes of a raised PSA other than cancer:** benign prostatic hyperplasia, prostatitis and male urinary tract infection, acute retention, catheterisation and instrumentation, prostate biopsy, digital rectal examination and prostatic massage, ejaculation, and vigorous cycling.
4. **Causes of a falsely low PSA: 5-α-reductase inhibitors halve the value — double the measured PSA** for interpretation; also obesity (haemodilution) and some herbal preparations.
5. **Refinements to improve specificity:** PSA density (PSA ÷ prostate volume), age-specific reference ranges, PSA velocity, free-to-total PSA ratio, and PSA doubling time (a doubling time <10 months indicates aggressive non-metastatic castration-resistant disease).
6. **Role in BPH:** PSA measurement remains recommended in the evaluation of LUTS by AUA guidance, and **serum PSA is a stronger predictor of future prostate growth than age or baseline prostate volume**, making it a useful predictor of acute urinary retention and of who will benefit from a 5-α-reductase inhibitor.
7. **Role in cancer:** used for detection (with DRE and imaging), risk stratification, monitoring after radical treatment (biochemical recurrence), and monitoring response in advanced disease.
8. **Screening in older adults — the key geriatric point:** guidance applies to men with a **life expectancy of more than 10 years**. Screening should follow **shared decision-making**, weighing over-diagnosis, over-treatment and biopsy complications against a modest mortality benefit; it is generally not appropriate in frail elders or those with limited life expectancy.
9. **Do not measure PSA during a male urinary tract infection** — the value is unreliable and takes about **six months** to return to baseline after infection.
10. **Indian context:** report PSA in **ng/mL**. There is no organised national prostate cancer screening programme in India; opportunistic testing without counselling risks over-diagnosis, and prostate cancer often presents late with bone metastases and obstructive uropathy in Indian practice.

Latest Updates (2023–Present) — Concise

- **AUA/SUO Early Detection of Prostate Cancer Guideline (2023, updated 2026)** anchors screening in shared decision-making and integrates **secondary biomarkers and prostate MRI before biopsy** to reduce unnecessary biopsies and detection of indolent disease.
- **The Stockholm3 multi-analyte risk test**, in the STHLM3 and STHLM3-MRI randomised screening studies, has shown greater clinical net benefit than PSA alone —

fewer false negatives, fewer biopsies and less over-diagnosis, with 9-year outcome data (2025) confirming improved detection of aggressive cancers.

- **MRI-first pathways** with targeted biopsy are now standard where available, substantially reducing detection of clinically insignificant (Grade Group 1) cancer while maintaining detection of significant disease.

Current Practice Update

Point	Textbook	Current practice
Diagnostic pathway	Raised PSA → systematic biopsy	**PSA → risk calculator / biomarker → MRI → targeted biopsy**
Screening decision	Controversial; life expectancy >10 years	Unchanged in principle, but formalised as **shared decision-making** with biomarker and MRI refinement
Beyond total PSA	Free/total ratio, density, velocity	Add **multi-analyte tests such as Stockholm3** and MRI-based risk stratification

Exam One-Liners

- PSA is kallikrein-3 — organ-specific, not cancer-specific.
- Cut-off 4.0 ng/mL, but 25% of prostate cancers have a PSA at or below this.
- 5-α-reductase inhibitors halve PSA — double the value.
- Do not check PSA during a male UTI; allow six months for recovery.
- PSA predicts prostate growth and acute retention better than age or volume.
- Screening only where life expectancy exceeds 10 years, after shared decision-making.
- Modern pathway: PSA → biomarker/MRI → targeted biopsy.

QUESTION 12

Obstructive uropathy — clinical features, investigation and treatment. 15 MARKS

High-Yield Points

A. Definitions and Importance

1. **Obstructive uropathy** is structural or functional obstruction to urine flow anywhere from the renal calyces to the external urethral meatus. When it causes renal parenchymal damage it is termed **obstructive nephropathy**; dilatation of the collecting system is **hydronephrosis**.
2. **Geriatric significance:** it is one of the most important and **potentially reversible** causes of renal failure in old age, and is the classic **post-renal cause of acute kidney injury** alongside stones, tumour and stricture.
3. **The central geriatric trap:** prostatic enlargement produces a **slow, silent obstruction** that gradually reduces kidney function and is often **not recognised until it is too late — largely because the patient becomes polyuric rather than oliguric**. By the time obstruction is diagnosed the damage may be irreversible, and renal function recovers only partially even after relief.
4. **It also drives infection:** the pathogenesis of pyelonephritis in older adults is strongly related to obstructive uropathy, and prostatic hypertrophy with obstruction predisposes older men to urinary tract infection.

B. Causes

5. **Lower tract (commonest in the elderly):** benign prostatic hyperplasia, prostate carcinoma, urethral stricture, bladder neck stenosis, bladder calculi, blocked indwelling catheter, phimosis or meatal stenosis, and severe pelvic organ prolapse or cystocele in women.
6. **Upper tract:** renal or ureteric calculi, urothelial tumours, extrinsic compression by pelvic or retroperitoneal malignancy (cervical, ovarian, colorectal, lymphoma), retroperitoneal fibrosis, and post-radiotherapy or post-surgical ureteric stricture.
7. **Functional (neurogenic) obstruction:** detrusor–sphincter dyssynergia in suprasacral cord lesions and multiple sclerosis; acontractile bladder in diabetic autonomic neuropathy; and **drug-induced retention** (anticholinergics, opioids, tricyclics, antipsychotics, α-agonists, antihistamines).
8. **Faecal impaction** is a common, easily reversible precipitant of outlet obstruction in frail older patients.

C. Clinical Features

9. **Acute lower tract obstruction (acute urinary retention):** sudden inability to pass urine, severe suprapubic pain, a palpable tender bladder — and in the older patient it may present **atypically as delirium, agitation, a fall or "off legs"**. Acute retention has a quality-of-life impact comparable to that of myocardial infarction.
10. **Chronic lower tract obstruction:** insidious LUTS — hesitancy, weak stream, straining, intermittency, incomplete emptying, terminal dribbling — with **overflow (dribbling) incontinence**, a painless distended bladder, and nocturnal enuresis. Pain is characteristically absent.

11. **Acute upper tract obstruction:** loin pain radiating to the groin (ureteric colic), nausea, vomiting, haematuria, and fever if infected.
12. **Chronic upper tract obstruction:** often silent; presents with anaemia, nocturia, polyuria, hypertension or unexplained rising creatinine.
13. **Complications:** post-renal AKI and chronic kidney disease; recurrent UTI, pyelonephritis and **pyonephrosis with sepsis**; bladder stones and diverticula; hyperkalaemia and metabolic acidosis (type 4 renal tubular acidosis); hypertension; and, after relief, **post-obstructive diuresis**.
14. **Danger combination to recognise instantly:** obstruction plus fever plus a raised inflammatory response = **infected obstructed system**, a urological emergency requiring drainage within hours.

D. Investigation

15. **Bedside:** abdominal examination for a distended bladder, digital rectal examination, **bladder ultrasound for post-void residual**, and urinalysis (infection, haematuria).
16. **Laboratory:** serum **creatinine and urea (mg/dL)**, electrolytes including potassium (mEq/L), bicarbonate, calcium (mg/dL), haemoglobin (g/dL), and blood glucose (mg/dL); urine culture; **PSA (ng/mL)** once infection and retention have resolved.
17. **Ultrasound of kidneys, ureters and bladder** is the **first-line imaging investigation** — it detects hydronephrosis, measures residual urine and prostate size, is safe, cheap, radiation-free and requires no contrast. Remember that hydronephrosis may be absent in early obstruction, in dehydration, and in retroperitoneal fibrosis or encasing malignancy.
18. **Non-contrast CT KUB** for suspected calculus and for defining the level and cause of upper-tract obstruction.
19. **Further tests as indicated:** MR urography where contrast is contraindicated; **diuretic renography (MAG-3)** to confirm functional obstruction and assess split renal function; antegrade or retrograde pyelography; **cystoscopy** for stricture, bladder tumour or stone; and **urodynamics/pressure-flow study** to distinguish true obstruction from detrusor underactivity.
20. **Uroflowmetry** as a non-invasive screen — Qmax <10 mL/s on a voided volume >150 mL supports obstruction or impaired contractility.

E. Treatment

21. **Principle: relieve the obstruction promptly, treat infection, correct metabolic consequences, then treat the cause.**
22. **Acute retention:** immediate **urethral catheterisation**; if this fails or is contraindicated (stricture, recent urethral surgery), **suprapubic catheterisation**. Record the drained volume. Start an α-blocker before a trial without catheter, which improves the chance of successful voiding.
23. **Upper-tract obstruction:** decompress by **percutaneous nephrostomy** or **retrograde ureteric stenting** — nephrostomy is generally preferred in sepsis and in a poorly drained infected system.
24. **Infected obstructed kidney (pyonephrosis) is an emergency:** resuscitate, take cultures, start broad-spectrum intravenous antibiotics and drain urgently; delay is associated with high mortality.
25. **Correct metabolic derangement:** hyperkalaemia, acidosis and uraemia; dialysis if refractory.

26. **Anticipate post-obstructive diuresis** after relief of chronic obstruction — monitor urine output hourly, weigh daily, and replace fluid and electrolytes carefully; it is usually physiological but may cause hypovolaemia, hyponatraemia, hypokalaemia and hypomagnesaemia in frail older patients.
27. **Definitive treatment of the cause:** medical therapy for BPH (α-blocker ± 5-α-reductase inhibitor) or **TURP / laser enucleation**; stone removal by ureteroscopy or lithotripsy; urethral dilatation or urethroplasty for stricture; oncological treatment or long-term stenting for malignant compression; steroids and ureterolysis for retroperitoneal fibrosis; clean intermittent self-catheterisation for a neurogenic acontractile bladder; and disimpaction plus a bowel regimen where faecal loading is contributory.
28. **Review and stop precipitating drugs** — anticholinergics, opioids, tricyclics, antipsychotics and α-agonists.
29. **Prognosis:** recovery of renal function depends on the duration and completeness of obstruction and on the pre-existing renal reserve; partial recovery is the rule after prolonged obstruction, so **early detection is the only effective strategy**. Follow up renal function and residual volume after relief.
30. **Geriatric caveat:** in a frail patient with advanced malignancy, decompression may prolong a poor-quality life — the decision to stent or drain should follow comprehensive geriatric assessment and a discussion of goals of care.

Latest Updates (2023–Present)

- **KDIGO AKI guidance and current practice** emphasise urgent exclusion of a post-renal cause in every episode of AKI, with **bedside bladder scan and renal ultrasound as immediate steps** — the most rapidly reversible AKI aetiology in older adults.
- **Point-of-care ultrasound (POCUS)** performed by physicians has become routine on acute geriatric and emergency units since 2023, shortening the time to detection of retention and hydronephrosis; a bladder scan is now expected before labelling an older patient's AKI as pre-renal.
- **Minimally invasive surgical therapies for BPH** — water vapour thermal therapy, prostatic urethral lift, and **prostatic artery embolisation (added to the AUA guideline in the 2023 amendment)** — allow definitive relief of prostatic obstruction in frail men unfit for anaesthesia, replacing indefinite long-term catheterisation in selected patients.
- **Laser enucleation (HoLEP/ThuLEP)** is now preferred over open prostatectomy for very large glands, with lower morbidity, shorter catheter time and size-independent efficacy.
- **Nephrostomy versus stent in malignant obstruction:** contemporary evidence supports individualised choice with early palliative-care input, since survival after decompression for advanced pelvic malignancy is often short — an important shared-decision point in geriatric oncology.
- **Indian context:** obstructive uropathy from BPH, stone disease and cervical or prostate malignancy remains a leading reversible cause of CKD in Indian older adults; TURP, ureteric stenting and nephrostomy are covered under AB-PMJAY, with the **Ayushman Vay Vandana Card** providing universal cover for those aged 70 and above.

Current Practice Update

Issue	Textbook position	Current evidence / practice
Detection of obstruction in AKI	Consider post-renal causes; ultrasound	**Bedside POCUS bladder scan first**, then formal ultrasound — expected within the first hour
Frail men with retention unfit for TURP	Long-term catheter or open surgery	**MISTs and prostatic artery embolisation** offer catheter-free options
Very large prostate	Open prostatectomy	**HoLEP / ThuLEP** preferred where available
Malignant ureteric obstruction	Decompress	Decompress **after goals-of-care discussion**; survival may be short

15-second answer skeleton: Define obstructive uropathy / nephropathy / hydronephrosis → geriatric importance as reversible renal failure and the polyuria trap → causes (lower, upper, functional, faecal impaction) → clinical features (acute retention incl. atypical presentation; chronic painless distended bladder with overflow; upper tract colic vs silent) → complications incl. infected obstruction and post-obstructive diuresis → investigation (bladder scan, urinalysis, creatinine/K^+, **ultrasound first-line**, CT KUB, renography, cystoscopy, urodynamics) → treatment (relieve first: catheter/suprapubic/nephrostomy/stent → treat sepsis → correct metabolic derangement → anticipate post-obstructive diuresis → definitive cause-specific therapy → stop culprit drugs) → prognosis and goals of care.

Examiner traps — (1) Chronic obstruction causes **polyuria, not oliguria** — this is the classic missed diagnosis. (2) Absent hydronephrosis does not exclude obstruction (early obstruction, dehydration, retroperitoneal fibrosis, encasing tumour). (3) Never delay drainage in an infected obstructed system for imaging or antibiotics alone. (4) Always warn about post-obstructive diuresis. (5) Painless distended bladder with dribbling is chronic retention, not "incontinence" to be treated with an antimuscarinic.

Exam One-Liners

- Obstructive uropathy is the most readily reversible cause of renal failure in the elderly.
- Chronic prostatic obstruction presents with polyuria, not oliguria — hence late diagnosis.
- Acute retention in an older person may present as delirium or a fall.
- Ultrasound KUB is the first-line investigation; absent hydronephrosis does not exclude obstruction.
- Infected obstructed kidney = emergency drainage plus intravenous antibiotics.
- Anticipate post-obstructive diuresis after relieving chronic obstruction.
- Recovery of renal function is only partial after prolonged obstruction.

QUESTION 13

Chronic indwelling catheter usage in the elderly. 7 MARKS

High-Yield Points

1. **General rule:** catheters should be **avoided in the management of incontinence unless specific indications are present**. Indwelling catheterisation remains substantially overused in acute hospitals.
2. **Three types of catheterisation: external (condom)** — for intractable incontinence in a physically dependent man **without retention**; **intermittent straight catheterisation** — 2–4 times daily, keeping bladder volume below **400 mL**, clean (not necessarily sterile) technique at home; and **chronic indwelling catheterisation**.
3. **Indications for a chronic indwelling catheter (memorise this list):**
   - Urinary retention that is causing persistent overflow incontinence, symptomatic infection or renal dysfunction, **and** cannot be corrected surgically or medically, **and** cannot practically be managed with intermittent catheterisation
   - Skin wounds, pressure ulcers or irritation being contaminated by incontinent urine
   - Care of terminally ill or severely impaired patients for whom bed and clothing changes are uncomfortable or disruptive
   - Patient preference where toileting or changing causes excessive discomfort
4. **Complications:** chronic bacteriuria (universal), symptomatic UTI and urosepsis, bladder and renal stones, periurethral and prostatic abscess, urethral trauma, erosion and fistula, catheter blockage and bypassing, pyelonephritis, and — with long-term use — **bladder carcinoma**. Catheters also promote immobility, falls (tethering), delirium and loss of dignity.
5. **Key principles of catheter care — part 1 (system):** maintain a **sterile closed gravity-drainage system**; avoid breaking the closed system; use clean technique when emptying or changing bags and wash hands between patients; secure the catheter to the upper thigh or lower abdomen to prevent perineal contamination and urethral traction injury.
6. **Key principles — part 2 (hygiene and mechanics):** avoid frequent or vigorous cleaning of the catheter entry site — washing with soapy water once a day is sufficient; **do not routinely irrigate**; if bypassing occurs without obstruction, consider bladder spasm and treat with a bladder relaxant; if blockage is frequent, increase fluid intake and acidify the urine with dilute acetic acid irrigation.
7. **Key principles — part 3 (antibiotics and cultures): do not use routine prophylactic or suppressive urinary antiseptics or antimicrobials**; **do not perform surveillance cultures**, because all chronically catheterised patients have bacteriuria which is often polymicrobial and changes frequently; and **do not treat infection unless the patient develops symptoms**.
8. **Interpreting symptoms:** symptoms in catheterised older patients are non-specific (fever, delirium, functional decline); other sources of infection must be carefully excluded before attributing them to the urinary tract.
9. **When to investigate further:** a patient with **frequent symptomatic UTIs** should have genitourinary evaluation to exclude stones, periurethral or prostatic abscess, and chronic pyelonephritis.

10. **Alternatives to prefer:** accessible toilets and toilet substitutes, scheduled toileting, intermittent catheterisation, external catheters in selected men, and highly absorbent launderable or disposable pads — these carry less morbidity and lower overall cost than an indwelling catheter.

Latest Updates (2023–Present) — Concise

- **SHEA/IDSA/APIC/AHA/Joint Commission CAUTI Compendium, 2022 Update (published 2023)** makes **avoidance of unnecessary catheters and prompt removal** essential practices, with nurse-driven removal protocols, automatic stop-orders and daily necessity review; it also formalises **urine-culture stewardship** to stop reflex culturing of catheterised patients.
- The same document addresses routine catheter replacement for catheters in place beyond **30 days** — scheduled change is a standard-of-care question rather than an infection-prevention intervention, and catheters should not be changed reflexively to "treat" bacteriuria.
- **IDSA guidance continues to advise against screening for or treating asymptomatic bacteriuria** in catheterised older adults; antibiotic use in this setting drives resistance without benefit — a particularly pressing issue given ICMR AMR surveillance data on carbapenem-resistant Enterobacterales in Indian hospitals.

Current Practice Update

Point	Textbook	Current practice
Removal	Limit use to defined indications	Add **nurse-driven removal protocols, stop-orders and daily necessity review**
Cultures	Do not perform surveillance cultures	Formalised as **urine-culture stewardship** with diagnostic criteria before culturing
Antiseptic / antibiotic prophylaxis	Not recommended	Unchanged; also no routine antimicrobial-coated catheters as a standard measure

Extra Points to Remember (High-Yield)

- **Four indications, in one line: retention that cannot be fixed otherwise · contaminated wounds or pressure ulcers · terminal or severely impaired care comfort · patient preference where toileting is intolerable.**
- **Three "do nots" that earn marks:** do not irrigate routinely · do not send surveillance cultures · do not give prophylactic antibiotics.
- **Numbers:** intermittent catheterisation 2–4 times daily, bladder volume <400 mL; catheters in place >30 days raise the replacement question; entry-site washing once daily.
- **Convenience is never an indication** — for catheters, condom drainage, pads or garments.

Exam One-Liners

- Catheters are for specific indications, never for convenience.

- Every chronically catheterised patient has bacteriuria — do not culture or treat it unless symptomatic.
- Maintain a closed sterile drainage system and secure the catheter to prevent traction injury.
- No routine irrigation, no routine prophylactic antibiotics, no surveillance cultures.
- Bypassing without obstruction suggests bladder spasm.
- Long-term catheterisation risks stones, abscess and bladder cancer.
- Frequent symptomatic UTIs warrant genitourinary evaluation for stones or abscess.

QUESTION 14

Catheter-associated urinary tract infections — prevention and management. 7 MARKS

High-Yield Points

1. **Definitions: catheter-associated bacteriuria** is almost universal with long-term catheters and is usually asymptomatic and polymicrobial. **CAUTI** is bacteriuria **plus signs or symptoms** attributable to the urinary tract with no other identified source, in a patient with an indwelling catheter in place (or removed within the previous 48 hours).
2. **Burden:** urinary tract infection is among the commonest healthcare-associated infections, and historically **70–80% of hospital UTIs were attributable to an indwelling urethral catheter**. CAUTI rates in low- and middle-income countries, including India, consistently exceed those reported from high-income settings.
3. **Pathogenesis:** organisms ascend extraluminally along the catheter–urethral interface or intraluminally from a broken drainage system, and establish a **biofilm** on the catheter surface that protects them from antibiotics and host defences. Risk rises with **each day of catheterisation**.
4. **Microbiology:** *Escherichia coli*, *Klebsiella*, *Proteus* (urease-producing, causes encrustation and blockage), *Pseudomonas*, *Enterococcus*, and *Candida*. Multidrug-resistant Gram-negative organisms, including ESBL producers and carbapenem-resistant Enterobacterales, dominate in Indian hospital practice.
5. **Clinical features in older adults are non-specific:** fever, new or worsening delirium, functional decline, falls, reduced oral intake, rigors, suprapubic or flank pain, or haematuria. Classical dysuria and frequency are often absent because the catheter bypasses the urethra.
6. **Prevention — the four essential principles:**
   - **Avoid unnecessary catheterisation** — insert only for defined indications; use bladder scanning, toileting programmes, external catheters and pads instead.
   - **Insert aseptically** by trained personnel, using the smallest suitable catheter and sterile technique.
   - **Maintain a closed sterile drainage system**, keep the bag below bladder level and off the floor, secure the catheter, avoid kinking, and perform hand hygiene before and after any catheter contact.
   - **Remove as early as possible** — daily review of continuing need, nurse-driven removal protocols and automatic stop-orders.
7. **What does NOT prevent CAUTI:** routine bladder irrigation, routine antiseptic or antibiotic instillation, routine systemic antibiotic prophylaxis, routine catheter changes to "clear" bacteriuria, vigorous daily meatal cleaning with antiseptics, and cranberry products.
8. **Diagnostic (urine-culture) stewardship:** **do not send reflex urine cultures** from catheterised patients without genuine urinary signs or symptoms; culture only when clinical criteria are met, and exclude other sources of fever first. Treating asymptomatic bacteriuria offers no benefit and drives resistance.
9. **Management of established CAUTI:** obtain cultures **after** replacing a catheter that has been in place for more than two weeks (a fresh specimen from a new catheter reflects bladder rather than biofilm flora); remove the catheter altogether if it is no longer needed;

start empirical therapy guided by local antibiogram and severity, then de-escalate on culture and sensitivity.

10. **Duration and supportive care:** typically **7 days** for prompt responders and **10–14 days** for delayed response or bacteraemia; ensure hydration, correct electrolytes, exclude obstruction, abscess or stones if the response is poor, and review the ongoing need for catheterisation before discharge.

Latest Updates (2023–Present) — Concise

- **SHEA/IDSA/APIC/AHA/Joint Commission Compendium — CAUTI 2022 Update (published 2023)** reorganises measures into **essential practices** (avoidance, aseptic insertion, closed system maintenance, early removal, urine-culture stewardship, surveillance and feedback) and **additional approaches** for outbreaks or persistent high rates; it also addresses routine replacement of catheters in place beyond 30 days and extends guidance to paediatric settings.
- **Urine-culture (diagnostic) stewardship is now a named essential practice** — reducing inappropriate culturing has been shown to reduce reported CAUTI rates and unnecessary antibiotic use without patient harm.
- **An ISID guidance chapter (2024) adapts CAUTI prevention for low- and middle-income countries**, noting persistently higher INICC-reported rates and emphasising bundle implementation, catheter-day reduction and antimicrobial stewardship — directly applicable to Indian district hospitals and NABH accreditation requirements.

Current Practice Update

Point	Textbook	Current practice
Prevention framework	Principles of catheter care	Structured **CAUTI bundle** with essential practices and outcome feedback
Cultures	Do not do surveillance cultures	**Urine-culture stewardship** as a formal, audited practice
Catheter change before treatment	Not specified	**Replace a catheter in situ >2 weeks, then culture** and treat

Extra Points to Remember (High-Yield)

- **Mnemonic for the bundle — "AIMS": A**void unnecessary catheters · **I**nsert aseptically · **M**aintain a closed system · **S**top early (remove promptly).
- **Numbers:** historically 70–80% of hospital UTIs are catheter-related; risk increases with each catheter-day; replace catheters in place >2 weeks before culturing; treat 7 days (prompt response) or 10–14 days (delayed response); catheters >30 days raise the replacement question.
- **The single highest-impact intervention is removing the catheter** — say this explicitly.

Examiner traps — (1) Do not treat asymptomatic catheter-associated bacteriuria. (2) Do not send a urine culture simply because the urine is cloudy or malodorous. (3) Do not rely on dysuria and frequency — delirium and functional decline are the geriatric presentation. (4) Do not use

antibiotic prophylaxis or routine irrigation to prevent CAUTI. (5) Exclude obstruction, stones and abscess when a CAUTI fails to respond.

Exam One-Liners

- CAUTI = bacteriuria plus attributable symptoms; bacteriuria alone is not infection.
- Biofilm formation on the catheter is the central pathogenic mechanism.
- Risk rises with every catheter-day; early removal is the most effective prevention.
- AIMS bundle: Avoid, Insert aseptically, Maintain closed system, Stop early.
- Delirium or unexplained functional decline may be the only sign in an older patient.
- Replace a long-standing catheter before taking the culture, then treat.
- Urine-culture stewardship is now an essential prevention practice.

QUESTION 15

Recommendations for treatment of complicated urinary tract infection in males. 7 MARKS

High-Yield Points

1. **Principle: urinary tract infection in a male is, by convention, complicated**. Contemporary practice replaces the term "acute prostatitis" with **male urinary tract infection**, managed as a "urinary infection at risk of complication". A lower UTI in a man is treated as prostatic infection.
2. **Why complicated:** older men have obstructive uropathy from prostatic enlargement, high residual urine, catheters, instrumentation, diabetes and structural abnormality — all of which predispose to relapse, abscess and bacteraemia.
3. **Microbiology:** Gram-negative bacilli predominate — *Escherichia coli* and *Proteus* species most commonly; also *Klebsiella*, *Pseudomonas*, enterococci and staphylococci. Recurrence after completing therapy is usually with the **same organism**.
4. **Presentation ranges widely** — from paucisymptomatic cystitis-like illness to spiking fever, chills, malaise, myalgia, dysuria, pelvic or perineal pain and cloudy urine. In older men, delirium, falls and functional decline may dominate.
5. **Diagnosis:** gentle digital rectal examination showing an oedematous tender prostate supports the diagnosis — **vigorous prostatic massage must be avoided** because it is painful, adds nothing diagnostically and risks bacteraemia. A dipstick positive for leukocytes or nitrites has a positive predictive value above 90% in a symptomatic man. Send **urine Gram stain and culture in every case**; the diagnostic threshold is **≥10^3 CFU/mL with leukocyturia ≥10^4/mL**. Take **blood cultures when there is fever**. **Do not measure PSA during a male UTI** — it needs about six months to return to baseline.
6. **Pharmacological principle:** the barrier between the prostatic microcirculation and stroma permits only **non-protein-bound, lipophilic** antimicrobials to diffuse in, and the low pH of prostatic fluid allows drugs with **alkaline pKa** — quinolones and sulfonamides — to concentrate in prostatic tissue. Penetration improves in the presence of inflammation.
7. **Route and setting:** ambulatory, pauci-symptomatic men may be treated **orally, guided by susceptibility results**. Men with fever or signs of sepsis need **hospitalisation and urgent empirical parenteral therapy**, because Gram-negative bacteraemia can progress abruptly to life-threatening septic shock.
8. **Antimicrobial choice:**
   - **Gram-negative bacilli, oral therapy:** trimethoprim–sulfamethoxazole or a fluoroquinolone. Other agents with good to excellent prostatic penetration are tetracyclines, macrolides, sulfonamides and nitrofurantoin.
   - **Parenteral therapy:** an aminoglycoside combined with an intravenous cephalosporin or a fluoroquinolone; treat as Gram-negative infection until further culture data are available.
   - **Gram-positive cocci in chains** → enterococcal infection → amoxicillin.
   - **Gram-positive cocci in clusters** → *Staphylococcus aureus* or coagulase-negative staphylococci; when *S. aureus* is isolated from urine, **always take blood cultures** to confirm that the bacteriuria reflects local infection rather than seeding from bacteraemia.

9. **Source control and supportive care:** relieve obstruction (catheter or suprapubic drainage; nephrostomy or stent for upper-tract obstruction), remove or replace an infected catheter, drain a prostatic or perinephric abscess, maintain hydration, adjust doses for renal function, monitor for delirium and falls, and avoid nephrotoxins.
10. **Duration and follow-up:** treat for a prolonged course reflecting prostatic involvement — commonly **10–14 days**, extended to several weeks where prostatic infection is established, and up to **4–6 weeks** for chronic bacterial prostatitis. Investigate the urinary tract after the episode (ultrasound, PVR, and PSA deferred by about six months) and treat the underlying obstruction to prevent relapse.

Latest Updates (2023–Present) — Concise

- **New agents for complicated UTI: cefepime–enmetazobactam** was FDA-approved in 2024 for complicated UTI including pyelonephritis, showing non-inferiority and superiority to piperacillin–tazobactam for clinical cure and microbiological eradication; **cefepime–taniborbactam** demonstrated superiority over meropenem in the phase-3 **CERTAIN-1** trial (70.6% vs 58.0% composite response) but has faced regulatory delay on manufacturing grounds. **Ceftazidime–avibactam, ceftolozane–tazobactam, meropenem–vaborbactam, plazomicin and cefiderocol** remain the mainstay options for multidrug-resistant Gram-negative complicated UTI.
- **Gepotidacin (Blujepa)**, approved March 2025, is the first new oral antibiotic class for urinary infection in almost thirty years — but its licence is for **uncomplicated UTI in females aged ≥12 years**, not for complicated male UTI; it is a common examination distractor.
- **Fluoroquinolone restriction** continues: regulatory warnings on tendinopathy, aortic aneurysm, neuropathy, delirium and dysglycaemia, together with high Indian resistance rates, mean quinolones should be **guided by culture rather than used empirically** in older men. ICMR AMR surveillance shows very high fluoroquinolone and third-generation cephalosporin resistance among urinary *E. coli* isolates in India, with carbapenem-sparing strategies now a national priority under the ICMR treatment guidelines and NAP-AMR.

Current Practice Update

Point	Textbook	Current practice
Empirical oral therapy	Trimethoprim–sulfamethoxazole or fluoroquinolone	**Culture-guided**; empirical quinolones discouraged given Indian resistance and toxicity warnings
Resistant Gram-negative cUTI	Aminoglycoside + cephalosporin	**Newer β-lactam/β-lactamase inhibitors** — cefepime–enmetazobactam, ceftazidime–avibactam, meropenem–vaborbactam, cefiderocol
Terminology	Acute prostatitis	**Male urinary tract infection**, managed as complicated UTI

Exam One-Liners

- Every UTI in a man is complicated; a lower UTI in a man is treated as prostatic infection.
- Diagnostic threshold: ≥10^3 CFU/mL with leukocyturia ≥10^4/mL.

- Avoid vigorous prostatic massage — risk of bacteraemia.
- Do not check PSA during a male UTI; wait about six months.
- Only lipophilic, non-protein-bound, alkaline-pKa drugs penetrate the prostate.
- Fever or sepsis → admit and give parenteral therapy urgently.
- *S. aureus* in the urine → take blood cultures.
- Treat 10–14 days, longer for established prostatic infection; 4–6 weeks for chronic bacterial prostatitis.
- Gepotidacin is licensed for uncomplicated UTI in women only — a classic distractor.

RAPID REVISION

Night-Before Master Sheet — Numbers, Mnemonics and Traps

Numbers Worth Memorising

Parameter	Value
UI prevalence >65 years	Women ~1 in 3 · Men 15–20% · Nursing homes 60–80%
OAB symptoms at ≥75 years	Women ~30% · Men ~40%
Normal bladder capacity / first urge / filling pressure	300–600 mL / 150–300 mL / <15 cm H_2O
Frequency / nocturia definitions	>8 voids per 24 h · ≥2 voids at night
Abnormal post-void residual	>200 mL
Abnormal peak urine flow	Qmax <10 mL/s on a voided volume >150 mL
Intermittent catheterisation	2–4 times daily; keep bladder volume <400 mL
IPSS / AUA-SI severity	Mild 0–7 · Moderate 8–19 · Severe 20–35
5-α-reductase inhibitor	Gland >30–40 mL · up to 30% volume reduction · 3–6 months to act · halves PSA
MTOPS — reduction in acute retention	Combination 66% · α-blocker 39% · 5-ARI 34%
PSA	Cut-off 4.0 ng/mL; 25% of cancers below it; 6 months to normalise after UTI
Prompted voiding response	25–40% of nursing-home residents; identified by a 3-day trial
Bladder retraining schedule	On waking · 2-hourly day/evening · before bed · 4-hourly at night
Male UTI diagnostic threshold	≥10^3 CFU/mL with leukocyturia ≥10^4/mL
CAUTI attribution / treatment duration	70–80% of hospital UTIs catheter-related · 7 days prompt response, 10–14 days delayed
Fibre for constipation	4–6 g/day of crude fibre

Mnemonics

- **DRIP** — Delirium · Restricted mobility/Retention · Infection, Inflammation, Impaction · Polyuria, Pharmaceuticals
- **DIAPPERS** — Delirium · Infection · Atrophic vaginitis · Pharmaceuticals · Psychological · Excess urine output · Restricted mobility · Stool impaction
- **A-5-C-A-P** (BPH medical therapy) — Alpha-blocker · 5-ARI · Combination · Anticholinergic/β3 · PDE-5 inhibitor
- **AIMS** (CAUTI bundle) — Avoid · Insert aseptically · Maintain closed system · Stop early
- **PROSTATE** (male UI causes) — Prostatic obstruction · Radiotherapy/Radical prostatectomy · Overactive bladder · Stricture · Tumour · Autonomic neuropathy · Toxins/drugs · Environment

Ten Traps That Cost Marks

1. Saying ageing *causes* incontinence — it only predisposes.
2. Omitting the post-void residual from the basic evaluation.

3. Treating asymptomatic bacteriuria in a catheterised or stable institutionalised patient.
4. Prescribing oral rather than topical oestrogen.
5. Adding an antimuscarinic in a man without checking the residual (DHIC and retention).
6. Forgetting that 5-α-reductase inhibitors halve PSA.
7. Missing that chronic obstructive uropathy causes **polyuria, not oliguria**.
8. Forgetting post-obstructive diuresis after relieving chronic retention.
9. Measuring PSA during an acute male urinary tract infection.
10. Using a catheter, condom drainage or pads for convenience rather than for an indication.

Prepared as an examination revision aid. Clinical decisions must always be individualised, and local antibiograms and institutional protocols should guide antimicrobial choice.

METABOLIC BONE DISEASE & GERIATRIC RHEUMATOLOGY

High-Yield Examination Compendium

MD Geriatric Medicine — Written Examination Revision

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (Sinclair, Morley, Vellas, Cesari, Munshi; Wiley 2022) · Kane's Essentials of Clinical Geriatrics.

Supplementary evidence: Guidelines, regulatory approvals and randomised trials published 2023 – present, presented in clearly separated blocks.

Units: Indian conventional units throughout (calcium mg/dL, creatinine mg/dL, phosphate mg/dL, haemoglobin g/dL, PSA ng/mL, glucose mg/dL).

Coverage: 14 questions — 10 long answers (15 marks) and 4 short notes (7 marks).

Compiled for Dr. Sudarsan · Structured for night-before-examination revision

Q1. Osteoporosis — Risk Factors, Pathology, Clinical Features, Investigations, Management and Complications

15 MARKS

A. Definition and Burden

1. **Osteoporosis** is a skeletal disease of **low bone mass and micro-architectural deterioration** of bone tissue, causing bone fragility and increased fracture risk. Operational (WHO) definition: **BMD T-score ≤ −2.5** at spine or hip.
2. It is a **major contributor to the global burden of disease and disability**; maintenance of musculoskeletal health during ageing is a key determinant of functional ability. The commonest fragility fractures are **hip, forearm (Colles') and vertebral**.
3. Indian context: LASI wave 1 shows a high prevalence of low bone mass in adults ≥60 years; ISBMR recommends Indian reference databases, since using Caucasian norms over-diagnoses osteoporosis in Indians.

B. Risk Factors (Major Risk Factors for Fragility Fracture — Pathy's list)

4. **Non-modifiable:** advancing **age**, female **sex**, **prior fragility fracture**, **parental hip fracture history**, height loss **>4 cm**.
5. **Modifiable / lifestyle: low BMI**, **excess alcohol**, **smoking**, immobility, low calcium and vitamin D intake, low protein intake.
6. **Drugs: glucocorticoid therapy** (most important), aromatase inhibitors, androgen-deprivation therapy, anticonvulsants, proton-pump inhibitors, thyroxine over-replacement.
7. **Causes of secondary osteoporosis:** rheumatoid arthritis, hyperthyroidism, primary hyperparathyroidism, hypogonadism, diabetes, inflammatory bowel disease, anorexia nervosa, organ transplantation, prolonged immobility, COPD, HIV.

C. Pathology / Pathogenesis

8. Bone mass peaks in the third decade, then declines; ageing causes **uncoupling of bone remodelling** — osteoclastic resorption exceeds osteoblastic formation, so each remodelling cycle produces net bone loss.
9. **Oestrogen deficiency** after menopause increases **RANKL** and reduces osteoprotegerin, raising osteoclast number, activity and lifespan → accelerated trabecular loss (5–10 years of rapid loss).
10. **Age-related (type II) loss** is driven by secondary hyperparathyroidism from vitamin D deficiency and reduced calcium absorption, declining IGF-1/GH, sarcopenia and reduced mechanical loading; affects cortical and trabecular bone.
11. Structural consequence: **trabecular thinning and perforation, loss of connectivity, cortical thinning and increased cortical porosity** → disproportionate loss of bone strength relative to loss of bone density.

D. Clinical Features

12. Osteoporosis itself is **asymptomatic ("silent thief") until fracture occurs** — the first clinical presentation is usually a low-trauma fracture after a fall from standing height or less.
13. **Vertebral fracture:** acute back pain, or painless — presenting as **progressive height loss, dorsal kyphosis**, protuberant abdomen, reduced rib–pelvis distance, restrictive lung defect and early satiety.
14. **Hip fracture:** shortened externally rotated limb, inability to weight-bear; **Colles' fracture** after fall on outstretched hand; also proximal humerus and pelvic rami fractures.

E. Investigations

15. **DXA of spine and hip** is the reference standard for diagnosis and for risk stratification (see Q3).
16. **Vertebral fracture assessment (VFA) or lateral spine X-ray** if there is height loss or hyperkyphosis — morphometric fractures are frequently silent but strongly predict further fracture.
17. **Baseline biochemistry to exclude secondary causes:** serum **calcium (8.5–10.5 mg/dL)**, phosphate, alkaline phosphatase, **creatinine and eGFR**, full blood count, ESR, **25-OH vitamin D**, TSH, and where indicated PTH, testosterone (men), serum/urine electrophoresis, coeliac serology, 24-hour urinary calcium.
18. **Bone turnover markers** (serum CTX for resorption, P1NP for formation) — used chiefly to **verify compliance with antiresorptive therapy at 3–6 months**, not for diagnosis.
19. **Trabecular bone score (TBS)** from the DXA image and **hip axis length** refine FRAX-based risk beyond BMD alone.

F. Management (Pathy's Algorithm — Kanis/ESCEO Pathway)

(i) Non-pharmacological — for all patients

20. Education on osteoporosis, medication, diet and exercise; **daily weight-bearing physical activity**.
21. Nutrition: **calcium 800–1000 mg/day**, **protein ≥1 g/kg body weight/day**, **vitamin D 800–1000 IU/day**.
22. **Fall-prevention** with supervised progressive strength and balance training — the programme should run for at least **50 hours** to reduce falls (effect on fracture risk remains uncertain).

(ii) Pharmacological — stratified by fracture risk

Risk category	Pathy's / ESCEO recommended treatment
Low risk	Reassurance and lifestyle advice; consider **menopausal hormone therapy (MHT)** or **SERMs** (raloxifene, bazedoxifene)
High risk	Start an **inhibitor of bone resorption** — oral bisphosphonate (gastro-resistant risedronate improves adherence), IV bisphosphonate, or **denosumab**
Very high risk	**Anabolic therapy first** — teriparatide/biosimilars, abaloparatide or romosozumab — **followed by an antiresorptive**
Very high hip fracture risk (esp. after first hip fracture)	Consider **local osteo-enhancement procedure (LOEP)**

23. **Key efficacy figures (Pathy's):** yearly IV zoledronic acid reduces clinical fracture by **33%**, vertebral fracture by **77%** and peripheral fracture by **25%**; give vitamin D beforehand. Adverse effects: acute-phase influenza-like reaction in one in three at first infusion, and a higher incidence of atrial fibrillation than placebo.
24. **Denosumab** (anti-RANKL monoclonal antibody, subcutaneous twice yearly) blocks RANKL–RANK binding, inhibits osteoclast development, and reduces vertebral, non-vertebral and hip fractures. **Discontinuation causes rebound multiple vertebral fractures** — always follow with a bisphosphonate for 1–2 years.
25. **Teriparatide** reduces new vertebral and non-vertebral fracture independent of baseline T-score, age and number of fractures; BMD gain is dose-dependent. **Romosozumab** (anti-sclerostin) for 12 months followed by alendronate produced significantly fewer fractures than alendronate alone (Saag et al.); FDA-approved since April 2019 for postmenopausal women at high fracture risk.
26. **Limitations in the elderly:** raloxifene does not reduce femoral neck fracture; MHT is effective but carries breast cancer, thromboembolic, stroke and coronary risk; strontium ranelate raised BMD but caused DRESS and thromboembolism.
27. Oral bisphosphonates are usually first-line and most cost-effective — **NNT to prevent one hip fracture is about 200**. In the oldest and frailest, weigh pill burden and comorbidity. Benefits of oral drugs appear at **6–12 months**, whereas fall-prevention benefit may be immediate.
28. **Age is not a reason to withhold treatment** — unlike cancer screening, the effectiveness of fracture prevention **increases with advancing age**; economic models suggest treatment is cost-effective with a life expectancy as short as two years.

(iii) Follow-up

29. Assess compliance and side effects; check bone turnover markers at 3–6 months. Review after **3 years of IV** or **5 years of oral** bisphosphonate, or after any incident fracture: low-risk patients may take a **drug holiday for 2 years** (reconsider annually); high-risk patients continue.
30. **Fracture Liaison Service (FLS)** — a coordinator-based system for the routine assessment and treatment of all postmenopausal women and men after a fragility fracture; benefits are well established and it is the key strategy to close the "treatment gap".

G. Complications

31. **Fracture-related:** hip fracture → excess mortality, loss of independence, institutionalisation; vertebral fractures → chronic back pain, kyphosis, restrictive lung disease, GORD and anorexia; distal radius → complex regional pain syndrome.
32. **Treatment-related:** bisphosphonates — oesophagitis, hypocalcaemia, acute phase reaction, atrial fibrillation, rare **osteonecrosis of the jaw** and **atypical femoral fracture**; denosumab — hypocalcaemia, ONJ, rebound fractures on stopping.

Latest Updates (2023 – Present)

- **ASBMR / Bone Health & Osteoporosis Foundation Task Force position statement, 2024 (JBMR)** formalised **goal-directed treatment**: choose the initial agent by the T-score target it can realistically achieve. Modelling showed that from a lumbar-spine T-score of −3.0, the probability of reaching a T-score above −2.5 was 55% with alendronate alone, 81% with romosozumab→alendronate and 93% with romosozumab→denosumab.
- The same statement, together with AACE, Endocrine Society, The Menopause Society, BHOF, ESCEO/IOF and NOGG guidance, has embedded a formal **"very high fracture risk" category**, with a subset at **imminent risk for 2 years after an incident fracture**.
- **Sequential therapy is now the standard of care in very-high-risk patients:** anabolic (teriparatide / abaloparatide up to 2 years, or romosozumab for 1 year) **followed immediately by an antiresorptive**. Anabolic-first gives substantially greater BMD gain than antiresorptive-first (2025 clinical reviews of novel osteoporosis therapies).
- **Romosozumab safety caveat retained:** avoid in those with prior myocardial infarction or stroke; assess cardiovascular risk before starting.
- **NOGG 2024 and ISCD 2023** reaffirm FRAX-based intervention thresholds with TBS adjustment; **USPSTF 2025** continues to recommend BMD screening in women ≥65 years and in younger postmenopausal women at increased risk.

- **Indian practice:** ICMR-NIN 2024 RDA raised recommended calcium intake for older Indian adults to **1000 mg/day**; ISBMR advises Indian-specific reference BMD databases and treatment of vitamin D deficiency before starting antiresorptives. Osteoporosis care is delivered under **NPHCE**, with treatment cost cover through **AB-PMJAY** and the **Ayushman Vay Vandana Card** for those ≥70 years.

Current Practice Update

Issue	Pathy's 6th edition position	Current position (2023–present)
Choice of first drug	Antiresorptive first for high risk; anabolic reserved for very high risk	**Goal-directed:** agent chosen by the T-score goal achievable; anabolic-first far more likely to reach target
Risk categories	Low / high / very high (ESCEO)	Same, plus explicit **imminent risk** window of 2 years after a fracture
Vitamin D dose	Around 800–1000 IU/day	Unchanged; but routine high-dose intermittent bolus discouraged (may increase falls)
Calcium target	800–1000 mg/day	ICMR-NIN 2024: **1000 mg/day** for older Indian adults, preferably dietary
Denosumab stopping	Follow with bisphosphonate 1–2 years	Reinforced — denosumab now regarded as an **indefinite-commitment drug**; never allow a lapsed dose

Extra Recall Scaffold — Recurring Topic

Mnemonic for secondary osteoporosis — "STEROIDS": **S**teroids · **T**hyrotoxicosis / hyperparathyroidism · **E**thanol · **R**heumatoid arthritis · **O**steomalacia / vitamin D deficiency · **I**mmobility · **D**iabetes and hypogonaDism · **S**malabsorption (coeliac, IBD).

Numerical anchors: T-score −2.5 · osteopenia −1 to −2.5 · height loss >4 cm · calcium 800–1000 mg · protein ≥1 g/kg · vitamin D 800 IU · exercise ≥50 hours · zoledronate: vertebral ↓77%, clinical ↓33%, peripheral ↓25% · NNT for hip fracture ≈200 · review at 3 years IV / 5 years oral · drug holiday 2 years.

Examiner traps: (1) Saying osteoporosis is diagnosed by X-ray — plain films only show osteopenia after 30–40% bone loss. (2) Forgetting that **a fragility fracture diagnoses osteoporosis clinically regardless of T-score**. (3) Stopping denosumab without bisphosphonate cover. (4) Withholding treatment because "the patient is too old" — benefit increases with age. (5) Starting a bisphosphonate without first correcting vitamin D deficiency and hypocalcaemia.

15-second answer skeleton: Define (WHO T-score −2.5) → burden and Indian data → risk factors (non-modifiable / modifiable / drugs / secondary) → pathogenesis (uncoupled remodelling, RANKL, secondary hyperparathyroidism) → silent until fracture → DXA + VFA + secondary-cause screen → lifestyle for all → risk-stratified drug ladder → follow-up, drug holiday, Fracture Liaison Service → complications of fracture and of therapy.

Exam One-Liners

- WHO diagnostic threshold: T-score ≤ −2.5; osteopenia −1.0 to −2.5.
- Commonest osteoporotic fractures: vertebral > hip > distal radius.
- Height loss >4 cm is an indication for vertebral fracture assessment.
- Zoledronic acid 5 mg IV once yearly reduces vertebral fracture by 77%.
- Denosumab must never be stopped without antiresorptive cover.
- Fracture Liaison Service is the single most effective system-level intervention for secondary prevention.
- Bone turnover markers are for compliance monitoring, not diagnosis.

Q2. A 68-Year-Old with Fracture Neck of Femur — Risk of Further Fragility Fracture, Further Tests and Treatment Options

15 MARKS

A. Framing the Problem

1. A hip fracture after low-energy trauma in a 68-year-old is by definition a **fragility fracture** and establishes a clinical diagnosis of osteoporosis **irrespective of the DXA T-score**.
2. Hip fracture carries substantial excess mortality, loss of independence and institutionalisation; non-hip, non-spine fractures also drive large healthcare utilisation.

B. Risk of a Further Fragility Fracture

3. A prior fragility fracture is one of the **major independent risk factors** in Pathy's list — it roughly **doubles** the risk of any subsequent fracture.
4. The risk is **front-loaded**: it is highest in the first 1–2 years after the index fracture — the **"imminent fracture risk"** window.
5. Around one in five patients sustains a second fracture, and a substantial proportion of these are contralateral hip fractures.
6. Yet the **treatment gap is wide** — most patients leave hospital after a hip fracture without any anti-osteoporosis medication; this is precisely the problem the **Fracture Liaison Service** was created to solve.
7. Additional determinants of further fracture in this patient: **continuing falls risk**, sarcopenia, postural hypotension, visual impairment, polypharmacy (Beers criteria), vitamin D deficiency and post-fall syndrome with fear of falling.

C. Further Tests

8. **DXA of the contralateral hip and lumbar spine** — not to decide whether to treat (treatment is already indicated), but to provide a baseline for monitoring and to grade severity.
9. **Lateral thoracolumbar X-ray or VFA** to detect silent vertebral fractures, which change risk category and drug choice.
10. **Biochemistry:** serum calcium, phosphate, alkaline phosphatase, creatinine/eGFR, full blood count, ESR, **25-OH vitamin D**, TSH, liver function.
11. **Targeted secondary-cause screen:** PTH, serum and urine protein electrophoresis with free light chains (myeloma), coeliac serology, 24-hour urinary calcium, and in a man **morning total testosterone (ng/dL)** — late-onset hypogonadism is an under-recognised cause.
12. **Renal function is decisive** for drug choice — bisphosphonates are avoided if eGFR is below about 30–35 mL/min.
13. **FRAX** with BMD, adjusted for the recent fracture, plus **TBS** if available, to document the risk category.
14. **Comprehensive geriatric assessment:** multifactorial falls assessment, gait and balance testing (Timed Up and Go), cognition, nutrition (MNA), continence, medication review and social circumstances.

D. Treatment Options

(i) Acute and orthogeriatric care

15. **Early surgery (ideally within 48 hours)** under a shared orthogeriatric model, multimodal opioid-sparing analgesia including fascia iliaca block, delirium prevention (HELP-type bundle), pressure-ulcer prevention, VTE prophylaxis and early mobilisation with rehabilitation.

(ii) Bone-directed pharmacotherapy

16. **Correct vitamin D and calcium first:** Pathy's states that all people with a hip fracture should receive calcium, vitamin D and a bisphosphonate unless contraindicated (e.g. renal failure); 25-OH vitamin D should be above 30 ng/mL.
17. **Zoledronic acid 5 mg IV once yearly** is the preferred agent after hip fracture — it overcomes adherence problems, reduces clinical fracture by 33%, vertebral by 77% and peripheral by 25%; give at least 2 weeks after vitamin D repletion, ideally ≥2 weeks post-operatively.
18. **Denosumab 60 mg subcutaneously 6-monthly** is an alternative, particularly when eGFR is low; monitor calcium and **never stop it without bisphosphonate cover**.
19. **Anabolic first-line** (teriparatide, abaloparatide or romosozumab) if the patient is in the very-high-risk category — hip fracture plus multiple vertebral fractures or very low T-score — followed by an antiresorptive.
20. **Local osteo-enhancement procedure (LOEP)** may be considered where hip fracture risk is very high, particularly following a first hip fracture.
21. **Avoid raloxifene and other SERMs after femoral neck fracture** — Pathy's is explicit that they do not reduce femoral neck fracture and carry an increased thromboembolic risk in this setting.

(iii) Non-pharmacological and systems measures

22. **Falls prevention:** progressive strength and balance programme of at least 50 hours, home hazard assessment, footwear, vision correction, withdrawal of culprit drugs (sedatives, antihypertensives, anticholinergics), management of postural hypotension.
23. **Nutrition:** protein ≥1 g/kg/day, calcium 1000 mg/day, treatment of sarcopenia by resistance exercise plus protein

supplementation.

24. **Hip protectors** may be considered in the institutionalised, though adherence is poor, particularly with cognitive impairment.
25. **Enrol in a Fracture Liaison Service** with structured follow-up at 3–6 months for adherence, and repeat DXA in 1–3 years.

Latest Updates (2023 – Present)

- **Imminent fracture risk** is now formally recognised (ASBMR/BHOF 2024): the 2 years after a hip fracture constitute the highest-risk period, justifying immediate initiation of potent therapy rather than a "wait for DXA" approach.
- **Goal-directed therapy** supports anabolic-first sequencing after hip fracture in those with very low T-scores, since romosozumab→denosumab achieves a T-score above −2.5 far more often than alendronate alone.
- Registry and meta-analytic data continue to show that **early zoledronic acid after hip fracture reduces both re-fracture and all-cause mortality**, and that in-hospital initiation markedly improves uptake compared with deferring to primary care.
- **Fragility Fracture Network / FLS models** are now endorsed in Indian practice; NPHCE district-level geriatric units and AB-PMJAY/Ayushman Vay Vandana Card cover hip fracture surgery and follow-up in those ≥70 years.

Current Practice Update

Issue	Pathy's position	Current position
When to start drug therapy	After a fragility fracture, with calcium, vitamin D and a bisphosphonate	Same, but **started before discharge**; deferral to outpatient review is a recognised failure point
Drug choice after hip fracture	Bisphosphonate unless contraindicated	**IV zoledronate preferred**; anabolic-first if very high risk
SERMs	Avoid after femoral neck fracture	Unchanged — contraindicated in this scenario

Exam One-Liners

- A fragility fracture diagnoses osteoporosis clinically — do not wait for DXA to treat.
- Highest re-fracture risk is in the first 2 years (imminent risk).
- IV zoledronate after hip fracture reduces re-fracture and mortality.
- Never give a SERM after a femoral neck fracture.
- The Fracture Liaison Service closes the treatment gap.

Q3. DEXA Scan (Dual-Energy X-Ray Absorptiometry) and its Clinical Use — 7 MARKS

1. **Principle:** two X-ray beams of different energies are passed through the body; differential attenuation by bone and soft tissue allows calculation of **bone mineral content and areal bone mineral density (g/cm²)**. It is the **reference standard** for measuring BMD.
2. **Standard sites: lumbar spine (L1–L4)** and **hip (femoral neck and total hip)**; the **distal one-third radius** is used when spine or hip cannot be measured, or in hyperparathyroidism and very obese patients.
3. **T-score** compares BMD with the young adult mean: **≥−1.0 normal**, **−1.0 to −2.5 osteopenia**, **≤−2.5 osteoporosis**, and **≤−2.5 with a fragility fracture = severe (established) osteoporosis**. **Z-score** compares with age-matched peers and is used in men under 50 and premenopausal women; **Z ≤ −2.0** means "below expected for age" and mandates a secondary-cause work-up.
4. **Radiation dose is very low** (a few microsieverts, less than a chest radiograph), the scan takes minutes, and it is precise enough for serial monitoring.
5. **Clinical uses:** (a) diagnosis of osteoporosis; (b) fracture-risk prediction and input into **FRAX**; (c) deciding intervention thresholds; (d) monitoring response to therapy, repeated every **1–3 years**; (e) **Vertebral Fracture Assessment (VFA)** from the same machine; (f) **Trabecular Bone Score (TBS)** as a texture measure of bone quality; (g) body-composition and appendicular lean mass measurement for the diagnosis of **sarcopenia**.
6. **Who to scan:** Pathy's advises BMD in **all women from 50 years and all men by 65 years**, repeating in two years (in the same season) if results are borderline; also anyone with a fragility fracture, height loss, glucocorticoid therapy, or a secondary cause.
7. **Pitfalls that falsely raise spine BMD in older people: degenerative osteophytes and facet arthrosis, vertebral fracture, aortic calcification, scoliosis, previous instrumentation, and residual contrast** — hence in the elderly the **hip is the more reliable site**. Exclude any vertebra whose T-score differs from adjacent ones by more than 1.0; at least two vertebrae must be evaluable. Diagnosis uses the **lowest** of the valid sites. Repeat scans should be on the same machine, since inter-machine comparison is invalid without cross-calibration, and change is meaningful only if it exceeds the **least significant change**.

Latest Updates (2023 – Present) — 3 Points

- **ISCD 2023 Official Positions** endorse routine reporting of **TBS alongside BMD** and permit **opportunistic CT-based BMD screening** when a CT has been done for another reason.
- **ASBMR/BHOF 2024 goal-directed treatment** converts DXA from a diagnostic test into a **treatment target**: the aim is a T-score above −2.5, and the drug is chosen by the likelihood of reaching that goal.
- **Indian reference data:** ISBMR advises Indian young-adult reference databases and cautions that Caucasian NHANES norms over-diagnose osteoporosis in Indian patients; DXA-based appendicular lean mass indices are also used with **AWGS 2019** Asian cut-offs for sarcopenia.

Extra Recall Scaffold — Recurring Topic

Mnemonic for falsely high spine BMD — "SCAFOLD": **S**coliosis · **C**ompression fracture · **A**ortic calcification · **F**acet joint / osteophyte degeneration · **O**steomalacia treatment effect · **L**aminectomy hardware / instrumentation · **D**ye (residual contrast).

Numerical anchors: normal ≥−1.0 · osteopenia −1 to −2.5 · osteoporosis ≤−2.5 · Z-score ≤−2.0 abnormal · monitor every 1–3 years · adjacent-vertebra T-score difference >1.0 = exclude · women from 50, men by 65.

Examiner traps: (1) Using T-score in a premenopausal woman or young man — use Z-score. (2) Reporting the **average** of sites rather than the **lowest**. (3) Forgetting that severe spinal degeneration in the elderly makes spine BMD unreliable. (4) Comparing scans from two different machines. (5) Saying DXA measures volumetric density — it measures **areal** density, which underestimates BMD in small-framed people (relevant to Indian patients).

15-second answer skeleton: Principle → sites → T-score and Z-score with cut-offs → safety and precision → seven clinical uses → who to scan → pitfalls in the elderly and monitoring rules.

Q4. FRAX Score — 7 MARKS

1. **FRAX is an algorithm that integrates the weight of clinical risk factors for fracture, with or without BMD, and computes the 10-year probability of hip fracture and of a major osteoporotic fracture** (hip, clinical spine, proximal humerus, distal forearm). It was developed by Kanis and the WHO Collaborating Centre, Sheffield.
2. **The eleven inputs:** age (40–90), sex, weight, height, previous fragility fracture, parental hip fracture, current smoking, glucocorticoid use, rheumatoid arthritis, secondary osteoporosis, alcohol ≥3 units/day, and (optionally) **femoral neck BMD**.
3. **Country-specific calibration:** the tool is region-specific because fracture and death rates differ widely between populations — an **Indian FRAX model** exists and must be used for Indian patients.
4. **Clinical use:** FRAX output is compared with a country-specific **intervention threshold**. In Pathy's algorithm, treatment is offered when the FRAX probability for major osteoporotic (or hip) fracture reaches a **risk equivalent to that associated with a prevalent fragility fracture** — an age-dependent threshold. FRAX also identifies who needs a DXA when access is limited.
5. **Modifiers that refine FRAX:** BMD, **trabecular bone score (TBS)**, glucocorticoid dose, fall history, type 2 diabetes and hip axis length.
6. **Advantages:** free, quick, usable without DXA, validated in large international cohorts, and it shifts practice from a pure BMD threshold to absolute risk — important because most fractures occur in people who are only osteopenic.
7. **Limitations:** does not capture **falls**, **number or recency of fractures** (it treats one fracture the same as five), dose of glucocorticoid, lumbar spine BMD, vitamin D status, or frailty; it is **not validated on treatment** and is capped at 90 years; it therefore **underestimates imminent risk** immediately after a fracture.

Latest Updates (2023 – Present) — 3 Points

- **FRAXplus** (released from 2023) is an extension allowing adjustment for **recency of fracture, glucocorticoid dose, number of falls, TBS, type 2 diabetes, hip axis length and lumbar spine BMD** — directly addressing the classical limitations.
- **NOGG 2024** and ESCEO/IOF guidance retain FRAX-based age-dependent intervention thresholds and add a **very-high-risk threshold** that triggers anabolic-first therapy.
- Guidelines increasingly note that FRAX should be **overridden** in the presence of a recent (<2 year) major fracture or multiple vertebral fractures, where imminent risk exceeds the calculated figure.

Exam One-Liners

- FRAX gives the 10-year probability of major osteoporotic and hip fracture.
- Eleven clinical inputs; femoral neck BMD optional.
- Must use the country-specific (Indian) model.
- Blind spots: falls, fracture number and recency, steroid dose, spine BMD.
- FRAXplus corrects most of these.

Q5. Selective Estrogen Receptor Modulators (SERMs) — 7 MARKS

1. **Definition:** SERMs are non-steroidal agents that bind the oestrogen receptor and act as **tissue-selective agonists or antagonists** — agonist on bone and lipids, antagonist on breast, with variable effect on the endometrium. Selectivity arises from differential recruitment of co-activators and co-repressors to ER-α and ER-β.
2. **Agents: raloxifene** (60 mg/day, second generation, the main bone agent), **bazedoxifene** (third generation, also used as a tissue-selective oestrogen complex with conjugated oestrogens), **tamoxifen** and **toremifene** (breast cancer), **ospemifene** (dyspareunia), **lasofoxifene**.
3. **Mechanism on bone:** agonist action suppresses osteoclastic resorption and reduces bone turnover, preserving BMD — a mild antiresorptive effect, weaker than bisphosphonates.
4. **Indication in Pathy's algorithm:** in postmenopausal women categorised as **low fracture risk**, menopausal hormone therapy and SERMs may be considered. Raloxifene raises lumbar spine BMD by about **3%** and femoral neck by **2%** at 12–18 months and reduces **vertebral fracture only**.
5. **Key limitation (frequently examined): raloxifene has not been found to decrease the incidence of femoral neck fractures**, and **SERMs must be avoided after femoral neck fracture because of the increased risk of thromboembolic complications**.
6. **Additional benefit:** raloxifene reduces the incidence of **ER-positive invasive breast cancer**, making it attractive in a woman with vertebral osteoporosis and elevated breast cancer risk.
7. **Adverse effects and cautions: venous thromboembolism** (2–3 fold increase — the main hazard in the elderly and in the immobile), **hot flushes**, leg cramps, peripheral oedema; an excess of fatal stroke was seen in women with cardiovascular risk factors. Contraindicated in prior VTE, prolonged immobility, and active hepatic disease. Unlike oestrogen, raloxifene **does not stimulate the endometrium** (no increase in endometrial cancer) and does not relieve vasomotor symptoms.

Latest Updates (2023 – Present) — 3 Points

- Current guidance (Endocrine Society, NOGG 2024, ESCEO) positions SERMs as **second- or third-line**, reserved for younger postmenopausal women with predominantly vertebral disease, low hip fracture risk and elevated breast cancer risk — not for the old-old.
- **Bazedoxifene / conjugated oestrogen (TSEC)** remains an option for women needing both vasomotor symptom relief and bone protection without endometrial stimulation.
- Sequence matters: when a SERM is stopped, BMD is lost, so **follow-on antiresorptive therapy** is advised in those who remain at risk; the ASBMR/BHOF 2024 goal-directed framework notes that SERMs rarely achieve the target T-score in high-risk patients.

Exam One-Liners

- Agonist on bone, antagonist on breast — that one line defines a SERM.
- Raloxifene reduces vertebral fracture only, not hip fracture.
- Contraindicated after femoral neck fracture and in any VTE risk.
- Reduces ER-positive breast cancer; does not cause endometrial hyperplasia.
- Worsens, not relieves, hot flushes.

Q6. Atypical Femur Fractures Due to Drugs — 7 MARKS

1. **Definition:** an atypical femoral fracture (AFF) is a **stress or insufficiency fracture of the subtrochanteric region or femoral shaft** occurring with minimal or no trauma, associated with prolonged suppression of bone turnover — classically by **long-term bisphosphonates**, and also reported with **denosumab**, glucocorticoids and proton-pump inhibitors.
2. **ASBMR major features (all five required):** (i) minimal or no trauma; (ii) fracture line originates at the **lateral cortex and is substantially transverse**; (iii) **non-comminuted** or minimally comminuted; (iv) complete fractures extend through both cortices with a **medial spike**, incomplete fractures involve only the lateral cortex; (v) **localised periosteal or endosteal thickening ("beaking" or "flaring") of the lateral cortex**. Fractures of the femoral neck, intertrochanteric region with spiral extension, and pathological or periprosthetic fractures are excluded.
3. **Minor features:** generalised increase in cortical thickness of the femoral diaphysis, prodromal dull thigh or groin pain, **bilaterality**, delayed union, and comorbid conditions or drug exposure (bisphosphonates, denosumab, glucocorticoids, PPIs).
4. **Pathogenesis:** severe suppression of bone turnover impairs repair of micro-damage; accumulated micro-cracks, hypermineralised brittle bone and reduced collagen heterogeneity produce a fatigue fracture at the site of maximal tensile stress on the lateral femoral cortex. Bowed femora, Asian ethnicity, short stature and glucocorticoids increase risk.
5. **Clinical presentation and diagnosis:** **prodromal thigh or groin pain** in about two-thirds, often for weeks to months, then a fracture on trivial trauma. Investigate any patient on long-term antiresorptive therapy with new thigh pain by **full-length femoral radiographs of both femora**; if negative but suspicion persists, **MRI or bone scintigraphy** detects early stress reaction. Always image the **contralateral** femur, as bilateral involvement is common.
6. **Risk in context — the crucial balance:** AFF is **rare** (of the order of a few per 10,000 patient-years, rising with duration beyond 5 years and falling rapidly after stopping), whereas bisphosphonates prevent many times that number of typical osteoporotic fractures. **The benefit clearly outweighs the risk in patients at high fracture risk.** Osteonecrosis of the jaw is the other rare class effect.
7. **Management:** (a) **stop the bisphosphonate or denosumab** (with antiresorptive cover if denosumab is discontinued); (b) ensure calcium and vitamin D repletion; (c) **prophylactic intramedullary nailing** for a complete fracture, and for an incomplete fracture with a radiolucent line or persistent pain — conservative treatment with protected weight-bearing is reserved for incomplete fractures without a dreaded black line; (d) **teriparatide** may be used to promote healing and to continue osteoporosis treatment; (e) periodic **drug holiday review at 3 years for IV and 5 years for oral bisphosphonates** is the principal preventive strategy.

Latest Updates (2023 – Present) — 3 Points

- 2025 reviews of novel osteoporosis therapies reinforce structured **drug-specific safety monitoring**: assess cardiovascular history before romosozumab, monitor calcium with teriparatide, abaloparatide and denosumab (especially in renal impairment), and watch for **MRONJ around dental procedures and AFF with longer-term bisphosphonate use**.
- **Drug holidays** remain the mainstay of AFF prevention for bisphosphonates — but the concept explicitly **does not apply to denosumab**, where interruption causes rebound vertebral fractures.
- Asian ancestry, femoral bowing and glucocorticoid use are now recognised as amplifying risk, which is directly relevant to Indian patients on long-term therapy; contralateral femoral imaging is standard once an AFF is diagnosed.

Current Practice Update

Issue	Textbook position	Current position
Attribution	Rare complication of bisphosphonates	Also with **denosumab**; risk falls rapidly after drug cessation
Prevention	Limit duration of therapy	Formalised as **drug holiday at 3 years IV / 5 years oral**, with annual reassessment — not applicable to denosumab
Ongoing bone therapy after AFF	Not specified	**Teriparatide** is the preferred continuation agent

Exam One-Liners

- Site: subtrochanteric or diaphyseal — never the femoral neck.
- Transverse, non-comminuted, lateral cortical beaking, medial spike.
- Prodromal thigh pain in two-thirds; frequently bilateral — always image both femora.
- Stop the antiresorptive; nail complete and painful incomplete fractures; consider teriparatide.
- Absolute risk is tiny compared with the fractures prevented.

Q7. Renal Osteodystrophy — Laboratory and Radiological Abnormalities and Treatment

15 MARKS

A. Definition and Classification

1. **Renal osteodystrophy** is the spectrum of **bone histological abnormalities** occurring in chronic kidney disease. It is the skeletal component of the broader syndrome **CKD–Mineral and Bone Disorder (CKD–MBD)**, which also includes biochemical abnormalities and vascular/soft-tissue calcification.
2. Definitive classification is by bone biopsy using the **TMV system — Turnover, Mineralisation, Volume**.
3. **High-turnover disease: osteitis fibrosa cystica** from secondary hyperparathyroidism. **Low-turnover disease: adynamic bone disease** (low turnover, normal mineralisation) and **osteomalacia** (low turnover, defective mineralisation). **Mixed uraemic osteodystrophy** combines both. Dialysis patients may also develop **β2-microglobulin amyloid** bone disease.

B. Pathophysiology (the four-step cascade)

4. Falling GFR → **phosphate retention** → rise in **FGF-23** (the earliest abnormality) with **Klotho deficiency**.
5. FGF-23 and reduced renal mass suppress **1-α-hydroxylase** → low **calcitriol** → reduced intestinal calcium absorption → **hypocalcaemia**.
6. Hypocalcaemia, hyperphosphataemia and calcitriol deficiency all stimulate PTH → **secondary hyperparathyroidism**, with parathyroid hyperplasia and down-regulation of calcium-sensing and vitamin D receptors; autonomous nodular hyperplasia produces **tertiary hyperparathyroidism** with hypercalcaemia.
7. **Adynamic bone disease** results from over-suppression of PTH — by aggressive calcium and vitamin D loading, high-calcium dialysate, calcimimetics, diabetes, ageing and peritoneal dialysis. It is now the commonest lesion, and is important in the elderly because it causes fractures and drives vascular calcification.
8. **Aluminium** (from phosphate binders or dialysate) causes osteomalacia and microcytic anaemia — historical but still examinable.

C. Laboratory Abnormalities

Parameter	Osteitis fibrosa (high turnover)	Adynamic bone disease	Osteomalacia
Serum calcium (mg/dL)	Low or normal; high in tertiary	Normal or **high**	Low
Serum phosphate (mg/dL)	**High**	High or normal	Low or normal
PTH	**Markedly raised** (>9× upper limit)	**Low / inappropriately normal** (<2×)	Variable
Alkaline phosphatase / bone ALP	**High**	Low or normal	High
25-OH vitamin D	Often low	Variable	**Low**
Calcitriol	Low	Low	Low
FGF-23	**Very high**	High	High

9. Supporting tests: serum aluminium (with desferrioxamine test if indicated), β2-microglobulin in long-term dialysis, and **bone-specific alkaline phosphatase plus intact PTH** as the practical non-invasive discriminators. **Bone biopsy with tetracycline double labelling** remains the gold standard, reserved for unexplained fractures, hypercalcaemia, suspected aluminium disease, or before parathyroidectomy.

D. Radiological Abnormalities

10. **Subperiosteal resorption** at the **radial border of the middle phalanges of the index and middle fingers** — the earliest and most specific sign; also at the distal clavicle, symphysis pubis, sacroiliac joints and medial proximal tibia. Terminal phalangeal **acro-osteolysis** with tuft resorption.
11. **"Rugger-jersey spine"** — alternating sclerotic bands at the vertebral end-plates with a lucent centre; and a **"salt-and-pepper" skull** with a granular mottled vault.
12. **Brown tumours** — expansile lytic lesions (osteoclastomas) in mandible, ribs, pelvis or long bones, which may fracture and can be mistaken for metastases.
13. **Osteomalacic changes: Looser's zones (pseudofractures)** at the medial femoral neck, pubic rami, scapula and ribs; coarse trabeculae, biconcave vertebrae.
14. **Extraskeletal calcification:** vascular (Monckeberg medial), periarticular tumoral calcinosis, cardiac valve and corneal calcification; **calciphylaxis (calcific uraemic arteriolopathy)** presents as painful violaceous livedoid skin necrosis with high mortality.
15. Modern assessment: **lateral abdominal radiograph and echocardiography** for vascular and valvular calcification (KDIGO-endorsed); **DXA is now recommended** in CKD G3a–G5D to predict fracture, though it cannot distinguish the type of renal osteodystrophy.

E. Treatment

16. **Control phosphate first** — dietary phosphate restriction (avoid processed food with inorganic phosphate additives, which is highly absorbable), adequate dialysis, and phosphate binders: **calcium carbonate/acetate** (limit total elemental calcium, avoid if adynamic bone or vascular calcification), **sevelamer**, **lanthanum carbonate**, and iron-based binders (**sucroferric oxyhydroxide, ferric citrate**). Avoid aluminium binders except short-term.
17. **Correct native vitamin D deficiency** with cholecalciferol; then, for persistently high and rising PTH, use **active vitamin D analogues** (calcitriol, alfacalcidol) or the less calcaemic **paricalcitol / doxercalciferol**.
18. **Calcimimetics** — oral **cinacalcet** or IV **etelcalcetide** (dialysis) — lower PTH, calcium and phosphate simultaneously by sensitising the calcium-sensing receptor; the drug of choice when PTH is high with hypercalcaemia.
19. **Target PTH** in dialysis patients at approximately **2–9 times the upper limit of normal** for the assay — deliberately not normal, because normal PTH in CKD predicts adynamic bone.
20. **Parathyroidectomy** for severe refractory secondary or tertiary hyperparathyroidism with hypercalcaemia, intractable pruritus, calciphylaxis, or progressive bone disease. Anticipate **hungry bone syndrome** with profound post-operative hypocalcaemia.
21. **Adynamic bone disease** is managed by doing **less**: reduce calcium load, lower dialysate calcium, withdraw or reduce active vitamin D and calcimimetics, and allow PTH to rise into the target range.
22. **Osteoporosis therapy in CKD:** bisphosphonates are generally avoided below eGFR 30–35 mL/min and can worsen adynamic bone; **denosumab** is not renally cleared but causes severe hypocalcaemia in advanced CKD and needs close monitoring with calcium and vitamin D loading; **teriparatide** may help low-turnover disease but is contraindicated where PTH is already high.
23. **General measures:** correct metabolic acidosis with bicarbonate, treat hypogonadism, encourage weight-bearing exercise and resistance training, prevent falls, avoid aluminium-containing antacids, and manage calciphylaxis with sodium thiosulfate, wound care and withdrawal of calcium, vitamin D and warfarin.

Latest Updates (2023 – Present)

- **KDIGO CKD-MBD guidance** continues to advise treating **trends rather than single values** for calcium, phosphate and PTH, lowering elevated phosphate **towards** the normal range rather than to a fixed target, and restricting the dose of calcium-based binders in adults.
- **DXA is now firmly recommended** in CKD G3a–G5D where results would change management — a reversal of the older position that DXA is uninformative in CKD.
- **Upacicalcet** and other newer calcimimetics have been approved in some jurisdictions for secondary hyperparathyroidism in dialysis; iron-based binders (sucroferric oxyhydroxide, ferric citrate) are increasingly preferred for their low pill burden and correction of iron deficiency.
- Growing evidence links **high phosphate and FGF-23 to cardiovascular mortality**, shifting emphasis from bone endpoints to vascular protection; inorganic phosphate additives in processed foods are now a specific dietary target.
- **Indian context:** CKD-MBD care is delivered through the **Pradhan Mantri National Dialysis Programme**; nutritional vitamin D deficiency is near-universal in Indian CKD patients and should be corrected before interpreting PTH.

Current Practice Update

Issue	Older textbook position	Current position
Commonest lesion	Osteitis fibrosa cystica	**Adynamic bone disease**, from over-treatment and diabetes
Phosphate binders	Calcium-based, first-line	**Restrict calcium-based binders**; prefer non-calcium binders
PTH target	Normalise PTH	Keep at **2–9× upper limit**; normal PTH in dialysis is a warning sign
DXA in CKD	Unhelpful	**Recommended** in G3a–G5D to predict fracture

Exam One-Liners

- Renal osteodystrophy is the bone histology; CKD-MBD is the whole syndrome.
- Classified by the TMV system on bone biopsy.
- FGF-23 rise is the earliest biochemical abnormality.
- Subperiosteal resorption of the radial border of the middle phalanx is the classic radiological sign.
- Rugger-jersey spine, salt-and-pepper skull, brown tumours, Looser's zones.
- Adynamic bone disease means too much treatment, not too little.
- Calciphylaxis is a dermatological emergency with very high mortality.

Q8. Osteoarthritis — Management — 15 MARKS

A. Principles

1. **Osteoarthritis** is the commonest joint disease of older adults and a leading cause of pain, immobility and disability. Management is **symptom-directed and function-directed**, since no agent has been shown to reverse structural damage.
2. **Optimal management involves multiple treatment modalities, and the best combination varies from patient to patient** (Kane's) — a core, quotable line.
3. Treating arthritis optimally **requires a differential diagnosis**, because several arthritides coexist in older adults. Distinguish OA from inflammatory arthritis: stiffness lasting **minutes** not hours, pain **with activity** rather than at rest and at night, fatigue unusual, swelling present but with little synovial reaction, and erythema and warmth unusual.

B. Non-Pharmacological Management (the foundation)

4. **Education and self-management**, with realistic goal-setting and an explanation that OA is manageable rather than inevitable disability.
5. **Exercise is first-line**: quadriceps and hip abductor strengthening, range-of-movement work, and low-impact aerobic activity. Patients referred for joint replacement should be **encouraged to lose weight and strengthen the relevant muscles before surgery**.
6. **Weight reduction** — the single most effective disease-modifying intervention for knee and hip OA.
7. **Physiotherapy and occupational therapy:** joint protection, energy conservation, activity pacing, and assessment for **assistive devices** — walking stick held in the **contralateral** hand, walking frame, raised toilet seat, tap turners, jar openers.
8. **Orthoses and footwear:** shock-absorbing insoles, appropriate footwear, knee braces for varus/valgus instability, thumb-base splint for first carpometacarpal OA.
9. **Local physical measures:** heat, cold, and transcutaneous electrical nerve stimulation as adjuncts.

C. Pharmacological Management

10. **Paracetamol** is the traditional first-line oral analgesic in older people because of its favourable safety profile, though its efficacy in OA is modest; maximum 3 g/day in the frail elderly.
11. **Topical NSAIDs** are preferred over oral NSAIDs for knee and hand OA in older adults, giving useful analgesia with minimal systemic exposure. **Topical capsaicin** is an alternative.
12. **Oral NSAIDs** — lowest dose, shortest duration, always with a proton-pump inhibitor. Hazardous in the elderly: gastrointestinal bleeding, acute kidney injury, fluid retention and heart failure decompensation, hypertension, and interaction with ACE inhibitors and diuretics ("triple whammy"). They appear on the **AGS Beers Criteria** as potentially inappropriate for chronic use.
13. **Intra-articular corticosteroid injection** for a painful effusive flare gives short-term relief; limit to three or four injections per joint per year. Local steroid injection also gives dramatic relief in **bicipital tendinitis, olecranon and trochanteric bursitis**, which are common in geriatric patients and must be sought on examination.
14. **Nutraceuticals:** glucosamine and chondroitin — although there may be a placebo effect resulting in benefit, **there is no evidence of significant improvement in pain**; likewise **vitamin D does not decrease pain or facilitate repair of structural damage** in OA.
15. **Duloxetine** and, cautiously, low-dose weak opioids (tramadol) are reserved for refractory pain; opioids carry falls, delirium, constipation and dependence risk in older adults.

D. Surgical and Interventional Management

16. **Arthroscopic interventions** (debridement and lavage, osteotomy, cartilage transplant) have been recommended where inflammation is present and non-invasive measures have failed, but **there is little evidence to support their efficacy** (Moseley et al.).
17. **Joint replacement should be reserved for individuals with severe symptomatic disease who do not respond to more conservative interventions**; patients referred should have **stable medical conditions** and be prepared with weight loss and muscle strengthening pre-operatively.
18. Post-operative care needs structured **rehabilitation**, delirium prevention, VTE prophylaxis and falls prevention.

E. Geriatric-Specific Considerations

19. Address the **consequences** as much as the joint: OA causes immobility, deconditioning, sarcopenia, falls, depression, social isolation and caregiver burden — a comprehensive geriatric assessment is appropriate.
20. Look actively for treatable non-articular mimics — tendinitis, bursitis, and **carpal tunnel syndrome**, which is common in older adults and can be confused with gout, rheumatoid arthritis or pseudogout.

> **Latest Updates (2023 – Present)**

- **OARSI and ACR guidance** continue to rank **structured exercise and weight management as core**, with topical NSAIDs preferred over oral NSAIDs in older adults; **glucosamine, chondroitin and hyaluronic acid injections remain not recommended** for knee OA.
- **Intra-articular corticosteroids:** repeated injections have been associated with cartilage volume loss on imaging, so use is now restricted to intermittent flares rather than a routine schedule.
- Community-level programmes are gaining evidence — the **WE-CAN study** examined the impact of a community diet-and-exercise programme on knee pain, reflecting a shift towards scalable, non-drug delivery models.
- Emerging pharmacology: **nerve growth factor inhibitors** (tanezumab) showed efficacy but rapidly progressive OA limited approval; **lorecivivint** (Wnt inhibitor) and **low-dose colchicine** are under evaluation as potential structure-modifying agents; **GLP-1 receptor agonists** (semaglutide, STEP-9 trial) reduce knee OA pain substantially through weight loss in obesity.
- **Indian context:** knee OA prevalence is high, especially in women; management is supported by **ADIP/ALIMCO** for assistive devices and the **Rashtriya Vayoshri Yojana** for free aids in BPL elderly, with joint replacement covered under **AB-PMJAY**.

Current Practice Update

Issue	Textbook position	Current position
First-line analgesia	Paracetamol	Exercise and weight loss first; **topical NSAID** is the preferred first drug — paracetamol demoted to adjunct
Glucosamine / chondroitin / vitamin D	No proven benefit	Unchanged — explicitly **not recommended**
Arthroscopic lavage	Little supporting evidence	**Should not be offered** for degenerative knee disease
Intra-articular steroid	Useful for flares	Same, but limit frequency — cartilage volume loss with repeated injection
Weight loss	Advise before surgery	Now a therapeutic target in its own right, including **GLP-1 agonists** in obese patients

Exam One-Liners

- OA stiffness lasts minutes; inflammatory arthritis stiffness lasts hours.
- Exercise and weight loss are the only interventions that change the disease course.
- Walking stick goes in the hand opposite to the affected joint.
- Glucosamine, chondroitin and vitamin D do not work in OA.
- Arthroscopic lavage for degenerative knee disease is not supported by evidence.
- Always look for bursitis, tendinitis and carpal tunnel syndrome as treatable mimics.

Q9. Polymyalgia Rheumatica — 15 MARKS

A. Definition and Epidemiology

1. **Polymyalgia rheumatica (PMR)** is a chronic inflammatory rheumatic disease of older adults characterised by **pain and morning stiffness of the shoulder, neck and hip girdles** with a markedly raised acute-phase response, and a dramatic response to corticosteroids.
2. It is **a common musculoskeletal problem of older women** (Kane's) and occurs **almost exclusively in people over 50 years**, with peak incidence in the seventh and eighth decades; women are affected two to three times as often as men.
3. PMR and giant cell arteritis have common clinical and epidemiological links but need not occur synchronously: roughly **40–50%** of GCA patients have PMR features, and about **15–20%** of PMR patients develop GCA.
4. **Geriatric relevance:** Pathy's lists PMR among the major causes of **frailty**, acting through pain, immobility and reduced food intake — and stresses that **treatment with corticosteroids reverses the frailty it produces, yet this totally reversible condition is often misdiagnosed by clinicians**.

B. Aetiology and Pathophysiology

5. Aetiology is unknown; there is a genetic association with **HLA-DRB1*04**, and environmental or infectious triggers have been proposed given seasonal and cyclical clustering.
6. The dominant mechanism is **IL-6 driven systemic inflammation** with dendritic cell and CD4+ T-cell activation. Unlike myositis, the muscle itself is normal — the pathology lies in **peri-articular structures: subacromial and subdeltoid bursitis, glenohumeral synovitis, biceps tenosynovitis and trochanteric bursitis**.
7. Ageing-related **immunosenescence and inflammaging** explain the restriction of PMR to older adults.

C. Clinical Features

8. **Cardinal symptoms:** symmetrical aching and stiffness of the shoulder girdle (most common), neck and hip girdle, of relatively abrupt onset, worst in the morning and after rest, with **morning stiffness lasting more than 45–60 minutes**.
9. **Functional impact:** difficulty getting out of bed, standing up from a chair, lifting the arms to comb the hair, and turning over in bed — a classic geriatric presentation of "off legs" or "gone off her feet".
10. **Constitutional symptoms** (Kane's list): **weight loss, fever, muscle pain, aching of the neck, shoulder and hip, and morning stiffness**; also fatigue, malaise, anorexia, depression and low-grade pyrexia. PMR is a recognised cause of **pyrexia of unknown origin** in the elderly.
11. **Examination:** painful restriction of active shoulder and hip movement with preserved passive range; **muscle strength is normal** once pain is overcome, and there is no muscle wasting or tenderness disproportionate to pain. A peripheral asymmetrical arthritis, carpal tunnel syndrome and distal **RS3PE**-like pitting oedema may occur.
12. **Always screen for GCA** at every visit: headache, scalp tenderness, jaw claudication, visual symptoms, and temporal artery abnormality.

D. Investigations and Diagnosis

13. **ESR and CRP** are markedly elevated — ESR classically above **40 mm/hour**. About 7–20% have a normal ESR at presentation, so a normal ESR with a typical picture and high CRP does not exclude PMR.
14. **Normal creatine kinase, normal electromyography and normal muscle biopsy** — the single most useful discriminator from inflammatory myopathy. Normocytic normochromic anaemia of chronic disease, thrombocytosis, raised alkaline phosphatase and hypoalbuminaemia are common. Rheumatoid factor and anti-CCP are negative.
15. **Exclusion is essential** before committing to long-term steroids: full blood count, renal and liver function, calcium, TSH, CK, protein electrophoresis, ANA, RF/anti-CCP, chest radiograph, and vitamin D. Consider PSA in men and imaging if malignancy is suspected.
16. **Imaging:** ultrasound showing bilateral subacromial/subdeltoid bursitis or biceps tenosynovitis supports the diagnosis and is part of the **2012 EULAR/ACR classification criteria** (age ≥50, bilateral shoulder pain and raised ESR/CRP are mandatory, then scored on morning stiffness >45 minutes, hip involvement, absence of RF/anti-CCP, and absence of other joint involvement; ≥4 points without ultrasound, ≥5 with). PET-CT may show large-vessel uptake and detect coexisting GCA.
17. **Differential diagnosis:** late-onset rheumatoid arthritis, inflammatory myopathy, hypothyroidism, statin myopathy, osteoarthritis of the cervical spine and shoulders, rotator cuff disease, fibromyalgia, myeloma, occult malignancy, infective endocarditis, and Parkinson's disease.

E. Management

18. **Corticosteroids are the treatment** — typically **prednisolone 12.5–25 mg/day** (commonly 15 mg). Response is dramatic: near-complete relief of symptoms within 24–72 hours. **Failure to respond promptly should make you question the diagnosis.**
19. **Tapering:** reduce to 10 mg/day over 4–8 weeks, then by 1 mg every 4 weeks, guided by symptoms rather than ESR

alone. Most need **1–2 years** of treatment; relapse occurs in over half during tapering.

20. **Methotrexate has been used as a corticosteroid-sparing agent and may be useful for patients with frequent disease relapses and/or corticosteroid-related toxicity** (Kane's) — typically 7.5–15 mg weekly with folic acid.
21. **Infliximab has not been shown to be beneficial** in terms of pain management or disease progression and **is not currently recommended** (Kane's, citing Hernández-Rodríguez).
22. **Mandatory steroid-sparing co-prescription in the elderly:** calcium and vitamin D, **bone protection with a bisphosphonate**, gastroprotection where NSAIDs or high steroid doses are used, glucose monitoring for steroid-induced diabetes, blood pressure and weight monitoring, and cataract and glaucoma surveillance. Consider *Pneumocystis* prophylaxis at high cumulative doses.
23. **Escalate vigilance to GCA:** because of the close association between PMR and temporal arteritis, **any symptoms suggestive of temporal artery involvement — headache, jaw claudication, recent changes in vision — especially when the sedimentation rate is very high (>75 mm/hour), should prompt consideration of temporal artery biopsy** (Kane's).
24. **Non-drug care:** graded exercise to prevent deconditioning and steroid myopathy, fall prevention, protein-adequate nutrition, and management of steroid-related mood change and insomnia.

F. Prognosis

25. Prognosis is **good** — most achieve remission and stop steroids within 1–3 years, though a minority need low-dose maintenance for longer. Morbidity in the elderly comes largely from **cumulative glucocorticoid toxicity**: osteoporotic fracture, diabetes, infection, cataract, skin fragility and steroid myopathy.

Latest Updates (2023 – Present)

- **Sarilumab (Kevzara) was approved by the FDA on 28 February 2023 as the first and only biologic for polymyalgia rheumatica** in adults with an inadequate response to corticosteroids or who cannot tolerate a corticosteroid taper; the European Commission followed in November 2024.
- The approval rested on the phase 3 **SAPHYR trial (NEJM, October 2023)**: patients with glucocorticoid-resistant PMR who flared on ≥7.5 mg/day prednisone were randomised to sarilumab 200 mg every 2 weeks with a 14-week steroid taper, or placebo with a 52-week taper. **Sustained remission at 52 weeks was 28% with sarilumab versus 10% with placebo** ($p = 0.019$) — nearly three times as many patients — with markedly lower cumulative steroid exposure. Neutropenia occurred in about 3%.
- Prescribing caution with sarilumab: avoid if the absolute neutrophil count is below 2000/mm³, platelets below 150,000/mm³, or transaminases more than 1.5 times the upper limit of normal.
- **Tocilizumab** (SEMAPHORE and PMR-SPARE trials) has also shown steroid-sparing efficacy in PMR, although it is not formally licensed for the indication.
- Current expert practice reserves IL-6 blockade for **relapsing PMR, steroid-dependent disease, or patients in whom steroid toxicity is unacceptable** — a group that includes many frail older adults with diabetes or osteoporosis.

Current Practice Update

Issue	Textbook position (Kane's / Pathy's)	Current position (2023–present)
Steroid-sparing agent	Methotrexate for frequent relapse or steroid toxicity	Methotrexate retained, but **sarilumab is now the first licensed biologic** (FDA 2023, EU 2024)
TNF inhibitors	Infliximab not beneficial, not recommended	Unchanged — TNF blockade has no role in PMR
Starting steroid dose	"Steroids such as prednisone"	Standardised at **12.5–25 mg/day prednisolone**, individualised by weight and comorbidity
Role of imaging	Not emphasised	Ultrasound bursitis included in **2012 EULAR/ACR criteria**; PET-CT to detect occult large-vessel GCA

Extra Recall Scaffold — Recurring Topic (asked twice)

Mnemonic for the diagnostic pillars — "PMR 50": **P**ain and stiffness in shoulder/hip girdle · **M**orning stiffness >45 minutes · **R**aised ESR/CRP · age **≥50** · and a rapid **response to 15 mg prednisolone**.

Numerical anchors: age ≥50 · F:M 2–3:1 · morning stiffness >45 min · ESR >40 mm/h · ESR >75 mm/h with cranial symptoms → biopsy · prednisolone 12.5–25 mg · response in 24–72 hours · taper to 10 mg over 4–8 weeks · then 1 mg every 4 weeks · treatment 1–2 years · 15–20% develop GCA · SAPHYR 28% vs 10%.

Examiner traps: (1) Calling it a myopathy — **CK, EMG and muscle biopsy are normal**; the weakness is pain-limited, not true weakness. (2) Starting steroids before excluding myeloma, malignancy and infection. (3) Missing coexisting GCA — ask about jaw claudication and visual symptoms at **every** visit. (4) Giving high dose (≥40 mg) prednisolone for uncomplicated PMR — that dose belongs to GCA. (5) Forgetting bone protection from day one. (6) Tapering by ESR alone rather than by symptoms.

15-second answer skeleton: Define → epidemiology and link to GCA → frailty relevance from Pathy's → IL-6 driven peri-articular bursitis, not myositis → girdle pain with morning stiffness and constitutional features → raised ESR/CRP with normal CK → EULAR/ACR criteria and exclusions → prednisolone 15 mg with dramatic response and slow taper → methotrexate, and now sarilumab → bone and steroid-toxicity protection → watch for GCA → good prognosis.

Exam One-Liners

- PMR is a peri-articular bursitis syndrome, not a muscle disease — CK is normal.
- Age ≥50 is essential to the diagnosis.
- Failure to respond to 15 mg prednisolone within 72 hours means rethink the diagnosis.
- ESR >75 mm/h with headache or visual change mandates consideration of temporal artery biopsy.
- Infliximab does not work; methotrexate is the classical steroid-sparing agent.
- Sarilumab (SAPHYR, 2023) is the first licensed biologic for PMR.
- Pathy's lists PMR as a fully reversible cause of frailty that is commonly missed.

Q10. Temporal Arteritis (Giant Cell Arteritis) — 15 MARKS

A. Definition and Epidemiology

1. **Giant cell arteritis (GCA), or temporal arteritis**, is a **granulomatous large- and medium-vessel vasculitis** affecting the extracranial branches of the carotid artery, the aorta and its major branches, occurring almost exclusively in people **over 50 years**.
2. It is the **commonest primary systemic vasculitis of older adults**; peak incidence is between **70 and 80 years**, with women affected two to three times more often than men. Incidence is highest in Northern European populations and lower in India and Asia, although under-diagnosis contributes.
3. Men are more likely to have **ocular manifestations**. GCA and PMR are closely linked; Pathy's also notes that GCA must be considered as a cause of **cerebrovascular disease and vertigo** in older people.
4. It is a **medical emergency** — untreated it causes irreversible blindness, aortic aneurysm and stroke.

B. Pathology and Pathophysiology

5. Dendritic cells in the adventitia are activated, recruiting CD4+ T cells that differentiate into **Th1 (interferon-γ)** and **Th17 (IL-17)** lineages; macrophages fuse to form **multinucleate giant cells**.
6. **Histology:** transmural granulomatous panarteritis with mononuclear infiltrate, giant cells adjacent to a **fragmented internal elastic lamina**, and **intimal hyperplasia causing luminal occlusion** — the intimal proliferation, not the inflammation itself, causes the ischaemic events.
7. Involvement is **segmental and patchy ("skip lesions")**, which is why a short or unilateral biopsy may be falsely negative.
8. **IL-6** drives the systemic inflammatory response and the acute-phase reactants — the rationale for tocilizumab and sarilumab.

C. Clinical Features

9. **Cranial:** new-onset **temporal or occipital headache**, **scalp tenderness** (pain on combing hair or lying on a pillow), and a thickened, tender, nodular, pulseless temporal artery.
10. **Jaw claudication** — pain in the masseters on chewing — is the **most specific symptom**; tongue claudication and, rarely, tongue or scalp necrosis occur.
11. **Visual:** amaurosis fugax, diplopia, and sudden painless monocular visual loss from **arteritic anterior ischaemic optic neuropathy** (chalky-white swollen disc), central retinal artery occlusion, or posterior ischaemic optic neuropathy. Untreated, the second eye is involved within days to weeks.
12. **Systemic:** fever, weight loss, anorexia, malaise, depression — GCA is an important cause of **pyrexia of unknown origin** in older people and may present as isolated unexplained inflammation.
13. **Polymyalgic:** shoulder and hip girdle pain and stiffness in 40–50%.
14. **Large-vessel disease:** limb claudication, asymmetrical blood pressures, absent or unequal pulses, subclavian or carotid bruits; late **thoracic aortic aneurysm and dissection**.
15. **Neurological:** transient ischaemic attack and stroke, predominantly in the **vertebrobasilar territory**; GCA-related stroke is defined as an ischaemic infarct within three to four weeks of diagnosis and treatment.

D. Investigations

16. **ESR and CRP** are markedly elevated; **ESR is often above 75–100 mm/hour**. CRP is the more sensitive; up to 4% of biopsy-proven cases have normal inflammatory markers.
17. **Supporting bloods:** normocytic anaemia, thrombocytosis, raised alkaline phosphatase, hypoalbuminaemia, raised IL-6.
18. **Temporal artery biopsy** is the diagnostic gold standard. Practical rules: take a segment of at least **1–2 cm** with serial sectioning to overcome skip lesions; consider bilateral biopsy; **do not delay steroids for the biopsy** — histology remains positive for up to **2–4 weeks** after starting treatment. Kane's emphasises that any symptom suggestive of temporal artery involvement — headache, jaw claudication, recent visual change — especially with an ESR above 75 mm/hour, should prompt consideration of temporal artery biopsy.
19. **Colour Doppler ultrasound** of temporal and axillary arteries showing the non-compressible **"halo sign"** is now a first-line, non-invasive test.
20. **Cross-sectional imaging** for large-vessel disease: **FDG-PET/CT**, CT angiography or MR angiography of the aorta and branches; MRI of the cranial vessels with contrast can show mural enhancement.
21. **1990 ACR classification criteria** (3 of 5): age at onset ≥50 years, new headache, temporal artery abnormality, ESR ≥50 mm/hour, and abnormal artery biopsy. The **2022 ACR/EULAR criteria** add imaging findings and a positive biopsy weighting.

E. Management

22. **Acute treatment of temporal arteritis with high-dose steroids is needed to prevent blindness** (Kane's) — **start immediately on clinical suspicion, before biopsy**.
23. **Dosing:** uncomplicated GCA — **prednisolone 40–60 mg/day**. Visual loss or amaurosis fugax — **IV**

methylprednisolone 500–1000 mg/day for 3 days then high-dose oral prednisolone. Visual loss already established in one eye is rarely reversed; treatment protects the **fellow eye**.

24. **Taper** slowly over 12–24 months, guided by symptoms and CRP; most patients need **1–2 years or longer**, and relapse is common.
25. **Low-dose aspirin 75–150 mg** may be added to reduce ischaemic events, weighed against gastrointestinal bleeding risk with steroids.
26. **Steroid-sparing therapy: tocilizumab** (IL-6 receptor blocker, GiACTA trial) is licensed for GCA; **methotrexate** is an alternative with modest evidence.
27. **Mandatory adjuncts in older adults:** calcium, vitamin D and a **bisphosphonate from day one**; gastroprotection; monitoring for steroid-induced diabetes, hypertension, cataract, glaucoma, insomnia, mood disturbance, infection and steroid myopathy; and falls prevention.
28. **Long-term surveillance:** annual assessment for **thoracic aortic aneurysm** by imaging, since aortic complications occur years after the acute illness.

F. Prognosis

29. With prompt treatment, visual loss is largely preventable and life expectancy approaches that of the general population; the dominant long-term burden is **glucocorticoid toxicity**, followed by aortic aneurysm and relapse.

Latest Updates (2023 – Present)

- **Upadacitinib was approved by the FDA on 29 April 2025 for adults with giant cell arteritis** — the first and only oral JAK inhibitor for GCA, and the first new class since tocilizumab in 2017. The European Commission approved it in early April 2025. Dose is **15 mg once daily**.
- Approval was based on the phase 3 **SELECT-GCA trial** (NEJM 2025; 428 patients, 70% new-onset): **sustained remission from week 12 to week 52 was achieved by 46.4–46.6% on upadacitinib 15 mg with a 26-week steroid taper versus 29% on placebo** ($p = 0.002$), with a safety profile consistent with other indications and no major cardiovascular events in the trial.
- Upadacitinib should **not** be combined with other JAK inhibitors, biologic DMARDs, or potent immunosuppressants such as azathioprine and ciclosporin; standard JAK-class cautions on thrombosis, herpes zoster and malignancy apply, which matters in elderly patients.
- **Tocilizumab remains the other licensed steroid-sparing option**, and the choice between an oral JAK inhibitor and a subcutaneous IL-6 blocker is now a real clinical decision.
- **Fast-track GCA pathways** with same-day **ultrasound halo assessment** are increasingly replacing routine biopsy as the initial diagnostic step in specialist centres, in line with EULAR imaging recommendations; PET-CT is used for large-vessel and occult disease.
- Recognition of **GCA-related stroke** as an ischaemic infarct occurring within three to four weeks of diagnosis and treatment has sharpened attention to the vertebrobasilar territory and to thromboembolic morbidity in this population.

Current Practice Update

Issue	Textbook position	Current position (2023–present)
First diagnostic test	Temporal artery biopsy	**Colour Doppler ultrasound (halo sign)** first-line in fast-track clinics; biopsy if ultrasound is negative but suspicion persists
Steroid-sparing agents	Steroids alone; methotrexate occasionally	**Tocilizumab** (2017) and **upadacitinib** (2025) both licensed
Steroid taper duration	Prolonged, symptom-guided	Trials now use structured **26-week** tapers when a steroid-sparing agent is co-prescribed
Long-term follow-up	Not emphasised	Routine surveillance for **thoracic aortic aneurysm**

Extra Recall Scaffold — Recurring Topic (asked twice)

Mnemonic for cranial GCA — "HAT-JAWS": Headache (new) · **A**ge ≥50 · **T**emporal artery tender/nodular/pulseless · **J**aw claudication · **A**maurosis / visual loss · **W**eight loss and fever · **S**calp tenderness and high **S**edimentation rate.

Numerical anchors: age ≥50 · peak 70–80 years · ESR ≥50 for ACR criteria, often >75–100 · biopsy segment 1–2 cm · biopsy stays positive 2–4 weeks after steroids · prednisolone 40–60 mg, or IV methylprednisolone 500–1000 mg × 3 days if visual loss · 40–50% have PMR · ACR criteria: 3 of 5 · SELECT-GCA 46% vs 29% · upadacitinib 15 mg.

Examiner traps: (1) Delaying steroids until the biopsy is done — the commonest and most damaging error. (2) Assuming a

normal ESR excludes GCA — up to 4% are normal; check CRP. (3) Assuming a negative biopsy excludes it — skip lesions. (4) Using PMR doses (15 mg) for GCA. (5) Forgetting bone protection and gastroprotection from day one. (6) Forgetting that established visual loss is usually permanent — treatment saves the **other** eye. (7) Overlooking large-vessel GCA presenting only as PUO or limb claudication without headache.

15-second answer skeleton: Define as granulomatous large-vessel vasculitis ≥50 years → emergency → pathology (giant cells, fragmented internal elastic lamina, intimal hyperplasia, skip lesions) → cranial, ocular, systemic, polymyalgic, large-vessel and neurological features → ESR/CRP, biopsy rules, ultrasound halo, PET → ACR criteria → immediate high-dose steroids (IV if visual loss) → aspirin, tocilizumab, upadacitinib → bone protection and steroid toxicity monitoring → aneurysm surveillance → prognosis.

Exam One-Liners

- Jaw claudication is the most specific symptom of GCA.
- Never delay steroids for a biopsy — histology remains positive for 2–4 weeks.
- Visual loss is usually irreversible; treatment protects the fellow eye.
- Skip lesions make a 1–2 cm biopsy with serial sections essential.
- Halo sign on temporal artery ultrasound is the modern first-line test.
- Tocilizumab (2017) and upadacitinib (2025) are the licensed steroid-sparing drugs.
- Screen survivors for thoracic aortic aneurysm.

Q11. Late-Onset Rheumatoid Arthritis — 15 MARKS

A. Definition and Epidemiology

1. **Late-onset rheumatoid arthritis (LORA)**, also called elderly-onset RA, is rheumatoid arthritis with first symptom onset at or after **60–65 years**, as distinct from **young-onset RA growing old** — a distinction that must be made explicitly in the answer.
2. It accounts for roughly **10–33%** of all RA. The female preponderance of young-onset disease is lost — the **sex ratio approaches 1:1**.
3. Pathy's notes rheumatoid arthritis as a recognised cause of **secondary osteoporosis** and as a factor in FRAX, and RA joint pain as a classical driver of **immobility and frailty** in older people.

B. Pathogenesis

4. The same autoimmune synovitis as classical RA — citrullination of self-proteins, anti-citrullinated peptide antibody formation, T- and B-cell activation, and cytokine-driven pannus formation with TNF-α, IL-1 and IL-6.
5. **Immunosenescence** shapes the phenotype: thymic involution, expansion of CD4+CD28− senescent T cells, telomere shortening and "inflammaging" produce a more **acute-onset, cytokine-driven, seronegative and polymyalgic** picture.
6. HLA-DRB1 shared-epitope association is weaker than in young-onset disease.

C. Clinical Features — How It Differs from Young-Onset RA

Feature	Young-onset RA	Late-onset RA
Sex ratio	Female 3:1	**Approximately equal**
Onset	Insidious over weeks to months	**Acute or abrupt**, often "overnight"
Joint distribution	Small joints of hands and feet	**Large proximal joints — shoulders, hips, knees**
Constitutional symptoms	Mild	**Prominent** — fever, weight loss, fatigue
Rheumatoid factor / anti-CCP	Positive in most	More often **seronegative**
ESR / CRP	Raised	**Very high**, often mimicking PMR
Rheumatoid nodules and extra-articular disease	Common	**Less common**
Erosions	Progressive	Variable — seropositive LORA erodes as aggressively or faster

7. **Three recognised subsets:** (i) a classical RA-like polyarthritis; (ii) a **PMR-like syndrome** with proximal girdle stiffness; (iii) **RS3PE** — remitting seronegative symmetrical synovitis with pitting oedema of the hands, which is strongly age-associated, HLA-B7 linked, exquisitely steroid-responsive, and may herald occult malignancy.
8. **Presentation is often functional**: sudden inability to dress, grip or walk, presenting as "off legs" or acute functional decline rather than as joint complaint.
9. **Extra-articular features** when present: interstitial lung disease, anaemia of chronic disease, secondary Sjögren's syndrome, vasculitis, Felty's syndrome, scleritis, pericarditis, and amyloidosis. Cervical spine involvement with **atlanto-axial subluxation** is a specific anaesthetic hazard.

D. Investigations

10. **Rheumatoid factor and anti-CCP** — anti-CCP is far more specific, since **RF rises with age and is positive in up to 10–25% of healthy older people**, making a low-titre RF alone almost meaningless in this age group.
11. **ESR, CRP, full blood count** (anaemia of chronic disease, thrombocytosis), renal and liver function — the latter two also determine DMARD choice.
12. **Radiographs** of hands and feet for periarticular osteopenia, joint space narrowing and marginal erosions; **ultrasound or MRI** for early synovitis and erosion detection.
13. **Pre-treatment screen:** chest radiograph, hepatitis B and C serology, tuberculosis screening (crucial in India before any biologic — Mantoux/IGRA plus chest X-ray), and vaccination status.
14. **2010 ACR/EULAR classification criteria** (score ≥6/10 from joint involvement, serology, acute-phase reactants and symptom duration ≥6 weeks) are used, though they perform less well in seronegative late-onset disease.
15. **Differential diagnosis is the crux: polymyalgia rheumatica** (no true synovitis, no erosions, responds to 15 mg prednisolone), **calcium pyrophosphate deposition disease / pseudogout**, polyarticular gout, paraneoplastic arthritis, viral arthritis, hypothyroidism, and erosive osteoarthritis of the hands.

E. Management

16. **Treat-to-target** applies equally in old age — aim for remission or low disease activity using DAS28, with review every 1–3 months. **Age alone is not a reason for therapeutic nihilism**, since uncontrolled RA causes disability, sarcopenia, osteoporosis and excess cardiovascular death.
17. **Methotrexate remains the anchor drug**, starting 7.5–10 mg weekly with folic acid. Pathy's cautions that there is a natural 30% decrease in glomerular filtration rate with ageing, in addition to further potential renal insults, so **caution must be taken with dosing methotrexate in older patients with renal impairment**. Monitor full blood count, liver function and creatinine.
18. **Alternative csDMARDs:** leflunomide, sulfasalazine, hydroxychloroquine (useful in mild disease and safest in the frail; needs retinal screening).
19. **Glucocorticoids** give rapid control as bridging therapy at the lowest effective dose for the shortest time; in older adults the cumulative harms — osteoporosis, diabetes, infection, cataract, skin fragility — are magnified. **Osteoporosis and gastrointestinal ulcer prophylaxis should be employed in all patients treated with oral steroids to minimise potentially devastating complications** (Pathy's, on steroid use in older adults).
20. **Biologic DMARDs** — TNF inhibitors, abatacept, tocilizumab, rituximab — are effective in older adults, though with a higher absolute infection risk. Abatacept has a comparatively favourable infection profile in the elderly.
21. **JAK inhibitors** (tofacitinib, baricitinib, upadacitinib) are effective orally, but the **ORAL Surveillance** safety signal restricts use in those over 65 with cardiovascular risk factors or a smoking history, because of increased major adverse cardiovascular events, venous thromboembolism and malignancy.
22. **NSAIDs should be minimised** — they appear on the AGS Beers Criteria and cause bleeding, renal impairment and heart failure in this age group.
23. **Comprehensive care:** physiotherapy and occupational therapy for joint protection and assistive devices, exercise to counter sarcopenia, cardiovascular risk assessment (RA is an independent cardiovascular risk factor), osteoporosis screening and treatment, vaccination (influenza, pneumococcal, herpes zoster — inactivated preparations only on immunosuppression), and management of depression and caregiver burden.
24. **Prognosis:** seropositive, erosive late-onset RA behaves as aggressively as young-onset disease and causes greater functional loss because of lower physiological reserve; seronegative and PMR-like variants often have a milder, more steroid-responsive course.

Latest Updates (2023 – Present)

- **ACR 2021 and EULAR 2022/2023 recommendations** both retain methotrexate as the anchor and treat-to-target as the strategy, but now place **explicit age- and comorbidity-based restrictions on JAK inhibitors** following ORAL Surveillance — directly relevant to the geriatric population.
- Registry data (2023–2025) show that biologic-treated older adults have higher serious infection rates than younger patients but comparable efficacy, supporting **risk-stratified rather than age-restricted** prescribing.
- Growing evidence that RA is associated with accelerated **sarcopenia ("rheumatoid cachexia")** and frailty, with resistance exercise and adequate protein intake now part of standard care.
- Interest in **difficult-to-treat RA** as a defined entity, and in newer targets (olokizumab, peresolimab, CAR-T for refractory autoimmunity) at trial stage.
- **Indian context:** mandatory tuberculosis screening before biologics is critical given high latent TB prevalence; biosimilar TNF inhibitors and rituximab have greatly improved affordability, with treatment cost cover under AB-PMJAY.

Current Practice Update

Issue	Textbook position	Current position
Treatment intensity in the elderly	Cautious, comorbidity-limited	**Treat-to-target regardless of age**; comorbidity guides drug choice, not intensity
JAK inhibitors	Effective oral option	**Restricted in over-65s** with cardiovascular risk or smoking history (ORAL Surveillance)
Methotrexate in renal impairment	Dose with caution	Unchanged and reinforced — check eGFR at every escalation
Muscle	Not emphasised	**Rheumatoid cachexia / sarcopenia** is now a treatment target

Exam One-Liners

- Late-onset RA begins at or after 60–65 years — different from young-onset RA that has aged.
- Equal sex ratio, abrupt onset, large proximal joints, more seronegative, very high ESR.
- Three subsets: classical polyarthritis, PMR-like, and RS3PE.
- RF is positive in up to a quarter of healthy older people — use anti-CCP.
- Methotrexate remains the anchor drug, dosed by renal function.

- JAK inhibitors are restricted above 65 years after ORAL Surveillance.
- Always screen for latent tuberculosis before a biologic in India.

Q12. Sjögren's Syndrome — Definition, Epidemiology, Pathophysiology, Presentation and Management

15 MARKS

A. Definition

1. **Sjögren's syndrome (Sjögren's disease)** is a chronic **systemic autoimmune exocrinopathy** characterised by lymphocytic infiltration and destruction of the exocrine glands — principally the lacrimal and salivary glands — producing the **sicca complex of dry eyes (keratoconjunctivitis sicca) and dry mouth (xerostomia)**, together with extraglandular systemic involvement.
2. **Primary Sjögren's** occurs alone; **secondary Sjögren's** occurs with another connective tissue disease, most often **rheumatoid arthritis**, systemic lupus erythematosus or systemic sclerosis.

B. Epidemiology

3. Prevalence is approximately **0.1–0.6%**; it is one of the commonest systemic autoimmune diseases.
4. **Female to male ratio is about 9:1**, with a bimodal peak in the 20s–30s and again **after the menopause, around 50–60 years**, so a large proportion of patients are older adults.
5. **Geriatric caution:** sicca symptoms are extremely common in old age from **age-related glandular atrophy, dehydration and anticholinergic polypharmacy** — dryness in an older person is far more often drug-induced than autoimmune, and this distinction is the crux of any exam answer.

C. Pathophysiology

6. **Genetic susceptibility** (HLA-DR3/DQ2, HLA-DRB1*03, IRF5 and STAT4 polymorphisms) plus an environmental trigger, classically a **viral infection** (EBV, HCV, HTLV-1), initiates glandular epithelial activation — hence the concept of **"autoimmune epithelitis"**.
7. Activated epithelial cells present autoantigens (**Ro/SSA and La/SSB**) and secrete chemokines that recruit **CD4+ T cells and B cells**, forming **periductal focal lymphocytic infiltrates** and, in some, ectopic germinal centres.
8. **Type I interferon signature** and **BAFF (B-cell activating factor)** overexpression drive B-cell survival, autoantibody production and hypergammaglobulinaemia — the rationale for anti-BAFF and B-cell directed therapy.
9. Glandular destruction, plus **anti-muscarinic M3 receptor antibodies** impairing residual secretory function, produces the sicca picture — explaining why dryness can exceed the degree of histological damage.
10. Persistent B-cell stimulation with germinal centre formation underlies the **risk of B-cell non-Hodgkin lymphoma**, typically MALT lymphoma of the parotid.

D. Clinical Presentation

(i) Glandular

11. **Ocular:** gritty, sandy foreign-body sensation, burning, photophobia, redness, blurring, stringy discharge; complications include filamentary keratitis and corneal ulceration.
12. **Oral:** dry mouth, difficulty swallowing dry food, need to sip water while talking, altered taste, tongue fissuring and depapillation, **rampant dental caries**, angular cheilitis and recurrent oral candidiasis.
13. **Salivary gland enlargement** — recurrent or persistent parotid or submandibular swelling. **A persistently hard, unilateral, enlarging parotid must raise suspicion of lymphoma.**
14. Other exocrine sites: dry nose, dry cough from xerotrachea, dry skin, and vaginal dryness with dyspareunia — a common and under-asked symptom in older women.

(ii) Extraglandular

15. **Constitutional:** profound **fatigue** (often the dominant complaint), low-grade fever, myalgia.
16. **Musculoskeletal:** non-erosive symmetrical polyarthritis and arthralgia; Raynaud's phenomenon.
17. **Cutaneous:** annular erythema and **palpable purpura from hypergammaglobulinaemic or cryoglobulinaemic vasculitis**.
18. **Renal: distal (type 1) renal tubular acidosis** with hypokalaemia and nephrocalcinosis; interstitial nephritis; less often glomerulonephritis with cryoglobulinaemia.
19. **Pulmonary:** interstitial lung disease (NSIP, LIP), bronchiectasis, xerotrachea.
20. **Neurological: peripheral sensory or sensory-ataxic neuropathy**, small-fibre neuropathy with burning feet, trigeminal neuropathy, mononeuritis multiplex, and rarely CNS disease.
21. **Haematological / malignant:** cytopenias, hypergammaglobulinaemia, and a **5–16 fold** increased risk of **non-Hodgkin lymphoma** — the single most important complication. Predictors: persistent parotid enlargement, purpura, low C4, cryoglobulinaemia, lymphadenopathy, splenomegaly and a low CD4 count.
22. **Obstetric/other:** anti-Ro antibodies cause congenital heart block in offspring (not relevant in the elderly but examinable).

E. Investigations

23. **Autoantibodies: anti-Ro/SSA** (most sensitive and part of the criteria) and **anti-La/SSB**; ANA positive in most; **rheumatoid factor positive in about 50%** even without RA.
24. **Supporting bloods:** raised ESR with normal CRP, **polyclonal hypergammaglobulinaemia**, anaemia, leucopenia, low C3/C4 (poor prognosis), cryoglobulins, and serum free light chains.
25. **Ocular tests: Schirmer's test ≤5 mm in 5 minutes**; **ocular staining score ≥5** with lissamine green or fluorescein (or Rose Bengal ≥4 by van Bijsterveld); tear break-up time.
26. **Oral tests:** unstimulated whole salivary flow **≤0.1 mL/minute**; salivary gland ultrasound showing a heterogeneous hypoechoic gland; sialography and scintigraphy are older methods.
27. **Minor labial salivary gland biopsy** — the histological gold standard; a **focus score ≥1** (one focus of ≥50 lymphocytes per 4 mm²) is diagnostic.
28. **2016 ACR/EULAR classification criteria** (score ≥4): anti-Ro/SSA positive (3), focus score ≥1 (3), ocular staining score ≥5 (1), Schirmer ≤5 mm/5 min (1), unstimulated salivary flow ≤0.1 mL/min (1). Exclusions include head and neck radiotherapy, hepatitis C, HIV, sarcoidosis, amyloidosis, IgG4-related disease and graft-versus-host disease.
29. **Disease activity tools: ESSDAI** for systemic activity and **ESSPRI** for patient-reported dryness, pain and fatigue.

F. Management

30. **No cure exists;** treatment is symptomatic for sicca and immunosuppressive for systemic disease. First, **stop or substitute anticholinergic drugs** — tricyclics, oxybutynin, antihistamines, antipsychotics, diuretics — which is frequently the highest-yield intervention in an older patient.
31. **Dry eyes:** preservative-free artificial tears and gels, ocular lubricant ointment at night, humidification, avoidance of fans and air conditioning; **topical ciclosporin 0.05%** or short-course topical steroid for inflammatory dryness; **punctal plugs or cautery** for refractory cases; treat coexisting blepharitis.
32. **Dry mouth:** frequent sips of water, sugar-free gum and lozenges, saliva substitutes, meticulous oral hygiene with **high-fluoride toothpaste and 3-monthly dental review**, and prompt treatment of candidiasis with nystatin or fluconazole (avoid sugar-containing preparations).
33. **Muscarinic agonists: pilocarpine 5 mg four times daily** or **cevimeline 30 mg three times daily** stimulate residual secretion. Cautions in older adults: sweating, flushing, nausea, urinary frequency, bradycardia; avoid in uncontrolled asthma, narrow-angle glaucoma and significant cardiac disease.
34. **Musculoskeletal disease: hydroxychloroquine** for arthralgia, fatigue and cutaneous disease (though RCT evidence for fatigue is weak); short courses of NSAIDs with caution; low-dose prednisolone for flares.
35. **Severe systemic disease** (vasculitis, interstitial lung disease, glomerulonephritis, severe neuropathy, cytopenias): glucocorticoids with **methotrexate, azathioprine, mycophenolate or cyclophosphamide**; **rituximab** for cryoglobulinaemic vasculitis, severe parotid swelling and lymphoma-associated disease, although the large TEARS and TRACTISS trials failed to show benefit for dryness itself.
36. **Vaginal dryness:** non-hormonal lubricants and, where appropriate, topical vaginal oestrogen — frequently overlooked in older women.
37. **Lymphoma surveillance:** examine glands and lymph nodes at each visit; investigate any persistent hard parotid swelling, new lymphadenopathy, falling C4, monoclonal band or cryoglobulins with imaging and biopsy.
38. **Prognosis:** life expectancy is near-normal in uncomplicated disease; excess mortality is driven by **lymphoma, vasculitis and interstitial lung disease**. Fatigue and dryness dominate quality of life.

Latest Updates (2023 – Present)

- **Ianalumab**, a dual-action B-cell targeting monoclonal antibody against BAFF-receptor, met its primary endpoint in the **paired phase 3 NEPTUNUS-1 and NEPTUNUS-2 trials** presented at ACR Convergence in October 2025 — the **first phase 3 studies in Sjögren's disease to meet their primary objective**, showing statistically significant improvement in ESSDAI. Phase 2b data had already shown sustained efficacy of the 300 mg dose at 52 weeks with a favourable 2-year safety profile.
- **Nipocalimab**, an FcRn blocker, significantly reduced disease activity and severity in moderate-to-severe disease in the phase 2 **DAHLIAS** trial (published in The Lancet, October 2025), with substantial reduction in Sjögren's-related autoantibodies. It holds FDA **Breakthrough Therapy Designation (November 2024)** and **Fast Track Designation (April 2025)**, with the phase 3 **DAFFODIL** study now enrolling.
- **Dazodalibep**, a non-antibody CD40-ligand antagonist, met its primary endpoint in both study populations — those with systemic disease activity and those with high symptom burden — in a phase 2 trial published in Nature Medicine (2024), significantly reducing disease activity and improving symptoms.
- **Iscalimab (anti-CD40)** improved and sustained disease activity in a phase 2b Lancet study; **telitacicept** (BAFF/APRIL blocker) and low-dose IL-2 improved ESSDAI in phase 2 trials.
- **Important negative signal:** across trials, none of these agents — nor rituximab, abatacept, infliximab, tocilizumab and others in a 2023 meta-analysis — has reliably improved **unstimulated salivary flow** or objective ocular parameters. Benefit is on systemic activity and symptoms, not on glandular secretion, and early intervention (within 3 years of disease onset) may be needed to affect flow.
- Practical consequence: the field is moving from a single "Sjögren's" label towards **endotype-directed therapy**, targeting the B-cell/interferon-high subset with biologics while continuing symptomatic and secretagogue therapy for

dryness.

Current Practice Update

Issue	Textbook position	Current position (2023–present)
Disease-modifying therapy	None — symptomatic treatment plus immunosuppression for organ disease	First **positive phase 3 programme (ianalumab, NEPTUNUS 2025)**; nipocalimab, dazodalibep, iscalimab, telitacicept in advanced development
Rituximab for dryness	Sometimes used	**Not effective for sicca** (TEARS, TRACTISS); reserve for vasculitis and lymphoma
Outcome measures	Symptom-based	**ESSDAI and ESSPRI** are the standard endpoints
Nomenclature	Sjögren's syndrome	Increasingly **"Sjögren's disease"**, reflecting primary disease status

Exam One-Liners

- Autoimmune epithelitis with lymphocytic infiltration of exocrine glands.
- Female to male ratio 9:1; second peak after the menopause.
- In older adults, exclude anticholinergic drugs before diagnosing Sjögren's.
- Anti-Ro/SSA and a labial gland focus score ≥1 carry 3 points each in the 2016 criteria.
- Schirmer ≤5 mm/5 min; unstimulated salivary flow ≤0.1 mL/min.
- Raised ESR with normal CRP and polyclonal hypergammaglobulinaemia is typical.
- Persistent hard parotid enlargement, purpura and low C4 predict lymphoma.
- Pilocarpine and cevimeline are the secretagogues; hydroxychloroquine for arthralgia.

Q13. Inflammatory Myopathies — 15 MARKS

A. Definition and Classification

1. The **idiopathic inflammatory myopathies (IIM)** are acquired, immune-mediated diseases of skeletal muscle producing **symmetrical proximal muscle weakness** with muscle inflammation, raised muscle enzymes and extramuscular involvement.
2. Pathy's classifies acquired myopathies into **idiopathic inflammatory myopathies — dermatomyositis (DM), polymyositis (PM) and inclusion body myositis (IBM)** — alongside **alcohol-related, drug-induced, endocrine and metabolic, and paraneoplastic myopathies**.
3. Modern classification adds **immune-mediated necrotising myopathy (IMNM)** and **antisynthetase syndrome**, and regards "polymyositis" as a shrinking diagnosis of exclusion.
4. **Geriatric significance: inclusion body myositis is the commonest acquired myopathy after 50 years**, and dermatomyositis in an older adult carries a high risk of **underlying malignancy**. IIM must always be separated from the far commoner **statin myopathy**, hypothyroid myopathy, PMR and sarcopenia.

B. Pathophysiology

5. **Dermatomyositis** is a **humoral, complement-mediated microangiopathy**: antibody and complement deposition (membrane attack complex) on endomysial capillaries causes capillary dropout, muscle ischaemia and the characteristic **perifascicular atrophy**. Interferon type I signature is prominent.
6. **Polymyositis** is a **cell-mediated** disease: CD8+ cytotoxic T cells invade non-necrotic muscle fibres expressing MHC class I — the histological hallmark of **endomysial inflammation**.
7. **Inclusion body myositis** combines autoimmune (CD8+ T-cell) inflammation with a **degenerative process** — rimmed vacuoles, congophilic amyloid, tau and TDP-43 aggregates, and mitochondrial abnormalities (ragged red, COX-negative fibres). This dual pathology explains its poor response to immunosuppression.
8. **Immune-mediated necrotising myopathy** shows scattered necrotic and regenerating fibres with sparse inflammation, and is associated with **anti-SRP** and **anti-HMGCR** antibodies — the latter typically statin-triggered and persisting after statin withdrawal.

C. Clinical Features

Feature	Dermatomyositis	Polymyositis	Inclusion body myositis
Age	Bimodal — children and adults >40	Adults >20	**>50 years**, commonest in the elderly
Sex	Female > male	Female > male	**Male > female**
Onset	Subacute, weeks to months	Subacute	**Insidious, over years**
Weakness pattern	Symmetrical proximal	Symmetrical proximal	**Asymmetrical; distal as well as proximal** — quadriceps and finger flexors
Skin	**Present**	Absent	Absent
Creatine kinase	High (5–50×)	High	**Normal or only mildly raised**
Response to steroids	Good	Good	**Poor / none**

9. **Core presentation:** painless, symmetrical, proximal weakness — difficulty rising from a chair or toilet, climbing stairs, and lifting the arms above the head. Myalgia is present in only about a third; **pain-free weakness is the rule**.
10. **Cutaneous features of dermatomyositis: heliotrope rash** (violaceous periorbital discolouration with oedema), **Gottron's papules** over the metacarpophalangeal and interphalangeal joints and **Gottron's sign** over elbows and knees, **shawl sign** and **V-sign** photodistributed erythema, **mechanic's hands**, periungual telangiectasia with ragged cuticles, calcinosis cutis and poikiloderma. Skin disease may precede muscle disease (**amyopathic dermatomyositis**).
11. **Extramuscular: dysphagia** from pharyngeal and upper oesophageal muscle involvement (also the commonest cause of aspiration in IBM), respiratory muscle weakness, **interstitial lung disease** (especially with antisynthetase antibodies and anti-MDA5), non-erosive arthritis, Raynaud's phenomenon, myocarditis and arrhythmia.
12. **Antisynthetase syndrome:** myositis, interstitial lung disease, arthritis, Raynaud's, fever and mechanic's hands, with **anti-Jo-1** or other anti-tRNA synthetase antibodies.
13. **Malignancy association — a key geriatric point:** dermatomyositis, particularly with **anti-TIF1-γ** or **anti-NXP2** antibodies, carries a markedly increased risk of occult cancer (ovary, lung, breast, colorectal, stomach, pancreas, and nasopharyngeal carcinoma in Asian populations). Risk is highest in the **first 1–3 years** around diagnosis. Pathy's separately recognises **paraneoplastic myopathies** as a category.
14. **Red flags for IBM:** a man over 50 with slowly progressive, asymmetrical weakness of the **quadriceps (causing falls and knee buckling) and long finger flexors (causing loss of grip)**, early dysphagia, and a CK that is normal or only mildly elevated, who has "failed steroids".

D. Investigations (Pathy's diagnostic framework)

15. **Clinical assessment** of the pattern, distribution and tempo of weakness — the first step in Pathy's myopathy chapter.
16. **Biochemical studies: creatine kinase** (the key screening test), aldolase, lactate dehydrogenase and transaminases (a raised ALT/AST from muscle is often mistaken for liver disease); also TSH, calcium, phosphate, vitamin D, potassium, renal function and ESR/CRP.
17. **Electrophysiology (EMG):** shows a **myopathic pattern** — small-amplitude, short-duration polyphasic motor unit potentials with early recruitment, plus spontaneous activity (fibrillations, positive sharp waves) indicating active inflammation. In IBM, mixed myopathic and neurogenic units are seen.
18. **Muscle biopsy** is the definitive test: perifascicular atrophy with perimysial and perivascular CD4/B-cell infiltrate in DM; endomysial CD8+ invasion of non-necrotic MHC-I expressing fibres in PM; **rimmed vacuoles with congophilic inclusions and ragged red fibres** in IBM; necrosis without inflammation in IMNM.
19. **Myositis-specific and myositis-associated antibodies:** anti-Jo-1 and other synthetases, **anti-Mi-2** (classic DM, good prognosis), **anti-TIF1-γ** and **anti-NXP2** (malignancy), **anti-MDA5** (clinically amyopathic DM with rapidly progressive ILD, high mortality), **anti-SAE**, **anti-SRP** and **anti-HMGCR** (necrotising myopathy), **anti-cN1A** (IBM).
20. **MRI of thigh muscles** with STIR sequences shows oedema and guides the biopsy site while excluding fatty replacement; useful when biopsy is difficult in a frail patient.
21. **Screening for complications and associations:** high-resolution CT chest and pulmonary function tests with DLCO for ILD, video-fluoroscopic swallow, ECG and echocardiography, and **age-appropriate malignancy screening** — CT chest/abdomen/pelvis, mammography, PSA, colonoscopy and pelvic ultrasound, repeated annually for 3 years in high-risk DM.
22. **Classification criteria:** the **2017 ACR/EULAR classification criteria** for adult and juvenile IIM have replaced the older Bohan and Peter criteria; the **2016 ACR/EULAR Myositis Response Criteria Total Improvement Score (TIS)** is the standard outcome measure in trials.

E. Differential Diagnosis (essential in the elderly)

23. **Drug-induced myopathies** — Pathy's classifies these as painful myopathy, painless myopathy, focal myopathy, periodic weakness and **acute rhabdomyolysis**; **statin-induced myopathy** is dealt with separately and is the single commonest mimic. Also gold-induced myopathy, colchicine, amiodarone, chloroquine, zidovudine, and alcohol-related myopathy.
24. **Endocrine and metabolic myopathies:** hypothyroidism, hyperthyroidism, **Graves' ophthalmopathy**, pituitary–adrenal axis disorders (Cushing's and steroid myopathy), primary hyperparathyroidism, **osteomalacia and disorders of vitamin D metabolism**.
25. **Others:** polymyalgia rheumatica (normal CK, normal EMG, normal biopsy), myasthenia gravis (fatigable, ocular/bulbar, normal CK), motor neurone disease, muscular dystrophies presenting late (facioscapulohumeral, oculopharyngeal, myotonic), sarcopenia and disuse atrophy, and electrolyte disturbance.

F. Management

26. **Corticosteroids are first-line** for DM, PM and IMNM: prednisolone **0.75–1 mg/kg/day** (or pulse methylprednisolone in severe disease), continued until strength improves and CK falls, then tapered slowly over 9–12 months.
27. **Steroid-sparing agents from the outset** in older adults, given the certainty of steroid toxicity: **methotrexate**, **azathioprine**, or **mycophenolate mofetil** — Pathy's specifically lists mycophenolate mofetil for dermatomyositis. Ciclosporin and tacrolimus are alternatives, particularly with interstitial lung disease.
28. **Intravenous immunoglobulin** for refractory or severe disease, dysphagia, or when immunosuppression is hazardous — it is now licensed for dermatomyositis. **Rituximab** is used in refractory disease and antisynthetase syndrome; cyclophosphamide for rapidly progressive ILD, often with tacrolimus.
29. **Cutaneous disease:** strict photoprotection, topical corticosteroids and calcineurin inhibitors, and **hydroxychloroquine**. Pruritus can be severe and disabling.
30. **Inclusion body myositis: no immunosuppressive therapy has been shown to alter the natural history** — management is supportive with **resistance and aerobic exercise**, occupational therapy, ankle-foot orthoses, walking aids, dysphagia assessment with diet modification, and cricopharyngeal dilatation or myotomy for severe dysphagia.
31. **Universal supportive care in the elderly:** physiotherapy and graded exercise (safe and beneficial even in active myositis), speech and language therapy for dysphagia with aspiration precautions, nutrition, **osteoporosis prophylaxis with calcium, vitamin D and a bisphosphonate from day one**, gastroprotection, glucose monitoring, screening for latent tuberculosis before immunosuppression, vaccination, and *Pneumocystis* prophylaxis on high-dose combined immunosuppression.
32. **Prognosis:** DM and PM generally respond well, with 5-year survival above 75–80%; adverse prognostic factors are older age, dysphagia, interstitial lung disease (especially anti-MDA5), cardiac involvement and underlying malignancy. IBM is **relentlessly progressive**, with most patients needing a walking aid within 5–10 years, though it does not markedly shorten life expectancy.

Latest Updates (2023 – Present)

- **Efgartigimod PH20 subcutaneous**, an FcRn blocker that accelerates degradation of pathogenic IgG, met its

primary endpoint in the phase 2 portion of the seamless phase 2/3 **ALKIVIA** study (89 adults with dermatomyositis, immune-mediated necrotising myopathy, polymyositis or antisynthetase syndrome, presented at EULAR 2025). The **least-squares mean Total Improvement Score at week 24 was 50.45 with efgartigimod versus 35.65 with placebo (p = 0.0004)**, with no new safety signals. This is the **first FcRn inhibitor study in inflammatory myopathy** and establishes proof of concept for the role of IgG autoantibodies; the phase 3 portion is fully enrolled.

- **Apremilast**, a PDE-4 inhibitor, has shown efficacy in refractory cutaneous dermatomyositis without underlying malignancy, apparently by reducing pro-inflammatory cytokine expression.
- **JAK inhibitors** (tofacitinib, baricitinib) are increasingly used off-label in refractory dermatomyositis and, notably, in **anti-MDA5 rapidly progressive interstitial lung disease**, where combination immunosuppression with a JAK inhibitor has improved historically dismal survival.
- **Intravenous immunoglobulin** is now formally approved for adult dermatomyositis following the ProDERM trial, moving it from rescue therapy towards earlier use.
- Myositis-specific antibody testing is now regarded as **central to classification, prognosis and malignancy risk stratification**, with proposals for antibody-defined phenotypic subgrouping replacing the older clinicopathological labels; **CAR-T cell therapy** has produced durable remissions in small refractory series.
- Consensus guidance now recommends **risk-stratified malignancy screening** — intensive imaging (CT chest/abdomen/pelvis ± PET-CT) for high-risk phenotypes such as anti-TIF1-γ-positive dermatomyositis in older adults, rather than blanket screening of all IIM.

Current Practice Update

Issue	Pathy's position	Current position (2023–present)
Classification	DM, PM, IBM as the idiopathic inflammatory myopathies	Expanded to include **IMNM and antisynthetase syndrome**; PM is now a diagnosis of exclusion; **antibody-based subgrouping**
Diagnostic criteria	Clinical, CK, EMG, biopsy	Same, formalised by the **2017 ACR/EULAR criteria**, with myositis antibody panels and thigh MRI
Refractory disease	Steroids plus mycophenolate, azathioprine, methotrexate	Plus **IVIG (licensed), rituximab, JAK inhibitors**, and investigational **efgartigimod (ALKIVIA)**
Exercise	Cautious	**Actively recommended**, including in active disease and IBM
Malignancy screening	Recognised as paraneoplastic myopathy	**Risk-stratified by antibody** — intensive screening for anti-TIF1-γ and anti-NXP2 dermatomyositis

Exam One-Liners

- Inclusion body myositis is the commonest acquired myopathy over 50 years and does not respond to steroids.
- IBM pattern: asymmetrical quadriceps and long finger flexor weakness with a near-normal CK.
- Dermatomyositis is complement-mediated microangiopathy with perifascicular atrophy.
- Polymyositis is CD8+ T-cell invasion of non-necrotic MHC-I positive fibres.
- Anti-TIF1-γ and anti-NXP2 mean look hard for cancer; anti-MDA5 means look hard at the lungs.
- Rimmed vacuoles equal inclusion body myositis.
- Statin-associated anti-HMGCR necrotising myopathy persists after the statin is stopped.
- Efgartigimod (ALKIVIA, 2025) is the first FcRn inhibitor to show benefit in myositis.

Q14. Psoriatic Arthropathy — 15 MARKS

A. Definition and Epidemiology

1. **Psoriatic arthritis (PsA)** is a chronic, **seronegative inflammatory arthritis associated with psoriasis**, belonging to the spondyloarthritis family, characterised by **enthesitis, dactylitis, axial disease, nail disease and skin psoriasis**.
2. It affects roughly **20–30%** of people with psoriasis; overall prevalence is about 0.1–0.25% of the population, with an **equal sex distribution** (unlike RA).
3. Peak onset is 30–50 years, but **elderly-onset PsA** (after 60) is recognised and characteristically has **more acute onset, higher inflammatory markers, more polyarticular and erosive disease, and more constitutional upset** — and is frequently misdiagnosed as late-onset RA, PMR or gout.
4. In about **85%** the skin disease precedes the arthritis (often by around 10 years); in 10–15% arthritis comes first or they appear together — so **always look for hidden psoriasis** in the scalp, retroauricular area, umbilicus, natal cleft and nails.

B. Pathogenesis

5. **Genetic:** strong familial clustering; **HLA-B27** associates with axial disease, HLA-C*06 with skin-predominant disease, and HLA-B38/B39 with peripheral arthritis.
6. **Immunological:** the **IL-23 / Th17 axis** is central — IL-23 drives Th17 and IL-17-producing resident entheseal cells; **TNF-α**, IL-17A/F and IL-22 mediate synovitis, enthesitis and new bone formation.
7. **The enthesis is the primary site** of disease (unlike the synovium in RA); mechanical stress ("deep Koebner phenomenon") at entheses triggers inflammation, explaining dactylitis and the pattern of joint involvement.
8. Uniquely, PsA shows **both erosion and new bone formation** — periostitis, enthesophytes, ankylosis and, at the extreme, **arthritis mutilans**.

C. Clinical Features — Moll and Wright's Five Patterns

9. **(i) Asymmetrical oligoarthritis** (≤4 joints) — classically described as the commonest at presentation.
10. **(ii) Symmetrical polyarthritis** — RA-like but seronegative, with DIP involvement; the commonest pattern in established disease.
11. **(iii) Distal interphalangeal predominant** — strongly associated with **nail disease** of the same digit.
12. **(iv) Spondylitis and sacroiliitis** — often asymmetrical, with inflammatory back pain and chunky non-marginal **paravertebral ossification**.
13. **(v) Arthritis mutilans** — rare, severely destructive, with **telescoping "opera-glass" digits** from osteolysis.
14. **Enthesitis** — Achilles tendon insertion, plantar fascia, lateral epicondyle, patellar tendon and iliac crest; heel pain in an older adult with psoriasis is enthesitis until proved otherwise.
15. **Dactylitis ("sausage digit")** — uniform swelling of the whole digit from combined tenosynovitis, synovitis and soft-tissue oedema; occurs in about a third and marks more severe disease.
16. **Nail disease** in up to 80–90% of those with arthritis: **pitting, onycholysis, subungual hyperkeratosis, oil-drop sign, splinter haemorrhages, ridging** — the single most useful clue when skin disease is inapparent.
17. **Extra-articular:** anterior **uveitis** (often insidious, bilateral and posterior, unlike the acute unilateral uveitis of ankylosing spondylitis), inflammatory bowel disease, and aortic root disease.
18. **Comorbidity burden — important in geriatrics:** a high prevalence of **metabolic syndrome, obesity, type 2 diabetes, hypertension, fatty liver, hyperuricaemia and gout**, and a significantly increased cardiovascular risk; also depression and osteoporosis. These comorbidities dictate drug choice and must be actively screened.

D. Investigations

19. **Seronegativity:** rheumatoid factor and anti-CCP are typically negative — but a low-titre RF may be present in older adults from age alone, and about 5–10% of PsA is anti-CCP positive (marking more erosive disease).
20. **ESR and CRP** may be raised, but are normal in up to half despite active disease; serum urate is often high, which confuses the picture with gout.
21. **Radiographs:** the hallmark is **erosion with adjacent new bone formation** — the **"pencil-in-cup" deformity**, acro-osteolysis, fluffy periostitis, ankylosis, asymmetrical sacroiliitis and non-marginal syndesmophytes. **Absence of periarticular osteopenia** helps distinguish it from RA.
22. **Ultrasound with power Doppler** and **MRI** detect enthesitis, dactylitis and early sacroiliitis before radiographic change.
23. **CASPAR classification criteria** (score ≥3 in the presence of inflammatory articular disease): current psoriasis (2 points), personal or family history of psoriasis (1), psoriatic nail dystrophy (1), negative rheumatoid factor (1), current or past dactylitis (1), and juxta-articular new bone formation on radiograph (1). Specificity approaches 99%.
24. **Screening tools** such as PEST and PASE are used in dermatology clinics to detect PsA early; **MDA (minimal disease activity)** and DAPSA are the treat-to-target measures.
25. **Differential diagnosis in the elderly:** late-onset rheumatoid arthritis, erosive/nodal osteoarthritis of the DIP joints

(Heberden's nodes — no inflammation, no nail change), **gout and CPPD**, reactive arthritis, and PMR.

E. Management (GRAPPA domain-based approach)

26. **General:** patient education, smoking cessation, **weight reduction** (obesity worsens disease and blunts drug response), structured exercise, physiotherapy for enthesitis and axial disease, occupational therapy and assistive devices, plus **aggressive cardiovascular and metabolic risk management**.
27. **Peripheral arthritis:** NSAIDs for mild disease (used sparingly in the elderly); local corticosteroid injection for mono/oligoarthritis; then **csDMARDs — methotrexate** (also treats skin), leflunomide, sulfasalazine (not for skin or axial disease); avoid ciclosporin in older adults.
28. **Inadequate response:** escalate to **biologic or targeted synthetic DMARDs** — **TNF inhibitors** (adalimumab, etanercept, infliximab, golimumab, certolizumab), **IL-17 inhibitors** (secukinumab, ixekizumab, and the IL-17A/F inhibitor **bimekizumab**), **IL-12/23 inhibitor** ustekinumab, **IL-23 inhibitors** (guselkumab, risankizumab), **JAK inhibitors** (tofacitinib, upadacitinib), the TYK2 inhibitor **deucravacitinib**, the PDE-4 inhibitor **apremilast**, and abatacept.
29. **Domain-directed choice (GRAPPA):** for **axial disease**, NSAIDs, physiotherapy and simple analgesia are strongly recommended, as are a JAK inhibitor, TNF inhibitor or IL-17 inhibitor — **csDMARDs do not work for axial disease**. For **enthesitis**, strongly recommended options include a TNF inhibitor, an IL-12/23, IL-17 or IL-23 inhibitor, a JAK inhibitor or a PDE-4 inhibitor. For **dactylitis**, GRAPPA strongly recommends a TNF inhibitor, an IL-12/23, IL-17 or IL-23 inhibitor, a JAK inhibitor or a PDE-4 inhibitor.
30. **Geriatric prescribing considerations:** apremilast is attractive in frail patients for its safety profile but causes diarrhoea and weight loss; **JAK inhibitors are restricted in those over 65** with cardiovascular risk factors or a smoking history (ORAL Surveillance); IL-17 inhibitors are avoided in inflammatory bowel disease and predispose to candidiasis; all biologics require **latent tuberculosis and hepatitis screening**, which is essential in India, plus vaccination and infection vigilance.
31. **Treat-to-target** aiming for minimal disease activity, with therapy tapering considered in sustained remission; surgery (synovectomy, arthroplasty, fusion) for established joint damage.
32. **Prognosis:** around 20% develop severe destructive disease; poor prognostic markers are polyarticular onset, raised ESR/CRP, early radiographic damage, dactylitis and nail disease. Excess mortality is largely **cardiovascular**.

Latest Updates (2023 – Present)

- **Bimekizumab**, a dual **IL-17A and IL-17F** inhibitor, received FDA approval for psoriatic arthritis in **September 2024** on the strength of two phase 3 trials (BE OPTIMAL in biologic-naive and BE COMPLETE in TNF-inadequate responders). Current GRAPPA-based practice includes bimekizumab alongside secukinumab and ixekizumab whenever IL-17 pathway agents are considered.
- **EULAR issued updated psoriatic arthritis management recommendations in 2024** — seven overarching principles and eleven recommendations — reinforcing a **treat-to-target strategy** and **early use of biologic or targeted synthetic DMARDs** (TNF, IL-17, IL-23 and JAK/TYK2 pathway inhibitors) in patients with clinically relevant disease.
- GRAPPA's 2021 domain-based recommendations remain the widely cited framework; at **ACR Convergence 2025** the emphasis shifted from "do we have therapies" to **how best to sequence and select** among them, given disease heterogeneity and a growing population of difficult-to-treat patients.
- **IL-23 inhibitors** (guselkumab, risankizumab) have consolidated their place with sustained efficacy and a favourable safety profile in older adults; oral **deucravacitinib** (TYK2) and the oral IL-23-receptor peptide **icotrokinra** are advancing as convenient oral options.
- **Indian context:** biosimilar TNF inhibitors have transformed access; mandatory latent tuberculosis screening before biologic therapy is critical given high background prevalence, and treatment costs are covered under AB-PMJAY and the Ayushman Vay Vandana Card for those ≥70 years.

Current Practice Update

Issue	Textbook position	Current position (2023–present)
Framework	Moll and Wright's five clinical patterns	**Domain-based** (peripheral arthritis, axial, enthesitis, dactylitis, skin, nails) as per GRAPPA and EULAR 2024
Methotrexate	First-line DMARD for all PsA	Retained for peripheral disease and skin, but **ineffective for axial disease, enthesitis and dactylitis** — escalate early
IL-17 blockade	Secukinumab, ixekizumab	Add **bimekizumab** (dual IL-17A/F, FDA-approved September 2024)
JAK inhibitors	Effective oral option	**Age- and cardiovascular-risk restricted** in the over-65s
Comorbidity	Noted	Cardiometabolic screening and weight management are now **part of the treatment plan**

Exam One-Liners

- PsA is an enthesitis-driven seronegative spondyloarthritis of the IL-23/Th17 axis.
- Five Moll and Wright patterns; DIP involvement and nail disease travel together.
- Dactylitis and nail pitting are the two bedside giveaways.
- "Pencil-in-cup" erosion with new bone formation, and no periarticular osteopenia.
- CASPAR criteria: score ≥3, specificity about 99%.
- csDMARDs do not work for axial disease, enthesitis or dactylitis.
- Bimekizumab (2024) is the newest IL-17A/F option; EULAR 2024 pushes early advanced therapy.
- Screen every patient for metabolic syndrome and cardiovascular risk.

Final Night Grid — One Line Per Topic

Topic	The one sentence to write first
Osteoporosis	Low bone mass with microarchitectural deterioration; T-score ≤−2.5, or any fragility fracture regardless of T-score.
Post-hip-fracture	Treat before discharge — imminent re-fracture risk is highest in the first 2 years; IV zoledronate plus a Fracture Liaison Service.
DEXA	Reference standard for BMD; diagnose on the lowest valid site, monitor every 1–3 years, beware degenerative spine in the elderly.
FRAX	10-year probability of hip and major osteoporotic fracture from 11 clinical factors ± femoral neck BMD; blind to falls and fracture recency.
SERMs	Bone agonist, breast antagonist; vertebral fracture protection only; contraindicated after femoral neck fracture.
Atypical femur fracture	Transverse subtrochanteric/diaphyseal fracture with lateral cortical beaking after prolonged turnover suppression; often bilateral.
Renal osteodystrophy	Bone histology of CKD classified by Turnover, Mineralisation and Volume; adynamic bone disease is now commonest.
Osteoarthritis	Exercise and weight loss are the only disease-modifying measures; topical before oral NSAIDs; joint replacement for refractory severe disease.
Polymyalgia rheumatica	Girdle pain and stiffness over 50 with high ESR, normal CK, and dramatic response to prednisolone 15 mg.
Temporal arteritis	Granulomatous large-vessel vasculitis — a sight-threatening emergency; steroids first, biopsy after.
Late-onset RA	Onset ≥60, equal sex ratio, abrupt, large proximal joints, often seronegative with very high ESR.
Sjögren's syndrome	Autoimmune epithelitis causing sicca; exclude anticholinergic drugs first; lifelong lymphoma vigilance.
Inflammatory myopathies	DM (complement microangiopathy), PM (CD8 cytotoxicity), IBM (rimmed vacuoles, steroid-unresponsive, commonest over 50).
Psoriatic arthropathy	Enthesitis-driven seronegative spondyloarthritis with dactylitis, nail disease and pencil-in-cup erosions.

How to use this document. *Each answer follows a fixed architecture: numbered high-yield points under thematic subheadings → "Latest Updates (2023–Present)" with inline citations → "Current Practice Update" table contrasting the textbook position with current evidence → an orange "Examiner's Tip" panel with mark-earning lines. Recurring topics carry an additional green "Extra Points to Remember" panel. Where the uploaded textbooks do not cover a topic, this is stated explicitly in a red panel.*

Q1. Management of hypertension in the elderly

15-MARK ANSWER | 18 POINTS

Definition and Epidemiology

1. **Hypertension** in older people is defined by the same thresholds as in the young, but the pattern differs: **systolic BP rises** with age while **diastolic BP plateaus or falls** after about 60 years.
2. Prevalence rises steeply with age. In India, **LASI Wave 1** found hypertension in about **46%** of adults aged 45 and above, with only about **32%** achieving control — awareness and control are the weak links, not availability of drugs.
3. **Ageing changes that cause hypertension:** arterial wall stiffness from collagen deposition and elastin loss, reduced nitric oxide bioavailability, impaired baroreceptor sensitivity, and reduced plasma renin activity.

Special Problems of Measurement in Old Age

4. Always measure **standing (orthostatic) BP** as well as sitting, because postural hypotension is common and treatment can worsen it. Pathy's advises orthostatic measurement at every visit.
5. Three pitfalls must be excluded before labelling a patient hypertensive: **white-coat hypertension** (common in the elderly), **masked hypertension**, and **pseudo-hypertension** (falsely high cuff readings from incompressible calcified arteries).
6. Use a large cuff for large arms, take the average of at least two readings on two occasions, and confirm with **home or ambulatory BP monitoring** where possible.

Evidence for Treating Older Patients

7. Treatment reduces stroke, heart failure and mortality at every age. **HYVET** (patients over 80, SBP ≥160 mmHg) showed a **30%** fall in stroke, **21%** fall in all-cause death and **64%** fall in heart failure.
8. **SPRINT-Senior** (age ≥75) showed intensive control (SBP <120) reduced cardiovascular events and death compared with a target of <140.
9. Cerebrovascular disease is an **indication for**, not a contraindication to, antihypertensive therapy.
10. Counter-evidence exists in the very frail: SBP below **120 mmHg** is associated with higher mortality in those over 85, and the **PARTAGE** study showed excess mortality in nursing-home residents on multiple antihypertensives with low achieved BP.

Non-Pharmacological Management

1. Salt restriction, a fruit-vegetable-low-fat-dairy (DASH-type) diet, potassium-, calcium- and magnesium-rich foods, weight optimisation, aerobic exercise, smoking cessation and alcohol limitation.
2. **Review and rationalise drugs that raise BP:** NSAIDs, decongestants and glucocorticoids. Regular medication review reduces polypharmacy and improves adherence.

Drug Therapy — Principles and Choice

3. Golden rule: **"start low, go slow"**, use once-daily long-acting agents, and monitor BP, creatinine and potassium after each dose change.
4. **Thiazide/thiazide-like diuretics** are first-line, especially for isolated systolic hypertension. **Chlorthalidone 12.5–25 mg** is preferred over hydrochlorothiazide. Watch hypokalaemia, hyponatraemia, hyperuricaemia and hyperglycaemia; avoid in gout.
5. **Calcium channel blockers** are superior for stroke prevention; **diuretics** are superior for heart failure prevention; **beta blockers are inferior** for preventing major cardiovascular events and should be reserved for compelling indications (ischaemic heart disease, heart failure, atrial fibrillation).
6. **ACE inhibitors / ARBs** are preferred in heart failure and in diabetes with albuminuria. **Never combine an ACE inhibitor with an ARB** in older people — the risk of acute kidney injury and hyperkalaemia rises sharply.

Individualisation and Targets

7. Pathy's key message: **lower BP in proportion to the patient's functional level.** Indiscriminate application of a single tight target to frail, multimorbid elders "may do more harm than good" — risks are falls, cognitive decline, acute kidney injury and hyperkalaemia.
8. Practical targets: aim for <130/80 mmHg in the **robust, independent** elder; accept <140/90 mmHg in the **frail or care-home resident**; consider deprescribing at the end of life. Assess frailty (e.g. Clinical Frailty Scale) before setting the target.

Latest Updates (2023–Present)

- **2025 AHA/ACC/multisociety High Blood Pressure Guideline** (JACC/Circulation, Aug 2025) replaces the 2017 guideline. It retains a treatment target of **<130/80 mmHg** for most adults, but now **encourages achieving SBP <120**

mmHg, based on SPRINT, STEP, ESPRIT and BPROAD. It explicitly permits **individualised, less stringent targets** for institutionalised patients, those with limited life expectancy and frail older adults.

- The 2025 guideline replaces the Pooled Cohort Equations with the **PREVENT risk equations** for treatment decisions, makes out-of-office measurement (ABPM/HBPM) the diagnostic standard, strongly endorses **single-pill combinations**, and adds a Class 2b recommendation for **renal denervation** in uncontrolled hypertension.
- **2024 ESC Hypertension Guideline** recommends a systolic target of **120–129 mmHg** in most treated adults, with explicit relaxation for symptomatic orthostatic hypotension, age ≥85 or moderate-to-severe frailty.
- **STEP trial** (Chinese patients aged 60–80) showed intensive control (110–130 mmHg) reduced cardiovascular events versus 130–150 mmHg — the first dedicated intensive-control trial in an exclusively older Asian population.
- **India:** the **India Hypertension Control Initiative (IHCI)** — ICMR, MoHFW and WHO-India — has scaled up simple standardised treatment protocols, single-pill combinations and free drug supply through Ayushman Arogya Mandirs; BP control in enrolled cohorts rose from about 26% at registration to about 60% at follow-up.

Current Practice Update

Textbook position (Pathy's 6e / Essentials 7e)	Current evidence (2023–2026)
Treatment goal <140/90 mmHg for uncomplicated hypertension; concern that outcomes are not improved below 130/85.	2025 ACC/AHA target <130/80 mmHg with encouragement toward <120 systolic; 2024 ESC target 120–129 systolic.
Risk estimated by Framingham-type or Pooled Cohort scores.	**PREVENT equations** now recommended, incorporating kidney and metabolic variables.
Stepped monotherapy with dose titration is standard.	**Single-pill combination as initial therapy** is now emphasised by both ACC/AHA and ESC to improve adherence.
Clinic BP is the basis of diagnosis; ABPM mentioned as adjunct.	Out-of-office measurement (HBPM/ABPM) is the diagnostic gold standard.
Frailty-based targets described as "awaited" research.	Guidelines now formally endorse individualised, relaxed targets in frailty and limited life expectancy; deprescribing trials (e.g. OPTIMISE) support careful de-intensification.

Examiner's Tip

Write these lines verbatim: "*Blood pressure must be measured both sitting and standing at every visit, and pseudo-hypertension excluded before labelling an older patient hypertensive.*" · "*HYVET established that treating patients over 80 with SBP ≥160 mmHg reduces stroke by 30% and heart failure by 64%.*" · "*Beta blockers are not first-line for uncomplicated hypertension in the elderly; thiazide-like diuretics and calcium channel blockers are.*" · "*The degree of BP lowering should be proportionate to the patient's functional level — a robust 80-year-old and a frail care-home resident do not share a target.*"

Q2. Isolated systolic hypertension and its management

15-MARK ANSWER | 17 POINTS | RECURRING TOPIC

Definition

1. **Isolated systolic hypertension (ISH)** = systolic BP ≥140 mmHg with diastolic BP <90 mmHg. Widened **pulse pressure** is the hallmark.
2. It is the **dominant pattern of hypertension in old age.** NHANES III showed that fewer than 20% of hypertensive people over 60 have a raised diastolic pressure, and this proportion falls further with advancing age.

Pathophysiology — the core examination point

3. ISH is caused by **large-artery stiffness**, not by raised peripheral resistance (which is the mechanism in the young).
4. Mechanism: fragmentation of **elastin**, increased **collagen** cross-linking, calcification of the media, and endothelial dysfunction with reduced nitric oxide → loss of aortic Windkessel function.
5. Consequence: the aorta cannot buffer stroke volume, so systolic pressure rises; the pulse wave travels faster and the **reflected wave returns in systole instead of diastole**, further augmenting systolic pressure and **lowering diastolic pressure** — hence the wide pulse pressure and reduced coronary perfusion pressure.
6. Pathy's highlights the therapeutic paradox: **current antihypertensives act mainly by reducing peripheral vascular resistance and have little effect on arterial stiffness**, which is why ISH is difficult to control and why drugs targeting stiffness are an unmet need.

Clinical Significance

7. ISH is a major independent risk factor for **stroke, coronary events, heart failure, atrial fibrillation, chronic kidney disease progression and cognitive decline.**
8. Wide pulse pressure predicts risk better than systolic pressure alone in the very old.
9. Low diastolic pressure (<60–65 mmHg) during treatment is a warning sign — coronary filling occurs in diastole, so excessive diastolic fall may precipitate myocardial ischaemia (the "J-curve").

Evaluation

0. Confirm with repeated and out-of-office readings; exclude white-coat effect and pseudo-hypertension; check orthostatic drop (postural hypotension was present in a substantial proportion of the SHEP cohort at baseline).
1. Assess target-organ damage: ECG/echocardiography for LV hypertrophy, urine albumin–creatinine ratio, creatinine/eGFR, fundoscopy, lipids and glucose.
2. Exclude secondary causes relevant to old age listed in *Essentials*: **atherosclerotic renovascular disease, primary hyperaldosteronism, hyperparathyroidism, chronic kidney disease and oestrogen therapy.**

Management

3. **Non-pharmacological:** sodium restriction, DASH-type diet, potassium-rich foods, aerobic exercise, weight optimisation, smoking cessation.
4. **First-line drugs: thiazide-like diuretics** (chlorthalidone/indapamide) and **dihydropyridine calcium channel blockers** (amlodipine). These are the classes proven in the landmark ISH trials.
5. **Landmark trials to quote: SHEP** (chlorthalidone-based; 36% stroke reduction), **Syst-Eur** (nitrendipine-based; 42% stroke reduction), **HYVET** (indapamide ± perindopril in the over-80s), and the **LIFE** ISH substudy (losartan superior to atenolol in ISH with LV hypertrophy).
6. Add an ACE inhibitor or ARB as second agent; use a low-dose two-drug combination rather than maximising a single drug. Avoid beta blockers unless there is a compelling indication.
7. **Titrate to the systolic target while watching the diastolic pressure and the standing pressure.** Reduce or stop treatment if the patient develops symptomatic postural hypotension, falls, or a diastolic pressure below about 60 mmHg.

Latest Updates (2023–Present)

- **2025 AHA/ACC guideline** makes no separate ISH target: the systolic goal of <130 mmHg (with encouragement toward <120) applies, but individualisation is explicitly allowed for frailty, orthostatic hypotension and limited life expectancy.
- **ESPRIT trial** (Lancet 2024) — intensive systolic lowering to <120 mmHg reduced major vascular events versus <140 mmHg in high-risk adults, strengthening the case for tighter systolic control in fit older patients.
- **STEP trial** (NEJM 2021, widely cited in 2023–2025 guidance) — in adults aged 60–80, a target of 110–130 mmHg reduced cardiovascular events; a substantial proportion of participants had a predominantly systolic pattern.
- **2024 ESC guideline** specifically advises that in patients aged ≥85, with orthostatic hypotension, or with moderate-to-severe frailty, the systolic target may be relaxed — the most explicit statement so far that ISH management is frailty-dependent.
- Interest continues in **anti-stiffness strategies** (SGLT2 inhibitors, mineralocorticoid receptor antagonists, advanced

glycation end-product cross-link breakers) and in **renal denervation** (Class 2b, 2025 ACC/AHA) for resistant systolic hypertension, but no drug is yet licensed specifically to reduce arterial stiffness.

Current Practice Update

Textbook position	Current evidence (2023–2026)
Systolic goal <140 mmHg; caution that benefit may not extend below 130 mmHg.	Systolic goal <130 mmHg (ACC/AHA 2025) or 120–129 mmHg (ESC 2024) in patients who tolerate it.
No drug targets arterial stiffness; new agents "required".	Still true — this remains an unmet need; renal denervation is the only new device-based option (Class 2b).
Frailty-adjusted targets described as unresolved.	Frailty-adjusted relaxation of targets is now written into ESC 2024 and ACC/AHA 2025.
Stepped care with single agents.	Low-dose single-pill combination therapy is preferred first-line for most.

Extra Points to Remember (recurring topic)

- **Pulse pressure = SBP − DBP.** A pulse pressure above 60–65 mmHg indicates significant arterial stiffening and independently predicts cardiovascular events in the elderly.
- **Pulse wave velocity** (carotid–femoral) is the reference measure of arterial stiffness; >10 m/s indicates target-organ damage.
- **Osler's manoeuvre** — a palpable, pulseless radial artery when the cuff is inflated above systolic pressure — is the classic bedside clue to pseudo-hypertension.
- **CAFE study** (Circulation 2006, cited in Pathy's): drugs differ in their effect on *central* aortic pressure even when brachial pressures are equal — amlodipine-based therapy lowered central pressure more than atenolol-based therapy.
- Mnemonic for first-line drugs in ISH: **"CD" — Calcium channel blocker and Diuretic** (thiazide-like).
- Remember the three ISH trial names in order of era: **SHEP → Syst-Eur → HYVET → (now) STEP and ESPRIT.**

Examiner's Tip

"*Isolated systolic hypertension is a disease of large-artery stiffness, not of increased peripheral resistance.*" · "*Loss of aortic elasticity causes early return of the reflected pulse wave in systole, raising systolic and lowering diastolic pressure, which widens the pulse pressure.*" · "*Thiazide-like diuretics and dihydropyridine calcium channel blockers are first-line, supported by SHEP, Syst-Eur and HYVET.*" · "*Treatment must be titrated against the standing blood pressure, and a diastolic pressure below 60 mmHg should prompt caution because coronary perfusion occurs in diastole.*"

Q3. Congestive cardiac failure — aetiology, clinical features, evaluation and management; drug categories, indications and side effects; approach to refractory heart failure

15-MARK ANSWER | 20 POINTS

Definition and Burden

1. **Heart failure (HF)** is a clinical syndrome of symptoms and signs caused by a structural or functional cardiac abnormality resulting in reduced cardiac output or raised filling pressures.
2. Prevalence rises with age — HF is present in **13–14%** of people over 80. Lifetime risk at age 40 is about 21% for men and 20% for women. Two-year and five-year mortality are approximately **60%** and **75%**, comparable to many common cancers.
3. **Indian and developing-country context:** ischaemic aetiology is proportionally less common; rheumatic heart disease, hypertension, idiopathic dilated cardiomyopathy and cor pulmonale contribute more. Patients present younger and at a more advanced stage.

Aetiology

4. **Commonest causes in the elderly:** ischaemic heart disease and hypertension — together they account for more than **75%** of overt heart failure in older patients.
5. Others: valvular disease (calcific aortic stenosis, mitral annular calcification), atrial fibrillation, cardiomyopathies (including cardiac amyloidosis), thyroid disease, anaemia, chronic kidney disease, alcohol, chemotherapy (anthracyclines, trastuzumab) and cor pulmonale.
6. **Ageing changes that predispose:** myocardial fibrosis and collagen deposition, reduced beta-adrenergic responsiveness, impaired ventricular relaxation, reduced maximum heart rate, and increased afterload from arterial stiffening.

Clinical Features

7. **Typical:** exertional dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, fatigue, ankle oedema, raised JVP, third heart sound, basal crackles, hepatomegaly, pleural effusion, ascites.
8. **Atypical presentations in old age (high-yield):** confusion or delirium, falls, anorexia and weight loss, nocturia, functional decline, unexplained fatigue. Pathy's notes that **one-third of older patients with HF do not display the classical signs**.
9. Individual symptoms and signs have **low sensitivity**; it is the constellation that supports the diagnosis. *Essentials* warns that HF is **over-diagnosed** in older adults — pedal oedema alone is not sufficient, as venous stasis mimics it.

Evaluation

10. **Step 1 — clinical probability:** symptoms, signs, prior cardiac history, abnormal ECG. A completely normal ECG makes HF very unlikely.
11. **Step 2 — natriuretic peptides.** ESC thresholds for further investigation: **BNP >35 pg/mL** or **NT-proBNP >125 pg/mL** in the non-acute setting. Normal levels virtually exclude HF; raised levels also carry prognostic weight. Equally predictive in HFrEF and HFpEF.
12. **Step 3 — echocardiography** to define ejection fraction, chamber size, wall thickness, valve disease and diastolic function. NICE: echocardiography first in those with previous MI; natriuretic peptide first in those without.
13. Supportive tests: chest X-ray (excludes COPD, fibrosis, malignancy), full blood count, renal function and electrolytes, thyroid function, glucose/HbA1c, iron studies, liver function, urinalysis.

Non-Pharmacological Management

14. Patient and carer education, daily weight monitoring, salt and fluid moderation, alcohol and smoking cessation, treatment of anaemia and iron deficiency, immunisation (influenza and pneumococcal), **supervised cardiac rehabilitation and exercise training**, adherence support, and multidisciplinary HF nurse follow-up. Pathy's stresses these are "often overlooked".

Drug Categories — Indications and Side Effects (HFrEF)

Class	Indication / evidence	Key adverse effects in the elderly
ACE inhibitors (enalapril, ramipril)	All HFrEF irrespective of NYHA class; cornerstone since CONSENSUS. Low doses still give benefit.	Hypotension, hyperkalaemia, rising creatinine, cough, angioedema. Contraindicated in bilateral renal artery stenosis.
ARBs (candesartan, valsartan)	ACE-inhibitor intolerance (cough).	Hyperkalaemia, hypotension. **Never combine with ACE inhibitor.**

Beta blockers (carvedilol, bisoprolol, nebivolol, metoprolol MR)	Symptomatic HFrEF NYHA I–IV added to ACE inhibitor; benefit shown up to age 80 (SENIORS used nebivolol in the elderly).	Fatigue, bradycardia, worsening exercise tolerance, bronchospasm in severe COPD. Start low, go slow.
MRAs (spironolactone, eplerenone)	Persisting symptoms despite ACE inhibitor + beta blocker.	Hyperkalaemia, renal impairment, gynaecomastia (spironolactone). Monitor K^+ and creatinine.
Loop diuretics (furosemide, torsemide)	Congestion and fluid overload — symptomatic benefit, no mortality benefit.	Dehydration, hypokalaemia, hyponatraemia, gout, ototoxicity, incontinence, falls.
Digoxin	Persisting symptoms, especially with AF. In over-70s use **0.125 mg/day**, target level 0.5–0.9 ng/mL.	Nausea, anorexia, heart block, arrhythmia, confusion. Toxicity increased by renal impairment and hypokalaemia.
Ivabradine	NYHA II–III, sinus rhythm, heart rate >70/min despite optimal therapy (SHIFT).	Headache, dizziness, phosphenes (visual brightness), bradyarrhythmia.
ARNI (sacubitril/valsartan)	NYHA II–III already on optimal therapy (PARADIGM-HF; 20% reduction in CV death/HF admission).	Hypotension, hyperkalaemia, angioedema. **36-hour washout** required after the last ACE inhibitor dose.
Hydralazine + nitrate	ACE inhibitor/ARB intolerance; African-ancestry patients.	Headache, tachycardia, lupus-like syndrome.

Device and Advanced Therapy

5. **Cardiac resynchronisation therapy (CRT)** for HFrEF with ventricular conduction delay; **ICD** for selected patients with reduced ejection fraction and reasonable life expectancy; consider left ventricular assist devices and transplantation only in highly selected younger-biological-age patients.

HFpEF and the Older Patient

6. Pathy's Table 34.8 summarises the historically negative HFpEF trials: **CHARM-Preserved, I-PRESERVE, PEP-CHF, SENIORS, DIG-ancillary, TOPCAT and PARAGON-HF** — none reduced mortality; several reduced hospitalisations. Management therefore centred on diuretics plus treatment of hypertension, ischaemia, AF and diabetes.

Approach to Refractory Heart Failure

7. **Confirm it is truly refractory:** check adherence, excess salt/fluid intake, and drugs that worsen HF (NSAIDs, glitazones, non-dihydropyridine calcium channel blockers, some antiarrhythmics).
8. **Search for a reversible precipitant:** uncontrolled AF or other arrhythmia, silent ischaemia, anaemia, iron deficiency, infection, thyroid dysfunction, renal failure, uncontrolled hypertension, severe valve disease, pulmonary embolism, cardiac amyloidosis.
9. **Escalate therapy:** optimise/uptitrate disease-modifying drugs; combine loop diuretic with a thiazide for **sequential nephron blockade**; switch oral to intravenous furosemide (infusion) for gut oedema; consider ultrafiltration; consider CRT; consider inotropes for short-term bridging only.
10. **Palliative approach:** as the disease reaches the terminal stage, prioritise symptom relief and quality of life — withdraw unnecessary drugs and blood tests, treat breathlessness and anxiety with judicious **opioids and benzodiazepines**, provide multidisciplinary emotional support, and consider home- or institution-based hospice care.

Latest Updates (2023–Present)

- **SGLT2 inhibitors are now foundational across the entire ejection fraction spectrum** — the 2023 ESC Focused Update extended dapagliflozin and empagliflozin from HFrEF to HFmrEF and HFpEF (DELIVER, EMPEROR-Preserved). Four-pillar therapy for HFrEF is now **ARNI/ACEi + beta blocker + MRA + SGLT2 inhibitor**, started rapidly and in parallel rather than sequentially (STRONG-HF).
- **FINEARTS-HF** (NEJM 2024): finerenone, a non-steroidal MRA, reduced cardiovascular death and total worsening HF events by **16%** in HF with LVEF ≥40%, with benefit consistent even at EF ≥60% — the first robust evidence that MRA blockade works in HFpEF.
- **2026 ACC Expert Consensus Decision Pathway on HFpEF** (JACC) replaces the 2023 version: SGLT2 inhibitor for all, plus a non-steroidal MRA with **finerenone as the MRA of choice** (spironolactone a reasonable alternative if cost or tolerance is prohibitive), and incretin-based therapy for BMI ≥30 kg/m². It recommends sequential use of the **H2FPEF** and **HFA-PEFF** scores and systematic exclusion of cardiac and non-cardiac mimics.
- **STEP-HFpEF** (semaglutide) improved KCCQ symptom score and exercise capacity in obesity-related HFpEF; **SUMMIT** (tirzepatide) additionally reduced cardiovascular death or worsening HF events.
- **Cardiac amyloidosis is now a treatable cause of HFpEF in the elderly** — see Q7.

- **Iron deficiency:** intravenous ferric carboxymaltose/derisomaltose reduces HF hospitalisation (AFFIRM-AHF, IRONMAN); iron studies are now part of routine HF work-up.

Current Practice Update

Textbook position	Current evidence (2023–2026)
HFrEF therapy = ACE inhibitor/ARB + beta blocker + MRA, with ivabradine and ARNI as add-ons; SGLT2 inhibitors described as a "future perspective".	Four-pillar therapy with SGLT2 inhibitors as an established first-line pillar, initiated early and simultaneously.
"Clinical studies in HFpEF so far have not shown benefits."	SGLT2 inhibitors (DELIVER, EMPEROR-Preserved) and finerenone (FINEARTS-HF) now show benefit; GLP-1 agents improve symptoms in obesity-related HFpEF.
Uptitration performed slowly over months.	STRONG-HF supports rapid, protocol-driven uptitration with close follow-up after decompensation.
Iron deficiency not emphasised.	Routine iron studies; IV iron reduces HF hospitalisation.

Examiner's Tip

"*More than 75% of heart failure in older patients is attributable to hypertension or coronary heart disease.*" · "*One-third of older patients with heart failure do not display the classical signs; presentation may be confusion, falls or functional decline.*" · "*BNP >35 pg/mL or NT-proBNP >125 pg/mL should prompt echocardiography; normal values make heart failure unlikely.*" · "*Contemporary HFrEF therapy rests on four pillars — ARNI or ACE inhibitor, beta blocker, mineralocorticoid receptor antagonist and SGLT2 inhibitor.*" · "*In refractory failure, first exclude non-adherence and drugs that worsen heart failure before escalating therapy.*"

Q4. Congestive heart failure — diagnostic evaluation

7-MARK ANSWER | 10 POINTS

1. **Why it is difficult in the elderly:** atypical presentation, multiple comorbidities that mimic HF (COPD, obesity, anaemia, venous stasis, renal disease), and cognitive impairment limiting history-taking. *Essentials* stresses that HF is **over-diagnosed** — pedal oedema alone is not enough.
2. **Step 1 — assess clinical probability** using the ESC algorithm: symptoms, signs, prior cardiac conditions and an abnormal ECG. Presence of one or more should prompt natriuretic peptide measurement.
3. **Step 2 — natriuretic peptides.** **BNP >35 pg/mL** or **NT-proBNP >125 pg/mL** (non-acute setting) warrant echocardiography. In acute breathlessness, BNP above about **300 pg/mL** favours a cardiac over a pulmonary cause. Normal values effectively rule out HF; levels also predict prognosis.
4. **Causes of falsely raised natriuretic peptides:** age, female sex, renal impairment, atrial fibrillation, pulmonary embolism, sepsis, anaemia. **Falsely low:** obesity, and treatment with ARNI alters BNP interpretation (use NT-proBNP).
5. **Step 3 — echocardiography** is the key confirmatory test: ejection fraction, chamber dimensions, wall thickness, diastolic parameters (E/e′, left atrial volume index, tricuspid regurgitant velocity), valvular lesions and pericardial disease. NICE: echocardiography first if previous MI; natriuretic peptide first if no previous MI.
6. **ECG:** looks for prior infarction, LV hypertrophy, atrial fibrillation, bundle branch block (relevant to CRT) and low voltage with LV hypertrophy (suggesting amyloidosis). A normal ECG makes HF very unlikely.
7. **Chest radiograph:** cardiomegaly, upper-lobe diversion, Kerley B lines, effusions; also excludes COPD, fibrosis and malignancy.
8. **Laboratory panel:** full blood count, urea, creatinine and electrolytes, eGFR, liver function, thyroid function, glucose/HbA1c, lipids, iron studies (ferritin and transferrin saturation), urinalysis.
9. **Classify by ejection fraction:** HFrEF (≤40%), HFmrEF (41–49%), HFpEF (≥50%) — HFpEF predominates in older women with hypertension.
10. **Assess functional and geriatric domains alongside cardiac ones:** NYHA class, six-minute walk, frailty, cognition, nutrition, polypharmacy and social support — these determine what treatment is feasible.

Latest Updates and Current Practice Update (concise)

- **Scoring systems for HFpEF are now standard.** The 2026 ACC HFpEF consensus pathway recommends sequential use of the **H2FPEF** and **HFA-PEFF** scores, with diastolic stress echocardiography or invasive exercise haemodynamics if the diagnosis remains uncertain — an approach absent from the textbooks.
- **Systematic search for mimics is now mandatory**, in particular **cardiac amyloidosis** (bone scintigraphy with ^{99m}Tc-PYP/DPD plus serum free light chains and immunofixation), constrictive pericarditis, hypertrophic cardiomyopathy and high-output states. Cardiac MRI with T1 mapping and extracellular volume quantification is increasingly used.
- **Practical change:** lung ultrasound (B-lines) and point-of-care echocardiography are now widely used at the bedside to distinguish cardiac from pulmonary dyspnoea, supplementing rather than replacing the natriuretic peptide–echocardiography pathway described in the textbooks.

> **Examiner's Tip**
>
> Draw the ESC algorithm as a flow diagram — *clinical probability → natriuretic peptide → echocardiography* — and label the cut-offs. Then add one line: "*In an older patient with HFpEF, unexplained left ventricular thickening, low ECG voltages and a history of bilateral carpal tunnel syndrome should prompt bone scintigraphy for transthyretin cardiac amyloidosis.*"

Q5. Refractory cardiac failure

7-MARK ANSWER | 10 POINTS

1. **Definition:** persistent symptoms of heart failure at rest or on minimal exertion (NYHA class IV) with recurrent congestion or low output, despite maximal tolerated guideline-directed therapy — corresponds to **ACC/AHA Stage D, advanced heart failure**.
2. **Recognition ("I NEED HELP" markers):** repeated hospitalisations, intravenous inotrope dependence, escalating diuretic requirement, intolerance of neurohormonal drugs because of hypotension, rising urea and creatinine, hyponatraemia, persistently low ejection fraction and cardiac cachexia.
3. **Step 1 — exclude pseudo-refractoriness:** poor adherence (common with polypharmacy and cognitive impairment), excess dietary salt and fluid, and inadequate drug doses.
4. **Step 2 — stop aggravating drugs:** NSAIDs, corticosteroids, glitazones, verapamil/diltiazem, class I antiarrhythmics, and drugs causing sodium retention.
5. **Step 3 — treat reversible precipitants:** uncontrolled atrial fibrillation or other arrhythmia, silent myocardial ischaemia, severe valve disease, anaemia and iron deficiency, thyroid dysfunction, infection, pulmonary embolism, renal failure, uncontrolled hypertension, sleep apnoea, and **previously undiagnosed cardiac amyloidosis**.
6. **Step 4 — overcome diuretic resistance:** use intravenous furosemide (bolus or infusion) because gut wall oedema impairs oral absorption; add a thiazide such as metolazone for **sequential nephron blockade**; add an MRA; consider acetazolamide (ADVOR) or an SGLT2 inhibitor; correct hypoalbuminaemia; monitor electrolytes and renal function closely.
7. **Step 5 — mechanical and device options:** ultrafiltration for genuinely diuretic-resistant congestion; cardiac resynchronisation therapy in ventricular dyssynchrony; revascularisation or valve intervention (including TAVI in older patients with aortic stenosis) where appropriate.
8. **Step 6 — advanced therapies:** intravenous inotropes (dobutamine, milrinone, levosimendan) are for short-term bridging or palliation only, as continuous inotropes increase mortality. Left ventricular assist devices and transplantation apply to a very small, carefully selected group and are usually limited by biological age and comorbidity.
9. **Step 7 — palliative and end-of-life care** (the geriatric emphasis in Pathy's): prioritise quality of life; withhold unnecessary blood tests and medications; treat breathlessness, agitation and anxiety with judicious opioids and benzodiazepines; discuss advance care planning and deactivation of ICD shocks; involve the multidisciplinary team; consider hospice care in the final days.
10. **Prognosis:** advanced heart failure carries a one-year mortality commonly exceeding 50%; discussions about ceilings of care should occur early rather than in the last admission.

Latest Updates and Current Practice Update (concise)

- **ADVOR trial** (NEJM 2022, now in practice): adding intravenous **acetazolamide** to loop diuretics improves decongestion in acute decompensated HF — a practical addition not present in the textbooks.
- **SGLT2 inhibitors improve diuretic efficiency and are continued (not stopped) during decompensation**; EMPULSE showed clinical benefit when empagliflozin was started in hospital. This reverses the older instinct to withhold new agents during decompensation.
- **Vericiguat** (VICTORIA) is licensed for worsening HFrEF after a recent decompensation, and **omecamtiv mecarbil** remains investigational; both extend the options for the patient who has exhausted the four pillars.

> **Examiner's Tip**
>
> Structure the answer as a numbered algorithm: *confirm → exclude non-adherence → stop culprit drugs → treat precipitants → break diuretic resistance → devices → advanced therapy → palliation.* Finish with: "*In the frail older patient, escalation to advanced therapies is usually inappropriate, and the correct next step is a structured conversation about goals of care and symptom-directed palliation.*"

Q6. Diastolic dysfunction

7-MARK ANSWER | 10 POINTS

1. **Definition:** impaired ventricular relaxation and/or increased chamber stiffness causing raised filling pressures at normal or near-normal ejection fraction. When symptomatic it manifests as **heart failure with preserved ejection fraction (HFpEF)**.
2. **Geriatric importance:** *Essentials* states plainly that **diastolic, not systolic, dysfunction is the primary cause of heart failure in older patients**, and that it is associated with a marked increase in all-cause mortality (Redfield 2003; Bursi 2006).
3. **Pathophysiology:** age-related myocardial fibrosis and collagen deposition, LV hypertrophy from chronic hypertension and arterial stiffening, impaired active relaxation (delayed calcium re-uptake by SERCA), titin stiffening, subendocardial ischaemia and microvascular inflammation.
4. **Consequences:** small increases in volume produce large increases in filling pressure → pulmonary congestion, especially with tachycardia (loss of diastolic filling time) or loss of atrial systole in atrial fibrillation. This explains the classic presentation of **flash pulmonary oedema** with new AF or a hypertensive surge.
5. **Causes:** hypertension with LV hypertrophy (commonest), coronary disease, diabetes, obesity, aortic stenosis, hypertrophic cardiomyopathy, restrictive/infiltrative disease (amyloidosis, haemochromatosis), and constrictive pericarditis as a mimic.
6. **Clinical features:** exertional dyspnoea, fatigue, orthopnoea and congestion indistinguishable from systolic failure at the bedside; a fourth heart sound (S4) and a sustained apex are suggestive; typically an older woman with hypertension, obesity, diabetes and atrial fibrillation.
7. **Diagnosis:** preserved ejection fraction (≥50%) plus objective evidence of raised filling pressures — echocardiographic **E/e′ >14–15**, septal e′ <7 cm/s, left atrial volume index >34 mL/m², tricuspid regurgitant velocity >2.8 m/s, LV hypertrophy — with raised natriuretic peptides.
8. **Management (textbook position):** treat congestion with diuretics, control heart rate with beta blockers to prolong diastolic filling, and treat the comorbidities that drive it — **hypertension, coronary disease, atrial fibrillation and diabetes**. Trials of digoxin and ARBs showed minimal benefit.
9. **Practical cautions:** these patients are preload-dependent — over-diuresis causes hypotension and acute kidney injury; avoid excessive rate reduction (chronotropic incompetence worsens exercise capacity) and avoid drugs that shorten diastole.
10. **Prognosis:** mortality approaches that of HFrEF, with hospitalisation driven as much by non-cardiac comorbidity as by cardiac events.

Latest Updates and Current Practice Update (concise)

- **The therapeutic desert has ended.** Contrary to the textbooks, HFpEF now has evidence-based drug therapy: **SGLT2 inhibitors** (EMPEROR-Preserved, DELIVER) reduce worsening HF events across the ejection fraction spectrum and are recommended for all; **finerenone** (FINEARTS-HF, 2024) reduced cardiovascular death and worsening HF events by 16%, including at EF ≥60%.
- **2026 ACC HFpEF Expert Consensus Decision Pathway**: SGLT2 inhibitor for all, plus a non-steroidal MRA (**finerenone preferred** over spironolactone), plus **semaglutide or tirzepatide** when BMI ≥30 kg/m²; diagnosis by sequential H2FPEF and HFA-PEFF scoring with systematic exclusion of mimics.
- **Amyloid must be excluded:** up to about 13% of older HFpEF patients with marked LV hypertrophy have transthyretin cardiac amyloidosis, which now has specific disease-modifying therapy.

> **Examiner's Tip**
>
> Write: "*Diastolic dysfunction, not systolic dysfunction, is the commonest substrate for heart failure in the elderly.*" · "*E/e′ greater than 14, left atrial enlargement and raised natriuretic peptides with a preserved ejection fraction establish the diagnosis.*" · "*HFpEF is no longer untreatable — SGLT2 inhibitors and finerenone now have outcome benefit.*" Adding the FINEARTS-HF result reliably earns a mark.

Q7. Cardiomyopathies — pathophysiology, aetiology, clinical features, diagnosis and treatment

15-MARK ANSWER | 18 POINTS

> **Textbook coverage note:** Neither *Pathy's* (6th ed.) nor *Essentials of Clinical Geriatrics* (7th ed.) contains a dedicated cardiomyopathy chapter. They refer to cardiomyopathy only in passing — as a cause of sudden cardiac death and ventricular arrhythmia, as an aetiology of heart failure (idiopathic dilated cardiomyopathy being relatively more prevalent outside the West), in relation to pacing in infiltrative cardiomyopathy such as sarcoidosis, and in describing idiopathic hypertrophic subaortic stenosis. The classification and management framework below is therefore drawn from current cardiology guidance, and is flagged accordingly.

Definition and Classification

1. **Cardiomyopathy** = myocardial disorder in which the heart muscle is structurally and functionally abnormal, in the absence of coronary disease, hypertension, valvular disease or congenital disease sufficient to explain the abnormality.
2. **Morphofunctional classification: dilated (DCM)**, **hypertrophic (HCM)**, **restrictive (RCM)**, **arrhythmogenic right ventricular cardiomyopathy (ARVC)**, and **non-dilated left ventricular cardiomyopathy (NDLVC)** — the last added by the 2023 ESC cardiomyopathy guideline.
3. **Aetiological classification:** genetic (familial) versus acquired (mixed forms exist).

Pathophysiology by Type

4. **Dilated:** ventricular dilatation with systolic dysfunction → reduced stroke volume → neurohormonal activation (RAAS, sympathetic) → adverse remodelling, mitral annular dilatation with functional regurgitation, mural thrombus and arrhythmia.
5. **Hypertrophic:** sarcomere protein mutations → myocyte hypertrophy and disarray with interstitial fibrosis → impaired relaxation, dynamic left ventricular outflow tract obstruction with systolic anterior motion of the mitral valve, microvascular ischaemia and arrhythmogenic substrate.
6. **Restrictive:** stiff, non-compliant ventricles with normal or near-normal systolic function and normal chamber size → severe diastolic impairment with biatrial enlargement and high filling pressures.
7. **Arrhythmogenic:** desmosomal mutations → fibrofatty replacement of myocardium → ventricular arrhythmia and sudden death.

Aetiology

8. **Dilated:** idiopathic/familial (titin, lamin A/C), ischaemic, alcohol, chemotherapy (anthracyclines, trastuzumab), viral myocarditis, thyroid disease, tachycardia-induced, peripartum, iron overload, nutritional (thiamine).
9. **Hypertrophic:** autosomal dominant sarcomere gene mutations (MYH7, MYBPC3); phenocopies include Fabry disease and amyloidosis.
10. **Restrictive (most relevant to geriatrics): cardiac amyloidosis** (transthyretin wild-type in the elderly, AL in plasma cell dyscrasia), sarcoidosis, haemochromatosis, endomyocardial fibrosis (important in tropical/Indian practice), radiation and hypereosinophilic syndrome.
1. **Indian context:** endomyocardial fibrosis, rheumatic heart disease as a differential, nutritional and alcoholic cardiomyopathy, and a relatively higher prevalence of idiopathic dilated cardiomyopathy than in the West.

Clinical Features

2. **Common to all:** exertional dyspnoea, fatigue, palpitations, syncope, embolic events, arrhythmia and sudden cardiac death.
3. **Dilated:** features of congestive failure with a displaced diffuse apex, S3, functional mitral regurgitation.
4. **Hypertrophic:** ejection systolic murmur that **increases** with Valsalva and standing and **decreases** with squatting; jerky/bisferiens pulse; murmur does not radiate to the carotids (contrast with aortic stenosis). *Essentials* warns that in older adults this may be misdiagnosed as aortic stenosis or mitral regurgitation, and that digoxin and diuretics may worsen symptoms.
5. **Restrictive/amyloid:** right-sided failure predominates with raised JVP, Kussmaul's sign, hepatomegaly, ascites, peripheral oedema; extracardiac clues of transthyretin amyloidosis include **bilateral carpal tunnel syndrome**, lumbar spinal stenosis, biceps tendon rupture, and intolerance of standard heart failure drugs because of hypotension.

Diagnosis

6. **ECG:** DCM — LBBB, poor R progression; HCM — LV hypertrophy with deep T inversion; amyloidosis — the classic mismatch of **low QRS voltages with echocardiographic LV thickening**, plus pseudo-infarct patterns and conduction block.

   Echocardiography defines the phenotype: chamber size, wall thickness, ejection fraction, outflow gradient, diastolic parameters and granular sparkling myocardium in amyloid; global longitudinal strain shows **apical sparing ("cherry-**

on-top") in amyloidosis.

7. **Advanced tests:** cardiac MRI with late gadolinium enhancement and T1/extracellular volume mapping; **^{99m}Tc-PYP/DPD bone scintigraphy** (Perugini grade ≥2) for transthyretin amyloidosis; serum free light chains with serum and urine immunofixation to exclude AL amyloidosis; genetic testing and family screening; endomyocardial biopsy where non-invasive tests are inconclusive; coronary angiography to exclude ischaemic disease.

Treatment

8. **DCM:** full guideline-directed HFrEF therapy (four pillars), device therapy (CRT/ICD), anticoagulation if AF or mural thrombus, and removal of the cause (alcohol, tachycardia, thyroid).
   HCM: beta blockers or verapamil; disopyramide for obstruction; avoid dehydration, vasodilators, digoxin and diuretic excess; septal reduction (myectomy or alcohol ablation) for refractory obstruction; ICD for high sudden-death risk.
   RCM/amyloid: cautious diuretics for congestion, treat arrhythmia, anticoagulate for AF regardless of risk score, and use disease-modifying therapy for transthyretin amyloidosis. Avoid digoxin and calcium channel blockers in amyloidosis (binding to amyloid fibrils increases toxicity).

Latest Updates (2023–Present)

- **2023 ESC Guideline on Cardiomyopathies** — the first standalone ESC cardiomyopathy guideline; introduces the phenotype **non-dilated left ventricular cardiomyopathy**, and places multimodality imaging and genetic testing with cascade family screening at the centre of the pathway.
- **Transthyretin cardiac amyloidosis is now a treatable disease of old age.** Three agents are approved: **tafamidis** (stabiliser, ATTR-ACT), **acoramidis** (stabiliser, ATTRibute-CM, FDA-approved 2024, halved cardiovascular hospitalisations), and **vutrisiran** (siRNA silencer, HELIOS-B, approved for ATTR-CM in March 2025, reduced all-cause death and recurrent cardiovascular events). Vitamin A supplementation is advised with silencer therapy. **Eplontersen** is in phase III (CARDIO-TTRansform).
- **2025 ACC Concise Clinical Guidance on ATTR-CM** (JACC) confirms that diagnosis can be made **non-invasively** by bone scintigraphy once a monoclonal protein screen is negative, and that MRAs and SGLT2 inhibitors — not previously used in amyloid — are now part of care. These agents slow progression but do not reverse established organ damage, so **early diagnosis is essential**.
- **Cardiac myosin inhibitors for obstructive HCM: mavacamten** (EXPLORER-HCM, VALOR-HCM) and **aficamten** (SEQUOIA-HCM) reduce outflow gradients and the need for septal reduction therapy — a completely new drug class since the textbooks were written.
- **Anticoagulation:** the 2024 ESC AF guideline recommends oral anticoagulation in **all** patients with AF and hypertrophic cardiomyopathy or cardiac amyloidosis, *irrespective of the CHA_2DS_2-VA score*.

Current Practice Update

Textbook position	Current evidence (2023–2026)
Cardiomyopathy mentioned only as a cause of heart failure and sudden cardiac death; no classification or management framework.	2023 ESC standalone cardiomyopathy guideline with five phenotypes and a genotype–phenotype pathway.
Cardiac amyloidosis effectively untreatable; diagnosis needed biopsy.	Non-invasive diagnosis by bone scintigraphy; three approved disease-modifying drugs (tafamidis, acoramidis, vutrisiran).
Obstructive HCM treated with beta blockers, verapamil, disopyramide and septal reduction.	Cardiac myosin inhibitors (mavacamten, aficamten) now available and reduce the need for invasive septal reduction.
Anticoagulation in AF guided by risk score alone.	Anticoagulate all patients with AF plus HCM or cardiac amyloidosis regardless of score.

Examiner's Tip

"*Cardiomyopathy is myocardial disease not explained by coronary, hypertensive, valvular or congenital heart disease.*" · "*In an older patient, low ECG voltages with echocardiographic left ventricular thickening should be assumed to be cardiac amyloidosis until excluded.*" · "*Bone scintigraphy with a negative monoclonal protein screen now allows non-invasive diagnosis of transthyretin cardiac amyloidosis.*" · "*The murmur of hypertrophic obstructive cardiomyopathy increases on Valsalva and standing and decreases on squatting — the reverse of aortic stenosis.*"

Q8. Cardiomyopathy (short note)

7-MARK ANSWER | 10 POINTS

1. **Definition:** structural and functional myocardial disease in the absence of coronary, hypertensive, valvular or congenital disease sufficient to explain it.
2. **Five phenotypes (2023 ESC):** dilated, hypertrophic, restrictive, arrhythmogenic right ventricular, and non-dilated left ventricular cardiomyopathy.
3. **Dilated:** dilated ventricle with reduced ejection fraction. Causes — idiopathic/familial, alcohol, chemotherapy, myocarditis, tachycardia-induced, thyroid, peripartum.
4. **Hypertrophic:** autosomal dominant sarcomere mutation with myocyte disarray; may obstruct the outflow tract. In older adults it may be mistaken for aortic stenosis; digoxin and diuretics worsen it.
5. **Restrictive:** stiff ventricles with preserved systolic function and biatrial enlargement. In the elderly the dominant cause is **cardiac amyloidosis**; endomyocardial fibrosis is important in Indian practice.
6. **Clinical features:** dyspnoea, fatigue, palpitations, syncope, embolism, arrhythmia and sudden death; right-sided congestion predominates in restrictive disease.
7. **Red flags for amyloidosis in an older patient:** HFpEF with marked left ventricular thickening, **low ECG voltages**, bilateral carpal tunnel syndrome, lumbar canal stenosis, and hypotension on standard heart failure drugs.
8. **Diagnosis:** ECG, echocardiography (including global longitudinal strain showing apical sparing), cardiac MRI with late gadolinium enhancement, ^{99m}Tc-PYP/DPD bone scintigraphy, serum free light chains and immunofixation, genetic testing, biopsy if needed.
9. **Treatment:** phenotype-directed — HFrEF four-pillar therapy and devices in dilated disease; beta blocker/verapamil, disopyramide and septal reduction in obstructive hypertrophic disease; cautious diuresis, arrhythmia control and disease-modifying therapy in amyloidosis.
10. **Family implications:** genetic counselling and cascade screening of first-degree relatives in inherited forms — a point examiners often expect but candidates omit.

Latest Updates and Current Practice Update (concise)

- **2023 ESC Cardiomyopathy Guideline** introduced the non-dilated left ventricular cardiomyopathy phenotype and mandated multimodality imaging plus genetic testing with family cascade screening.
- **Three approved drugs for transthyretin cardiac amyloidosis** — tafamidis, acoramidis (2024) and vutrisiran (2025) — have converted a formerly untreatable cause of HFpEF in the elderly into a treatable one; the textbooks predate all three.
- **Mavacamten and aficamten** (cardiac myosin inhibitors) are new first-in-class oral therapies for obstructive hypertrophic cardiomyopathy.

> **Examiner's Tip**
>
> For a short note, use a three-column mental table — *phenotype / cardinal abnormality / commonest cause in the elderly* — and finish with the amyloid red flags. Adding "*the textbooks describe cardiac amyloidosis as untreatable; three disease-modifying drugs are now licensed*" demonstrates current reading.

Q9. Dilated cardiomyopathy

7-MARK ANSWER | 10 POINTS

1. **Definition:** left ventricular or biventricular **dilatation with systolic dysfunction** not explained by abnormal loading conditions or coronary artery disease.
2. **Epidemiology:** Pathy's notes that **idiopathic dilated cardiomyopathy is relatively more prevalent in developing countries and Arabic populations** than in the West, and that non-ischaemic causes of heart failure (rheumatic disease, Chagas disease, hypertension) dominate outside high-income settings — directly relevant to Indian practice.
3. **Aetiology:** idiopathic/familial (titin truncating variants, **lamin A/C** — the latter associated with conduction disease and requiring early ICD), alcohol, anthracyclines and trastuzumab, viral myocarditis, tachycardia-induced, peripartum, thyrotoxicosis and hypothyroidism, iron overload, thiamine deficiency, and HIV.
4. **Pathophysiology:** myocyte loss and interstitial fibrosis → reduced contractility → neurohormonal activation (sympathetic, RAAS, natriuretic peptides) → progressive remodelling with eccentric hypertrophy, annular dilatation causing functional mitral regurgitation, stasis with mural thrombus, and re-entrant ventricular arrhythmia.
5. **Clinical features:** congestive heart failure with a displaced diffuse apex, S3 gallop, pansystolic murmur of functional mitral regurgitation, raised JVP, hepatomegaly and oedema; also arrhythmia, thromboembolism and sudden death.
6. **ECG:** sinus tachycardia, atrial fibrillation, left bundle branch block, poor R-wave progression, ventricular ectopy, non-sustained ventricular tachycardia.
7. **Echocardiography** is the key test: dilated chambers, globally reduced ejection fraction, functional mitral regurgitation, sometimes apical thrombus. Cardiac MRI with late gadolinium enhancement distinguishes ischaemic (subendocardial) from non-ischaemic (mid-wall) patterns and refines arrhythmic risk.
8. **Additional work-up:** coronary angiography or CT coronary angiography to exclude ischaemic cardiomyopathy; thyroid function, iron studies, HIV serology, alcohol history; genetic testing and family screening in familial disease.
9. **Treatment:** remove the cause (alcohol abstinence, rate control of incessant tachycardia, correct thyroid or iron abnormality); full **four-pillar HFrEF therapy** — ARNI or ACE inhibitor/ARB, beta blocker, mineralocorticoid receptor antagonist and SGLT2 inhibitor — plus diuretics for congestion, ivabradine if heart rate remains >70 in sinus rhythm, anticoagulation for atrial fibrillation or documented thrombus, CRT for conduction delay, and ICD in selected patients with a reasonable life expectancy.
10. **Prognosis and geriatric caveat:** some patients show substantial recovery of ejection fraction with optimal therapy ("heart failure with improved ejection fraction"), and therapy should **not** be withdrawn once function recovers (TRED-HF). In very frail elders, tolerability, symptom control and quality of life take precedence over full-dose uptitration and device therapy.

Latest Updates and Current Practice Update (concise)

- **SGLT2 inhibitors are now a first-line pillar** in dilated cardiomyopathy with reduced ejection fraction (DAPA-HF, EMPEROR-Reduced); the textbooks list them only as an emerging possibility.
- **STRONG-HF** supports rapid, protocol-driven uptitration of all four pillars within weeks of decompensation, with close biochemical and clinical review — replacing the traditional slow month-by-month titration.
- **2023 ESC Cardiomyopathy Guideline** makes genetic testing and cascade family screening standard in dilated cardiomyopathy, and highlights **lamin A/C and filamin C variants** as indications for earlier ICD implantation irrespective of ejection fraction thresholds.

> **Examiner's Tip**
>
> "*Dilated cardiomyopathy is ventricular dilatation with systolic dysfunction in the absence of abnormal loading conditions or coronary disease sufficient to explain it.*" · "*Always exclude a reversible cause — alcohol, tachycardia, thyroid disease and iron overload — before labelling it idiopathic.*" · "*Guideline-directed therapy should not be withdrawn when the ejection fraction recovers.*"

Q10. Atrial fibrillation and its management

15-MARK ANSWER | 19 POINTS

Definition and Epidemiology

1. **Atrial fibrillation (AF)** is uncoordinated atrial electrical activation with loss of effective atrial mechanical function — the commonest sustained arrhythmia in older people.
2. Prevalence rises from **<0.5%** at age 40–50 to **5–15%** at age 80. Men are affected earlier, but in old age there are more women with AF than men. Lifetime risk at age 55 is about 35%.
3. **Stroke risk rises steeply with age** — from about 1.5% per year at 50–59 years to **23.5%** at 80–89 years. Up to 30% of all ischaemic strokes are attributable to AF, and AF-related strokes are larger and more disabling.
4. AF also causes heart failure (in 20–30%), a 60% relative increase in risk of significant cognitive decline, impaired quality of life in over 60%, and up to a 3.5-fold increase in all-cause mortality.

Aetiology and Ageing Substrate

5. **Ageing changes:** atrial amyloid deposition, loss of sinoatrial pacemaker myocytes, and collagen/fibrous replacement of conducting tissue and myocardium.
6. **Risk factors:** hypertension (each 10 mmHg rise in systolic BP raises AF risk by 11–16%), heart failure, valvular disease (especially mitral), ischaemic heart disease, diabetes, obesity, obstructive sleep apnoea, alcohol, hyperthyroidism, chronic kidney disease and systemic inflammation.

Classification

7. **First detected → paroxysmal** (self-terminating, usually within 48 hours) → **persistent** (>7 days or requiring intervention) → **long-standing persistent** (≥1 year with a rhythm-control strategy still intended) → **permanent** (a statement of intent — no further attempt at sinus rhythm). Permanent AF is re-designated long-standing persistent if the plan changes.

Clinical Features and Diagnosis

8. May be asymptomatic (found on routine examination or device interrogation) or present with palpitations, dyspnoea, fatigue, angina, syncope, falls, heart failure, stroke or delirium.
9. ECG shows absent P waves with an irregularly irregular ventricular response. **A regular rhythm with a fibrillatory baseline in a patient with AF implies complete AV block with an escape rhythm** — a classic examination point. Slow ventricular rates are common in the elderly because of AV nodal disease.
10. Ambulatory monitoring is matched to symptom frequency: 24-hour Holter for daily symptoms; 48–72 hours or patch for several times weekly; 7-day for weekly; event recorder for monthly; implantable loop recorder for less frequent symptoms. Pacemaker-detected **atrial high-rate episodes >200 bpm** should prompt further investigation.

Management Pillar 1 — Stroke Prevention

1. Score every patient with **CHA_2DS_2-VASc**: Congestive heart failure 1, Hypertension 1, Age ≥75 **2**, Diabetes 1, Stroke/TIA/thromboembolism **2**, Vascular disease 1, Age 65–74 1, Sex category (female) 1 — maximum 9.
2. Anticoagulate all men with score ≥2 and women with score ≥3 (Class I); consider at 1 (men) and 2 (women). **Every patient over 75 with AF therefore qualifies** unless there is a major contraindication.
3. **DOACs are preferred over warfarin** in non-valvular AF (Class I). Warfarin (INR 2–3) remains mandatory for **moderate-to-severe mitral stenosis and mechanical prosthetic valves**, as no DOAC trial included these patients.
4. Warfarin reduces stroke by about **64%**; aspirin reduces it by only about 22% with substantial bleeding risk, so **antiplatelet therapy is no longer recommended for stroke prevention in AF**. BAFTA showed warfarin superior to aspirin in community elderly.
5. Use **HAS-BLED** to identify and correct modifiable bleeding risks and to flag patients needing closer review — **not** to withhold anticoagulation. *Essentials* lists among its "Don'ts": **do not withhold anticoagulation for atrial fibrillation because of fall risk.**
6. For patients with a genuine contraindication (recurrent intracranial haemorrhage, recurrent embolic stroke despite adequate anticoagulation), consider **percutaneous left atrial appendage occlusion** (WATCHMAN) — procedural complication risk about 4%; surgical LAA exclusion may be added during cardiac surgery.

Management Pillar 2 — Rate Control

7. **Beta blockers** are the most effective agents for controlling rate on exertion and are first-line with hypertension, ischaemic heart disease or stable LV dysfunction. **Non-dihydropyridine calcium channel blockers** (verapamil, diltiazem) are alternatives when airways disease is present but must be avoided in reduced LV systolic function and pulmonary oedema. **Digoxin** — use 0.125 mg/day in the elderly, monitor levels and renal function; it controls rate at rest but not on exertion. **Amiodarone** can be used for rapid control but long-term use is limited by thyroid, pulmonary, hepatic, ocular and skin toxicity. Lenient rate control (resting rate <110 bpm) was non-inferior to strict control in **RACE**

II.

Management Pillar 3 — Rhythm Control

8. Classical trials (AFFIRM, RACE, STAF, HOT CAFE, PIAF) showed **no survival advantage** for rhythm over rate control, so rhythm control was traditionally reserved for symptom relief. Options are cardioversion (electrical or pharmacological), antiarrhythmic drugs (amiodarone, sotalol, flecainide only if no structural disease) and catheter ablation. Ablation is effective in symptomatic paroxysmal AF and is **not less successful in older patients**, though success is higher with shorter AF duration; risks and benefits must be weighed individually.

Integrated Care

9. The **ABC pathway** (Avoid stroke — Better symptom control — Cardiovascular and comorbidity optimisation) improves outcomes in anticoagulated AF patients. Additional geriatric considerations: cognitive impairment reduces adherence (missed DOAC doses cause periods of under-anticoagulation because of the short half-life); dementia is not in itself a contraindication, especially in multi-infarct dementia where anticoagulation may halt stepwise decline; and warfarin interacts with many drugs and with vitamin K-rich foods.

Latest Updates (2023–Present)

- **2024 ESC/EACTS AF Guideline** replaces ABC with the **AF-CARE** framework: **C**omorbidity and risk-factor management, **A**void stroke and thromboembolism, **R**educe symptoms by rate and rhythm control, **E**valuation and dynamic reassessment.
- **The risk score has changed: CHA_2DS_2-VA** — sex category has been **removed** from the ESC score, giving a maximum of 8; anticoagulation is recommended at a score ≥2 and should be considered at 1, using the same threshold for men and women.
- **Subclinical/device-detected AF:** NOAH-AFNET 6 and ARTESIA led to a new IIb recommendation to consider anticoagulation in selected patients with device-detected subclinical AF at high thromboembolic risk without major bleeding risk factors.
- **Early rhythm control is now favoured** (EAST-AFNET 4): rhythm control within 12 months of diagnosis reduces cardiovascular outcomes; catheter ablation is a **first-line** option in suitable patients with paroxysmal AF. The threshold for early cardioversion has been reduced from 48 to **24 hours**, with a "wait-and-see" approach encouraged for spontaneous conversion.
- **Anticoagulate regardless of score** in AF with hypertrophic cardiomyopathy or cardiac amyloidosis; continue anticoagulation for ≥2 months after ablation irrespective of risk score.
- **Left atrial appendage occlusion:** LAAOS III showed a 33% reduction in stroke/systemic embolism when surgical LAA closure was added to anticoagulation during cardiac surgery (Class IA); the OPTION trial (2024–25) supports percutaneous LAAO as an alternative to DOAC after ablation in selected patients.
- **Factor XI inhibitors** (asundexian, abelacimab, milvexian) promised bleeding-free anticoagulation, but **OCEANIC-AF was stopped early for inferior efficacy** of asundexian versus apixaban — an important negative result. Trials in other populations continue.
- **India:** AF is under-detected and under-anticoagulated; rheumatic (valvular) AF remains common, and these patients require **warfarin, not a DOAC**. Cost, INR monitoring access and bleeding risk in the presence of untreated Helicobacter-related peptic disease are practical barriers.

Current Practice Update

Textbook position	Current evidence (2023–2026)
CHA_2DS_2-VASc with sex category; anticoagulate men ≥2, women ≥3.	**CHA_2DS_2-VA** (ESC 2024) — sex removed; single threshold ≥2 for both sexes.
ABC pathway for integrated care.	**AF-CARE** framework, with comorbidity and risk-factor control promoted to the first pillar.
Rate control equivalent to rhythm control; ablation second-line after drug failure.	**Early rhythm control improves outcomes** (EAST-AFNET 4); ablation is first-line in suitable paroxysmal AF.
Device-detected atrial high-rate episodes: investigate and treat as AF if confirmed on ECG.	Formal IIb recommendation to consider anticoagulation in high-risk subclinical AF (NOAH-AFNET 6, ARTESIA).
Cardioversion window of 48 hours.	Reduced to **24 hours**, with a wait-and-see strategy for spontaneous conversion.

Examiner's Tip

Draw the CHA_2DS_2-VASc table with the doubled items highlighted, then write: "*Every patient over 75 with atrial fibrillation should be anticoagulated unless there is a major contraindication.*" · "*Anticoagulation must not be withheld because of fall risk — the number of falls needed to offset the benefit of anticoagulation is impractically high.*" · "*The 2024 ESC guideline removed sex from the risk score, which is now CHA_2DS_2-VA.*" · "*Patients with rheumatic mitral stenosis or a mechanical valve must receive warfarin, not a DOAC.*"

Q11. Sick sinus syndrome

7-MARK ANSWER | 10 POINTS

1. **Definition: Sick sinus syndrome (sinus node dysfunction)** is a constellation of electrocardiographic abnormalities — sinus bradycardia, **chronotropic incompetence** (inadequate sinus response to exercise), sinoatrial exit block, and sinus arrest, particularly following paroxysms of atrial tachyarrhythmia (**tachy-brady syndrome**).
2. **It is primarily a disease of older people.** The substrate is age-related loss of specialised pacemaker myocytes in the sinoatrial node with collagen and fibrous tissue deposition, compounded by ischaemic and degenerative change from hypertension and coronary atherosclerosis.
3. **Associations:** both paroxysmal and chronic atrial fibrillation are commonly associated with sinus node disease; dysfunction may progress until no sinus beats occur at all, and conduction disease frequently coexists at the AV node.
4. **Secondary/reversible causes must be excluded first:** drugs (beta blockers including topical eye drops, verapamil/diltiazem, digoxin, amiodarone), hypothyroidism, hyperkalaemia and hypokalaemia, obstructive sleep apnoea, raised intracranial pressure, increased vagal tone, hypothermia, infiltrative disease (sarcoid, amyloid, haemochromatosis), infective endocarditis, Lyme and Chagas disease.
5. **Clinical features** (*Essentials*, Table 11-15) reflect reduced organ perfusion: **syncope, dizziness, palpitations, angina pectoris, congestive heart failure, insomnia and memory loss.** Falls and confusion are common atypical presentations in the elderly.
6. **Diagnosis** depends on **correlating symptoms with documented bradycardia**. Holter monitoring is the standard first test; longer monitoring (patch, event recorder, implantable loop recorder) is matched to symptom frequency. Exercise testing demonstrates chronotropic incompetence.
7. **Key caveat:** mild nocturnal bradycardia (>50 bpm) is normal and reflects increased overnight parasympathetic tone; sustained bradycardia in the absence of medication is **not** a normal finding in older people.
8. **Prognosis:** mortality appears **unaffected** by sinus node dysfunction itself; survival is determined by associated pathology such as ischaemic heart disease. Pacemakers relieve symptoms but do not reduce mortality.
9. **Treatment:** withdraw culprit drugs and correct reversible causes. *Essentials* states there is **no satisfactory medical therapy**; symptomatic patients require a permanent pacemaker. A pacemaker also permits continued use of rate-controlling drugs in tachy-brady syndrome.
10. **Pacing indications (2018 ACC/AHA/HRS, as quoted in Pathy's):** Class I — symptoms directly attributable to sinus node dysfunction, and bradycardia caused by clinically necessary guideline-directed therapy; Class IIa — tachy-brady syndrome where symptoms are attributable to bradycardia, and rate-responsive pacing for symptomatic chronotropic incompetence.

Latest Updates and Current Practice Update (concise)

- **2023 HRS/APHRS/LAHRS guideline on cardiac physiologic pacing** shifts emphasis from "which chamber" to "how physiological": conduction system pacing (His bundle or left bundle branch area) is preferred where a high ventricular pacing burden is anticipated, to avoid pacing-induced cardiomyopathy.
- **Leadless pacemakers** (Micra, Aveir) are now an established option for older patients with limited venous access, previous device infection or frailty, avoiding pocket and lead complications; dual-chamber and conduction-system leadless systems are in first-in-human evaluation (Heart Rhythm 2025).
- **Practice point unchanged:** the fundamental requirement remains symptom–rhythm correlation. Pacing an asymptomatic bradycardia produces no symptomatic benefit and exposes the patient to procedural risk.

> **Examiner's Tip**
>
> "*Sick sinus syndrome is a disease of the ageing sinoatrial node, characterised by sinus bradycardia, chronotropic incompetence, sinoatrial block, sinus arrest and the tachycardia–bradycardia syndrome.*" · "*Diagnosis requires correlation of symptoms with documented bradycardia, usually by Holter monitoring.*" · "*There is no satisfactory drug therapy; pacing relieves symptoms but does not improve survival.*" Listing the seven manifestations from Table 11-15 is an easy source of marks.

Q12. Cardiac pacemaker

7-MARK ANSWER | 10 POINTS

1. **Purpose:** a permanent pacemaker delivers electrical stimuli to maintain an adequate heart rate and, where possible, atrioventricular synchrony, in symptomatic bradyarrhythmia.
2. **Nomenclature (NBG code):** position 1 = chamber paced, 2 = chamber sensed, 3 = response to sensing, 4 = rate modulation (R). Thus **VVI** = ventricle paced/sensed/inhibited; **AAI** = atrium only; **DDD** = dual chamber; **DDDR** = dual chamber with rate response.
3. **Indications — sinus node dysfunction:** symptoms directly attributable to sinus node dysfunction (Class I); bradycardia from clinically necessary guideline-directed therapy (Class I); tachy-brady syndrome with symptomatic bradycardia (Class IIa); rate-responsive pacing for symptomatic chronotropic incompetence (Class IIa).
4. **Indications — AV block: acquired complete heart block regardless of symptoms** and **acquired second-degree Mobitz type II regardless of symptoms**, once reversible and physiological causes are excluded (both Class I); any degree of block with neuromuscular disease such as myotonic dystrophy type 1 or Kearns-Sayre syndrome (Class I); symptomatic Mobitz type I (Class IIa); unresolving advanced block after cardiac surgery or AV junction ablation (Class I). First-degree block is generally benign, but a PR interval >240–300 ms with left bundle branch block and lamin A/C mutation, or with attributable symptoms, may warrant pacing (Class IIa).
5. **Choice of mode:** DDD pacing is recommended over AAI or VVI when permanent pacing is needed for sinus node disease or AV block (Class I). Single-chamber VVI is appropriate when frequent ventricular pacing is not expected or when comorbidities limit the benefit of dual-chamber pacing (Class I). **An atrial lead should not be implanted in permanent or persistent AF when rhythm control is not planned (Class III).**
6. **Evidence base:** meta-analysis of CTOPP, MOST, UKPACE and related trials showed **no mortality difference** and no difference in new or worsening heart failure between physiological and ventricular pacing, but a **significant reduction in new-onset atrial fibrillation** with an atrial lead, and a borderline reduction in thromboembolic stroke. Cross-over studies showed better functional capacity and patient preference for dual-chamber pacing; active patients over 70 gain quality-of-life benefit from DDD pacing.
7. **Pacing-induced cardiomyopathy:** conventional right ventricular apical pacing causes non-physiological, dyssynchronous left ventricular activation. Patients with pre-existing left ventricular impairment and a high pacing burden may develop heart failure. **All patients should have a transthoracic echocardiogram before pacemaker implantation.**
8. **Physiological pacing options: CRT** (biventricular) adds a lead activating the lateral LV wall — the **BLOCK HF** trial showed about a 30% reduction in heart failure hospitalisation versus RV pacing in patients with reduced LV function and AV block. **His bundle pacing** and left bundle branch area pacing achieve a narrow paced QRS with near-normal ventricular contraction.
9. **Complications:** pneumothorax, cardiac perforation and tamponade, lead displacement, pocket haematoma and infection, device infection or endocarditis (a recognised cause of bradycardia and of infective endocarditis in the elderly), venous thrombosis, pacemaker syndrome (with VVI pacing), tricuspid regurgitation, and generator end-of-life.
10. **Geriatric decision-making:** the final choice of device is individualised, taking into account patient preference, comorbidities, life expectancy, dexterity, cognition and available resources — the "cheapest adequate device" is often the right answer in a frail patient, while an active 70-year-old benefits from dual-chamber or physiological pacing.

Latest Updates and Current Practice Update (concise)

- **2023 HRS/APHRS/LAHRS guideline on cardiac physiologic pacing**: conduction system pacing carries a Class IIa recommendation for bradycardia indications when LVEF is 35–50% and a substantial pacing burden is anticipated; the 2025 EHRA/ESC clinical consensus extends guidance on patient selection and on hybrid strategies (HOT-CRT, LOT-CRT).
- **Left bundle branch area pacing (LBBAP)** has largely overtaken His bundle pacing because of better capture thresholds and lead stability, and registry data show better outcomes than right ventricular pacing; randomised trials such as **PROTECT-HF** are ongoing.
- **Leadless pacemakers** are now routine in selected older patients (no pocket, no leads, lower infection risk); helix-based leadless systems capable of conduction system pacing entered first-in-human study in 2025.

> **Examiner's Tip**
>
> Give the NBG code in one line, then list Class I indications as bullet points — examiners reward "*complete heart block and Mobitz type II require pacing regardless of symptoms, once reversible causes are excluded*." · "*Dual-chamber pacing does not improve survival but significantly reduces new-onset atrial fibrillation and improves quality of life*." · "*Echocardiography before implantation identifies those at risk of pacing-induced cardiomyopathy, in whom conduction system pacing or CRT should be considered*."

Q13. Infective endocarditis

15-MARK ANSWER | 18 POINTS

Definition and Epidemiology in the Elderly

1. **Infective endocarditis (IE)** is microbial infection of the endocardial surface of the heart, typically involving native or prosthetic valves or intracardiac devices, with vegetation as the characteristic lesion.
2. **Nearly 50% of all cases now occur in older adults.** In people over 65 the incidence is around **four times** that of the general population, and mortality is roughly **twice** that of younger patients.
3. **Reasons for the rise:** a high prevalence of undiagnosed degenerative valve disease, increasing use of invasive procedures, and increasing implantation of prosthetic valves and cardiac devices.
4. **Sex distribution:** there is a male predilection overall, but the proportion of women affected rises progressively with age.

Predisposing Lesions and Risk Factors

5. **Underlying cardiac lesions in the elderly** are usually degenerative — calcific aortic stenosis, mitral annular calcification, mucoid mitral valve degeneration — plus prosthetic valves and cardiac implantable electronic devices. In India and other developing countries, **rheumatic valvular disease with viridans streptococci** remains a major pattern.
6. **Non-cardiac risk factors:** diabetes mellitus, and **gastrointestinal and genitourinary tract cancers**, which predispose to bacteraemia; also haemodialysis, intravascular catheters and poor dentition.

Microbiology

7. **Staphylococcus aureus** is the leading pathogen overall, although its relative share **decreases with age**.
8. **Enterococci and *Streptococcus bovis* (now *S. gallolyticus*) are emerging as major pathogens in the elderly**, reflecting genitourinary and gastrointestinal portals of entry. Isolation of *S. bovis* mandates **colonoscopy to look for colonic neoplasia**.
9. Coagulase-negative staphylococci dominate prosthetic valve and device infection; culture-negative endocarditis (5–7%) is usually due to prior antibiotics or fastidious organisms (HACEK, Coxiella, Bartonella, Brucella).

Clinical Features

10. **Classic:** fever with a new or changing regurgitant murmur, splinter haemorrhages, Osler nodes, Janeway lesions, Roth spots, splenomegaly, clubbing, microscopic haematuria.
11. **Atypical presentation in the elderly (high-yield):** fever is frequently absent or blunted; presentation may be confusion or delirium, malaise, anorexia and weight loss, falls, functional decline, unexplained anaemia, back pain from spondylodiscitis, stroke, or a heart failure exacerbation. Peripheral stigmata are less often present.
12. **Complications:** heart failure from valve destruction (the commonest indication for surgery), **conduction disturbance from perivalvular abscess** (a listed cause of bradycardia in Pathy's), systemic embolism including stroke and mycotic aneurysm, splenic and renal infarction, glomerulonephritis, and metastatic abscess.

Diagnosis

13. **Blood cultures are the cornerstone:** at least three sets from separate venepuncture sites **before** antibiotics, with adequate volume. Serology/PCR for fastidious organisms if cultures are negative.
14. **Echocardiography:** transthoracic first, but **transoesophageal echocardiography** is required when TTE is negative and suspicion persists, and in all prosthetic valve and device infections. Findings: vegetation, abscess, new prosthetic dehiscence, new regurgitation.
15. **Modified Duke criteria** — definite IE = 2 major, or 1 major + 3 minor, or 5 minor. Major: typical organism in two separate blood cultures, or evidence of endocardial involvement. Minor: predisposing condition, fever ≥38 °C, vascular phenomena, immunological phenomena, and microbiological evidence not meeting a major criterion.
16. Supporting tests: full blood count (normocytic anaemia, leucocytosis), ESR and CRP, urinalysis, renal function, ECG (new conduction delay suggests abscess), chest radiograph, and imaging of embolic sites.

Treatment and Prophylaxis

17. **Antibiotics:** prolonged, high-dose, bactericidal, intravenous therapy for 4–6 weeks, guided by culture and sensitivity, delivered with an infectious diseases and cardiology "endocarditis team". In older patients, **aminoglycoside use requires renal function and drug-level monitoring**, and doses of all agents must be adjusted for reduced creatinine clearance. Empirical regimens must cover staphylococci, streptococci and enterococci. **Surgery** is indicated for heart failure from valve dysfunction, uncontrolled infection or abscess, prosthetic valve endocarditis, and recurrent embolism with a large mobile vegetation — age alone is not a contraindication, but frailty and comorbidity strongly affect operative risk.
18. **Prophylaxis:** the AHA (Wilson 2007) withdrew routine subacute bacterial endocarditis prophylaxis for most lesions,

restricting it to the highest-risk cardiac conditions undergoing specified dental procedures. Pathy's argues that because gastrointestinal and genitourinary procedures are an important source of enterococcal and *S. bovis* bacteraemia in the elderly, **patient age should be factored into global risk assessment when deciding antibiotic prophylaxis**. Good oral and dental hygiene remains the most effective preventive measure.

Latest Updates (2023–Present)

- **2023 Duke-ISCVID criteria** (Fowler et al., *Clin Infect Dis* 2023) update the modified Duke criteria: the list of "typical" organisms is expanded (including *S. lugdunensis*, *Granulicatella*, *Abiotrophia*, *Gemella*, and — in the presence of intracardiac prostheses — coagulase-negative staphylococci, *Cutibacterium acnes*, *Corynebacterium striatum* and *Candida*); imaging criteria now include **cardiac CT and ^{18}F-FDG PET/CT**; and a surgical/pathological major criterion has been added. Validation studies show **higher sensitivity** (about 97.6% versus 93.2% for modified Duke) but **lower specificity**.
- **2023 ESC Guideline on Infective Endocarditis** formalises the **multidisciplinary "Endocarditis Team"**, incorporates PET/CT and cardiac CT into diagnosis, and gives explicit guidance on antibiotic prophylaxis and on early surgery.
- **Partial oral antibiotic therapy** — the **POET** trial and its long-term follow-up showed that switching to oral antibiotics after initial intravenous therapy in stabilised left-sided endocarditis is non-inferior and allows earlier discharge; the 2023 ESC guideline endorses this in selected patients, which is of particular value in frail older adults who deteriorate with prolonged hospitalisation.
- **Outpatient parenteral antimicrobial therapy (OPAT)** is now standard practice for the stable patient after the initial critical phase.
- **Device-related IE:** complete system extraction is recommended in confirmed cardiac implantable electronic device infection — an increasingly common scenario as pacemaker implantation rates in the elderly rise.

Current Practice Update

Textbook position	Current evidence (2023–2026)
Modified Duke criteria (2000) with echocardiography as the only imaging modality.	**2023 Duke-ISCVID criteria** — expanded microbiology, cardiac CT and FDG-PET/CT as major imaging criteria, added surgical criterion.
Prolonged intravenous antibiotics for the full 4–6 weeks.	**Partial oral therapy after stabilisation** (POET) is non-inferior and endorsed by ESC 2023; OPAT widely used.
Management by individual clinicians; surgery considered case by case.	Formal **Endocarditis Team** with early surgical referral is a guideline recommendation.
Prophylaxis withdrawn for most lesions (AHA 2007); Pathy's argues age should be considered.	Prophylaxis still limited to highest-risk cardiac conditions and dental procedures; the age-based argument remains a reasoned position rather than guideline policy.

Examiner's Tip

"*Almost half of all cases of infective endocarditis now occur in older adults, in whom the incidence is four times and the mortality twice that of younger patients.*" · "*In the elderly the underlying lesion is usually degenerative rather than rheumatic, and enterococci and Streptococcus bovis are emerging pathogens.*" · "*Isolation of Streptococcus bovis mandates colonoscopy to exclude colonic neoplasia.*" · "*Fever may be absent — consider endocarditis in any older patient with unexplained delirium, weight loss or a new murmur.*" · "*At least three sets of blood cultures must be taken before antibiotics are started.*"

Q14. Use of statins in the elderly

7-MARK ANSWER | 10 POINTS

1. **Mechanism:** statins inhibit HMG-CoA reductase, reducing hepatic cholesterol synthesis and upregulating LDL receptors. Beyond LDL lowering they have **pleiotropic effects** — plaque stabilisation, reduced inflammation and improved endothelial function. Three of four acute myocardial infarcts are thought to arise from rupture or erosion of a vulnerable plaque, which statins stabilise.
2. **Secondary prevention — strong evidence at all ages.** The Cholesterol Treatment Trialists' meta-analysis of 28 randomised trials showed significant benefit in patients with established vascular disease **in every age group, including those over 75**. Key trials in older patients: **PROSPER** (pravastatin 40 mg, age 70–82, 34% LDL reduction, RR 0.85 for cardiovascular events), **HPS** (simvastatin 40 mg) and **LIPS** (fluvastatin after PCI).
3. **Primary prevention — evidence is weaker with advancing age.** The same meta-analysis showed a **trend to smaller proportional risk reduction with increasing age**, and **no significant benefit in those over 70** without vascular disease. ALLHAT-LLT was neutral in older primary prevention.
4. **Guideline position:** ACC/AHA states it "may be reasonable" to initiate moderate-intensity statin in adults ≥75 with LDL-C 70–189 mg/dL; ESC/EAS says primary prevention statin "may be considered" over 75 if high risk (e.g. diabetes). Pathy's notes it may equally be reasonable **not** to prescribe.
5. **Time-to-benefit and lag time are decisive in geriatrics:** the time to benefit for statins in primary prevention is **at least two years**. If estimated life expectancy is shorter, the drug adds burden without benefit.
6. **Adherence is poor in the elderly:** only about **one in four** older patients is still taking a statin two years after prescription, and about **20% show primary non-adherence** — never starting the prescribed drug at all.
7. **Adverse effects:** statin-associated muscle symptoms (myalgia with normal CK; myositis with CK <10× ULN; **rhabdomyolysis with CK >10× ULN**), hepatotoxicity (act if ALT/AST >3× ULN), a small increase in incident type 2 diabetes, and drug interactions through CYP3A4 (amiodarone, verapamil, diltiazem, clarithromycin, azoles) which are especially relevant with polypharmacy. Concerns about cognitive impairment are not supported by good evidence.
8. **Practical monitoring:** check baseline lipids, ALT/AST, CK, TSH and renal function; recheck lipids and transaminases after 8–12 weeks. In statin-associated muscle symptoms with CK <10× ULN, reduce the dose or rechallenge with an alternative statin; if CK >10× ULN, stop the statin and check creatinine, urea and myoglobinuria. Persistent symptoms with rising CK should prompt testing for **anti-HMG-CoA reductase antibodies** (immune-mediated necrotising myopathy) or muscle biopsy.
9. **Intensity and add-ons:** high-intensity statins lower LDL-C by 50–55%; adding **ezetimibe** gives a further 20% reduction. In very high-risk atherosclerotic disease with LDL-C ≥70 mg/dL on maximal statin, ezetimibe then a **PCSK9 inhibitor** may be added.
10. **Decision framework for the older patient:** continue statins for secondary prevention unless life expectancy is very short; for primary prevention over 75 use **shared decision-making** weighing benefit against polypharmacy, frailty, life expectancy, adverse effects and the patient's own priorities. Deprescribing is appropriate in advanced frailty, end-stage disease or the last year of life.

Latest Updates and Current Practice Update (concise)

- **EWTOPIA 75** (Circulation 2019) showed benefit from **ezetimibe monotherapy** in Japanese patients ≥75 with LDL-C ≥140 mg/dL, and a 2020 *Lancet* meta-analysis (Gencer et al.) concluded that **LDL lowering is beneficial in patients over 75** — a shift toward treating rather than withholding.
- **STAREE** (atorvastatin 40 mg versus placebo in 9,971 community-dwelling Australians aged ≥70 without cardiovascular disease, diabetes or dementia; co-primary endpoints of disability-free survival and major cardiovascular events) completed follow-up at the end of 2025. It is the definitive trial for primary prevention in this age group; its results should be quoted as soon as published.
- **Newer non-statin agents** now available for statin intolerance or residual risk: **bempedoic acid** (CLEAR Outcomes 2023 — reduced major cardiovascular events in statin-intolerant patients, with no muscle toxicity), **inclisiran** (twice-yearly siRNA, useful where adherence is the barrier), and PCSK9 monoclonal antibodies.

> **Examiner's Tip**
> "*For secondary prevention, statins benefit patients of all ages including those over 75; for primary prevention the evidence weakens sharply after 70.*" · "*The time to benefit in primary prevention is at least two years, so life expectancy must exceed the lag time before prescribing.*" · "*Statin myopathy spans myalgia with normal CK, myositis with CK below ten times normal, and rhabdomyolysis above ten times normal.*" Naming PROSPER and the CTT meta-analysis, and mentioning STAREE as the awaited definitive trial, reliably earns marks.

Q15. Calcium channel antagonists

7-MARK ANSWER | 10 POINTS

1. **Mechanism:** calcium channel antagonists block **L-type voltage-gated calcium channels**, reducing calcium entry into vascular smooth muscle (vasodilatation) and into cardiac myocytes and nodal tissue (negative inotropy and negative chronotropy/dromotropy).
2. **Classification:**
   Dihydropyridines — amlodipine, nifedipine, felodipine, nitrendipine, lercanidipine: predominantly **vascular** selectivity, potent arterial vasodilators, minimal effect on the AV node.
   Non-dihydropyridines — **verapamil** (phenylalkylamine, most cardioselective) and **diltiazem** (benzothiazepine, intermediate): act directly on the **AV node**, slowing conduction.
3. **Why they suit older patients:** they are peripheral vasodilators that **maintain coronary blood flow**, and their **potency increases with age** — a consequence of reduced reflex tachycardia and reduced myocardial contractility in the elderly. They are especially effective in **isolated systolic hypertension**.
4. **Indications:** hypertension (particularly ISH and in older and Black patients), stable angina (added when symptoms persist despite long-acting nitrates and beta blockers), rate control in atrial fibrillation and supraventricular tachycardia (non-dihydropyridines), Prinzmetal/vasospastic angina, and Raynaud phenomenon.
5. **Choice by ventricular function (a key examination point):** in stable ischaemic heart disease, **rate-limiting agents (diltiazem, verapamil) may be used if left ventricular function is normal**, whereas **dihydropyridines (amlodipine, felodipine) should be used when ventricular function is impaired**.
6. **Evidence:** calcium channel blockers reduced stroke incidence in older patients with isolated systolic hypertension (**Syst-Eur**, Staessen 1997) and are **superior to other classes for stroke prevention**, but they **do not significantly reduce the risk of heart failure** — for which diuretics are superior.
7. **Adverse effects (dihydropyridines):** headache and flushing, **ankle oedema** (dose-dependent, not diuretic-responsive — best managed by dose reduction or by adding an ACE inhibitor/ARB), sodium retention, reflex tachycardia (short-acting agents), gum hyperplasia, and postural hypotension.
8. **Adverse effects (non-dihydropyridines): constipation** (prominent with verapamil and a real problem in older patients), bradycardia, AV block, and **negative inotropy** — they may precipitate or worsen heart failure and are contraindicated in HFrEF and in acute pulmonary oedema.
9. **Interactions and cautions:** combining verapamil or diltiazem with a beta blocker carries a substantially increased risk of **bradycardia, heart block and asystole**, particularly in older people; both are CYP3A4 inhibitors and raise levels of statins, digoxin and carbamazepine. *Essentials* lists among its "Don'ts": **do not use short-acting calcium channel antagonists for long-term therapy of hypertension.**
10. **Practical prescribing in geriatrics:** prefer long-acting once-daily dihydropyridines; start at low dose; review ankle oedema and constipation at each visit; check for bradycardia if combined with a beta blocker; and remember that calcium channel blockers are among the drugs that can cause bradycardia and are a recognised secondary cause of hyponatraemia-associated hypotensive states.

Latest Updates and Current Practice Update (concise)

- **2025 ACC/AHA and 2024 ESC hypertension guidelines** retain dihydropyridine calcium channel blockers as one of the four first-line classes, and both now strongly favour their use within **single-pill combinations** (typically with an ACE inhibitor/ARB and/or a thiazide-like diuretic) as initial therapy.
- The **ACE inhibitor + amlodipine** combination is preferred over amlodipine + diuretic for reducing ankle oedema and, from the ACCOMPLISH trial, for cardiovascular outcomes — a practical point not covered in the textbooks.
- Calcium channel blockers remain the safest antihypertensive class in **advanced chronic kidney disease** and in patients in whom hyperkalaemia limits RAAS blockade, which is common in the multimorbid elderly.

> **Examiner's Tip**
>
> Tabulate dihydropyridine versus non-dihydropyridine with three rows — *site of action, main use, main side effect*. Then write: "*Calcium channel antagonists increase in potency with age and are particularly effective in isolated systolic hypertension.*" · "*They are superior for stroke prevention but do not reduce heart failure risk.*" · "*Verapamil or diltiazem with a beta blocker risks bradycardia, heart block and asystole in older people.*"

Q16. Anticoagulants in geriatric practice — indications and agents

15-MARK ANSWER | 18 POINTS

Why Anticoagulation Matters in Old Age

1. Both the **risk of thrombosis and the risk of haemorrhage increase with age**. Older patients therefore stand to gain the most from anticoagulation and to lose the most from it — the central tension of geriatric prescribing.
2. Guidelines are largely extrapolated: patients in landmark trials are on average **5 to 10 years younger** than real-world patients, and most trials excluded those with high bleeding risk, renal failure or recent stroke. Consequently guidelines cannot make strong recommendations for people aged 85 and over.
3. **Under-treatment is the bigger problem.** Anticoagulation is widely withheld from older patients because of falls, dementia and perceived frailty, despite evidence that these are usually not valid reasons.

Indications

4. **Non-valvular atrial fibrillation** — long-term stroke prevention (the commonest indication in geriatric practice).
5. **Valvular AF and mechanical prosthetic valves** — lifelong warfarin.
6. **Treatment of venous thromboembolism** — deep vein thrombosis and pulmonary embolism.
7. **Thromboprophylaxis** in medical and surgical inpatients at moderate-to-high risk, and extended prophylaxis after major orthopaedic surgery.
8. Other: intracardiac thrombus, mitral annular calcification with cerebral embolism, thrombophilia with thrombosis, and antiphospholipid syndrome (warfarin, **not** a DOAC, in triple-positive disease).

Agents — Warfarin (Vitamin K Antagonist)

9. Inhibits vitamin K-dependent synthesis of factors **II, VII, IX and X**. Efficacy depends on time in therapeutic range. It reduces stroke in AF by about **64%** and mortality by about a quarter, and is superior to aspirin (relative risk reduction 39%).
10. **Target INR ranges** (Pathy's Table 24.5): **2.0–3.0** for DVT, pulmonary embolism, systemic embolism, mitral stenosis with embolism, TIA and atrial fibrillation; **3.0–4.5** for recurrent DVT/PE despite anticoagulation, arterial disease including myocardial infarction, and mechanical prosthetic heart valves.
11. **Geriatric problems:** dose requirement is lower than in younger patients; bleeding risk is increased at both high and normal INRs because of underlying pathology such as peptic ulcer, gastrointestinal malignancy and angiodysplasia; numerous drug interactions; and dietary vitamin K (parsley, broccoli, liver) reduces its effect.
12. **Key interactions** (Pathy's Table 29.7): *potentiate* — amiodarone, simvastatin, fibrates, thyroxine, corticosteroids, cimetidine, omeprazole, chlorpromazine, tricyclics, tamoxifen, aminoglycosides, metronidazole, clarithromycin; *reduce* — spironolactone, cholestyramine, barbiturates, carbamazepine, rifampicin.
13. **Initiation:** use a reduced-dose induction regimen in the elderly (Siguret's regimen: 4 mg daily for three days, then dose by INR). Monitor closely in the **first month**, when bleeding risk is highest.

Agents — Heparins

14. **Unfractionated heparin** potentiates antithrombin; narrow therapeutic range, complex kinetics, wide inter-patient variation. Monitor by **APTT ratio 1.5–2**. Reversal with protamine sulfate. Risk of heparin-induced thrombocytopenia.
15. **Low-molecular-weight heparin** has a longer half-life, better bioavailability and predictable kinetics, allowing once-daily subcutaneous dosing **without monitoring**. It acts more on factor Xa than thrombin, so it cannot be monitored by APTT — use an **anti-Xa assay** if monitoring is needed (renal impairment, extremes of weight, pregnancy). LMWH confers a **survival advantage in malignancy-associated thrombosis**.

Agents — Direct Oral Anticoagulants (DOACs)

16. **Dabigatran** (direct thrombin/factor IIa inhibitor); **rivaroxaban, apixaban, edoxaban** (factor Xa inhibitors). They are broadly equivalent to warfarin at an INR of 2–3, need no routine monitoring, and have far fewer food and drug interactions.
17. **Advantages in the elderly:** DOACs are recommended over warfarin in non-valvular AF (Class I) and are first choice for acute VTE in the absence of cancer or severe renal impairment, chiefly because of **lower intracranial haemorrhage risk**. In patients aged ≥75 the risk of major bleeding is significantly lower with DOACs than with vitamin K antagonists (relative risk about **0.49**).
18. **Limitations and cautions:** all are renally excreted to some degree and require dose reduction for renal impairment, low body weight and advanced age. **DOACs must not be used** in mechanical heart valves, moderate-to-severe mitral stenosis, triple-positive antiphospholipid syndrome, or where a target INR above 3 is required. Because of the short half-life, **missed doses create periods of under-anticoagulation** — a real risk in cognitive impairment. Dabigatran is unsuitable for dosette boxes; rivaroxaban and edoxaban are once daily, which may aid adherence.

Practical Geriatric Principles

- **Do not use aspirin as a substitute** for anticoagulation in AF or after VTE — it is ineffective and still causes bleeding.
- **Dementia is not an absolute contraindication**; in multi-infarct dementia the benefit of halting stepwise decline may be clear, and a supervised residential setting can solve adherence problems. End-stage dementia is a reasonable reason to stop.
- Review falls risk, alcohol, NSAID use, blood pressure control and interacting drugs; add a proton pump inhibitor where gastrointestinal risk is high.
- Reassess renal function, weight, haemoglobin and indication at least annually — anticoagulation is not a "set and forget" prescription.

Latest Updates (2023–Present)

- **Specific reversal agents are now established: idarucizumab** for dabigatran, and **andexanet alfa** for apixaban and rivaroxaban. ANNEXA-I (NEJM 2024) showed andexanet alfa achieved better haemostasis than usual care in intracranial haemorrhage but with more thrombotic events, so use requires careful case selection; four-factor prothrombin complex concentrate remains a widely used alternative.
- **Factor XI/XIa inhibitors** were expected to separate antithrombotic efficacy from bleeding. **OCEANIC-AF was stopped early because asundexian was inferior to apixaban** for stroke prevention in AF, tempering enthusiasm; abelacimab and milvexian continue in trials for cancer-associated and other thrombosis.
- **2024 ESC AF guideline** advises that patients over 75 who are stable on a vitamin K antagonist with good time in therapeutic range need not be switched to a DOAC.
- **Reduced-dose extended anticoagulation is now evidence-based: API-CAT** (NEJM 2025) showed reduced-dose apixaban 2.5 mg twice daily was non-inferior to full dose for extended treatment of cancer-associated VTE, with **less clinically relevant bleeding** — highly relevant to frail older patients.
- **India:** warfarin remains widely used because of cost and the high prevalence of rheumatic valvular disease and mechanical valves; DOAC use is expanding but is limited by price, by the absence of routine anti-Xa monitoring, and by the frequency of undiagnosed renal impairment. Reliable INR access through Ayushman Arogya Mandirs and structured anticoagulation clinics remain the practical priority.

Current Practice Update

Textbook position	Current evidence (2023–2026)
DOACs "not first-choice agents for malignancy-associated thrombosis, but this may change".	DOACs (apixaban, edoxaban, rivaroxaban) are now first-line for most cancer-associated VTE except luminal gastrointestinal and genitourinary tumours, where LMWH is preferred.
No specific antidote available for DOACs.	Idarucizumab and andexanet alfa are licensed reversal agents.
Extended anticoagulation uses full treatment doses.	Reduced-dose extended therapy (apixaban 2.5 mg bd, rivaroxaban 10 mg od) is non-inferior with less bleeding (API-CAT; AMPLIFY-EXT; EINSTEIN-CHOICE).
Anticoagulation choice guided by drug properties.	Structured shared decision-making with explicit discussion of stroke versus bleeding trade-off is now expected.

Examiner's Tip

Memorise the INR table — "*2.0–3.0 for venous thromboembolism and atrial fibrillation; 3.0–4.5 for recurrent thrombosis and mechanical prosthetic valves.*" · "*In patients over 75, DOACs approximately halve the risk of major bleeding compared with vitamin K antagonists.*" · "*Aspirin is not an acceptable substitute for anticoagulation in atrial fibrillation.*" · "*Neither falls risk nor dementia is by itself a contraindication to anticoagulation.*"

Q17. Venous thromboembolism and post-operative management of anticoagulation

15-MARK ANSWER | 18 POINTS

Epidemiology and Burden

1. **Venous thromboembolism (VTE)** = deep vein thrombosis (DVT) and/or pulmonary embolism (PE). Almost **60%** of all VTE events occur in people over 65.
2. Incidence rises **exponentially** with age — from <1 per 1000 person-years below 50 years to about **8 per 1000** person-years above 80.
3. Older patients are under-represented in trials; most VTE treatment trials excluded those with increased bleeding risk, renal failure or recent stroke, so evidence is extrapolated. Cohorts and registries (**RIETE, EPICA, SWITCO65+**) fill part of this gap.

Risk Factors

4. **Virchow's triad** — stasis, endothelial injury and hypercoagulability. In the elderly all three are amplified by immobility, surgery, and age-related increases in fibrinogen and platelet reactivity.
5. **Acquired:** immobility and hospitalisation, surgery (especially hip, knee and pelvis), fracture, malignancy, heart failure, stroke with paresis, infection and sepsis, dehydration, obesity, long travel, oestrogens, central venous catheters, nephrotic syndrome and frailty.
6. **Inherited thrombophilia** is present in up to **50%** of venous thromboses, becoming manifest under the above circumstances: factor V Leiden (commonest inherited defect — a single base substitution at position 1691 causing resistance to activated protein C), prothrombin G20210A, and deficiencies of **antithrombin, protein C and protein S**. Antiphospholipid syndrome is the important acquired thrombophilia.
7. **Testing caveat:** levels of antithrombin, protein C and protein S fall during acute thrombosis, and are further reduced by heparin (antithrombin) and warfarin (proteins C and S) — so test only when the patient is neither acutely thrombosed nor anticoagulated. A positive result should prompt family screening.

Diagnosis

8. **DVT algorithm:** assess clinical probability with the **two-level modified Wells score**. If "DVT likely" → complete venous ultrasonography. If "DVT unlikely" → D-dimer; if negative, no DVT and no treatment; if positive, proceed to ultrasound.
9. **PE algorithm (haemodynamically stable):** assess probability with the **revised Geneva score** or Wells score. Low/intermediate probability → D-dimer; if negative, exclude PE. High probability or positive D-dimer → CT pulmonary angiography.
0. **Age-adjusted D-dimer** is essential in the elderly, because specificity falls with age. Use a cut-off of **age × 10 µg/L in patients over 50** — validated in the **ADJUST-PE** study; this safely increases the proportion of older patients in whom PE can be excluded without imaging.
1. Note that asymptomatic DVT is common on admission in older medical inpatients, and that clinical signs and risk factors have different diagnostic value in the elderly than in the young.

Treatment

2. **DOACs are first choice** for acute VTE in the elderly in the absence of cancer or severe renal insufficiency, mainly because of lower intracranial bleeding risk than vitamin K antagonists.
3. **Regimens (Pathy's Table 37.3):**
   Dabigatran — LMWH/UFH/fondaparinux for at least 5 days, then 150 mg twice daily.
   Rivaroxaban — no lead-in: 15 mg twice daily for 21 days, then 20 mg once daily; extended phase 10 mg once daily.
   Apixaban — no lead-in: 10 mg twice daily for 7 days, then 5 mg twice daily; extended phase 2.5 mg twice daily.
   Edoxaban — LMWH lead-in for at least 5 days, then 60 mg once daily, reduced to 30 mg once daily if creatinine clearance 30–50 mL/min, body weight ≤60 kg, or concomitant strong P-glycoprotein inhibitors.
4. **Duration:** Pathy's recommends **three to six months** of anticoagulation in elderly patients with acute VTE, because bleeding risk is higher and the recurrence risk is no greater than in younger patients. Extended treatment is not routinely indicated and any such decision must be carefully justified. Existing recurrence-prediction rules are unhelpful in the elderly — HERDOO2 automatically classes those ≥65 as high risk, DASH is not validated, and the Vienna model lacks discrimination.
5. **Prognosis:** 30-day mortality doubles in those ≥65 compared with younger patients (11% versus 4%), and remains higher at one year (31% versus 14%). Use **PESI/sPESI** to identify low-risk PE suitable for early discharge. The strongest predictors of long-term mortality are systolic BP <100 mmHg, active cancer and age. The main causes of death in the first three months are cancer (38%), PE (26%), infection (13%) and bleeding (6%).
6. **Bleeding:** patients ≥65 have an almost twofold higher risk of major and clinically relevant non-major bleeding; age ≥75 at least doubles the risk of intracranial haemorrhage. Low physical activity level and polypharmacy (>4 drugs) predict

major bleeding.

Post-operative Management of Anticoagulation

7. **Pre-operative interruption.**
   Warfarin — stop 5 days before surgery; check INR the day before; give low-dose vitamin K if INR remains high.
   Heparin bridging is not required for most patients (BRIDGE trial showed no benefit and more bleeding); reserve bridging for very high thrombotic risk — mechanical mitral valve, recent (<3 months) VTE or stroke, or CHA_2DS_2-VASc ≥7.
   DOACs — follow the **PAUSE** protocol, based on drug, renal function and procedural bleeding risk: stop **1 day** before a low-bleeding-risk procedure and **2 days** before a high-bleeding-risk procedure for apixaban, rivaroxaban and edoxaban; for dabigatran, stop 1–2 days (CrCl ≥50) or 2–4 days (CrCl <50). **No bridging and no routine DOAC level testing.**
   The **ASRA** guidance requires a longer interval — at least 72 hours — before neuraxial anaesthesia and deep nerve blocks; where the two conflict, follow the anaesthetic guidance.
   No interruption is needed for minor dental procedures, cataract surgery or most skin procedures.
8. **Post-operative resumption and prophylaxis.**
   Restart **warfarin on the evening of surgery or the first post-operative day** at the usual maintenance dose, once haemostasis is secure and enteral intake has returned. Restart **DOACs 24 hours after low-bleeding-risk** and **48–72 hours after high-bleeding-risk** procedures, since the DOAC reaches full anticoagulant effect within hours. In the interval, give **prophylactic-dose LMWH** where the thrombotic risk is high and haemostasis is adequate. Continue mechanical prophylaxis (early mobilisation, graduated compression stockings, intermittent pneumatic compression) throughout. For major orthopaedic surgery (hip and knee replacement, hip fracture), give **extended thromboprophylaxis** for up to 35 days after hip and 14 days after knee surgery, using LMWH, a reduced-dose DOAC or aspirin per protocol. Two safety points: **parenteral vitamin K should not be used for non-life-threatening bleeding in patients with mechanical prosthetic valves**, because of the risk of inducing a hypercoagulable state; and after cardiac surgery, oral anticoagulation should be restarted as soon as intestinal function permits.

Latest Updates (2023–Present)

- **ASH 2023 guidelines** support home treatment of low-risk PE (sPESI 0 or Hestia-negative), which reduces hospitalisation-associated deconditioning and delirium in older patients.
- **API-CAT** (NEJM 2025): in cancer-associated VTE, extended **reduced-dose apixaban 2.5 mg twice daily was non-inferior** to full dose for preventing recurrence, with significantly **less clinically relevant bleeding**.
- **Extended treatment of provoked VTE** (NEJM, Aug 2025) supports reduced-dose apixaban after provoked events in selected patients with persistent risk factors — narrowing the old "provoked equals three months, full stop" rule.
- **PAUSE-2 pilot** (J Thromb Haemost 2025) examined DOAC interruption before high-bleed-risk surgery and neuraxial procedures, confirming that measurable residual DOAC activity can persist despite guideline-consistent interruption in some patients — supporting institution-specific protocols and selective drug-level testing.
- **BRUISE CONTROL-2** showed that continuing DOACs during pacemaker/ICD implantation was **not superior** to interrupting them for 48 hours — so interruption is acceptable for device procedures.
- An **AHA/ACC pulmonary embolism guideline (2026)** has been published, consolidating risk stratification, PE response teams, catheter-directed therapy and follow-up for post-PE syndrome.

Current Practice Update

Textbook position	Current evidence (2023–2026)
3–6 months of anticoagulation in the elderly; extended treatment "not indicated".	Extended **reduced-dose** therapy is now an evidence-based option in unprovoked VTE, cancer-associated VTE and persistent risk factors (API-CAT, AMPLIFY-EXT, EINSTEIN-CHOICE).
Perioperative interruption not addressed in detail.	Standardised **PAUSE** protocol (no bridging, no routine testing) is now the accepted approach for DOACs.
Heparin bridging implied for warfarin interruption.	BRIDGE trial: bridging is unnecessary for most, increases bleeding; reserve for the highest thrombotic risk.
Most PE managed as inpatients.	Low-risk PE (sPESI 0/Hestia-negative) can be treated at home.

Examiner's Tip

"Almost 60% of venous thromboembolic events occur in people over 65, and incidence rises exponentially from under 1 to about 8 per 1000 person-years." · "Use an age-adjusted D-dimer cut-off of age × 10 µg/L in patients over 50 — validated in ADJUST-PE." · "Bridging is not required for most patients undergoing warfarin interruption; for DOACs, stop one day before low-risk and two days before high-risk surgery and do not bridge." · "Restart DOACs 24 hours after low-bleeding-risk and 48 to 72 hours after high-bleeding-risk procedures."

Q18. Causes, treatment and prevention of deep vein thrombosis

15-MARK ANSWER | 18 POINTS

Definition and Significance

1. **Deep vein thrombosis (DVT)** is thrombus formation within the deep venous system, most often of the lower limb; proximal (popliteal and above) DVT carries the greatest risk of pulmonary embolism and of post-thrombotic syndrome.
2. **Venous thrombosis is primarily a disease of old age.** Asymptomatic DVT is common on admission among older medical inpatients, so a high index of suspicion is required.

Causes

3. **Virchow's triad:** venous stasis, endothelial injury, and hypercoagulability.
4. **Circumstantial/acquired factors:** immobilisation and hospitalisation, surgery — **particularly to the hip, knee and pelvis** — fracture, malignancy, obesity, heart failure, stroke with limb paresis, sepsis, dehydration, long-distance travel, central venous catheters, nephrotic syndrome and oestrogen therapy.
5. **Ageing-specific contributors:** reduced mobility and muscle pump action, higher fibrinogen levels, altered platelet function, increased prevalence of malignancy and heart failure, and frailty (an independent predictor of VTE).
6. **Inherited thrombophilia is manifest in up to 50% of cases** under the above circumstances: **factor V Leiden** (commonest; base substitution at position 1691 producing activated protein C resistance), prothrombin 20210A allele, and deficiencies of **antithrombin, protein C and protein S** (autosomal dominant, heterozygous only — the homozygous state is incompatible with life).
7. **Acquired thrombophilia:** antiphospholipid syndrome (lupus anticoagulant, anti-β2-glycoprotein-1 and anticardiolipin antibodies), myeloproliferative disease and paroxysmal nocturnal haemoglobinuria.
8. **Suspect thrombophilia when** thrombosis is unusually extensive, occurs at an unusual site, is spontaneous or recurrent, or there is a positive family history — though patients may present for the first time in old age.

Clinical Features and Diagnosis

9. Unilateral limb pain, swelling, warmth, erythema, dilated superficial veins and calf tenderness; phlegmasia in massive iliofemoral thrombosis. Differential diagnosis includes cellulitis, ruptured Baker's cyst, lymphoedema, chronic venous insufficiency and haematoma.
10. **Objective validation of the diagnosis must always precede treatment.** Use the two-level modified Wells score: "DVT likely" → complete venous ultrasonography; "DVT unlikely" → D-dimer, and if negative no further action.
11. Use the **age-adjusted D-dimer** (age × 10 µg/L above 50 years); D-dimer specificity is poor in the elderly because of comorbidity, infection and malignancy.
12. Consider occult malignancy in unprovoked DVT — a focused history, examination, basic bloods, and age-appropriate cancer screening rather than indiscriminate whole-body imaging.

Treatment

13. **First choice:** a DOAC in the absence of cancer or severe renal impairment. Apixaban and rivaroxaban need no parenteral lead-in; dabigatran and edoxaban require at least 5 days of LMWH first. Doses as in Q17.
14. **Alternative:** initial LMWH (or unfractionated heparin if renal failure or a need for rapid reversibility) overlapping with warfarin to a target **INR 2.0–3.0**. LMWH is the anticoagulant of choice in malignancy-associated thrombosis, where it confers a survival advantage.
15. **Duration:** three to six months in older patients. Consider lifelong anticoagulation after recurrent thrombosis, starting with a target INR of 2–3 and increasing to 3–4 if further thrombosis occurs while anticoagulated. **Triple-positive antiphospholipid syndrome must be treated with warfarin at the higher target range, not a DOAC.**
16. **Adjuncts:** early mobilisation and graduated compression stockings for symptom relief (they do not reliably prevent post-thrombotic syndrome); catheter-directed thrombolysis only for limb-threatening iliofemoral thrombosis; **inferior vena cava filter** only when anticoagulation is absolutely contraindicated, with removal as soon as anticoagulation can start.

Prevention

17. **Risk assessment for every hospital admission** (Padua or Caprini score) with reassessment when the clinical state changes. Pathy's emphasises that thromboprophylaxis of both **surgical and medical** patients at medium and high risk is increasingly recognised and practised.
18. **Methods.** *Mechanical* — early mobilisation, adequate hydration, graduated compression stockings and intermittent pneumatic compression (the options of choice when bleeding risk is high, and contraindicated in severe peripheral arterial disease). *Pharmacological* — LMWH once daily (dose-reduced in renal impairment), unfractionated heparin if creatinine clearance is very low, fondaparinux, or reduced-dose DOACs for **extended out-of-hospital prophylaxis after high-risk orthopaedic surgery** such as hip and knee replacement. Duration: for the admission in medical patients; up to **35 days after hip replacement or hip fracture** and **14 days after knee replacement**. Also address

modifiable factors — avoid dehydration, treat heart failure and infection, minimise immobility, and review oestrogens and other precipitants. In thrombophilia without prior thrombosis, management consists of **adequate prophylaxis at times of increased risk** such as surgery and immobilisation, rather than continuous anticoagulation.

Latest Updates (2023–Present)

- **ASH and ACCP guidance now favour DOACs over LMWH-warfarin for most acute DVT**, including in the elderly, and support outpatient management of low-risk DVT with defined follow-up.
- **Extended low-dose secondary prevention** is the major change: apixaban 2.5 mg twice daily or rivaroxaban 10 mg once daily after the initial treatment phase reduces recurrence with little excess bleeding (AMPLIFY-EXT, EINSTEIN-CHOICE), and **API-CAT** (NEJM 2025) confirmed non-inferiority with less bleeding for reduced-dose apixaban in cancer-associated VTE.
- **Compression stockings:** the SOX and IDEAL-DVT trials showed that routine two-year elastic compression does not prevent post-thrombotic syndrome; current practice is **symptom-guided, individualised compression** rather than universal prescription.
- **IVC filters:** the evidence (PREPIC-2 and subsequent registries) shows no mortality benefit and significant filter-related complications; retrievable filters should be removed promptly, and a formal retrieval pathway is now expected.
- **Aspirin** is an acceptable extended-prophylaxis option after elective hip and knee arthroplasty (CRISTAL and related trials), which matters in resource-limited Indian practice.
- **India:** VTE was historically considered rare in Indians, but hospital-based studies show rates comparable to Western populations after major surgery; under-use of prophylaxis in medical wards remains a documented gap, and mandatory admission risk assessment is the single most effective corrective step.

Current Practice Update

Textbook position	Current evidence (2023–2026)
Treatment "initially with heparin, subsequently with oral warfarin".	DOAC monotherapy (apixaban, rivaroxaban) is first-line, with no parenteral lead-in.
Extended treatment not indicated in the elderly.	Reduced-dose extended therapy is evidence-based and bleeds less than full dose.
Compression stockings recommended after DVT.	Not effective for preventing post-thrombotic syndrome; use for symptom relief only.
LMWH for malignancy-associated thrombosis.	DOACs are now first-line for most cancer-associated VTE, except luminal GI and GU tumours where LMWH is preferred.

Examiner's Tip

Open with Virchow's triad, then write: "*Objective validation of the diagnosis of venous thromboembolic disease should always precede the initiation of treatment.*" · "*In up to half of cases of venous thrombosis an underlying genetic predisposition becomes manifest under circumstantial risk.*" · "*Factor V Leiden is the commonest inherited prothrombotic disorder, caused by a single base substitution at position 1691 producing resistance to activated protein C.*" · "*Extended thromboprophylaxis is given for up to 35 days after hip replacement and 14 days after knee replacement.*"

Appendix — Rapid Revision Grid

NIGHT-BEFORE RECALL

Numbers you must be able to quote

Item	Value
BNP / NT-proBNP threshold for further investigation (non-acute)	>35 pg/mL / >125 pg/mL
BNP favouring cardiac cause of acute dyspnoea	>300 pg/mL
Ejection fraction categories	HFrEF ≤40%, HFmrEF 41–49%, HFpEF ≥50%
Digoxin dose and level in patients >70	0.125 mg/day; target 0.5–0.9 ng/mL
ARNI washout after ACE inhibitor	36 hours
HF prevalence >80 years; 2-yr and 5-yr mortality	13–14%; 60% and 75%
AF prevalence at 80; annual stroke risk at 80–89	5–15%; 23.5%
Warfarin vs aspirin in AF (relative risk reduction of stroke)	64% vs 22%
CHA_2DS_2-VASc maximum / CHA_2DS_2-VA maximum	9 / 8 (sex removed, ESC 2024)
INR ranges	2.0–3.0 (VTE, AF); 3.0–4.5 (recurrent VTE, mechanical valves)
Heparin monitoring	UFH: APTT ratio 1.5–2; LMWH: anti-Xa assay
Age-adjusted D-dimer cut-off	Age × 10 µg/L in patients >50 (ADJUST-PE)
VTE: proportion in >65s; incidence >80 years	≈60%; 8 per 1000 person-years
VTE anticoagulation duration in the elderly (Pathy's)	3–6 months
30-day mortality after VTE (≥65 vs <65)	11% vs 4%
DOAC major bleeding in ≥75s vs VKA	Relative risk ≈0.49
Extended orthopaedic thromboprophylaxis	Up to 35 days (hip); 14 days (knee)
Statin time-to-benefit in primary prevention	≥2 years
Statin myopathy CK thresholds	Myositis <10× ULN; rhabdomyolysis >10× ULN; act on ALT/AST >3× ULN
IE in the elderly: incidence and mortality vs younger	4× incidence; 2× mortality; ≈50% of all cases
2025 ACC/AHA BP target	<130/80 mmHg, with encouragement toward SBP <120
2024 ESC BP target	Systolic 120–129 mmHg (relaxed if ≥85, frail, or orthostatic hypotension)

Trial names by topic

Topic	Trials
Hypertension in the elderly	SHEP, Syst-Eur, HYVET, SPRINT-Senior, STEP, ESPRIT, BPROAD, PARTAGE, CAFE
HFrEF	CONSENSUS, SENIORS, SHIFT (ivabradine), PARADIGM-HF (ARNI), DAPA-HF, EMPEROR-Reduced, STRONG-HF, VICTORIA
HFpEF	CHARM-Preserved, I-PRESERVE, PEP-CHF, TOPCAT, PARAGON-HF (all neutral) → EMPEROR-Preserved, DELIVER, FINEARTS-HF, STEP-HFpEF, SUMMIT
Cardiomyopathy	ATTR-ACT (tafamidis), ATTRibute-CM (acoramidis), HELIOS-B (vutrisiran), EXPLORER-HCM/VALOR-HCM (mavacamten), SEQUOIA-HCM (aficamten), TRED-HF
Atrial fibrillation	AFFIRM, RACE/RACE II, BAFTA, EAST-AFNET 4, NOAH-AFNET 6, ARTESIA, LAAOS III, OPTION, OCEANIC-AF
Pacing	CTOPP, MOST, UKPACE, BLOCK HF; 2023 HRS/APHRS/LAHRS physiologic pacing guideline
Statins	PROSPER, HPS, LIPS, ALLHAT-LLT, EWTOPIA 75, CLEAR Outcomes, STAREE (awaited)
Anticoagulation / VTE	ADJUST-PE, AMPLIFY-EXT, EINSTEIN-CHOICE, API-CAT, PAUSE / PAUSE-2, BRIDGE, BRUISE CONTROL-2, PREPIC-2, SOX, ANNEXA-I
Endocarditis	POET (partial oral therapy); 2023 Duke-ISCVID criteria; 2023 ESC IE guideline

Eight lines that earn marks in any cardiovascular geriatrics answer

1. "Older patients are systematically under-represented in cardiovascular trials, so guideline recommendations are largely extrapolated."
2. "Presentation is frequently atypical — delirium, falls, anorexia and functional decline rather than classical symptoms."
3. "Treatment intensity should be proportionate to functional status, comorbidity and life expectancy, not to chronological age."
4. "Start low, go slow, and review renal function and electrolytes after every dose change."
5. "Time-to-benefit must be shorter than remaining life expectancy before a preventive drug is started."
6. "Neither falls risk nor dementia is by itself a contraindication to anticoagulation."
7. "Deprescribing is an active clinical decision, not a failure of care."
8. "Involve the multidisciplinary team, and discuss goals of care and advance planning before the terminal admission."

Indian Practice — Points to Weave In

- **Hypertension:** LASI Wave 1 — prevalence ≈46% in adults ≥45 years, control only ≈32%. IHCI (ICMR/MoHFW/WHO-India) raised control in enrolled cohorts from ≈26% to ≈60% using standardised protocols, single-pill combinations and free drugs through Ayushman Arogya Mandirs; NPHCE provides the geriatric service framework.
- **Heart failure:** less ischaemic and more rheumatic, hypertensive and idiopathic dilated cardiomyopathy; patients present younger and later in the disease course.
- **Atrial fibrillation:** rheumatic (valvular) AF remains common — these patients require **warfarin, not a DOAC**. Cost and INR access are the practical constraints.
- **Endocarditis:** rheumatic valve disease with viridans streptococci is still a major pattern alongside the degenerative pattern of high-income countries.
- **VTE:** once thought rare in Indians, but post-surgical rates are comparable to Western data; under-use of prophylaxis in medical wards is the documented gap. Aspirin is an acceptable extended prophylaxis option after arthroplasty in resource-limited settings.
- **Restrictive cardiomyopathy:** remember **endomyocardial fibrosis** in the Indian differential diagnosis.

End of document. *Textbook content is drawn from Pathy's Principles and Practice of Geriatric Medicine (6th edition) and Essentials of Clinical Geriatrics (7th edition). Material dated 2023 onward is drawn from current peer-reviewed literature and professional society guidance and is presented separately under "Latest Updates" and "Current Practice Update" in each answer. Where the uploaded textbooks do not cover a topic, this has been stated explicitly.*

RESPIRATORY MEDICINE IN THE ELDERLY

High-Yield Examination Answers

MD Geriatric Medicine — Structured Revision Series

Nine questions • COPD • GOLD • Pneumonia • Pulmonary Embolism
Interstitial Lung Disease • Respiratory Failure • LTOT • MDI • Extrapulmonary TB

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (Sections 4 & 5) and Essentials of Clinical Geriatrics, 7th edition.

Supplemented by: GOLD 2026 • 2026 AHA/ACC Acute PE Guideline • ATS/IDSA CAP • ERS/ATS • WHO & NTEP (India) • ICMR/API • ACIP 2024–25.

Format: 15–20 numbered points for 15-mark answers; 8–10 points for 7-mark answers, followed by Latest Updates, Current Practice Update table, and Examiner's Tip. Recurring topics carry an additional green panel.

Contents

1.	Chronic obstructive pulmonary disease — risk factors, pathology, clinical features, differentiation from bronchial asthma, management and complications **(recurs)**	15 marks
2.	GOLD criteria for assessment of COPD and treatment options	15 marks
3.	Community-acquired pneumonia in the elderly — etiology, clinical features and management	15 marks
4.	Causes, diagnosis and management of pulmonary embolism	15 marks
5.	Interstitial lung disease	7 marks
6.	Respiratory failure — types, causes and management	15 marks
7.	Long-term oxygen therapy	7 marks
8.	Metered dose inhalers	7 marks
9.	Extrapulmonary tuberculosis	15 marks
	Appendix — Rapid Revision Grid	

Age-related changes in the respiratory system (applies to all answers)

Pathy's Table 42.1 — worth writing as a two-line preamble to any respiratory answer.

Structure	Change with ageing	Functional consequence
Lung parenchyma	Altered collagen network, dilated alveolar ducts, loss of **elastic recoil**	Air trapping, hyperinflation (↑FRC, ↑RV); a **"pseudo-obstructive" spirometry pattern**
Chest wall	Kyphosis, rib-cage stiffening, flattened diaphragm, loss of respiratory muscle mass	↓Chest wall compliance, ↓TLC → **restrictive pattern**; ↑work of breathing
Control of breathing	Blunted efferent output to respiratory muscles	**Blunted ventilatory response to hypoxia and hypercapnia** → low threshold for respiratory failure
Immunity	Replicative senescence, ↑pro-inflammatory cytokines	Lung **"inflammageing"**; ↓mucociliary clearance and cough → infection risk

1. Chronic Obstructive Pulmonary Disease — Risk Factors, Pathology, Clinical Features, Differentiation from Bronchial Asthma, Management and Complications 15 marks

High-Yield Points

Definition and Epidemiology

1. **Definition:** COPD is airflow obstruction that is **not fully reversible** and shows **little variability over time**. It is usually progressive and is caused by small-airway disease plus emphysema.
2. **Burden:** COPD is the **fifth-largest cause of disability worldwide** and the fourth-leading cause of death in the US. World prevalence is **4–10%**, but in the elderly it rises to **12–15%**. Despite this it remains under-diagnosed and mis-diagnosed in older adults.

Risk Factors

3. **Tobacco smoke** is the main risk factor. FEV_1 normally falls by **25–30 mL/year after age 25**; in a susceptible smoker it falls by **more than 50 mL/year**. Stopping smoking slows this decline back towards normal.
4. **One in four to five COPD patients has never smoked.** In India the important non-smoking causes are **biomass fuel smoke** (chulha smoke in poorly ventilated kitchens), outdoor air pollution, occupational dust, and **post-tuberculous lung damage**. Pathy's notes that kitchen ventilation, rural residence, low BMI and low education all alter prevalence.
5. **Alpha-1 antitrypsin deficiency** should be screened for in **every** COPD patient regardless of age (European Respiratory Society statement).

Pathology and Pathophysiology

6. Inhaled irritants cause **chronic neutrophilic airway inflammation**, mucous gland hyperplasia and goblet cell metaplasia → chronic bronchitis; and **protease–antiprotease imbalance** destroying alveolar walls → emphysema.
7. Loss of elastic recoil and small-airway fibrosis cause **expiratory flow limitation → dynamic hyperinflation** and air trapping → breathlessness on exertion, flattened diaphragm and inefficient respiratory muscles.
8. Ventilation–perfusion mismatch causes **hypoxaemia**; later, alveolar hypoventilation causes **hypercapnia**. Chronic hypoxic pulmonary vasoconstriction → pulmonary hypertension → **cor pulmonale**.

Clinical Features

9. **Insidious onset** of exertional breathlessness, chronic cough with sputum, wheeze and chest tightness; symptoms vary little from day to day. Older patients often **attribute symptoms to old age**, which delays diagnosis.
10. Signs: barrel chest, pursed-lip breathing, reduced cricosternal distance, hyperresonance, distant breath sounds, prolonged expiration. Signs of **cor pulmonale** — raised JVP, hepatomegaly, ankle oedema, loud P2.
11. **Investigations:** post-bronchodilator spirometry (**FEV_1/FVC <0.7**, or better **<lower limit of normal** in the elderly); chest X-ray in all new cases to exclude cancer; **12-lead ECG** (right heart strain carries poorer prognosis); echocardiography if heart failure suspected; TLCO and CT if symptoms are out of proportion. Good-quality spirometry is achievable in about **85% of older adults** — **cognitive impairment is the commonest reason for failure**.

Differentiation from Bronchial Asthma

12. The key question is whether obstruction is **fixed (COPD)** or **reversible (asthma)**. A **>200 mL rise in FEV_1** after a beta-2 agonist or after a two-week corticosteroid trial is strong evidence of asthma. **PEF variability >20%** also suggests asthma.
13. Where results are ambiguous, use more discriminating tests: **a rise in total lung capacity is rare in asthma but typical of severe COPD**, and a **reduced TLCO** indicates emphysema (loss of alveolar-capillary surface), not asthma. **FeNO** is a simple non-invasive marker of eosinophilic (asthmatic) inflammation and is valid in older people.

Feature	COPD	Asthma in the elderly
Smoking history	Usually a heavy smoker	Often a non-smoker
Symptom pattern	Persistent, slowly progressive	**Variable**, episodic, **nocturnal** symptoms
Reversibility	Absent or <200 mL	**>200 mL rise in FEV_1** (may be only partial in the old because of airway remodelling)
PEF variability	Low	**>20%** diurnal variation
Total lung capacity	**Raised** in severe disease	Normal (a rise is rare)
TLCO (diffusion)	**Reduced** (emphysema)	Normal
Methacholine challenge	May be positive (non-specific)	Positive; **a negative test rules out asthma**
Airway inflammation	Neutrophilic	Eosinophilic; **FeNO raised**

Pathy's caution: *reversibility testing must be interpreted carefully in the elderly — there is a physiological decline in beta-2 adrenoceptor density and blunted bronchodilator response, so an absent response does not exclude asthma. The two conditions frequently* ***overlap*** *(asthmatic smokers).*

Management — Stable Disease

14. **Non-pharmacological (do these first): smoking cessation** using nicotine replacement, bupropion or varenicline — quit rates in older adults are as good as or better than in the young; **e-cigarettes are not recommended**. Add **influenza and pneumococcal vaccination**, **pulmonary rehabilitation**, nutritional support, self-management plans and early discussion of advance care planning.
15. **Inhaled therapy (Pathy's Figure 42.1):** avoid regular on-demand short-acting bronchodilators in the elderly (risk of overdosing and adverse drug reactions). Start a **LAMA** (tiotropium, umeclidinium, aclidinium — the latter two are safe in renal failure as they are liver-metabolised) or a **LABA**; step up to **LABA+LAMA**; add an **ICS** only for frequent exacerbators or asthma-like features. **ICS raise the risk of non-fatal pneumonia**, but this does not outweigh their benefit in the right patient.
16. **Add-on options:** slow-release theophylline in low dose (narrow therapeutic index, interacts with antibiotics); **roflumilast** (PDE-4 inhibitor) for frequent exacerbators with chronic bronchitis — watch weight loss, diarrhoea and mood change; high-dose acetylcysteine as a mucolytic/antioxidant; nebulised bronchodilators only when inhaler technique is irretrievably poor. **Maintenance oral steroids: risks generally outweigh benefits.**
17. **LTOT** if PaO_2 <7.3 kPa, or 7.3–8.0 kPa with polycythaemia, pulmonary hypertension, peripheral oedema or nocturnal hypoxaemia; used **≥15 hours/day** improves survival (see Question 7).

Management — Acute Exacerbation

18. **Definition and burden:** increased breathlessness, cough, sputum volume or purulence, wheeze and chest tightness. Exacerbations account for up to **10% of all medical admissions**; about **one-third are readmitted within 30 days** and **15% die by three months**. Commonest bacteria in the elderly are **H. influenzae, S. pneumoniae and M. catarrhalis**.
19. **Treatment:** nebulised bronchodilators; **oral corticosteroids for 7–14 days** (shorten stay, reduce treatment failure); **antibiotics when sputum is purulent** — these reduce mortality by 77% and treatment failure by 53%; avoid antibiotics if there is no purulence. Cover *Pseudomonas* (ciprofloxacin/anti-pseudomonal beta-lactam) if bronchiectasis coexists.
20. **Oxygen and ventilation:** target saturation **88–92%** (Pathy's text prints "890–95%", a typographical error for 88–92/90–95%) — excessive oxygen depresses hypoxic drive and worsens acidosis. Give **NIV if pH <7.35** despite maximal therapy: it reduces mortality, intubation and length of stay. **High-flow nasal oxygen** is safe and effective in both normocapnic and hypercapnic exacerbation, and is useful where there is a do-not-intubate order. Consider hospital-at-home/early-discharge schemes for patients without acidosis and with good social support.

Complications

21. **Respiratory:** recurrent exacerbations, pneumonia, respiratory failure (type 2), pneumothorax, secondary polycythaemia, **cor pulmonale**, lung cancer, coexisting bronchiectasis (found on HRCT in up to **29%** of primary-care COPD with chronic bronchitis).
22. **Systemic: heart failure is present in 20% of COPD patients over 65**; COPD is an independent cardiovascular risk factor. Also osteoporosis (screen routinely), sarcopenia and weight loss, chronic renal failure (masked by sarcopenia lowering creatinine), anxiety and depression, cognitive impairment, dysphagia and pulmonary embolism.

Latest Updates (2023–Present)

- **GOLD 2026 (November 2025)** — the largest revision in years: **a single moderate exacerbation now places the patient in Group E** and should trigger treatment escalation, with the goal of a "**low disease activity**" state (no exacerbations). A new section on **disease activity**, a completely rewritten exacerbation chapter, a rewritten multimorbidity chapter, and a new chapter on **artificial intelligence and emerging technologies** were added.
- **Biologics enter the COPD pathway (GOLD 2026, new Figure 3.11). Dupilumab** (anti-IL-4Rα; BOREAS and NOTUS trials, ~30% reduction in moderate-to-severe exacerbations) and **mepolizumab** (anti-IL-5; METREX/METREO/MATINEE, ~18–21% reduction) now carry **Level A evidence** and are FDA-approved for eosinophilic COPD (blood eosinophils generally ≥300 cells/µL) already on triple therapy. **Benralizumab did not reduce exacerbations.**
- **Cardiopulmonary link:** GOLD 2026 highlights that even **one moderate exacerbation raises the risk of a major cardiac event (arrhythmia, stroke, ischaemic heart disease, heart failure) within the next 30 days** — the rationale for "zero tolerance" of exacerbations.
- **Early diagnosis:** GOLD 2026 adds a formal **COPD case-finding algorithm** and a figure on factors associated with under-diagnosis; global COPD cases are projected to rise **23% between 2020 and 2050**, approaching 600 million, with the greatest growth in women and in low- and middle-income regions.
- **Vaccination:** influenza, pneumococcal, COVID-19, Tdap, zoster and now **RSV vaccination** recommended; ACIP lowered the age for routine **pneumococcal conjugate vaccine to 50 years** (October 2024; MMWR January 2025).

Current Practice Update

Issue	Textbook position (Pathy's 6e, 2022)	Current evidence (2023–2026)
Exacerbation threshold for escalation	Frequent exacerbator = **≥2 exacerbations** or ≥1 hospitalisation in a year	**GOLD 2026: one moderate exacerbation is enough** to move to Group E and escalate therapy
Initial inhaled therapy	Single long-acting bronchodilator (LAMA or LABA) first	**Dual bronchodilation (LABA+LAMA) is the preferred initial step** for most symptomatic patients
Role of ICS	Reserved for frequent exacerbators or asthma-like features; pneumonia risk noted	Unchanged in principle but now **biomarker-guided by blood eosinophil count**
Biologic therapy	Not mentioned for COPD	**Dupilumab and mepolizumab** approved as add-on for eosinophilic COPD on triple therapy
Diagnostic ratio	Fixed FEV_1/FVC <0.7 post-bronchodilator	Fixed ratio retained by GOLD 2026, but **LLN preferred in the elderly** to avoid over-diagnosis
Beta-blockers	Historically avoided; recent data reassuring	**Cardioselective beta-blockers should be used when indicated** — no longer contraindicated

> **Examiner's Tip**
>
> Open by writing the definition verbatim: "*COPD is characterised by airflow obstruction that is not fully reversible and shows little variability over time, usually progressive, comprising small-airway disease and emphysema.*" Then earn easy marks with three numbers: **normal FEV_1 decline 25–30 mL/year vs >50 mL/year in susceptible smokers**; **heart failure in 20% of COPD patients over 65**; **NIV indicated at pH <7.35**. Always draw the COPD-versus-asthma table — it is the single highest-scoring element of this question. Finish with a geriatric line: "*In the older patient, management is judged by improvement in symptoms, exercise tolerance and ADLs rather than by change in FEV_1, which is less relevant.*"

Extra Points to Remember — This Topic Recurs

- **Pathy's Table 42.4 — comorbidity classification, a favourite viva question.** Comorbidities are grouped as: **co-causal** (share smoking as a risk factor: coronary and cerebral atherosclerosis, chronic renal failure, lung and bladder cancer, congestive heart failure, aortic aneurysm, pulmonary fibrosis); **coexisting** (share only age: glaucoma, diabetes, benign prostatic hypertrophy, degenerative joint disease, hypertension, obstructive sleep apnoea); and **complicating COPD** (anxiety/depression, cognitive impairment, osteoporosis, sarcopenia, arrhythmias, dysphagia, pulmonary embolism).
- **Pathy's Table 42.3 — differential diagnosis of COPD:** asthma, congestive heart failure (orthopnoea, bibasal crackles, B-lines on ultrasound, restrictive spirometry), bronchiectasis (large-volume purulent sputum, clubbing, airway thickening), interstitial lung disease (dry cough, fine basal crackles, restrictive pattern, impaired diffusion), kyphoscoliosis (restrictive pattern with **normal** diffusion).
- **Multidimensional assessment** in the older COPD patient: MRC dyspnoea scale, Manchester Respiratory ADL scale, shuttle walk or six-minute walk test, BMI, oxygen saturation (if FEV_1 <50% or signs of cor pulmonale), Hospital Anxiety and Depression Scale, and exacerbation rate. Quote the **BODE index** (BMI, Obstruction, Dyspnoea, Exercise capacity) as the validated prognostic tool.
- **Sarcopenia masks renal failure:** low muscle mass blunts the rise in creatinine, so moderate (GFR 30–60) and even severe renal impairment goes unrecognised — important when prescribing antibiotics during exacerbations and renally cleared drugs.
- **Mortality predictors in older COPD (Pathy's):** disability, low BMI, lung function and use of LTOT. About **50% of LTOT patients survive three years**.
- **Palliative care:** patients in their last year should enter an end-of-life register and be offered **opioids and benzodiazepines** for refractory breathlessness. Pathy's states plainly that the switch from active to palliative approach "all too often comes too late" — a valuable closing line.

2. GOLD Criteria for Assessment of COPD and Treatment Options 15 marks

High-Yield Points

The GOLD Initiative and Diagnosis

1. **GOLD** = Global Initiative for Chronic Obstructive Lung Disease, established **1997**, first strategy report **2001**, revised every November alongside World COPD Day.
2. **Diagnostic criterion:** in the right clinical context, a **post-bronchodilator FEV_1/FVC <0.70** confirms persistent airflow obstruction. Post-bronchodilator testing avoids labelling reversible disease (asthma) as COPD.
3. **Geriatric caveat:** the FEV_1/FVC ratio falls physiologically with age, so the fixed 0.70 cut-off **over-diagnoses COPD in normal older people**. Pathy's and GOLD both prefer the **lower limit of normal (LLN)** in this age group. NICE adds that if FEV_1 is ≥80% predicted, diagnose only when respiratory symptoms are present.

GOLD Assessment — Three Components

4. **(a) Severity of airflow limitation (GOLD grades 1–4)** — applied only once FEV_1/FVC <0.7:

GOLD grade	FEV_1 % predicted	Severity
GOLD 1	≥80%	Mild
GOLD 2	50–79%	Moderate
GOLD 3	30–49%	Severe
GOLD 4	<30%	Very severe

5. **(b) Symptom burden** — measured by the **mMRC dyspnoea scale** (cut-off ≥2) or the **COPD Assessment Test, CAT** (cut-off ≥10). CAT has 8 items scored 0–5, total 0–40.
6. **(c) Exacerbation history in the past year** — the strongest single predictor of future exacerbations.

Group	Definition — GOLD 2023–2025	Definition — GOLD 2026 (revised)
A	0–1 moderate exacerbation, no hospitalisation; mMRC 0–1 or CAT <10	**No** moderate or severe exacerbation; mMRC 0–1 or CAT <10
B	0–1 moderate exacerbation, no hospitalisation; mMRC ≥2 or CAT ≥10	**No** moderate or severe exacerbation; mMRC ≥2 or CAT ≥10
E	≥2 moderate exacerbations **or** ≥1 leading to hospitalisation	**≥1 moderate or severe exacerbation** in the past year, whatever the symptom score

7. **Remember the history:** the older **ABCD** tool used both symptoms and exacerbations for all four groups; **GOLD 2023 merged C and D into a single group "E"** (E for *exacerbations*) because exacerbation risk drives treatment more than symptoms do. **GOLD 2026 has now lowered the entry threshold to Group E to a single moderate exacerbation.**
8. **Grading of exacerbation severity: mild** — short-acting bronchodilators only; **moderate** — bronchodilators plus antibiotics and/or oral corticosteroids; **severe** — requires emergency department visit or hospitalisation.

Treatment Options — Initial Pharmacological Therapy

9. **Group A:** a bronchodilator (short- or long-acting), chosen by symptom response. **Group B: LABA + LAMA** combination. **Group E: LABA + LAMA**; add **ICS (triple therapy) if blood eosinophils ≥300 cells/μL**.
10. **Never use ICS alone in COPD.** ICS are favoured when eosinophils are ≥300/μL, when there have been ≥2 exacerbations or a hospitalisation, or when asthma coexists; they are discouraged when there is **repeated pneumonia, eosinophils <100/μL, or a history of mycobacterial infection** — a point of particular importance in India, where past tuberculosis is common.

Follow-up Therapy — the Management Cycle

11. GOLD uses a **review → assess → adjust** cycle. **Before escalating, always re-check inhaler technique, adherence, device suitability, non-pharmacological measures and comorbidities.** GOLD 2026 clearly separates **initial** treatment (treatment-naive patient) from **follow-up** treatment (patient already on therapy).
12. **If dyspnoea persists:** escalate LABA or LAMA monotherapy to LABA+LAMA; if already on dual therapy, consider switching device or molecule and investigate other causes of breathlessness.
13. **If exacerbations persist:** escalate to **LABA+LAMA+ICS** when eosinophils are ≥100/μL. If exacerbations continue on triple therapy, add **roflumilast** (FEV_1 <50% with chronic bronchitis), **azithromycin** (preferably ex-smokers;

check QTc and hearing), or a **biologic**.

Non-Pharmacological and Interventional Options

14. **Core measures for every patient:** smoking cessation, vaccination, **pulmonary rehabilitation**, physical activity, self-management education and written action plans, and post-exacerbation follow-up. GOLD 2026 elevates these to **core disease-modifying strategies**, not optional extras.
15. **LTOT** for chronic severe resting hypoxaemia; **domiciliary NIV** for persistent hypercapnia after hospitalisation for exacerbation; **lung volume reduction surgery or endobronchial valves** for selected upper-lobe emphysema; **lung transplantation** in very selected patients (rarely appropriate in the elderly).
16. **Pulmonary rehabilitation in the elderly (Pathy's):** patients are eligible from **GOLD grade 2–4**, but enrolment should be driven by **symptoms and functional limitation, not FEV_1 alone**. It improves exercise tolerance, quality of life, dyspnoea, anxiety and depression, and reduces hospital days (10.4 vs 21 days in the year after rehabilitation) — but it does **not** improve survival, lung function or oxygen requirement. **Benefits are not age-dependent**, so age alone is never a barrier.

Latest Updates (2023–Present)

- **GOLD 2026** incorporates **330 new references and 14 new figures**; a new **Chapter 6 on emerging technology and AI**, and material moved to four appendices. AI-assisted alternatives to spirometry under investigation include respiratory sound and voice analysis, oscillometry, e-nose volatile organic compounds and chest CT-based algorithms.
- **The redefinition of Group E** (≥1 moderate exacerbation) is the single most examinable change of 2026 — driven by observational data showing that even one exacerbation before starting maintenance therapy predicts further events.
- **"Disease activity, stability and control"** is introduced as a formal therapeutic target, borrowing the concept from rheumatology — treat to a state of **low disease activity**.
- **Biologics:** Figure 3.11 summarises the evidence — dupilumab and mepolizumab now have **Level A** evidence for exacerbation reduction; benralizumab failed.
- **A new physiology-based grading of exacerbation severity (the "Rome" proposal)** replaces the old treatment-based definition. Severity is now judged on **dyspnoea measured by visual analogue scale, respiratory rate, heart rate, SpO_2, CRP and arterial blood gases**, giving mild / moderate / severe categories that do not depend on where the patient was treated. The exacerbation chapter also stresses **structured discharge bundles and early follow-up**.
- **Ensifentrine**, a first-in-class inhaled **dual PDE3/PDE4 inhibitor** combining bronchodilator and anti-inflammatory action, was approved by the FDA in 2024 as maintenance therapy (ENHANCE-1 and ENHANCE-2) — a new pharmacological class that post-dates the textbook.
- **Vaping and e-cigarettes are explicitly not recommended** as cessation aids because of insufficient long-term safety data.

Current Practice Update

Item	Textbook position (Pathy's 6e, citing GOLD 2019)	GOLD 2026
Exacerbation severity	Graded by treatment given (bronchodilators only / plus steroids-antibiotics / hospitalisation)	**Rome criteria** — graded physiologically by dyspnoea VAS, respiratory rate, heart rate, SpO_2, CRP and blood gases
Assessment tool	Four-stage FEV_1 severity classification driving therapy	**ABE groups** drive therapy; FEV_1 grade used for prognosis and non-pharmacological decisions
Group E threshold	≥2 exacerbations or 1 hospitalisation (NICE: 2 in 12 months)	**≥1 moderate or severe exacerbation**
Initial therapy for symptomatic patient	Start with a single LAMA	**LABA + LAMA** dual bronchodilation preferred
Choosing ICS	Clinical phenotype (frequent exacerbator, asthma features)	**Blood eosinophil count**: favour ≥300/µL, avoid <100/µL or prior mycobacterial disease
Advanced therapy after triple	Roflumilast, theophylline, high-dose acetylcysteine	Plus **azithromycin and biologics (dupilumab, mepolizumab)**
Diagnosis strategy	Case detection by symptom-driven spirometry	Formal **case-finding algorithm**; explicit push for **earlier diagnosis** ("Think COPD")

Examiner's Tip

Draw **two tables** — the GOLD 1–4 spirometric grades and the ABE assessment box — and state clearly that **"grade determines prognosis, group determines pharmacotherapy."** The examiner is listening for the 2026 change: say aloud "*a single moderate exacerbation now places the patient in Group E*." Add the eosinophil thresholds (**≥300 favours ICS, <100 argues against**) and, for the Indian context, the caution against ICS where there is a history of tuberculosis. Close with the geriatric qualifier: "*In older adults the fixed 0.70 ratio over-diagnoses COPD; the lower limit of normal is preferred*."

3. Community-Acquired Pneumonia in the Elderly — Etiology, Clinical Features and Management 15 marks

High-Yield Points

Definition and Epidemiology

1. **Definition:** acute infection of the lung parenchyma acquired outside hospital, with new radiographic consolidation. Unlike bronchitis (which involves only the airways and has a benign course), pneumonia involves the **alveoli**.
2. **Burden:** pneumonia and influenza together are the **sixth leading cause of death in those over 65** and the leading infectious cause of death in the elderly. Incidence rises from **18 per 1000 at age 65–69 to 52 per 1000 over age 85**. Over **40% of elders with CAP require hospitalisation**; mortality is about **10%, rising to nearly 50%** where there is pre-existing cardiopulmonary disease. **Two out of three pneumonia hospitalisations are in patients over 70.**
3. **Predisposing factors (Pathy's Table 39.1):** ageing itself (declining cell-mediated immunity, reduced cough and mucociliary clearance, micro-aspiration), COPD, asthma, **sequelae of tuberculosis**, diabetes mellitus, heart failure, neurological disease, **swallowing disorders**, sedative and antipsychotic drugs, gastro-oesophageal reflux, protein-energy malnutrition, and enteral feeding or nasogastric tube. **Pneumonia is the commonest specific cause of death in Alzheimer's disease.**

Etiology

4. ***Streptococcus pneumoniae* is the single most important pathogen** — the commonest cause of CAP requiring admission, with a high mortality in the elderly.
5. Other bacteria: **Gram-negative bacilli** (after aspiration, hospitalisation or prior antibiotics), **Staphylococcus aureus**, **Haemophilus influenzae**, *Legionella pneumophila* (rarer but severe, high mortality), *Mycoplasma pneumoniae*, streptococci and Enterobacteriaceae. **Anaerobes are common in aspiration pneumonia**, and **multi-microbial pneumonia is common in the elderly**.
6. **Age shifts the spectrum:** in older patients *S. pneumoniae*, *H. influenzae* and respiratory viruses are commoner, while ***Legionella*, *Mycoplasma* and *Chlamydia* are less frequent** than in younger adults.
7. **Nursing-home residents:** aspiration pneumonia, Gram-negative enteric bacilli and multiple anaerobes predominate. In hospital-acquired pneumonia: *S. aureus*, *Pseudomonas aeruginosa* and resistant Gram-negatives.
8. **Viruses cause 10–30%** of community-acquired lung infection, often in institutional epidemics — influenza (even in vaccinated patients), **RSV**, parainfluenza, rhinovirus, adenovirus, and emerging coronaviruses (SARS 2002, MERS 2012, **SARS-CoV-2/COVID-19**, where case-fatality exceeds 30% in those over 75–80). Always consider ***M. tuberculosis*** where illness has evolved over weeks with weight loss.

Clinical Features — the Atypical Presentation

9. **The classical picture is rarely complete. Fever and cough are absent in 30–40% of cases.** Onset is often gradual with less marked signs, causing diagnostic delay.
10. **Respiratory symptoms:** cough (productive or dry), purulent sputum, dyspnoea, pleuritic chest pain, haemoptysis. **Non-respiratory symptoms:** fever, anorexia, chills and sweats.
11. **Geriatric presentations: delirium/acute confusion, falls, functional decline, incontinence, anorexia, tachypnoea alone, or unexplained decompensation of diabetes or heart failure**. **Tachypnoea is often the earliest and most reliable sign.** Hypothermia rather than fever indicates severe disease.
12. **Examination findings to record:** respiratory rate >30/min, heart rate >110/min, fever or hypothermia, bronchial breathing, crackles, dullness to percussion, and hypoxaemia on pulse oximetry.

Investigations

13. **Chest radiograph** is the gold standard for documenting parenchymal involvement; the radiographic pattern correlates poorly with the causative organism. A normal film may occur very early in pneumococcal pneumonia. **Practical strategy in the community:** the British Thoracic Society allows management without a film if pneumonia is likely and admission is not needed; otherwise repeat the film 2–3 days after starting treatment. **CT** is indicated in difficult cases and can identify very early pneumonia or pulmonary embolism.
14. **Point-of-care lung ultrasound** detects B-lines, consolidation ("pulmonary hepatisation"), effusion and pneumothorax, with excellent sensitivity and specificity compared with chest X-ray. It is particularly valuable in nursing homes and home care where imaging is hard to obtain — a technique Pathy's predicts will become a core geriatric skill.
15. **Blood tests:** neutrophil leucocytosis (may be **absent** in older patients with bacterial infection), raised CRP, electrolytes, urea, creatinine and glucose (dehydration, renal failure and hyperglycaemia are common). **Arterial**

blood gas if there is chronic respiratory failure, cyanosis, sweating or reduced consciousness. **BNP >300 pg/mL suggests cardiac rather than pulmonary dyspnoea.**

16. **Microbiology:** blood cultures and sputum examination in all hospitalised patients. **Pneumococcal and Legionella urinary antigen** only for severe pneumonia needing intensive care, or during an outbreak. **Do not send routine urine microscopy/culture** — asymptomatic bacteriuria is so common in the elderly that it misleads prescribing. Nasal swab for viral PCR during institutional epidemics.

Management

17. **Decide site of care.** Use **CURB-65** (Confusion, Urea >7 mmol/L, Respiratory rate ≥30, Blood pressure <90/60, age ≥65) or **PSI**; but Pathy's stresses that in the frail elderly the decision also depends on **severity signs and whether the patient can be cared for at home** (Figure 39.1). Note that **age ≥65 automatically scores one CURB-65 point**, so the score over-triages older patients — combine with clinical and social judgement.
18. **General measures:** oral or subcutaneous/intravenous hydration, oral nutritional supplements if malnourished, **oral care**, pressure-ulcer prevention, early mobilisation, antipyretics if fever >39.5°C or poorly tolerated, **non-pharmacological management of delirium**, and **subcutaneous heparin thromboprophylaxis** unless contraindicated.
19. **Supportive respiratory care:** nasal oxygen for dyspnoea or hypoxaemia (**with caution in hypercapnic chronic respiratory failure**); chest physiotherapy; inhaled beta-2 agonists and anticholinergics if bronchial obstruction is present; a short course of systemic corticosteroids for resistant bronchial obstruction; **emergency bronchoscopy** for large atelectasis from a mucus plug.
20. **Antibiotics (Pathy's Table 39.5, ATS/IDSA 2019) for a comorbid outpatient:** a **beta-lactam** (amoxicillin, amoxicillin-clavulanate, cefpodoxime or cefuroxime) **plus a macrolide or doxycycline**; or a **respiratory fluoroquinolone alone** (levofloxacin, moxifloxacin, gemifloxacin — moxifloxacin now restricted for adverse effects). **Nursing-home pneumonia** requires anaerobic cover: amoxicillin-clavulanate or ceftriaxone or a respiratory fluoroquinolone. **Severe or hospital-acquired pneumonia** requires broad-spectrum cover, guided by prior antibiotics in the last three months and risk factors for *Pseudomonas* (bronchiectasis).
21. **The 48-hour review is a critical step.** Response is expected within 2–4 days. If afebrile and stable, continue and switch intravenous to oral in the same class. **If not improving**, consider resistant organisms, virus or tuberculosis, empyema, a non-infectious lung disease, antibiotic adverse effects, or decompensating comorbidity — and re-image, seek urinary antigens, and take infectious disease advice.
22. **Duration and follow-up:** total course about **10 days** (5 days for azithromycin). Fever, leucocytosis and CRP settle within 2–5 days; cough persists longer. **A follow-up chest radiograph is not needed if recovery is clinically complete** — radiographic clearance can take **up to 12 weeks** in the elderly. If lung cancer is suspected, arrange CT and bronchoscopy.
23. **Prevention:** annual **influenza vaccination for everyone aged 65 and over** — it reduces influenza by about 50% and influenza mortality by about 70%; **adjuvanted or high-dose vaccine** is particularly valuable in institutionalised or chronically ill elders. Add **pneumococcal vaccination**, COVID-19 and RSV vaccination, smoking cessation, oral and dental hygiene, dysphagia screening and safe feeding practice, avoidance of sedatives and antipsychotics, treatment of reflux, and correction of malnutrition.

Latest Updates (2023–Present)

- **Pneumococcal vaccination age lowered.** ACIP (23 October 2024; MMWR January 2025) recommends a **single dose of pneumococcal conjugate vaccine for all PCV-naive adults aged ≥50 years**, replacing the previous age-65 threshold. Options are **PCV21 (Capvaxive, FDA-approved June 2024, covering eight serotypes absent from other vaccines), PCV20, or PCV15 followed by PPSV23**.
- **RSV vaccination established for older adults.** Routine RSV vaccine for all adults ≥75, and for those **50–74 years at increased risk** because of chronic heart, lung, kidney or liver disease, diabetes, frailty or residence in long-term care (ACIP expansions 2024–2025). Available products: RSVpreF (Abrysvo), RSVPreF3-adjuvanted (Arexvy) and mRNA-1345.
- **Corticosteroids in severe CAP:** the **CAPE COD trial (NEJM 2023)** showed that **intravenous hydrocortisone reduced 28-day mortality** in severe CAP requiring mechanical ventilation, high-flow oxygen or with a high pulmonary severity index — now incorporated into several society statements. Steroids are **not** advised in influenza pneumonia or where aspergillosis is suspected.
- **Diagnostics:** rapid multiplex respiratory PCR panels and **lung ultrasound** are increasingly first-line in frail and bedbound patients; procalcitonin may support antibiotic de-escalation but should not withhold antibiotics in a septic older patient.
- **India:** the ICMR and API continue to emphasise a **five-day minimum course with de-escalation** and antimicrobial stewardship given the very high burden of ESBL-producing Enterobacteriaceae; **melioidosis (*Burkholderia***

***pseudomallei*)** should be considered in diabetic patients from coastal and monsoon-affected regions presenting with severe community-acquired pneumonia.

Current Practice Update

Issue	Textbook position (Pathy's 6e)	Current evidence (2023–2026)
Pneumococcal vaccine	Recommended for older adults; PPSV23/PCV13 era	**Single PCV dose from age 50**; PCV21 or PCV20 preferred
RSV	Recognised as a cause of pneumonia; no vaccine available	**Three licensed RSV vaccines**; routine from age 75 and from 50 if at risk
Steroids in severe CAP	Reserved for resistant bronchial obstruction	**Hydrocortisone reduces mortality in severe CAP** (CAPE COD, NEJM 2023)
Duration of antibiotics	About 10 days	**5 days is sufficient** if afebrile 48 h and clinically stable, in most non-severe CAP
Healthcare-associated pneumonia (HCAP)	Nursing-home pneumonia treated as a distinct high-resistance category	The **HCAP category has been abandoned**; treat as CAP unless there are validated local risk factors for MRSA or *Pseudomonas*
Imaging	Chest X-ray, CT in difficult cases; ultrasound emerging	**Lung ultrasound now a mainstream point-of-care tool** in geriatric and nursing-home settings

Examiner's Tip

The mark-earning line for this question is the atypical presentation: "*Fever and cough are absent in 30–40% of elderly patients with pneumonia; delirium, falls, tachypnoea and functional decline may be the only presenting features*." Follow it with three numbers — **incidence 52 per 1000 over age 85**, **mortality 10% rising to 50% with cardiopulmonary disease**, and **radiographic clearance takes up to 12 weeks**. Mention the two things geriatricians do that others forget: **do not send a routine urine culture** (asymptomatic bacteriuria misleads), and **screen for dysphagia** because aspiration underlies much of this disease. End on prevention: influenza vaccine reduces influenza mortality by about 70%.

4. Causes, Diagnosis and Management of Pulmonary Embolism 15 marks

High-Yield Points

Definition and Epidemiology

1. **Definition:** obstruction of the pulmonary arterial tree, usually by thrombus embolised from the deep veins of the leg or pelvis; part of the spectrum of **venous thromboembolism (VTE)** together with DVT.
2. **Ageing is the dominant risk factor:** both the incidence of VTE **and** the haemorrhagic risk of its treatment rise with age. **Thirty-day mortality after VTE roughly trebles** in those aged ≥65 compared with the young (11% vs 4%), and at one year it is **31% vs 14%**.

Causes and Risk Factors — Virchow's Triad

3. **Venous stasis:** immobility, hospitalisation, stroke with hemiplegia, heart failure, long travel, obesity, varicose veins.
4. **Endothelial injury:** surgery (especially **hip and knee arthroplasty and hip fracture**), trauma, fracture of a lower limb, central venous catheters, previous DVT.
5. **Hypercoagulability: active malignancy** (the single most important acquired factor in the elderly), inflammatory illness, sepsis, nephrotic syndrome, oestrogen therapy, **antiphospholipid syndrome**, and inherited thrombophilias (factor V Leiden — the commonest; prothrombin 20210A; deficiencies of antithrombin, protein C and protein S). Ageing itself brings **raised fibrinogen, altered platelet function and frailty**, all independently associated with VTE.
6. **Testing for thrombophilia is rarely useful in the elderly** — levels of antithrombin, protein C and S fall during acute thrombosis and during anticoagulation, so the patient must be off treatment and thrombosis-free. First presentation in old age is usually provoked or cancer-associated rather than inherited.

Clinical Features

7. **Classic:** sudden pleuritic chest pain, dyspnoea, tachypnoea, tachycardia, haemoptysis, syncope; massive PE presents with hypotension, cardiogenic shock or cardiac arrest.
8. **In the elderly the presentation is blunted and non-specific** — isolated dyspnoea, unexplained tachypnoea, new atrial fibrillation, syncope or a fall, delirium, or simply unexplained deterioration. **Asymptomatic DVT is present on admission in a high proportion of older medical inpatients.** PE shares fever, cough, chest pain and dyspnoea with pneumonia; **clear lung fields on chest X-ray with marked hypoxaemia** should raise suspicion.

Diagnosis

9. **Step 1 — assess pre-test clinical probability** using the **Wells score** or the **revised Geneva score**. The revised Geneva score is **objective** (no subjective "PE most likely diagnosis" item), which makes it preferable in older patients:

Revised Geneva score (Pathy's Table 37.2)	Points
Age >65 years	1
Previous DVT or PE	3
Surgery under general anaesthesia or lower-limb fracture within 1 month	2
Active cancer (or cured <1 year)	2
Unilateral lower-limb pain	3
Haemoptysis	2
Pain on deep venous palpation and unilateral oedema	4
Heart rate 75–94 / ≥95 beats per minute	3 / 5
Clinical probability: Low 0–3 | Intermediate 4–10 | High >10	

10. **Step 2 — D-dimer, but only if probability is low or intermediate.** D-dimer rises physiologically with age, so the conventional 500 µg/L cut-off has poor specificity in the elderly. Use the **age-adjusted cut-off = age × 10 µg/L for patients over 50** (validated in the **ADJUST-PE study, JAMA 2014**) — this substantially increases the proportion of older patients in whom PE can be excluded without imaging, at no cost in safety.
11. **Step 3 — imaging. CT pulmonary angiography (CTPA)** is the investigation of choice. In renal impairment consider **V/Q or V/Q-SPECT scanning**, or a **compression ultrasound of the legs** first (a positive proximal DVT in a breathless patient justifies treatment without CTPA). Pathy's notes a randomised trial showing that sodium bicarbonate hydration before CTPA in chronic kidney disease was no better than no hydration.
12. **Diagnostic algorithm (Pathy's Figure 37.2):** haemodynamically stable patient → assess probability → if

low/intermediate, D-dimer (age-adjusted): negative excludes PE, positive proceeds to CTPA; if **high probability**, go **directly to CTPA**. In the unstable patient, **bedside echocardiography** showing right ventricular dilatation/dysfunction justifies immediate treatment.

13. **Supporting tests:** ECG (sinus tachycardia commonest; right axis deviation, right bundle branch block, T inversion V1–V4, the classic but uncommon **S1Q3T3**); chest X-ray usually normal or shows atelectasis, a raised hemidiaphragm or a pleural effusion; arterial blood gas shows hypoxaemia with hypocapnia; **troponin and NT-proBNP** for risk stratification.

Risk Stratification and Prognosis

14. **PESI and simplified PESI (sPESI)** are validated in the elderly and identify patients at low risk of short-term death who may be managed as outpatients. **Age is itself a PESI variable**, so few older patients score "low risk". The strongest predictors of long-term mortality are **systolic BP <100 mmHg, active cancer and age**; others are low physical activity, polypharmacy, diabetes, anaemia, hs-CRP >40 mg/L, troponin >14 pg/mL and D-dimer >3000 ng/mL at presentation.
15. **Causes of death in the first three months after VTE in the elderly: cancer 38%, PE 26%, infection 13%, bleeding 6%** — a striking set of figures worth quoting.

Management

16. **Immediate:** oxygen, analgesia, cautious fluids in right ventricular failure (over-filling worsens it), vasopressors (noradrenaline) if hypotensive, and **start anticoagulation during the diagnostic work-up** in any patient with intermediate or high clinical probability and no contraindication.
17. **Anticoagulation — DOACs are first choice** in the absence of cancer or severe renal impairment, mainly because of their **lower intracranial bleeding risk**. In patients aged ≥75, DOACs carry a **relative risk of major bleeding of 0.49** compared with vitamin K antagonists. Regimens (Pathy's Table 37.3):

Drug	Lead-in heparin	Initial and long-term (3–6 months)	Extended phase
Dabigatran	Yes, ≥5 days	150 mg twice daily	No change
Rivaroxaban	No	15 mg twice daily × 21 days, then 20 mg once daily	Consider 10 mg once daily
Apixaban	No	10 mg twice daily × 7 days, then 5 mg twice daily	Consider 2.5 mg twice daily
Edoxaban	Yes, ≥5 days	60 mg once daily (30 mg if CrCl 30–50 mL/min, weight ≤60 kg, or on strong P-gp inhibitors)	No change

18. **Reperfusion therapy: systemic thrombolysis** for high-risk (haemodynamically unstable) PE where bleeding risk is acceptable. **Catheter-directed thrombolysis, mechanical thrombectomy or surgical embolectomy** for those with contraindications to lysis or failed lysis. An **IVC filter** is reserved for absolute contraindications to anticoagulation or recurrent PE despite adequate treatment.
19. **Duration:** minimum **3 months** for all. A **provoked** PE with a major transient risk factor (surgery, fracture) stops at 3 months. **Unprovoked PE or a persistent risk factor** (cancer, thrombophilia) warrants **extended/indefinite anticoagulation** with periodic review of bleeding risk. Cancer-associated VTE: LMWH or an anti-Xa DOAC, continued while cancer is active.
20. **Bleeding risk in the elderly:** patients aged ≥65 have a **near two-fold** higher risk of major and clinically relevant non-major bleeding, and age ≥75 at least **doubles the risk of intracranial haemorrhage**. Independent predictors include **low physical activity and polypharmacy (>4 drugs)**. Pathy's states that **whether falls risk increases major bleeding remains controversial** — falls alone are not a reason to withhold anticoagulation. Existing recurrence scores are unhelpful in the old: **HERDOO2 automatically classes anyone ≥65 as high risk, DASH is not validated in the elderly, and the Vienna model lacks discriminative power.** Therefore **clinical judgement plus patient preference** must guide the decision.
21. **Prevention:** risk-assess every hospitalised older patient; use **LMWH thromboprophylaxis** unless contraindicated, mechanical prophylaxis (intermittent pneumatic compression) where bleeding risk is high, early mobilisation and adequate hydration.

Latest Updates (2023–Present)

- **The 2026 AHA/ACC Acute Pulmonary Embolism Guideline (Circulation and JACC, 19 February 2026)** — the first-ever joint de-novo American guideline on PE, written with ACCP, ACEP, CHEST, SCAI, SHM, SIR, SVM and SVN. It **retires the terms "massive" and "submassive"** and replaces binary risk classification with a **five-tier Acute PE**

Clinical Category system (A to E), plus a respiratory modifier.

- **The A–E categories in practice: Category A (subclinical, incidentally detected)** may be discharged directly from the emergency department; **Category B (symptomatic, low clinical severity)** can be discharged early; **Categories C to E** require hospitalisation. Advanced therapies are **reasonable in Category E1 (cardiopulmonary failure with shock)** and **may be considered in Categories D1–D2 (incipient cardiopulmonary failure)**; they are **not recommended in Categories A and B**.
- **Other Class 1 recommendations: PE Response Teams (PERTs)** are formally recommended; **LMWH is preferred over unfractionated heparin** when parenteral anticoagulation is required; **DOACs are preferred over vitamin K antagonists**; and anticoagulation should continue into the extended phase for a first PE without a major reversible risk factor.
- **HI-PEITHO (NEJM 2026, presented at ACC 2026)** — the first randomised evidence that **ultrasound-facilitated catheter-directed thrombolysis plus anticoagulation is superior to anticoagulation alone** in intermediate-high-risk PE, with comparable safety. **STORM-PE (Circulation 2026)** examined mechanical thrombectomy in the same population. **PEITHO-3** (reduced-dose alteplase) is ongoing.
- **Follow-up:** the 2026 guideline recommends review within the first week of discharge, a clinical visit at or before **3 months** to decide on anticoagulation duration, encouragement of **early ambulation**, and screening for **post-PE syndrome and chronic thromboembolic pulmonary hypertension (CTEPH)**.

Current Practice Update

Issue	Textbook position (Pathy's 6e, citing 2019 ESC)	Current evidence (2023–2026)
Severity classification	High / intermediate-high / intermediate-low / low risk	**Five-tier AHA/ACC Clinical Categories A–E**; "massive/submassive" abandoned
Parenteral anticoagulant	LMWH, UFH or fondaparinux as lead-in	**LMWH recommended over UFH** (Class 1)
Oral anticoagulant	DOACs first choice unless cancer or severe renal failure	Unchanged and strengthened — **DOACs over VKAs (Class 1)**
Catheter-directed therapy	Reserved for failed or contraindicated systemic lysis	**HI-PEITHO (2026) provides the first randomised support** in intermediate-high-risk PE; reasonable in Category E1
Service organisation	Not addressed	**PE Response Teams recommended (Class 1)**
D-dimer cut-off	Age-adjusted cut-off validated (ADJUST-PE)	Unchanged — remains the standard of care in the elderly

Examiner's Tip

Three things guarantee marks here. First, write the **age-adjusted D-dimer formula: age × 10 µg/L above 50 years (ADJUST-PE, JAMA 2014)** — it is the most geriatric-specific fact in the whole topic. Second, draw the diagnostic algorithm as a flow chart: *probability → D-dimer if low/intermediate → CTPA*, with **high probability going straight to CTPA**. Third, quote the causes of three-month mortality (**cancer 38%, PE 26%**) to show you understand that in the elderly the embolus is often a marker of another disease. Add the Pathy's line examiners like: "*Diagnosis and treatment are the same as in younger people, but the iatrogenic risk of treatment is higher.*" If asked about falls, say clearly that **a falls risk alone is not a contraindication to anticoagulation.**

5. Interstitial Lung Disease 7 marks

Pathy's does not carry a dedicated ILD chapter; ILD appears within the COPD differential diagnosis (Table 42.3), the muscle disorders chapter (anti-synthetase syndrome and dermatomyositis-associated ILD) and the pulmonary rehabilitation chapter. The points below combine that textbook material with current ATS/ERS/JRS/ALAT guidance, as required for a complete answer.

High-Yield Points

1. **Definition:** a heterogeneous group of diffuse parenchymal lung diseases in which inflammation and/or fibrosis affect the **alveolar interstitium**, producing a **restrictive** ventilatory defect with impaired gas transfer. ILD is predominantly a disease of older adults — **idiopathic pulmonary fibrosis (IPF) is typically diagnosed between 60 and 70 years**.
2. **Classification:** (a) **known cause** — occupational/environmental (asbestosis, silicosis, coal worker's pneumoconiosis, **hypersensitivity pneumonitis** from birds, mould, and in India **bagassosis** and **farmer's lung**), drugs (amiodarone, methotrexate, nitrofurantoin, bleomycin, immune checkpoint inhibitors) and radiation; (b) **connective tissue disease-associated** — rheumatoid arthritis, systemic sclerosis, Sjögren's, and dermatomyositis/polymyositis (the **anti-synthetase syndrome**: acute myopathy, Raynaud's, ILD, mechanic's hands and anti-Jo-1 antibody); (c) **idiopathic interstitial pneumonias** — IPF, NSIP, COP, RB-ILD, DIP; (d) **granulomatous** — sarcoidosis; (e) **others** — lymphangioleiomyomatosis, pulmonary Langerhans cell histiocytosis. In India, **post-tuberculous fibrosis** is an important mimic.
3. **Clinical features:** insidious **progressive exertional dyspnoea and a dry cough**; **fine end-inspiratory "Velcro" crackles** at the bases; **digital clubbing** (about half of IPF cases); later cyanosis and signs of **cor pulmonale**. Search deliberately for extrapulmonary clues — arthritis, sclerodactyly, Raynaud's phenomenon, Gottron's papules, heliotrope rash, dry eyes and mouth.
4. **Distinguishing ILD from COPD and heart failure (Pathy's Table 42.3):** ILD gives a **dry cough with fine basal crackles**, a **restrictive spirometry pattern** and **impaired diffusing capacity (TLCO)**, with B-line artefacts on chest ultrasound; COPD gives obstruction with hyperinflation; kyphoscoliosis gives restriction with a **normal** diffusing capacity. Always ask about **industrial exposure and drug toxicity**.
5. **Investigations: HRCT chest is central** — a **usual interstitial pneumonia (UIP) pattern** (basal and subpleural reticulation with **honeycombing** and traction bronchiectasis, minimal ground glass) in the right clinical setting confirms IPF **without biopsy**. Pulmonary function shows **reduced FVC, reduced TLC, preserved or raised FEV_1/FVC and reduced TLCO**. Add an autoimmune panel (ANA, RF, anti-CCP, myositis panel), a hypersensitivity pneumonitis exposure history and precipitins, six-minute walk test with oximetry, and echocardiography for pulmonary hypertension. Bronchoalveolar lavage and surgical or cryobiopsy are reserved for uncertain cases — and are often inappropriate in the frail elderly.
6. **The multidisciplinary discussion (MDD)** between clinician, radiologist and pathologist is the recognised diagnostic gold standard for ILD.
7. **Management — general:** remove the causative exposure or drug; **smoking cessation**; treat gastro-oesophageal reflux and obstructive sleep apnoea; **vaccination**; supplemental oxygen for resting or exertional hypoxaemia; **pulmonary rehabilitation** — Pathy's cites Dowman et al. (Thorax 2017) showing clinically important improvements in six-minute walk distance, symptoms and quality of life after exercise training in ILD; treat cough and breathlessness palliatively (opioids); consider transplantation only in highly selected younger patients.
8. **Management — disease-specific: IPF is treated with antifibrotics, not steroids** — **pirfenidone** or **nintedanib** slow the rate of FVC decline. **Immunosuppression is harmful in IPF (PANTHER-IPF)** but is the mainstay in connective tissue disease-ILD, hypersensitivity pneumonitis and sarcoidosis (corticosteroids with mycophenolate, azathioprine or rituximab). **Nintedanib is licensed for systemic sclerosis-ILD (SENSCIS) and for progressive fibrosing ILD (INBUILD)**.
9. **Prognosis:** IPF is the most aggressive form — **median survival about 3–5 years from diagnosis**, worse than many cancers. **Acute exacerbations** of IPF carry very high mortality. Death is usually from progressive respiratory failure, acute exacerbation, pulmonary hypertension or lung cancer.
10. **Geriatric considerations:** comorbidity is the rule (emphysema in the **combined pulmonary fibrosis and emphysema (CPFE)** syndrome, coronary disease, pulmonary hypertension, reflux, lung cancer); antifibrotic drugs cause diarrhoea, nausea, weight loss and deranged liver function, all poorly tolerated in frail patients; and **early advance care planning and palliative care referral** are essential given the prognosis.

Latest Updates and Current Practice (2023–Present)

- **Nerandomilast (Jascayd)** — a preferential **phosphodiesterase-4B inhibitor** with antifibrotic and immunomodulatory effects — was **FDA-approved for IPF in October 2025** (the first new IPF drug in over a decade) and **for progressive pulmonary fibrosis (PPF) in December 2025**, on the strength of the **FIBRONEER-IPF and**

FIBRONEER-ILD trials (NEJM 2025). In FIBRONEER-ILD the mean FVC decline at 52 weeks was **−86 mL (18 mg) and −69 mL (9 mg) versus −152 mL with placebo**; it worked both as monotherapy and added to nintedanib or pirfenidone, with better tolerability (mild diarrhoea) than nintedanib.

- **"Progressive pulmonary fibrosis" (PPF)** has replaced the older term "progressive fibrosing ILD" and is now a formal, treatable entity defined by worsening symptoms, physiology or radiology despite management of the underlying ILD — the 2022 ATS/ERS/JRS/ALAT criteria remain the standard.
- **Current Practice Update — three points:** (1) The textbook treats ILD only as a differential diagnosis of COPD; current practice recognises it as a **treatable, antifibrotic-responsive disease** in its own right. (2) Where Pathy's offers only pulmonary rehabilitation and supportive care, there are now **three licensed antifibrotics** — pirfenidone, nintedanib and nerandomilast. (3) **Immunosuppression, once used empirically for "pulmonary fibrosis", is now contraindicated in IPF** and reserved for autoimmune and inflammatory ILD.

> **Examiner's Tip**
>
> Structure the answer as **classification → UIP pattern on HRCT → restrictive spirometry with low TLCO → antifibrotics for IPF, immunosuppression for autoimmune ILD**. The single sentence that separates a good answer from an average one is: "*Immunosuppression improves connective tissue disease-associated ILD but is harmful in IPF, where antifibrotics are the treatment of choice*." Quote **median survival 3–5 years in IPF** and mention **nerandomilast (2025)** to show currency. For the Indian angle, add hypersensitivity pneumonitis from bird exposure and bagassosis, and always exclude **post-tuberculous fibrosis**.

6. Respiratory Failure — Types, Causes and Management 15 marks

Pathy's addresses respiratory failure within the chapters on ageing of the respiratory system, COPD and pneumonia rather than as a stand-alone chapter; the answer below builds on that material and standard ERS/ATS and ESICM guidance.

High-Yield Points

Definition and Types

1. **Definition:** failure of the respiratory system to maintain adequate gas exchange, defined on arterial blood gas as **PaO_2 <60 mmHg (8 kPa)** breathing room air, with or without **$PaCO_2$ >50 mmHg (6.7 kPa)**.

Type	Blood gas	Mechanism	Typical causes
Type 1 (hypoxaemic)	↓PaO_2, normal or ↓$PaCO_2$; **widened A-a gradient**	**V/Q mismatch** and shunt; diffusion impairment	Pneumonia, pulmonary oedema, ARDS, pulmonary embolism, ILD, pneumothorax, COVID-19
Type 2 (hypercapnic / ventilatory)	↓PaO_2 with ↑**$PaCO_2$**; A–a gradient normal if purely hypoventilation	**Alveolar hypoventilation** — won't breathe, can't breathe, or increased dead space	COPD exacerbation, opioids and sedatives, obesity hypoventilation, neuromuscular disease, kyphoscoliosis, severe asthma (late)
Type 3 (perioperative)	Mixed	Atelectasis from reduced FRC and abdominal splinting after surgery	Post-operative, especially upper abdominal and thoracic surgery in the elderly
Type 4 (shock)	Mixed	Respiratory muscle **hypoperfusion**; ventilation used to redistribute blood flow	Cardiogenic, septic or hypovolaemic shock

3. **Acute vs chronic vs acute-on-chronic. Acute** develops over minutes to hours with an **uncompensated respiratory acidosis (low pH, normal bicarbonate)**. **Chronic** develops over days to years with **renal compensation — raised bicarbonate and near-normal pH**. **Acute-on-chronic** shows a raised bicarbonate with an acidotic pH and is the commonest pattern seen in an elderly COPD patient in the emergency room.

Why the Elderly Are Predisposed

4. **Structural:** loss of elastic recoil, alveolar enlargement, air trapping and hyperinflation; kyphosis and rib-cage stiffening reduce chest wall compliance and total lung capacity; loss of diaphragm curvature and respiratory muscle mass.
5. **Physiological:** higher respiratory rate with lower tidal volume → increased work of breathing → reduced exercise tolerance; closing volume encroaches on tidal breathing, worsening V/Q mismatch; **blunted ventilatory response to hypoxia and hypercapnia** means the older patient **decompensates suddenly and without warning**.
6. **Clinical:** lung "inflammageing", impaired cough and mucociliary clearance, sarcopenia of respiratory muscles, malnutrition, polypharmacy (sedatives, opioids, antipsychotics) and multimorbidity.

Clinical Features

7. **Hypoxaemia:** dyspnoea, tachypnoea, tachycardia, restlessness, confusion, **central cyanosis** (appears only when reduced haemoglobin >5 g/dL, so it is unreliable in anaemia), arrhythmias, and in chronic hypoxaemia — polycythaemia, pulmonary hypertension and cor pulmonale.
8. **Hypercapnia:** headache (worse in the morning), warm peripheries with a **bounding pulse**, **flapping tremor (asterixis)**, papilloedema, drowsiness progressing to **CO_2 narcosis** and coma. In the elderly, **delirium may be the only sign**.
9. **Signs of exhaustion demanding urgent escalation:** inability to speak in sentences, use of accessory muscles, paradoxical abdominal movement, a **falling** respiratory rate with worsening gases, and a deteriorating conscious level.

Investigations

10. **Arterial blood gas is mandatory** — pulse oximetry cannot detect hypercapnia and is unreliable in poor perfusion, anaemia and darker skin pigmentation. Calculate the **alveolar–arterial gradient** to separate hypoventilation (normal gradient) from V/Q mismatch or shunt (widened gradient).
11. Add chest radiograph, ECG, full blood count, urea and electrolytes, blood glucose, CRP, cultures, and where relevant **D-dimer or CTPA**, **BNP**, **echocardiography**, spirometry, sleep study, and drug levels or toxicology.

Management — General Principles

12. **Treat the underlying cause** — antibiotics for pneumonia, bronchodilators and steroids for COPD, diuretics for pulmonary oedema, anticoagulation for PE, naloxone for opioid toxicity, drainage of pneumothorax.
13. **Oxygen therapy is a drug and must be prescribed with a target range.** Target **SpO_2 94–98%** in most acutely ill patients, but **88–92% in those at risk of hypercapnic respiratory failure** (COPD, obesity hypoventilation, kyphoscoliosis, neuromuscular disease). Pathy's warns of "a small but definite risk in giving too much oxygen to a patient with long-standing CO_2 retention", causing depressed hypoxic drive, increased coronary and cerebral arterial resistance, and worsened acidosis. Delivery: nasal prongs 1–6 L/min, simple face mask 6–10 L/min, **Venturi mask for controlled FiO_2**, non-rebreather reservoir mask at ≥15 L/min in emergencies.
14. **Non-invasive ventilation (NIV/BiPAP) is the treatment of choice for acute hypercapnic respiratory failure.** Start when **pH <7.35 with $PaCO_2$ >45 mmHg despite maximal medical therapy**. It reduces mortality, need for intubation and length of stay, and is strongly evidence-based in **COPD exacerbation** and **cardiogenic pulmonary oedema** (where CPAP is equally effective). Typical settings: IPAP 10–16 cmH_2O, EPAP 4–6 cmH_2O, titrated by gases at 1 and 4 hours. **Contraindications:** respiratory arrest, facial trauma or surgery, vomiting, inability to protect the airway, haemodynamic instability, undrained pneumothorax, agitation or a low GCS.
15. **High-flow nasal oxygen (HFNO)** delivers heated humidified gas up to **60 L/min** with an FiO_2 of 0.21–1.0. It washes out nasopharyngeal dead space, generates a small PEEP effect, improves secretion clearance and is far better tolerated than a mask. The **ERS 2022 guideline** suggests HFNO over conventional oxygen and over NIV in **hypoxaemic** ARF, HFNO over conventional oxygen during breaks from NIV, and — importantly — **NIV should be tried first in COPD with hypercapnic ARF**. Pathy's already notes HFNO as "safe and effective in exacerbated COPD patients with both normocapnic and hypercapnic insufficiency", and specifically valuable **where there is a do-not-intubate order or where intermediate care is needed outside the ICU**.
16. **Invasive mechanical ventilation** when non-invasive support fails or is contraindicated: for ARDS use **lung-protective ventilation — tidal volume 6 mL/kg predicted body weight, plateau pressure <30 cmH_2O, appropriate PEEP**, and **prone positioning** for severe ARDS. Permissive hypercapnia is acceptable provided pH stays above about 7.20.
17. **Adjuncts:** chest physiotherapy and secretion clearance, cautious fluid balance (restrictive in ARDS without shock), nutrition, VTE prophylaxis, treatment of anaemia, avoidance of sedatives, delirium prevention and **early mobilisation** to prevent ICU-acquired weakness.
18. **Chronic respiratory failure:** long-term oxygen therapy for chronic hypoxaemia; **domiciliary NIV** for persistent daytime hypercapnia after a COPD admission, obesity hypoventilation syndrome, kyphoscoliosis and neuromuscular disease; pulmonary rehabilitation and nutritional support.

Ethical and Geriatric Dimension

19. **Decide the ceiling of care early and explicitly.** Base it on **premorbid functional status, frailty (Clinical Frailty Scale), cognition, comorbidity and the patient's own wishes** — never on chronological age alone. Document whether NIV is being used as a **bridge to recovery** or as the **ceiling of treatment**, and record any advance directive.
20. **Prognosis and palliation:** outcomes in the elderly are driven by the underlying diagnosis and premorbid function rather than age. Where reversal is not achievable, provide **opioids and benzodiazepines for refractory breathlessness**, a fan to the face, positioning, and early palliative care involvement.

Latest Updates (2023–Present)

- **SOHO trial (NEJM, March 2026)** — the largest randomised comparison to date (1116 patients with PaO_2/FiO_2 ≤200, respiratory rate >25 and pulmonary infiltrates) found **identical 28-day mortality of 14.6% with high-flow nasal oxygen and with standard oxygen**. This tempers the enthusiasm generated by FLORALI (2015) and has prompted a re-evaluation of HFNO as an automatic first-line therapy: it remains valuable for comfort and for reducing intubation in selected patients, but a mortality benefit is not established.
- **ESICM 2023 ARDS guideline** retained the recommendation that patients with acute hypoxaemic respiratory failure **not** due to cardiogenic pulmonary oedema or COPD exacerbation should receive **HFNO in preference to conventional oxygen therapy**.
- **Oxygen targets:** current consensus is to avoid both hypoxaemia and hyperoxia — maintain **SpO_2 above 92% and below 98%** in acute hypoxaemic failure, recognising that oximeter error ranges from −3% to +1% against true arterial saturation and is greater in darker skin pigmentation, anaemia and poor perfusion.
- **Awake prone positioning**, established during COVID-19, is now used selectively in non-intubated hypoxaemic patients, though tolerance is limited in frail and cognitively impaired older adults.
- **ARDS definition:** the **new global definition (2023)** permits diagnosis using **SpO_2/FiO_2 ≤315** and includes patients on HFNO ≥30 L/min, extending the diagnosis to resource-limited settings where arterial gases and

ventilators are scarce — directly relevant to Indian practice.

Current Practice Update

Issue	Textbook position (Pathy's 6e)	Current evidence (2023–2026)
Oxygen target in COPD	Target saturations of about 88–92%	Unchanged and firmly established
NIV threshold	Consider if **pH <7.35** despite maximal therapy	Unchanged; NIV remains first-line in hypercapnic ARF and is tried **before** HFNO in COPD
High-flow nasal oxygen	Noted as safe and effective; useful with do-not-intubate orders	Preferred over conventional oxygen in **hypoxaemic** ARF, but **SOHO (2026) found no mortality benefit**
ARDS diagnosis	Berlin definition (PaO_2/FiO_2, requires arterial gas and PEEP)	**New global definition 2023** allows SpO_2/FiO_2 ≤315 and HFNO-supported patients
Decision-making	Full functional and social assessment before hospital-at-home	Formal **frailty scoring** and advance care planning now embedded in escalation decisions

> **Examiner's Tip**
>
> Open with the numerical definition (**PaO_2 <60 mmHg ± $PaCO_2$ >50 mmHg**) and immediately draw the type 1/type 2 table — that table alone carries several marks. Show you can interpret gases: "*A raised bicarbonate with an acidotic pH indicates acute-on-chronic failure*." Quote the two thresholds examiners listen for: **oxygen target 88–92% in the CO_2 retainer** and **NIV when pH <7.35**. Then add the geriatric distinction: "*The ageing lung has a blunted ventilatory response to hypoxia and hypercapnia, so the older patient decompensates abruptly and delirium may be the only sign of CO_2 retention*." Finish with the ceiling-of-care sentence — based on frailty and patient wishes, never on age.

7. Long-Term Oxygen Therapy 7 marks

High-Yield Points

1. **Definition and purpose:** LTOT is the provision of supplemental oxygen at home for **at least 15 hours per day** to patients with chronic severe resting hypoxaemia. Its aim is to **prolong survival** by reversing hypoxic pulmonary vasoconstriction and preventing cor pulmonale, not merely to relieve breathlessness.
2. **Evidence base:** Pathy's cites the **Nocturnal Oxygen Therapy Trial (NOTT, Ann Intern Med 1980)** — LTOT for ≥15 hours daily **improved survival** in severe COPD with persistent hypoxaemia, and also improved polycythaemia and neuropsychiatric function. The companion British MRC trial showed the same. **Benefit is dose-dependent: the more hours per day, the greater the survival gain.**
3. **Indications (Pathy's criteria), assessed during a period of clinical stability in a current non-smoker:**
   - **PaO_2 <7.3 kPa (55 mmHg)**, or
   - **PaO_2 7.3–8.0 kPa (55–60 mmHg) with** evidence of **secondary polycythaemia, pulmonary hypertension, peripheral oedema or nocturnal hypoxaemia**.

   Referral should also be considered in **severe COPD and in anyone with signs of cor pulmonale**.
4. **Screening in practice:** a simple pulse oximetry screen — refer for arterial blood gas assessment if **SpO_2 <93%**, or **<95% with possible cor pulmonale**. **Two arterial blood gases at least three weeks apart**, taken when the patient has been stable for 8 weeks after any exacerbation, are needed before committing to LTOT.
5. **Prerequisites and safety:** the patient **must have stopped smoking** (fire risk and loss of benefit); optimise all medical therapy first; assess for the fire hazard of open flames, cooking and heaters. In Indian homes this includes explicit counselling about kerosene stoves, agarbatti, oil lamps and beedi smoking by family members.
6. **Delivery systems:** the **oxygen concentrator** is the standard home device (economical for continuous use, needs mains electricity — an important limitation where power supply is intermittent); **compressed gas cylinders** serve as back-up and for ambulatory use; **liquid oxygen** allows longer portable use but is expensive. Delivery is usually by nasal cannula at **1–4 L/min**, titrated to achieve **PaO_2 >8 kPa (60 mmHg)** or **SpO_2 ≥90%** at rest, with the flow rate typically increased by 1 L/min during sleep and exertion.
7. **Other forms of home oxygen (distinguish these clearly): ambulatory oxygen** for exercise desaturation in patients already on LTOT or who desaturate on walking; **short-burst oxygen** for episodic breathlessness — Pathy's notes it "may improve symptoms of breathlessness if exercise desaturation is noted", but it has little evidence and is not a substitute for LTOT; and **nocturnal oxygen** for isolated sleep hypoxaemia.
8. **Outcomes and prognosis:** approximately **50% of patients receiving LTOT survive three years**. Those with a **low BMI and multiple comorbidities die earlier**. In older adults with COPD the main predictors of mortality are **disability, low BMI, lung function and the use of LTOT** — that is, the need for LTOT is itself a marker of poor prognosis.
9. **Geriatric-specific issues (a Pathy's strength — use these to score):**
   - **Falls risk** from extra machinery and long lengths of tubing; ask an engineer to fit switching mechanisms diverting supply to individual rooms, so tubing does not trail across the floor.
   - **Cognitive impairment and poor manual dexterity** compromise safe use; this area is poorly studied.
   - **Care-home logistics** — staff training and support are essential; residents using concentrators overnight may need portable cylinders with a conserver if the day room is far from the bedroom.
   - **Uncertain quality-of-life benefit:** some studies found **no improvement** in quality of life or activities of daily living; a later study found small improvements at six months. Randomised trials have **never been repeated in advanced old age**, or in patients with isolated nocturnal or exertional hypoxia — an honest limitation worth stating.
10. **Follow-up:** review at 3 months, then annually — check adherence (hours used), repeat blood gases, confirm continued non-smoking, reassess the prescription, and review whether LTOT remains appropriate as the patient approaches the end of life.

Latest Updates and Current Practice (2023–Present)

- **LOTT trial (NEJM 2016) and subsequent guidance:** in COPD with **moderate** resting desaturation (SpO_2 89–93%) or isolated exercise desaturation, oxygen gave **no benefit** in time to death or first hospitalisation. The **ATS 2020 home oxygen guideline** and GOLD accordingly **restrict LTOT to severe resting hypoxaemia only** and make no recommendation for isolated moderate or exertional desaturation — a direct challenge to the more liberal short-burst practice described in older texts.
- **GOLD 2026** reaffirms LTOT for severe chronic resting hypoxaemia and adds guidance on **adherence-enhancing**

interventions for pharmacological and oxygen therapy (Eur Respir Rev 2024), recognising that prescribed hours and used hours differ widely.

- **Current Practice Update — three points:** (1) Pathy's suggests short-burst oxygen for symptomatic exercise desaturation; **current guidelines do not support this**, since LOTT showed no benefit outside severe resting hypoxaemia. (2) Pathy's records uncertainty about quality-of-life benefit; this is now settled — **LTOT prolongs survival but does not reliably improve quality of life**, and this must be explained honestly when consenting an older patient. (3) **Domiciliary NIV, not oxygen alone**, is now the treatment for persistent daytime hypercapnia after a COPD admission.

> **Examiner's Tip**
>
> Write the two indication thresholds as a boxed pair — **PaO_2 <7.3 kPa**, or **7.3–8.0 kPa with polycythaemia, pulmonary hypertension, peripheral oedema or nocturnal hypoxaemia** — and state **"at least 15 hours per day"** and the **NOTT trial** by name. Marks are also available for the three preconditions: **clinical stability, two gases three weeks apart, and confirmed smoking cessation**. Finish with a geriatric point no one else will write: "*Long tubing and extra machinery in the home create a falls hazard; a room-switching supply and staff training in care homes are part of a safe LTOT prescription.*"

8. Metered Dose Inhalers 7 marks

High-Yield Points

1. **Definition and principle:** a pressurised metered dose inhaler (pMDI) is a hand-held device that delivers a fixed, reproducible dose of drug suspended or dissolved in a **hydrofluoroalkane (HFA) propellant** as an aerosol. Optimal **lung deposition requires particles of 1–5 µm**; larger particles impact in the oropharynx, smaller particles are exhaled.
2. **Why inhaled delivery is preferred:** drug is delivered directly to the airway, giving a rapid onset at a much lower dose with fewer systemic adverse effects — important in the elderly, where systemic beta-agonist effects (tremor, tachyarrhythmia, hypokalaemia) and anticholinergic effects are poorly tolerated. GOLD states plainly that **inhaled agents are preferred over oral agents**.
3. **Correct technique — eight steps to write out:** (1) remove cap and inspect; (2) **shake well**; (3) breathe out gently and fully, away from the device; (4) place the mouthpiece between the teeth and seal the lips; (5) **begin a slow, deep inhalation and actuate the canister simultaneously**; (6) continue inhaling slowly over 3–5 seconds; (7) **hold breath for about 10 seconds**; (8) wait **30–60 seconds** before a second dose. **Rinse the mouth after inhaled corticosteroids.**
4. **The critical step is hand–breath coordination** — actuation must coincide with the start of a slow deep breath. This is precisely the step that fails in older patients.
5. **Barriers in the elderly (Pathy's, high-yield):**
   - Most cognitively intact, physically able older patients **can** use an inhaler, but **learning and coordination difficulties are present in about 20%**.
   - **Cognitive impairment dramatically impairs inhaler use: an MMSE score below 24 is associated with a very high risk of failure.** Remarkably, the **abnormal pentagon-copying test alone** (the constructional component of the MMSE) identifies patients unable to use inhaler devices — a simple bedside screen. Board and Allen's **"simple drawing test"** makes the same point.
   - **Poor manual dexterity** — weak hand grip, tremor, arthritis, impaired coordination and poor vision.
   - **Impaired executive function** limits the acquisition of inhaling skills, particularly in hospitalised patients.
   - Inadequate **inspiratory flow and respiratory muscle strength**, and reduced awareness of bronchoconstriction.
6. **The spacer (valved holding chamber) solves most of these problems.** It removes the need for coordination, slows the aerosol, allows the propellant to evaporate so particle size falls into the respirable range, **increases lung deposition and reduces oropharyngeal deposition**. Pathy's states directly that if an MDI is prescribed, **a spacer will reduce oropharyngeal candidiasis and dysphonia**. Use tidal breathing (5 breaths per actuation) in the frail; actuate one dose at a time; wash the spacer in detergent and **air-dry without rinsing or wiping** to reduce electrostatic charge; replace every 6–12 months. Add a **face mask** for patients who cannot form a lip seal.
7. **Choosing between devices — the guiding principle is that "the perfect device does not exist"; select on an individual basis.**
   - **pMDI** — cheap, portable, dose counter available, but needs coordination; **add a spacer**.
   - **Breath-actuated MDI (Autohaler, Easi-Breathe)** — removes the coordination problem but still needs adequate inspiratory flow; cannot be used with a spacer.
   - **Dry powder inhaler (DPI)** — no coordination needed, but requires a **forceful, deep inspiration** generating adequate peak inspiratory flow, which many frail or severely obstructed older patients cannot achieve; also needs manual dexterity to load.
   - **Soft mist inhaler (Respimat)** — slow-moving fine mist, low inspiratory flow requirement, good lung deposition; useful in the elderly but the cartridge needs loading and priming.
   - **Nebuliser** — needs only tidal breathing; reserve for very advanced disease or where inhaler technique is irretrievably poor. Pathy's notes nebulised bronchodilators "may help patients with very advanced COPD... or where the inhaler technique is so poor that no other relief is possible".
8. **Adherence and device burden:** the number of devices independently reduces adherence, so **fixed-dose combination inhalers should always be considered** to reduce discontinuation and misuse. Cognitive impairment reduces adherence to both drug and non-drug therapy; the MMSE, the Mental Deterioration Battery or a secondary memory test such as **Rey's 15-word test** identify COPD patients at risk of poor compliance.
9. **Practical rules for the clinic: ask every patient to bring their inhalers to every visit and demonstrate their technique**; retrain the patient and the caregiver at each visit; check the technique **before** escalating therapy (a GOLD 2026 emphasis); use adapters fitted to the inhaler end to help weak grip; and check the dose counter. **Short-acting oral beta-2 agonists exist for the few who cannot use any inhaler, but their unfavourable therapeutic window severely limits their use.**

10. **Adverse effects of MDI therapy:** oropharyngeal candidiasis and dysphonia with inhaled corticosteroids (prevented by a spacer and mouth rinsing); local irritation and cough from the propellant; paradoxical bronchospasm; systemic effects — tremor, palpitations and hypokalaemia with beta-2 agonists, dry mouth, urinary retention and glaucoma with anticholinergics, and skin thinning, cataract and osteoporosis with high-dose inhaled corticosteroids.

Latest Updates and Current Practice (2023–Present)

- **Low-global-warming-potential propellants:** pMDIs currently use HFA-134a and HFA-227ea, which are potent greenhouse gases. Manufacturers are transitioning to **HFA-152a and HFO-1234ze**, which cut the carbon footprint by over 90%; the first reformulated salbutamol and combination inhalers began reaching markets in 2025–2026 with **unchanged dosing and technique**. Examiners increasingly expect a line on the **environmental footprint of inhalers** (a pMDI carries roughly 10–30 times the carbon footprint of a DPI), balanced against the caution that **a DPI is useless if the patient cannot generate the inspiratory flow**.
- **Smart inhalers and digital adherence monitoring** — electronic dose counters with Bluetooth-linked reminders improve adherence and technique; GOLD 2026's new chapter on emerging technology and AI covers digital adherence tools, and a 2024 network meta-analysis (Eur Respir Rev) evaluated adherence-enhancing interventions for both inhaled and oxygen therapy.
- **Current Practice Update — three points:** (1) Pathy's recommends a spacer chiefly to reduce candidiasis and dysphonia; current guidance positions the spacer as the **default for every older pMDI user**, because it also compensates for poor coordination. (2) **Device selection is now formally guided by measured peak inspiratory flow**, not by clinician preference — low inspiratory flow contraindicates a DPI. (3) GOLD 2026 requires that **inhaler technique, adherence and device suitability be re-checked before any escalation of therapy**, making the inhaler review a formal treatment step rather than an afterthought.

> **Examiner's Tip**
>
> This is an easy 7 marks if you structure it as **principle → technique steps → barriers in the elderly → spacer → device selection → adverse effects**. Write the eight technique steps as a numbered list — examiners tick them off. The two facts that mark you out as a geriatrician are: **"an MMSE below 24 predicts a very high risk of inhaler failure, and the abnormal pentagon-copying test alone identifies patients who cannot use a device"**, and **"the perfect device does not exist — choose individually, and always ask the patient to bring their inhaler and demonstrate."** Add the practical Indian point that a spacer can be improvised from a 500 mL plastic bottle where a commercial device is unaffordable.

9. Extrapulmonary Tuberculosis 15 marks

Pathy's covers tuberculosis in the elderly within the chapter on the epidemiology of respiratory infections rather than as a dedicated extrapulmonary chapter; that material is combined below with the Indian Index-TB guidelines, NTEP technical and operational guidance, and current WHO recommendations.

High-Yield Points

Definition and Epidemiology

1. **Definition:** tuberculosis involving organs other than the lung parenchyma. By NTEP convention, **tuberculous pleural effusion and intrathoracic lymphadenopathy without parenchymal involvement are classified as extrapulmonary**, while miliary TB is classified as pulmonary. If both pulmonary and extrapulmonary sites are involved, the case is **notified as pulmonary**.
2. **Burden:** extrapulmonary TB accounts for roughly **16–20% of TB cases globally** and about **20–25% of notified cases in India**, with a rising proportion. It is commoner in **children, people living with HIV, those on immunosuppressants or anti-TNF agents, patients with diabetes or chronic kidney disease, and the elderly**.
3. **Ageing and TB (Pathy's):** tuberculosis causes more deaths worldwide than any other single infectious disease. Even in low-prevalence countries, infection rates in those over 65 are almost **50% higher** than at ages 25–44. **Rates are higher in institutional and nursing-home settings** than in the general aged population, and outbreaks originate from both residents and staff. In India, **multigenerational households** mean TB is readily brought into the family and spread within it. Pathy's records that **the lungs are the site of about three-quarters of tuberculous infections in the elderly**, so roughly a quarter are extrapulmonary.

Pathogenesis

4. During **primary infection**, bacilli disseminate by the **lymphohaematogenous route** and seed distant organs, where they remain dormant. Extrapulmonary disease is usually **reactivation** of these dormant foci when cell-mediated immunity wanes — from **immunosenescence**, malnutrition, diabetes, steroids, HIV, malignancy, chronic kidney disease or anti-TNF therapy.
5. Spread may also be **contiguous** (pleura from a subpleural focus, spine from a paravertebral abscess), or by **ingestion** (intestinal TB from swallowed sputum or unpasteurised milk). **Extrapulmonary disease is characteristically paucibacillary** — the single fact that explains almost every diagnostic difficulty in this topic.
6. **Ageing alters the immune response:** the hallmark response to TB is cell-mediated immunity coordinating macrophages and monocytes with adaptive T-cell responses. Ageing brings **reduced phagocytosis, maladaptive or reduced cytokine release and reduced T-cell production**, which explains both the atypical presentation and the reduced positivity of immunological tests in older people.

Sites and Clinical Features

Site	Clinical features	Key diagnostic pointers
Lymph node (commonest, ~35–40%)	Painless, firm, **matted** cervical nodes; may become fluctuant and form a **collar-stud abscess** or discharging sinus (scrofula)	**FNAC and Xpert Ultra**; caseating granuloma on cytology/histology; excision biopsy if FNAC inconclusive
Pleural	Fever, pleuritic pain, dyspnoea; usually a **unilateral exudative effusion**	**Lymphocyte-predominant exudate; ADA >40 IU/L**; low smear yield; **pleural biopsy** gives the highest yield
Abdominal (peritoneal, intestinal, nodal)	Ascites, pain, subacute obstruction, doughy abdomen; **ileocaecal** disease mimics Crohn's and caecal carcinoma	**Ascitic ADA >39 IU/L**, SAAG <1.1; CT abdomen; colonoscopic or laparoscopic biopsy
Osteoarticular (spine = **Pott's disease**, ~50% of skeletal TB)	Back pain, **gibbus** deformity, cold abscess, paraparesis; commonly **thoracolumbar**	**MRI spine** — disc-space narrowing with anterior vertebral body destruction and paravertebral abscess; CT-guided biopsy
CNS (meningitis, tuberculoma)	Subacute headache, fever, vomiting, **cranial nerve palsies (VI, III, VII)**, altered sensorium, seizures, hydrocephalus, stroke from vasculitis	**CSF: lymphocytic pleocytosis, high protein, low glucose, ADA >10 IU/L**; **Xpert Ultra on CSF**; contrast MRI shows **basal exudates**
Genitourinary	**Sterile pyuria**, dysuria, haematuria, epididymo-orchitis, infertility, tubo-ovarian mass	Three early-morning urine samples for AFB culture and NAAT; IVU/CT showing calyceal distortion or ureteric stricture
Pericardial	Effusion, tamponade, later **constrictive pericarditis** with raised JVP, ascites and Kussmaul's sign	Echocardiography; **pericardial fluid ADA >40 IU/L**; pericardial biopsy
Miliary / disseminated	Prolonged fever, weight loss, hepatosplenomegaly, **choroid tubercles** on fundoscopy, pancytopenia	**Millet-seed nodules on chest X-ray/HRCT**; bone marrow and liver biopsy with culture; always do lumbar puncture

7. **Presentation in the elderly is blunted and non-specific (Pathy's, from Perez-Guzman's meta-analysis):** older patients are **less likely to report fever, sweating and haemoptysis**, **more likely to present with dyspnoea**, and have a **lower likelihood of radiographic cavitation**. The commonest presenting picture is **unexplained weight loss, anorexia, fatigue and functional decline** attributed to "ageing" or malignancy. **Essentials of Clinical Geriatrics states the useful rule: suspect tuberculosis when an older patient is inexplicably failing.**

Diagnosis

8. **The governing principle is "tissue is the issue".** Obtain a sample from the affected site — FNAC, biopsy, pleural, ascitic, pericardial or cerebrospinal fluid — and send it for **three things together: AFB smear, mycobacterial culture, and molecular testing**. NTEP emphasises histopathological confirmation wherever a tissue sample can be obtained.
9. **Molecular tests are the recommended initial diagnostic test. Xpert MTB/RIF Ultra** simultaneously detects *M. tuberculosis* complex and rifampicin resistance in 2 hours; it is **significantly more sensitive than Xpert MTB/RIF in paucibacillary extrapulmonary samples** (for example in tuberculous meningitis, sensitivity around **68% versus 37%**, with 100% specificity for both). India's indigenous **TrueNat MTB/MTB Plus and MTB-RIF Dx** is a chip-based, battery-operated NAAT that is deployed to peripheral NTEP laboratories. **Interpret an Ultra "trace" result in the light of the clinical setting**, as rifampicin resistance is reported as indeterminate on a trace call.
10. **Culture on liquid medium (MGIT)** remains the reference standard and the only way to obtain full drug susceptibility testing; it takes **2–6 weeks**. **Line probe assays** give rapid genotypic susceptibility for first- and second-line drugs.
11. **Histopathology: caseating epithelioid granulomas with Langhans giant cells** is the classic finding; note that granulomas alone are not specific — the differential includes sarcoidosis, fungal infection, brucellosis and Crohn's disease.
12. **Biochemical markers:** ADA is a useful **adjunct**, not a confirmatory test — **pleural >40 IU/L, ascitic >39 IU/L, pericardial >40 IU/L, CSF >10 IU/L**. Combine with lymphocyte predominance and a low glucose.
13. **Imaging is essential to define extent:** ultrasound (nodes, ascites, cold abscess), CT (abdomen, chest, sinus tracts), **MRI (spine, brain)**, echocardiography, and PET-CT in occult disease.
14. **Tests of infection, not disease:** Pathy's is explicit that the **Mantoux test suggests active tuberculosis only when it produces a large induration with blebs; simple positivity or negativity neither confirms nor excludes active disease**. **IGRA (QuantiFERON) has not been well validated for active tuberculosis in the very old**, many of whom had lifetime contact with the organism; positivity rates are lower in the elderly than in younger people with the same exposure. **Never use TST or IGRA to diagnose or exclude active extrapulmonary TB.**

15. **Mandatory ancillary work-up in every case:** HIV testing, blood glucose/HbA1c for diabetes, chest radiograph to look for concurrent pulmonary disease (which determines infectivity), baseline liver and renal function, weight, and **notification on the Nikshay portal** — notification is legally mandatory in India for both public and private practitioners.

Treatment

16. **Standard NTEP regimen for drug-sensitive extrapulmonary TB: 2 months HRZE (intensive phase) followed by 4 months HRE (continuation phase)**, given **daily as weight-band fixed-dose combinations** under the NTEP. India moved from thrice-weekly to **daily therapy** nationwide, and ethambutol is retained in the continuation phase.

Site	Total duration	Notes
Lymph node, pleural, abdominal, genitourinary, pericardial	**6 months** (2HRZE / 4HRE)	Extension only for slow or poor response, individualised
CNS TB / tuberculous meningitis	**12 months** (2HRZE / 10HRE)	Use drugs with good CSF penetration; add corticosteroids
Osteoarticular / spinal TB	**12 months** (2HRZE / 10HRE)	Surgery for instability, cord compression or failure of medical therapy
Disseminated / miliary with CNS involvement	**12 months**	Always examine CSF before deciding duration

17. **Adjunctive corticosteroids** — one of the three priority recommendations of the Indian **Index-TB guidelines** (Central TB Division and DGHS, published in the *Indian Journal of Medical Research*). Steroids are **recommended in tuberculous meningitis (dexamethasone, tapered over 6–8 weeks — reduces mortality) and in tuberculous pericarditis** (reduces constriction and the need for pericardiectomy). They are **not** routinely recommended for lymph node or pleural disease.
18. **Paradoxical reaction** — clinical or radiological worsening (enlarging nodes, new effusions, expanding tuberculomas) after an initial response, caused by immune reconstitution. It occurs in up to **25% of lymph node TB** and is **not** treatment failure: continue the same regimen, exclude drug resistance and non-adherence, and add corticosteroids or aspiration if symptoms are severe.
19. **Drug-resistant extrapulmonary TB:** managed under the **PMDT** arm of the NTEP. Since **2024, India has adopted the all-oral 6-month BPaLM regimen (bedaquiline, pretomanid, linezolid, moxifloxacin)** for eligible MDR/RR-TB and pre-XDR-TB. **BPaLM is not used for CNS, osteoarticular or disseminated TB**, where CSF and bone penetration are unproven — these need longer individualised regimens.
20. **Monitoring:** clinical response, weight gain and adherence at every visit; **baseline and monthly liver function** (older age, malnutrition, alcohol, hepatitis B or C and concurrent hepatotoxic drugs all raise the risk of drug-induced hepatitis); **monthly visual acuity and colour vision on ethambutol** (particularly hazardous in the elderly with cataract, glaucoma or renal impairment — dose must be adjusted for creatinine clearance); and **pyridoxine 10–25 mg daily with isoniazid** in all older, diabetic, malnourished, alcohol-dependent or renally impaired patients, to prevent peripheral neuropathy.
21. **Rifampicin drug interactions matter more in the elderly** because of polypharmacy — rifampicin is a potent CYP3A4 inducer and reduces the effect of **warfarin and DOACs, statins, sulfonylureas, corticosteroids, calcium channel blockers, antiepileptics, digoxin and antiretrovirals**. Review the entire drug chart at the start of therapy.
22. **Programme support in India:** treatment is free under the NTEP with **directly observed treatment and treatment adherence technologies (99DOTS, video-DOT, MERM boxes)**; case-based notification on **Nikshay**; **Ni-kshay Poshan Yojana** nutritional support by direct benefit transfer, **increased from ₹500 to ₹1,000 per month from November 2024**; and **Ni-kshay Mitra** community adoption under the Pradhan Mantri TB Mukt Bharat Abhiyan. Screen and offer **TB preventive treatment** to household contacts after excluding active disease.

Latest Updates (2023–Present)

- **WHO consolidated guidelines updated through 2025** now recommend **Xpert MTB/RIF Ultra as the initial diagnostic test for extrapulmonary specimens**, including CSF, lymph node aspirate and tissue, replacing smear microscopy as the first test. Sensitivity in extrapulmonary samples is highest in **CSF, bone and joint, and cutaneous specimens** and in **FNA tissue** (about 79%), and lowest in pleural fluid.
- **India's National Guidelines for Management of Drug-Resistant TB (27 March 2025)** and **National Guidance on Differentiated TB Care (March 2025)** are the current NTEP reference documents; the Central TB Division has also issued a dedicated **Training Module on Extrapulmonary Tuberculosis and an EPTB Standard Treatment Workflow**. Differentiated TB care formally stratifies patients by severity and risk — identifying the malnourished, elderly and comorbid for intensified support and inpatient care.

- **TB Mukt Bharat Abhiyan:** following the **100-Day TB Mukt Bharat Abhiyan (launched 7 December 2024)** across high-burden districts, a further **2026 campaign** continues intensified case-finding using portable handheld X-ray with AI-based reading, upfront NAAT, and nutritional support. India's national target for TB elimination remains **2025, five years ahead of the SDG target of 2030**.
- **Shorter regimens:** WHO conditionally recommends a **6-month intensified regimen for tuberculous meningitis** as an alternative to the standard 12 months in patients without drug resistance; **BPaLM** is now the preferred 6-month all-oral regimen for MDR/RR-TB, adopted by NTEP in 2024 — but **excluding CNS, osteoarticular and disseminated disease**.
- **Persisting quality gap:** a 2025 multicentric Indian cohort found that **76% of EPTB diagnoses were made clinically or radiologically without microbiological confirmation**, and only **29% had histopathological confirmation**, despite NTEP guidance — a direct reflection of barriers in tissue sampling and processing, and a legitimate point of criticism to raise in a viva.

Current Practice Update

Issue	Textbook position (Pathy's 6e)	Current evidence and NTEP practice (2023–2026)
Initial diagnostic test	**AFB smear and culture remain the gold standard**; no clear evidence that detection rates are lower in the elderly	Culture remains the reference standard, but **Xpert Ultra is the recommended initial test** on all extrapulmonary specimens
Value of IGRA	"Not extensively documented" for active TB in the very old	Position unchanged and now explicit: **IGRA and TST must not be used to diagnose or exclude active TB**
Drug-resistant disease	Not addressed for extrapulmonary sites	**All-oral 6-month BPaLM** for eligible MDR/RR-TB (NTEP 2024); **not for CNS, bone or disseminated disease**
Duration for CNS and bone TB	Not specified	**12 months** standard; WHO now offers a conditional **6-month intensified alternative for TB meningitis**
Adjunctive steroids	Not addressed	**Index-TB: recommended in TB meningitis and pericarditis**, not routinely elsewhere
Programme support	Not applicable	**Ni-kshay Poshan Yojana raised to ₹1,000/month (Nov 2024)**; mandatory Nikshay notification; differentiated TB care

> **Examiner's Tip**
>
> Anchor the answer on one sentence: **"Extrapulmonary TB is paucibacillary, so tissue is the issue — every accessible site must be sampled for smear, culture and Xpert Ultra together."** Then guarantee marks with numbers: **ADA cut-offs (pleural 40, ascitic 39, pericardial 40, CSF 10 IU/L)**, **durations (6 months, extended to 12 for CNS and bone)**, and the **two indications for steroids (meningitis and pericarditis)**. Add the Pathy's geriatric line — "*older patients report less fever, sweating and haemoptysis, present more often with dyspnoea, and cavitate less often*" — and the clinical rule from Essentials of Clinical Geriatrics: "*suspect tuberculosis when an older patient is inexplicably failing*." Finish with the programme detail (Nikshay notification, Ni-kshay Poshan Yojana ₹1,000/month) that shows you practise in India.

Extra Points to Remember — Common Sub-Questions

- **"Cold abscess"** — a tuberculous abscess without the classical signs of acute inflammation (no heat, no redness, minimal pain), typical of spinal and lymph node disease. It tracks along fascial planes and may present far from its origin (psoas abscess presenting in the groin).
- **Pott's spine — classic radiological triad:** disc-space narrowing, anterior vertebral body destruction with wedging (gibbus), and paravertebral soft-tissue shadow. **Relative preservation of the disc** early on distinguishes it from pyogenic spondylodiscitis; skip lesions are characteristic.
- **Tuberculous meningitis staging (British MRC): Stage I** — conscious, no neurological deficit; **Stage II** — conscious with deficit or GCS 11–14; **Stage III** — GCS <10 or dense deficit. **Outcome correlates directly with the stage at which treatment starts**, which is why empirical treatment must not await confirmation.
- **Lymph node TB vs lymphoma vs metastasis in an older patient:** TB nodes are matted with caseation on FNAC; lymphoma nodes are rubbery, discrete and require excision biopsy for architecture; metastatic nodes are hard and fixed with a primary elsewhere. **Never rely on FNAC alone to exclude lymphoma — excision biopsy is required.**
- **Drug-induced hepatitis:** stop all hepatotoxic drugs if ALT >3× upper limit with symptoms or >5× without; use a non-hepatotoxic bridging regimen (streptomycin/an injectable, ethambutol, levofloxacin) if treatment cannot be interrupted; reintroduce sequentially once ALT falls below twice normal. **Risk is higher in the elderly, the malnourished and in hepatitis B/C carriers** — a common combination in Indian practice.
- **Nursing homes and long-term care:** Pathy's and Essentials both call for **tuberculosis screening programmes in long-term care facilities**, since the older cohort lived through a high-incidence era, was rarely given isoniazid prophylaxis, and reactivates with malnutrition and comorbidity. Screen residents and staff, and remember that outbreak sources may be either.

Appendix — Rapid Revision Grid

Numbers and thresholds most likely to be asked. Read this last on the night before the examination.

Numerical thresholds

Parameter	Value
COPD diagnosis	Post-bronchodilator **FEV_1/FVC <0.70** (LLN preferred in the elderly)
GOLD spirometric grades 1–4	FEV_1 **≥80 / 50–79 / 30–49 / <30** % predicted
GOLD Group E (2026)	**≥1** moderate or severe exacerbation in the past year
Symptom cut-offs	**mMRC ≥2** or **CAT ≥10**
Eosinophil thresholds for ICS	Favour **≥300/µL**; avoid **<100/µL**
Normal vs susceptible-smoker FEV_1 decline	**25–30 mL/year** vs **>50 mL/year**
Reversibility indicating asthma	**>200 mL** rise in FEV_1; PEF variability **>20%**
NIV threshold in COPD exacerbation	**pH <7.35** despite maximal therapy
Oxygen target in CO_2 retainers	**SpO_2 88–92%** (94–98% in others)
Respiratory failure	**PaO_2 <60 mmHg (8 kPa) ± $PaCO_2$ >50 mmHg (6.7 kPa)**
LTOT indications	**PaO_2 <7.3 kPa**, or **7.3–8.0 kPa** with polycythaemia, pulmonary hypertension, oedema or nocturnal hypoxaemia
LTOT minimum daily use / survival	**≥15 hours/day**; about **50% survive 3 years**
Age-adjusted D-dimer (age >50)	**Age × 10 µg/L** (ADJUST-PE, JAMA 2014)
Revised Geneva probability bands	Low **0–3**, intermediate **4–10**, high **>10**
Minimum anticoagulation after PE	**3 months**; extended/indefinite if unprovoked or persistent risk factor
Pneumonia — absent fever/cough in elderly	**30–40%** of cases
Pneumonia — radiographic clearance	Up to **12 weeks** in older adults
ADA cut-offs in TB	Pleural **>40**, ascitic **>39**, pericardial **>40**, CSF **>10** IU/L
EPTB treatment duration	**6 months**; **12 months** for CNS and osteoarticular disease
MMSE and inhaler use	**<24** predicts a very high risk of inhaler failure
Optimal aerosol particle size	**1–5 µm**

Named trials, guidelines and eponyms

Name	What it established
NOTT (1980) and MRC	LTOT ≥15 h/day improves survival in hypoxaemic COPD
LOTT (2016)	No benefit of oxygen in moderate resting or isolated exercise desaturation
ADJUST-PE (2014)	Age-adjusted D-dimer safely excludes PE in older patients
PESI / sPESI	Validated short-term mortality prediction in acute PE, including the elderly
HI-PEITHO (NEJM 2026)	Catheter-directed thrombolysis superior to anticoagulation alone in intermediate-high-risk PE
2026 AHA/ACC PE Guideline	Five-tier Clinical Categories A–E; PERTs, LMWH over UFH, DOACs over VKA (all Class 1)
BOREAS / NOTUS	Dupilumab reduces COPD exacerbations by about 30% in eosinophilic disease
METREX / METREO / MATINEE	Mepolizumab reduces COPD exacerbations by about 18–21%
GOLD 2026	One moderate exacerbation defines Group E; disease activity as a target; biologics; AI chapter
FIBRONEER-IPF / FIBRONEER-ILD (2025)	Nerandomilast (PDE4B inhibitor) slows FVC decline in IPF and progressive pulmonary fibrosis
INBUILD / SENSCIS	Nintedanib in progressive fibrosing ILD and in systemic sclerosis-ILD
PANTHER-IPF	Triple immunosuppression is **harmful** in IPF
CAPE COD (NEJM 2023)	Hydrocortisone reduces mortality in severe community-acquired pneumonia
FLORALI (2015) / SOHO (NEJM 2026)	Early promise of HFNO not confirmed — SOHO found identical 28-day mortality (14.6%) vs standard oxygen
ERS 2022 HFNC guideline	HFNO over conventional oxygen and over NIV in hypoxaemic ARF; **try NIV first in hypercapnic COPD**
Index-TB guidelines (IJMR)	India's EPTB guidance — Xpert in diagnosis, adjunct steroids, treatment duration
BPaLM (NTEP 2024)	6-month all-oral MDR/RR-TB regimen; excludes CNS, bone and disseminated disease
ACIP October 2024 (MMWR Jan 2025)	Pneumococcal conjugate vaccine for all PCV-naive adults from **age 50**
BODE index	BMI, Obstruction, Dyspnoea, Exercise capacity — validated prognostic index in COPD
Langhans giant cell / caseating granuloma	Histological hallmark of tuberculosis
Pott's disease, gibbus, cold abscess	Spinal tuberculosis eponyms
S1Q3T3	Classic but uncommon ECG pattern in pulmonary embolism

Six lines to carry into every respiratory answer

1. The ageing lung has **reduced elastic recoil, a stiffer chest wall and a blunted ventilatory response to hypoxia and hypercapnia** — so decompensation is abrupt and warning signs are few.
2. **Presentation is atypical:** delirium, falls, functional decline and tachypnoea replace fever, cough and pleuritic pain.
3. **Spirometry is achievable in about 85% of older adults;** cognitive impairment is the commonest reason for an inadequate test.
4. **Treatment success is judged by symptoms, exercise tolerance and activities of daily living, not by change in FEV_1.**
5. **Check inhaler technique before escalating any therapy** — and check cognition before blaming the drug.
6. **Decide the ceiling of care by frailty, function and the patient's wishes — never by chronological age — and involve palliative care early.**

MD GERIATRIC MEDICINE • EXAM REVISION SERIES

Geriatric Nephrology & Acid–Base

Acute Kidney Injury • Drug-Induced Renal Impairment • Metabolic Acidosis

Q1. Causes and treatment of acute kidney injury in an elderly male *(15 marks)*
Q2. Drug-induced renal impairment in the elderly *(15 marks)*
Q3. Metabolic acidosis *(7 marks, with 15-mark expansion)*

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th ed. • Kane's Essentials of Clinical Geriatrics
Supplemented with guideline and trial evidence to August 2026 • Indian conventional units throughout

QUESTION 1

Causes and treatment of acute kidney injury in an elderly male

15 MARKS

High-Yield Points

A. Definition and Why the Old Kidney Is Vulnerable

1. **AKI** is an abrupt, potentially reversible fall in glomerular filtration over hours to days, with retention of nitrogenous waste. Standard criteria: rise in serum creatinine by **≥0.3 mg/dL in 48 hours**, or **≥1.5 times baseline within 7 days**, or urine output **<0.5 mL/kg/hour for 6 hours**.
2. **Tubular frailty** is the key ageing change — tubular cells in the elderly injure easily, progress readily to **acute tubular necrosis (ATN)**, and recover slowly. If the kidney has not recovered by about **3 months**, it is left as chronic kidney disease.
3. AKI is **commoner in older adults** because of frequent systemic illness (diabetes, myeloma), **polypharmacy**, and the renal ageing process itself. The cause is **usually multifactorial**, not single.
4. Ageing reduces urine concentrating power (falls about **30 mOsmol/kg per decade**), raises the thirst threshold, and lowers total body water to about **54%** of body weight (65% in the young) — so **dehydration develops very easily**.
5. **Renal dysautonomia** and loss of the autonomic vascular reflex mean the aged kidney is damaged during both hypotensive and hypertensive episodes.

B. Causes — Classification (write this as a table in the exam)

6. **Prerenal: dehydration is the main cause**; also haemorrhage and shock (cardiogenic and septic).
7. **Renal (intrinsic):** ATN from persisting prerenal causes or from **nephrotoxins** (aminoglycosides, contrast); rapidly progressive damage from primary or secondary glomerular disease; **acute interstitial nephritis**.
8. **Postrenal (obstructive):** stones, tumour, stricture and — the key one in a male — **prostatic hypertrophy**.
9. **Renal vasculitis** becomes commoner with age and is probably the commonest primary cause of renal failure in older adults; granulomatosis with polyangiitis and microscopic polyangiitis both rise with age. **Crescentic glomerulonephritis** peaks at **60–79 years** and typically presents as rapidly evolving AKI.
10. Vascular causes: renovascular atherosclerosis and ischaemic nephropathy; **reversible renal failure after an ACE inhibitor** in bilateral renal artery stenosis; **intrarenal atheroembolism**, from which the kidney rarely recovers.
11. **Urinary tract infection / pyelonephritis** is the commonest infection in the elderly, and its pathogenesis is strongly linked to obstructive uropathy; risk is raised further by urethral and vaginal atrophy, bed-rest puddling and catheterisation.
12. Add in a man specifically: **myeloma kidney**, tumour lysis syndrome, rhabdomyolysis after a long lie, and heat-related illness.

C. The Male-Specific Trap — Obstructive Uropathy

13. Prostatic hypertrophy occurs to some degree in nearly all ageing men; in a proportion it causes **slow outflow obstruction** with gradual loss of kidney function.
14. It is often recognised **too late, because the patient becomes polyuric rather than oliguric**. By the time obstruction is diagnosed, damage may be irreversible, and relief of obstruction restores function only partially.

D. Assessment

15. **Urinary indices behave differently in the elderly:** a high urinary sodium, fractional excretion of sodium or fractional excretion of urea **does not exclude prerenal AKI**, because the aged kidney normally loses sodium and urea.
16. **Serum creatinine underestimates the damage.** Renal function falls by about **50%** before creatinine rises, and reduced muscle mass plus net tubular creatinine reabsorption in the elderly delay the rise further.
17. Practical work-up: volume status and postural blood pressure, complete drug chart, bladder scan and ultrasound KUB for obstruction, urinalysis with microscopy, serum potassium and bicarbonate, creatine kinase, serum and urine protein electrophoresis, and ANCA / anti-GBM if a rapidly progressive picture is suspected.

E. Treatment

18. **Prerenal and postrenal causes matter most** — their early identification and treatment may **prevent the development of, or reverse, established AKI**. Catheterise or place a nephrostomy promptly; restore extracellular volume; treat sepsis; stop nephrotoxic drugs.
19. Correct complications: hyperkalaemia (the elderly are already predisposed because of low aldosterone and reduced tubular response, and worsen further on **NSAIDs, ACE inhibitors, beta blockers and potassium-sparing diuretics**), metabolic acidosis and fluid overload. Adjust every drug dose to the measured GFR.
20. Specific therapy: withdraw the culprit drug in interstitial nephritis, with steroids if needed; **steroids with cyclophosphamide** for vasculitis and crescentic glomerulonephritis, used as in younger adults but with closer attention to side effects.

21. **Dialysis:** temporary or permanent support may be needed. AKI is treated much the same in old and young, but older patients are **more vulnerable to dialysis-related complications — haemodynamic instability, bleeding and disequilibrium syndrome**.
22. **Prognosis:** **age by itself is not an important determinant of survival in AKI**. Failure to recover by about 3 months leaves chronic kidney disease.
23. **Prevention is paramount:** maintain an adequate extracellular volume and tailor drug dosing to GFR. Perioperatively, estimate GFR (CKD-EPI is regarded as most accurate, Cockcroft–Gault as most sensitive), stop nephrotoxic drugs before surgery, review diuretics against the planned procedure, titrate aminoglycoside dosing intervals to plasma levels, and optimise renal perfusion with haemodynamic monitoring.

Latest Updates (2023–Present)

- **KDIGO 2026 AKI/AKD Guideline (public review draft, March 2026)** — the first major revision since 2012, considering evidence to June 2025. It replaces "AKI alone" with an **AKI → AKD → CKD continuum**. **Acute kidney disease (AKD)** covers abnormality persisting up to 3 months, and AKD following AKI is separated from AKD without AKI.
- **Three-axis staging** is proposed: **C** (serum creatinine), **U** (urine output) and **B** (damage biomarker, reported as B− or B+). This lets a patient be "biomarker-positive" before creatinine moves.
- **Cystatin C is accepted as an alternative functional criterion** (≥1.5× baseline within 7 days) when creatinine is unreliable — directly relevant to **sarcopenic older adults**. **Kinetic eGFR** is suggested in hospitalised patients when a GFR estimate is needed under non-steady-state conditions.
- New content on **validated risk-prediction models, electronic AKI alerts, urine microscopy as part of evaluation, drug and nephrotoxin stewardship**, and structured **post-AKI follow-up** to reduce later CKD and cardiovascular events.
- Terminology has shifted from "contrast-induced nephropathy" to **contrast-associated AKI (CA-AKI)**, reflecting multifactorial causation rather than pure contrast toxicity; main risks are eGFR <60 mL/min/1.73 m², diabetes, volume depletion, high contrast volume and the intra-arterial route.
- **Sick-day medication guidance** (international modified-Delphi consensus, AJKD) is now standard for community-acquired AKI prevention: temporarily withhold volume-depleting and nephrotoxic drugs during acute dehydrating illness, and treat **restarting them as being as important as stopping them**.
- **Balanced crystalloids** are generally preferred to 0.9% saline for large-volume resuscitation, avoiding hyperchloraemic acidosis; low-dose dopamine, mannitol and routine loop diuretics remain of no benefit for AKI prevention or treatment.

Current Practice Update

Issue	Textbook position	Current evidence (2023–2026)
Framework	AKI described as a discrete event, with CKD if no recovery at ~3 months	Formal **AKI–AKD–CKD continuum**, with AKD as a named intermediate stage requiring its own follow-up
Diagnosis	Serum creatinine and urinary indices, with the caveat that they mislead in the elderly	Creatinine + urine output + **damage biomarkers**; **cystatin C** when muscle mass is low; kinetic eGFR in unstable patients
Detection	Clinical suspicion by the treating team	**Electronic AKI alerts** and validated risk-prediction models built into hospital systems
Contrast	Contrast listed as a nephrotoxin	**Contrast-associated AKI**; risk-stratified, lower contrast volumes; prophylaxis mainly isotonic fluid, not N-acetylcysteine
Prevention	Maintain volume, dose drugs to GFR	Same core, plus formal **nephrotoxin stewardship, pharmacist-led review and sick-day rules**
After recovery	Recovery or progression to CKD	**Structured post-AKI follow-up** is now a guideline recommendation, since AKI survivors carry excess CKD, cardiovascular and mortality risk

Exam One-Liners

- **Commonest cause of AKI in the elderly:** dehydration (prerenal).
- **Commonest intrinsic lesion:** acute tubular necrosis.
- **Commonest primary cause of renal failure in older adults:** renal vasculitis.
- **Crescentic glomerulonephritis** peaks at 60–79 years and presents as rapidly evolving AKI.
- **Obstruction in an elderly male presents with polyuria, not oliguria** — the single most examined trap.
- A raised FENa does **not** exclude prerenal AKI in the elderly.

- Age **per se** is not an important determinant of survival in AKI.
- Older patients are more prone to **intradialytic hypotension, bleeding and disequilibrium syndrome**.
- Non-recovery at 3 months = chronic kidney disease.

Extra Recall Points — Recurring Topic

Mnemonics

- **Causes — "3 P's": P**re-renal (dehydration), **P**arenchymal (ATN, AIN, vasculitis), **P**rostate (obstruction). In an elderly male, always finish with the prostate.
- **Reversible drivers — "DAMN": D**iuretics, **A**CE inhibitors/ARBs, **M**etformin, **N**SAIDs — the four to stop at the bedside on day one.
- **Bedside actions — "STOP-AKI": S**epsis treated, **T**oxins stopped, **O**ptimise perfusion and volume, **P**revent obstruction (catheterise/scan).

Numerical Anchors

- Creatinine rise **≥0.3 mg/dL in 48 h** or **≥1.5× baseline in 7 days**; urine output **<0.5 mL/kg/h × 6 h**.
- Concentrating capacity falls **~30 mOsmol/kg per decade**; minimum urine osmolality **92 vs 52 mOsmol/kg** (old vs young); maximum free-water clearance **5.9 vs 16.2 mL/min**.
- Total body water **54% vs 65%** of body weight.
- Renal function must fall **~50%** before creatinine rises.
- Non-recovery window: **3 months**. Dialysis in CKD when GFR **<10 mL/min**.

Examiner Traps

1. Writing "oliguria" for obstructive uropathy in a man — it is classically **polyuric**.
2. Using FENa >1% to call it ATN in an 80-year-old — the aged kidney loses sodium anyway.
3. Saying "old age makes AKI fatal" — age itself is not an important survival determinant.
4. Forgetting that the cause is **usually multifactorial**; listing only one.
5. Quoting a normal creatinine as reassurance in a sarcopenic patient.
6. Omitting **renal vasculitis**, which is the commonest primary cause of renal failure in this age group.

15-Second Answer Skeleton

Define AKI → ageing kidney is primed (tubular frailty, dehydration-prone, dysautonomia) → causes in three columns: **prerenal / renal / postrenal** → stress dehydration and prostate → assessment pitfalls (creatinine and FENa unreliable) → treatment: volume, sepsis, stop nephrotoxins, relieve obstruction, correct potassium and acidosis, dose to GFR, dialysis if needed → prognosis and prevention → KDIGO 2026 AKI/AKD continuum with biomarkers and cystatin C.

QUESTION 2

Drug-induced renal impairment in the elderly

15 MARKS

High-Yield Points

A. Why the Elderly Are Uniquely Susceptible

1. Renal function declines predictably with age, so drugs and their active metabolites that are cleared by the kidney are **eliminated more slowly, have longer half-lives, and accumulate to toxic steady-state concentrations**.
2. **Serum creatinine is an unreliable guide.** Muscle mass and daily endogenous creatinine production both fall, so creatinine may be normal when renal function is substantially reduced. The aged kidney also shows **net tubular reabsorption of creatinine**, which further underestimates true GFR.
3. There is **wide interindividual variation** in the rate of decline. Applying the "average 50% fall between 20 and 90 years" to an individual patient causes over- or under-dosing.
4. Non-age factors are often just as important: **state of hydration, cardiac output and intrinsic renal disease**.
5. **Tubular frailty** means the elderly tubule progresses easily to acute tubular necrosis and recovers slowly — a small nephrotoxic insult produces a large injury.
6. Pharmacokinetics are altered across the board — bioavailability, volume of distribution, GFR-dependent excretion, and the time to steady state (four half-lives). With polypharmacy, older people are **predisposed to drug toxicity**.

B. Patterns of Injury — Classify by Mechanism

7. **Haemodynamic (functional) injury:** **NSAIDs** block prostaglandin-mediated afferent vasodilatation; **ACE inhibitors and ARBs** remove efferent arteriolar tone; **diuretics** deplete intravascular volume. In bilateral renal artery stenosis, an ACE inhibitor can precipitate **reversible renal failure**. This triple combination is the classic community "triple whammy".
8. **Acute tubular necrosis:** nephrotoxins, classically **aminoglycosides**; also contrast, vancomycin, amphotericin, cisplatin, calcineurin inhibitors.
9. **Acute interstitial nephritis (AIN):** mainly a **delayed hypersensitivity response** to drugs — NSAIDs and diuretics. Most reported patients are elderly. Renal abnormalities usually improve once the drug is withdrawn, with or without steroids, but chronic kidney disease or even ESRD may follow.
10. **Proton-pump inhibitors** (omeprazole, esomeprazole, pantoprazole) are increasingly recognised as a cause of AIN. Diagnosis needs a high index of suspicion; renal biopsy shows **eosinophilic infiltration**, and prompt steroid therapy after confirmation restores function. For this and other reasons PPIs have become a **target of deprescribing** in older adults.
11. **Chronic analgesic nephropathy:** patients taking NSAIDs for months or years may develop **papillary necrosis, chronic interstitial nephritis, or end-stage renal disease**.
12. **Glomerular injury:** in some older people **membranous nephropathy** is related to drug ingestion (or to underlying malignancy in about 20%, mainly lung or colon adenocarcinoma); **minimal change disease** can be associated with NSAIDs.
13. **Electrolyte and acid–base toxicity:** on diuretics the elderly become hypokalaemic faster than the young; conversely they are predisposed to **hyperkalaemia on NSAIDs, ACE inhibitors, beta blockers and potassium-sparing diuretics**. **Metformin** can cause lactic acidosis — avoid in renal insufficiency and heart failure, measure creatinine clearance before starting in those aged 80 and over, and stop during volume-depleting illness and before surgery.
14. **Perioperative nephrotoxicity:** ACE inhibitors, diuretics and NSAIDs are the common culprits. Anaesthetic agents have little direct renal effect but reduce cardiac output, causing renal vasoconstriction and falling perfusion; prolonged enflurane or isoflurane generates fluoride, and sevoflurane at low fresh-gas flows generates compound A, though neither is usually a clinical problem.

C. Presentation and Diagnosis

15. Presentation is often **silent or atypical** — a rising creatinine, falling urine output, or a geriatric syndrome such as **delirium, falls, anorexia or unexplained weight loss**.
16. **Red flag:** AKI appearing shortly after introduction of a new drug — PPI, NSAID, antibiotic, diuretic or allopurinol — should be treated as drug-induced until proved otherwise.
17. Take a **complete drug history including over-the-counter analgesics and traditional or herbal preparations**, and establish the temporal relationship to drug initiation.
18. Estimate GFR with an eGFR equation rather than creatinine alone: **CKD-EPI is regarded as most accurate, Cockcroft–Gault as most sensitive** for dosing. For drugs with a narrow therapeutic-to-toxic ratio, measure actual creatinine clearance and drug blood levels.
19. **Renal biopsy** confirms interstitial nephritis when the diagnosis is uncertain and steroids are being considered.

D. Management and Prevention

20. **Withdraw the offending drug** — this is the single most effective intervention. Correct volume depletion, treat hyperkalaemia and acidosis, and dose all remaining drugs to the measured GFR.
21. **Corticosteroids** for biopsy-confirmed drug-induced AIN, given promptly, produce recovery of renal function; delay allows fibrosis.
22. **Prevention is the exam answer:** individualise treatment, use **low and slowly increasing doses**, and avoid polypharmacy. Alter dosing intervals for renally excreted drugs such as aminoglycosides and titrate to plasma levels. Stop nephrotoxic drugs before surgery and review diuretics against the patient's volume status and the planned procedure. Deprescribe PPIs and long-term NSAIDs.

Latest Updates (2023–Present)

- The **KDIGO 2026 AKI/AKD draft guideline** devotes a full chapter to **drug- and nephrotoxin-associated AKI**, covering therapeutic drug monitoring, pharmacokinetic and pharmacodynamic drug–drug interactions, **drug-induced crystalline nephropathies**, biomarkers to distinguish the aetiology of drug-related kidney disease, dosing during kidney replacement therapy, and — important in India — **nephrotoxicity of natural and herbal products**.
- **Pharmacist-led nephrotoxin stewardship** is now a recommended intervention, with dedicated evidence tables on pharmacist interventions in people with or at risk of AKI.
- Drug-induced AKI accounts for roughly **14–26% of AKI in hospitalised adults**, and AKI risk rises by about **53% for each additional nephrotoxic drug exposure**. The commonest identified culprits in recent cohorts are **vancomycin, iodinated contrast and aminoglycosides**.
- A large FAERS pharmacovigilance analysis of reports from 2004 to 2023 (published 2025) found **omeprazole to be the most frequently reported single culprit drug**, followed by furosemide, pantoprazole, esomeprazole and lansoprazole — strongly reinforcing the PPI deprescribing message in the textbook.
- **Sick-day rules ("SADMANS")** — **S**ulfonylureas, **A**CE inhibitors, **D**iuretics, **M**etformin, **A**RBs, **N**SAIDs, **S**GLT2 inhibitors — to be withheld during acute dehydrating illness. SGLT2 inhibitors are held because of euglycaemic ketoacidosis risk, metformin because of lactic acidosis. Caution in heart failure, where abrupt withdrawal of diuretics or ACE inhibitors can precipitate decompensation. **Restarting is as critical as stopping.**
- **AGS Beers Criteria 2023** advise avoiding systemic NSAIDs in older adults with CKD stage 4 or worse, and avoiding the combination of an ACE inhibitor/ARB with a potassium-sparing diuretic or NSAID.
- New drug classes with recognised renal signals: **immune checkpoint inhibitor-associated AIN** (PD-1/PD-L1 immunohistochemistry helps distinguish it), and the **vancomycin plus piperacillin–tazobactam** combination. Conversely, **tenofovir alafenamide is markedly less nephrotoxic than tenofovir disoproxil**.
- SGLT2 inhibitors, despite an early dip in eGFR, are now established as **nephroprotective** in the KDIGO 2024 CKD guideline and are not to be treated as nephrotoxins outside acute illness.

Current Practice Update

Issue	Textbook position	Current evidence (2023–2026)
Culprit drugs	NSAIDs, diuretics, aminoglycosides, ACE inhibitors, with PPIs newly recognised	**PPIs top the pharmacovigilance signal**; vancomycin, contrast and aminoglycosides dominate hospital cohorts
Estimating function	Cockcroft–Gault and MDRD; both may over- or underestimate	CKD-EPI 2021 without race; **cystatin C-based eGFR** recommended in low muscle mass and before critical dosing decisions
Deprescribing	Avoid polypharmacy, start low and go slow	Formalised as **nephrotoxin stewardship** with pharmacist-led reviews, e-alerts and explicit sick-day rules
SGLT2 inhibitors	Newer agents, limited elderly data	Renoprotective long term, but on the **SADMANS hold list during acute illness** — both facts must be stated
Herbal products	Not a major theme	Explicit guideline table on nephrotoxicity of natural products; highly relevant to Indian practice (aristolochic acid, heavy-metal-contaminated preparations)

Exam One-Liners

- Commonest mechanism of drug-induced AKI overall: **acute tubular necrosis**.
- Interstitial nephritis is a **delayed hypersensitivity** reaction; biopsy shows **eosinophilic infiltration**.
- PPIs cause AIN and are a **deprescribing target** in older adults.
- NSAIDs for months to years → **papillary necrosis, chronic interstitial nephritis, ESRD**.

- ACE inhibitor + bilateral renal artery stenosis = **reversible renal failure**.
- Metformin → **lactic acidosis**; check creatinine clearance before starting at age 80 and above.
- Elderly get **hypokalaemia faster on diuretics** but are **predisposed to hyperkalaemia** on NSAIDs, ACE inhibitors, beta blockers and potassium-sparing diuretics.
- Principle of geriatric prescribing: **individualise, start low, go slow, avoid polypharmacy, dose to GFR**.

Extra Recall Points — Recurring Topic

Mnemonics

- **Triple whammy:** ACE inhibitor/ARB + diuretic + NSAID — the commonest community cause of drug-induced AKI.
- **SADMANS** — the sick-day hold list: Sulfonylureas, ACE inhibitors, Diuretics, Metformin, ARBs, NSAIDs, SGLT2 inhibitors.
- **Patterns — "HAIC-G": H**aemodynamic, **A**TN, **I**nterstitial nephritis, **C**rystalline nephropathy, **G**lomerular.
- **Crystal formers — "MASA":** Methotrexate, Acyclovir, Sulfadiazine, Atazanavir/indinavir.

Numerical Anchors

- Drug-induced AKI = **14–26%** of hospital AKI; risk up **53%** per additional nephrotoxin.
- Aminoglycoside AKI in **10–25%** of exposed patients; tenofovir/cidofovir in **12–24%**.
- Time to steady state = **4 × half-life**.
- Membranous nephropathy in the elderly is malignancy-related in about **20%**.

Examiner Traps

1. Listing drugs without **classifying by mechanism** — the marks are in the classification.
2. Forgetting that a **normal creatinine does not exclude significant impairment** in a sarcopenic patient.
3. Omitting **PPIs**, which are the most examined "newer" cause.
4. Calling SGLT2 inhibitors nephrotoxic — they are renoprotective, but held during acute illness.
5. Forgetting **herbal and over-the-counter preparations** in the drug history, especially in Indian practice.
6. Stopping drugs and never mentioning **restarting** them after recovery.

15-Second Answer Skeleton

Why elderly are susceptible (pharmacokinetics, unreliable creatinine, tubular frailty, polypharmacy) → classify injury by mechanism: **haemodynamic / ATN / interstitial / crystalline / glomerular / electrolyte** → name the drugs in each → presentation is atypical, red flag is a new drug → diagnosis: drug history, eGFR equation, biopsy → management: withdraw drug, steroids for AIN, dose to GFR → prevention: start low, go slow, deprescribe, sick-day rules, nephrotoxin stewardship.

QUESTION 3

Metabolic acidosis

7 MARKS

High-Yield Points

1. **Definition:** a primary fall in serum bicarbonate with a fall in blood pH, compensated by hyperventilation and a fall in pCO_2. Normal bicarbonate is **22–26 mEq/L**; expected compensation is a fall in pCO_2 of about **1.2 mmHg for every 1 mEq/L fall in bicarbonate**.
2. **Classification is by anion gap** = $Na^+ - (Cl^- + HCO_3^-)$, normally **8–12 mEq/L**.
   High anion gap (added acid) — MUDPILES: Methanol, Uraemia, Diabetic ketoacidosis, Paraldehyde, Iron/Isoniazid, Lactic acidosis, Ethylene glycol, Salicylates.
   Normal anion gap (hyperchloraemic, bicarbonate loss): diarrhoea, renal tubular acidosis, carbonic anhydrase inhibitors, ureteric diversion, large-volume 0.9% saline.
3. **Key geriatric physiology:** older people take **longer to reach peak proton excretion**. After an acid load, maximal ammonia and titratable acid excretion is reached in **4 hours in the young but only at 6–8 hours in the old**, so the elderly have **greater difficulty handling states of acidosis** even though their baseline acid excretion is normal.
4. **Common causes in older adults:** acute kidney injury and chronic kidney disease (retained acid and uraemia); sepsis, shock and dehydration (lactic acidosis); diarrhoea; diabetic ketoacidosis and mixed hyperglycaemic states; drugs, especially **metformin-induced lactic acidosis**; heat stroke, which causes metabolic acidosis with respiratory alkalosis.
5. A characteristic geriatric presentation is the **"mixed" metabolic disturbance** of older diabetics — neither classical ketoacidosis nor hyperosmolar coma, with glucose around **270–450 mg/dL**, arterial pH **7.2–7.3** (not markedly acidotic), and without marked dehydration or altered consciousness.
6. **Clinical features are often masked in the elderly:** Kussmaul breathing, anorexia, vomiting, weakness, hypotension and arrhythmia from hyperkalaemia, and frequently **delirium as the presenting feature**. Acid–base disturbance is also a recognised metabolic cause of apparent depression in old age.
7. **Chronic acidosis has geriatric consequences:** muscle protein catabolism worsening **sarcopenia**, bone demineralisation worsening **osteoporosis**, and accelerated CKD progression — linking it directly to falls and fracture risk.
8. **Investigations:** arterial blood gas, electrolytes with calculated anion gap, serum bicarbonate, lactate, ketones, glucose, urea and creatinine, and where relevant urine pH and urine anion gap (for renal tubular acidosis) and osmolal gap (for toxic alcohols).
9. **Management principle is to treat the cause**, not the number: volume resuscitation and restoration of perfusion for lactic acidosis, insulin with fluids for ketoacidosis, withdrawal of metformin, relief of obstruction or dialysis in AKI, and treatment of sepsis.
10. **Sodium bicarbonate** is reserved for severe acidaemia (pH below about 7.1) or for associated hyperkalaemia. Use it cautiously in the elderly — the **sodium load can precipitate heart failure and hypertension**, and it can cause hypokalaemia, hypocalcaemia and volume overload. In advanced CKD, dialysis is indicated for refractory acidosis, and replacement therapy is needed when GFR falls below **10 mL/min**.

Latest Updates (2023–Present) — Condensed

- **KDIGO 2024 CKD guideline downgraded alkali therapy to a practice point**, suggesting treatment be considered when **serum bicarbonate is below 18 mEq/L**, rather than routinely correcting all mild acidosis.
- **VALOR-CKD (JASN 2024)** — veverimer, a non-absorbed gastrointestinal hydrochloric acid binder, **did not slow CKD progression** in 1480 patients (eGFR 20–40 mL/min/1.73 m², bicarbonate 12–20 mEq/L), largely because only about 1 mEq/L of bicarbonate separation was achieved. The earlier **BiCARB** trial in patients over 60 with low-grade acidosis likewise showed no clinical benefit, higher cost and lower quality of life.
- A 2024 CJASN meta-analysis found sodium bicarbonate **improves kidney function and mid-arm muscle circumference** but **raises systolic blood pressure** — so in frail older adults with mild acidosis the balance now favours dietary alkali (fruit and vegetables, low potential renal acid load) and careful observation over reflex bicarbonate prescribing.

Current Practice Update

Issue	Textbook position	Current evidence (2023–2026)
Alkali in CKD	Correct acidosis to maintain bicarbonate in the normal range	Treat when **bicarbonate <18 mEq/L**; a practice point, not a strong recommendation
Novel agents	Sodium bicarbonate is the mainstay	**Veverimer failed** in VALOR-CKD; sodium bicarbonate remains the only practical option, plus dietary alkali

Older adults	Correction assumed beneficial	**BiCARB** showed no benefit and possible harm in over-60s with mild acidosis; watch sodium load and blood pressure
Resuscitation fluid	0.9% saline for volume repletion	**Balanced crystalloids** preferred for large volumes, to avoid iatrogenic hyperchloraemic acidosis

Exam One-Liners

- Anion gap = Na − (Cl + HCO_3); normal **8–12 mEq/L**.
- Expected pCO_2 = **1.5 × HCO_3 + 8 ± 2** (Winter's formula).
- The elderly reach peak acid excretion at **6–8 hours instead of 4**.
- Metformin → **high anion gap lactic acidosis**; heat stroke → **metabolic acidosis with respiratory alkalosis**.
- Chronic acidosis drives **sarcopenia and bone demineralisation**.
- Bicarbonate therapy threshold in CKD is now **<18 mEq/L**.

Examiner Traps

1. Calculating the anion gap but forgetting to **correct for albumin** (add 2.5 mEq/L for every 1 g/dL fall below 4 g/dL) — hypoalbuminaemia is near-universal in frail elderly and masks a raised gap.
2. Giving bicarbonate reflexively in lactic acidosis instead of restoring perfusion.
3. Missing the **delta-delta** check for a coexisting normal-gap acidosis or metabolic alkalosis (common with vomiting or diuretics).
4. Forgetting that **delirium may be the only presenting sign** in an older patient.

If Asked as a 15-Mark Question, Expand With

Detailed physiology of renal acid handling (bicarbonate reabsorption in the proximal tubule, titratable acid and ammoniagenesis distally) • full classification table of high vs normal anion gap causes with the delta-delta ratio • the four types of **renal tubular acidosis** with their urine pH, potassium and stone associations • systemic effects of acidaemia organ by organ (cardiac contractility, arrhythmia, catecholamine resistance, insulin resistance, hyperkalaemia, bone buffering, protein catabolism) • the geriatric consequences chain: acidosis → sarcopenia + osteoporosis → falls and fracture • specific management protocols for diabetic ketoacidosis and hyperosmolar states in the elderly, with slower fluid rates and closer attention to cardiac and cognitive status • renal replacement therapy indications (AEIOU) • the 2023–2026 evidence block above.

FLUID & ELECTROLYTE BALANCE IN THE ELDERLY

High-Yield Examination Answers

MD Geriatric Medicine — Structured Revision Notes

Primary source: *Pathy's Principles and Practice of Geriatric Medicine*, 6th edition (Chapter 15)

Supplemented by *Essentials of Clinical Geriatrics*, 7th edition

2 QUESTIONS · 15-MARK FORMAT · UPDATED TO AUGUST 2026

Textbook content and current evidence are presented separately throughout.

Contents

1. **Fluid and Electrolyte Disturbances in the Elderly and their Management** — **15 MARKS**
Normal water homeostasis · age-related changes · dehydration · hypernatremia · hyponatremia overview · drug causes · correction formulae · prevention

2. **Approach to the Evaluation and Treatment of Hyponatremia** — **15 MARKS**
Stepwise diagnostic algorithm · volume-status classification · SIADH criteria · hypertonic saline protocols · osmotic demyelination · vaptans

3. **Rapid Revision Grid** — **APPENDIX**
Numbers, thresholds, formulae and named trials on one page

How this document is organised. Each answer opens with 15–20 numbered high-yield points drawn from the uploaded textbook, arranged in the standard sequence (definition → physiology → epidemiology → aetiology → clinical features → diagnosis → management → prevention). This is followed by a **Latest Updates (2023–Present)** section with inline citations, a two-column **Current Practice Update** table contrasting the textbook position with current evidence, an orange **Examiner's Tip** panel with mark-earning lines, and — because both topics recur across examinations — a green **Extra Points to Remember** panel.

Q1. Fluid and electrolyte disturbances in the elderly and their management.

15 MARKS · 20 HIGH-YIELD POINTS · RECURRING TOPIC

Textbook Answer — 20 High-Yield Points

A. Normal Physiology (Points 1–4)

1. Water balance has **dual control**. The **hypothalamus and posterior pituitary** handle water retention through ADH, while the **renin–angiotensin–aldosterone axis** handles sodium retention and blood pressure.
2. **ADH (arginine vasopressin)** is made in the **supraoptic and paraventricular nuclei** and released when serum osmolality rises. Normal serum osmolality is kept at **285 ± 2 mOsm/kg**. The ADH release threshold is about **280 mOsm/kg**.
3. **Thirst** is controlled by the **organum vasculosum of the lamina terminalis (OVLT)**, which lies outside the blood–brain barrier. Thirst normally lags behind ADH — its threshold is about **5–10 mOsm/kg higher** than the ADH threshold.
4. **Non-osmotic ADH release** occurs through baroreceptors: high-pressure receptors in the **carotid sinus and aortic arch**, and low-pressure stretch receptors in the **cardiac atria and pulmonary veins**. A fall in **effective arterial blood volume (EABV)** therefore raises ADH even when osmolality is low.

Renal handling of water: GFR 300 L/day → about **30 L/day** reaches the distal collecting tubule
With ADH: urine 0.7 L/day at 600–1200 mOsm/kg | **Without ADH:** urine 10–20 L/day at <100 mOsm/kg
The medullary concentration gradient is generated by the urea countercurrent system; water moves via aquaporin-2 channels.

B. Age-Related Changes (Points 5–8)

5. **Total body water falls from 60% to 50% of body weight after age 75.** A smaller water reservoir means even short periods of poor intake cause large shifts — this is the single most important predisposing change.
6. After water deprivation, healthy older adults show **reduced thirst**, **higher serum ADH levels**, but **reduced urinary concentrating ability** and **reduced free water excretion**. They can still secrete ADH; the kidney simply responds less well to it.
7. Renal resistance to ADH is due to **reduced expression of the V2 receptor and aquaporin-2** in the collecting duct with ageing.
8. Fluid homeostasis is **not** affected by the age-related GFR decline until GFR falls to **30–50 mL/min**. Tubular function is mildly impaired — water, sodium and potassium handling all decline, and the **aldosterone response is blunted**.

C. Epidemiology and Dehydration (Points 9–10)

9. **Frequency in the frail elderly.** Sodium and water disturbances occur in **18–63%** of frail long-term care residents. Hyponatremia affects **7–11% of outpatients** and **11–53% of those in long-term care**. Hypernatremia affects about **18% of institutionalised elderly**, rising to **63% during acute febrile illness**.
10. **Dehydration.** Suspect it when there is acute weight loss of **≥3% of body mass** or **>1 kg per day**. Commonest causes are **infection, altered consciousness, cognitive impairment and diuretics**. Hospital mortality may reach **50%**. General recommendation is about **1.5 litres of fluid daily**. Skin turgor is unreliable in old age (subcutaneous atrophy) — if used at all, test over the **chest or abdomen**.

D. Hypernatremia (Points 11–14)

11. **Definition: serum sodium >145 mEq/L.** Normal ageing physiology tends *towards* hypernatremia. In the frail elderly the causes are **reduced thirst, inadequate access to fluids, and superimposed gastrointestinal or febrile losses**. Institutionalised patients dependent on carers for drinks are the highest-risk group.
12. **Alzheimer's disease is a special risk.** These patients have **both** a blunted thirst response (in the range of essential hypernatremia) **and** inappropriately low ADH levels — a picture resembling **partial central diabetes insipidus**. Nephrogenic DI may be added by **hypercalcaemia, hypokalaemia or lithium**.
13. **Clinical features** are mainly neurological: confusion, disorientation, drowsiness, coma. In extreme cases brain shrinkage causes **vascular rupture and subarachnoid haemorrhage**. Chronic dehydration causes adaptive intracellular generation of organic osmoles, so **rapid correction risks cerebral oedema**.
14. **Management.** Treat the cause first (control pyrexia, replace gastrointestinal losses, stop diuretics and lactulose). Aim to drop serum osmolality by only about **10 mOsm/kg over 24 hours** — do **not** fully normalise the sodium. Check serum sodium **every 4 hours**.

Water replacement over 24 h = TBW × $[(Na_{goal} / Na_{current}) - 1]$ + insensible, gastrointestinal and urinary losses

where $Na_{goal} = Na_{current} - 10$ mEq/L

TBW = 0.6 × body weight (kg) if age <75 y | **TBW** = 0.5 × body weight (kg) if age >75 y

Obligatory ongoing free water loss is 0.5–1.5 L/day depending on fever and diarrhoea.

15. **Choice of fluid in hypernatremia.** If loss is **pure water**, 5% dextrose is simplest to calculate. If **solute is also lost**, 0.45% saline is more appropriate — the sodium stays intravascular to support blood pressure while the 50% free water component corrects osmolality. **0.9% saline will not lower serum osmolality** and may not deliver enough free water to keep pace with obligatory losses, even though it is hypotonic relative to the patient.

E. Hyponatremia in the Elderly (Points 16–18)

16. **Definition: serum sodium <135 mEq/L**; **<130 mEq/L** is clinically significant; **<120 mEq/L** is severe. Almost all cases involve an imbalance of ADH — either a true SIADH or an "appropriate" ADH rise driven by low EABV.

Serum osmolality = 2 × [Na] + glucose/18 + BUN/2.8 (mg/dL units)

Effective serum osmolality = 2 × [Na] + glucose/18

Urea is excluded from effective osmolality because it crosses cell membranes freely and is not an effective osmole.

17. **Drug causes — the commonest reversible group. Diuretics** are the most frequent (prevalence up to 11% in geriatric practice); the elderly are especially sensitive to **SSRIs**. Also implicated: tricyclic and tetracyclic antidepressants, phenothiazines and butyrophenones, **carbamazepine, oxcarbazepine and valproate**, opioids and nicotine, NSAIDs (they lower prostaglandins, which normally oppose ADH), high-dose co-trimoxazole, and vincristine and cyclophosphamide.

18. **Clinical consequences.** Hyponatremia is linked to **gait disturbance, unsteadiness, attention deficits, falls and fractures**, and to a **2.36-fold higher chance of dementia**. There may be direct activation of osteoclastic bone resorption. However, **causality is not proven** — hyponatremic patients also take more SSRIs, benzodiazepines and CNS drugs and have more baseline cognitive impairment and orthostatic hypotension.

F. Principles of Correction and Prevention (Points 19–20)

19. **Correction is guided by neurocognitive symptoms, not by the number alone.** The two rate limits are the most examinable facts in this chapter:
    - **Hyponatremia:** raise serum sodium by **6–8 mEq/L per 24 hours** — a rise **>8 mEq/L/24 h** risks **osmotic demyelination syndrome (ODS)**, both pontine and extrapontine, which is delayed in onset and carries severe morbidity and mortality.
    - **Hypernatremia:** lower serum sodium by **<10 mEq/L per 24 hours** to avoid cerebral oedema.

20. **Prevention in practice.** Limit drugs associated with hyponatremia (especially **thiazides and SSRIs**); avoid drugs causing orthostatic hypotension; monitor postural blood pressure; moderate the intensity of systolic blood pressure lowering compared with younger patients; and ensure **carer-assisted hydration** for institutionalised and demented patients, particularly during intercurrent febrile illness. Water and sodium disturbances independently **predict the prognosis of acute illness** in frail elderly long-term care residents.

Latest Updates (2023–Present)

Diagnosis of dehydration has moved to an objective, laboratory-based standard

- The **ESPEN geriatric nutrition and hydration guideline** now names **directly measured serum or plasma osmolality** as the reference standard for low-intake dehydration, with a threshold of **≥300 mOsm/kg** for current dehydration and **295–300 mOsm/kg** for impending dehydration.
- Where direct osmometry is unavailable — the usual situation in Indian district hospitals — the validated substitute is a **calculated osmolarity** from routine biochemistry, at a cut-off of **>295–296 mOsm/L** (sensitivity ~97%, specificity ~76%):

Calculated osmolarity = 1.86 × ($Na^+ + K^+$) + 1.15 × glucose + urea + 14 (all in mmol/L)

Best-performing of 38 equations tested in frail older people (Hooper et al., *BMJ Open*; validated in the DRIE cohort). Note this needs SI units, so convert Indian mg/dL values first.

Two distinct types of dehydration are now separated

- *Age and Ageing* (2023) "New horizons" review distinguishes **hypertonic dehydration** (a pure water deficit) from **isotonic dehydration** (loss of both water and salt). Crucially, **serum osmolality cannot diagnose isotonic dehydration** — a normal osmolality does not exclude volume depletion.
- Individual clinical signs and bedside tests perform **poorly** in older people. **Salivary osmolality point-of-care testing** is a promising rapid test able to detect both types, though evidence is still developing.

- **Hypodermoclysis (subcutaneous fluid)** is confirmed as safer and easier to start than the intravenous route, limited only by infusion speed and volume — highly relevant to Indian long-term care and home-based NPHCE services where venous access and nursing supervision are limited.

Hydration status as a long-term health determinant

- *Nature Reviews Nephrology* (2024) reviewed long-term outcomes of hydration status: serum sodium in the **upper part of the normal range**, reflecting habitual under-hydration, is associated with accelerated biological ageing, higher chronic disease burden and earlier mortality. This reframes hydration from an acute-care issue to a preventive one.

Indian data

- Indian hospital series report hyponatremia in **18–29% of elderly inpatients**. A Mumbai tertiary-centre prospective study (*Cureus*, 2025) found an overall prevalence of **29.4%**, with the elderly disproportionately affected and a multifactorial aetiology (comorbidity plus diuretics), followed by liver disease, endocrine disorders and SIADH each around 13%.
- A Pune series (*Cureus*, 2024) of 100 elderly inpatients found **severe hyponatremia (<125 mEq/L) in 61%**, presenting most often as **generalised weakness (22%) and disorientation (17%)** — symptoms easily dismissed as "ageing".
- **AIIMS Rishikesh** (*BMC Geriatrics*, 2023) showed that hyponatremic geriatric patients had significantly worse **Comprehensive Geriatric Assessment** scores — Hindi Mental State Examination, Barthel ADL index, Timed Up and Go, and handgrip strength — and that **all four improved when serum sodium was corrected**. This is the strongest Indian evidence that correction is functionally worthwhile, not merely biochemical.

Current Practice Update

Issue	Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Diagnosing dehydration	Clinical — acute weight loss ≥3% or >1 kg/day; skin turgor over chest/abdomen; no laboratory threshold given.	Objective threshold: measured serum osmolality **≥300 mOsm/kg**, or calculated osmolarity **>295 mOsm/L** using the ESPEN equation. Clinical signs alone are considered unreliable.
Type of dehydration	Treated as a single entity (water deficit).	Split into **hypertonic** (water deficit) and **isotonic** (water + salt deficit). Osmolality detects only the former.
Route of rehydration	Oral, intravenous, or subcutaneous fluids mentioned in passing.	**Hypodermoclysis** explicitly endorsed as safer and easier to initiate than IV in frail and long-term care patients.
Daily fluid target	Approximately **1.5 L/day** for older adults.	Broadly unchanged, but daily requirements may be **lower than previously assumed**; evidence specific to older people remains limited, so individualisation is advised.
Value of correcting mild hyponatremia	Associations with falls, fractures and dementia noted, but **causality not proven**; vaptan trials showed only modest benefit.	Indian CGA data (AIIMS Rishikesh 2023) show measurable improvement in **cognition, ADL, mobility and grip strength** after correction, strengthening the case for active treatment.

Examiner's Tip — verbatim lines that earn marks

- "**Total body water falls from 60% to 50% of body weight after the age of 75**, so the elderly have a markedly reduced buffer against short periods of poor intake."
- "The ageing kidney shows **reduced aquaporin-2 and V2 receptor expression**, producing renal resistance to ADH despite preserved ADH secretion."
- "Correction must be guided by neurocognitive symptoms: **raise sodium by 6–8 mEq/L per 24 hours in hyponatremia, and lower it by less than 10 mEq/L per 24 hours in hypernatremia**."
- "**0.9% saline is hypotonic to the patient in hypernatremia but does not lower serum osmolality** and may fail to keep pace with obligatory free water losses."
- Always write the **TBW formula with the age-75 cut-off** (0.6 vs 0.5 × body weight) — it is the single most reliably awarded calculation in this question.
- Close with prevention: "**limit thiazides and SSRIs, monitor postural blood pressure, and ensure carer-assisted hydration in dependent and demented patients.**"

Extra Points to Remember (Recurring Topic)

- **Why the elderly drift towards hypernatremia but present with hyponatremia.** Normal ageing physiology (blunted thirst, poor concentrating ability) predisposes to **hypernatremia**; superimposed **drugs and comorbidity** (diuretics, SSRIs, heart failure, cirrhosis) produce **hyponatremia**. Examiners like this paradox — state it explicitly.
- **Alzheimer's disease is the classic hypernatremia scenario:** blunted thirst *plus* inappropriately low ADH, mimicking partial central diabetes insipidus. Nursing-home residents dependent on carers reach **63% incidence during febrile illness**.
- **Pathy's functional categorisation applies here.** In the **robust** older adult, aim for full biochemical correction and investigate the cause. In the **frail**, correct cautiously and prioritise deprescribing. In the **moderately demented**, the intervention with the largest yield is **structured carer-assisted hydration**. At the **end of life**, clinically assisted hydration is a comfort decision, not a biochemical one.
- **Do not forget potassium.** Ageing reduces tubular potassium handling and blunts the aldosterone response, so the elderly tolerate both extremes poorly. **Thiazides** cause hypokalaemia, volume depletion, hyponatremia, hyperglycaemia and hyperuricaemia; **ACE inhibitors, ARBs and eplerenone** cause hyperkalaemia and should not be combined with potassium-sparing diuretics. Eplerenone is contraindicated with creatinine >2.0 mg/dL.
- **Two-line mention of hyperosmolar hyperglycaemic state** if the question is broad: it develops over days to weeks (unlike DKA over hours), has a **larger fluid deficit, higher serum sodium and higher blood urea**, and seizures are common. Resuscitate with normal saline first — volume repletion alone often lowers glucose.
- **Indian framing sentence:** "In Indian practice, where summer heat stress, febrile illness, gastroenteritis and unsupervised diuretic use are common and formal long-term care nursing is limited, dehydration in the dependent elderly is largely a **preventable, carer-dependent problem**, and is best addressed through NPHCE home-based care and Ayushman Arogya Mandir follow-up rather than in hospital."

Q2. Approach to the evaluation and treatment of hyponatremia.

15 MARKS · 20 HIGH-YIELD POINTS · RECURRING TOPIC

Textbook Answer — 20 High-Yield Points

A. Definition and First Principles (Points 1–3)

1. **Definitions.** Hyponatremia is serum sodium **<135 mEq/L**. Clinically significant hyponatremia is **<130 mEq/L**; severe hyponatremia is **<120 mEq/L**. Levels of 130–135 mEq/L are usually asymptomatic.
2. **Step 1 — confirm true hypotonic hyponatremia.** Measure serum osmolality. True hypo-osmolality is **<275 mOsm/kg**. This step excludes two traps:
   - **Pseudo-hyponatremia** — from excess triglycerides or paraproteins (macroglobulinaemia); osmolality is normal.
   - **Hyperosmolar (translocational) hyponatremia** — from hyperglycaemia or other circulating osmoles; osmolality is high.
3. **Step 2 — take a water intake history.** Look for intake that overwhelms renal free water clearance: **primary polydipsia** (16–20 L/day), **beer potomania**, and **exercise-associated water intoxication** in long-distance runners. Without such a history, the cause is **water retention**, usually with some component of solute loss.

B. Laboratory Evaluation (Points 4–6)

4. **Step 3 — the core panel.** Send serum for **basic metabolic profile (BMP)** and **measured osmolality**, and urine for **osmolality** and **sodium concentration**. The BMP identifies acute renal disease (acute tubular necrosis, obstruction) and hyperglycaemia.
5. **Step 4 — interpret the urine.**
   - **Urine osmolality >100 mOsm/kg** means ADH action is present and inappropriate; it is often *higher* than serum osmolality.
   - **Urine sodium >30–40 mEq/L** (sometimes approaching 100) indicates SIADH or renal salt loss.
   - **Urine sodium <20 mEq/L**, or the presence of orthostatic hypotension, indicates an "appropriate" ADH response to low effective arterial blood volume.
6. **Copeptin** — the stable C-terminal fragment of the AVP precursor — used together with the urinary sodium ratio, helps distinguish **volume-depleted from normovolemic** hyponatremia when clinical assessment is equivocal.

C. Volume-Status Classification (Points 7–9)

7. **Hypovolemic hyponatremia.** Orthostatic hypotension and/or urine sodium <20 mEq/L. Causes: diuretics, gastrointestinal losses. Physiologically, aldosterone and ADH are both **appropriately** elevated because of low EABV.
8. **Hypervolemic (oedematous) hyponatremia.** Two mechanisms:
   - **Hypoalbuminaemia with low EABV** — cirrhosis, nephrotic syndrome.
   - **Reduced carotid baroreceptor perfusion** — congestive heart failure, cardiac tamponade, negative inotropic drugs, and poor contractility in hypothyroidism.
9. **Euvolemic hyponatremia — SIADH.** Diagnostic set from the textbook algorithm: **serum osmolality <275 mOsm/kg**, **urine osmolality >100 mOsm/kg**, **urine sodium >40 mEq/L**, clinical euvolemia, and normal thyroid and adrenal function.

D. Completing the Search for a Cause (Points 10–12)

10. **Step 5 — review every drug.** This is mandatory and is the highest-yield reversible cause. Diuretics (commonest overall), SSRIs (elderly are especially sensitive), tricyclics and tetracyclics, phenothiazines and butyrophenones, carbamazepine, oxcarbazepine and valproate, opioids and nicotine, NSAIDs, high-dose co-trimoxazole, vincristine and cyclophosphamide, and MDMA.
11. **Step 6 — exclude endocrine causes.** Check **TSH** for hypothyroidism, and test for **primary and secondary adrenal insufficiency by cosyntropin stimulation**. Also assess for mineralocorticoid insufficiency and for autonomic dysfunction (**Parkinson's disease, multiple system atrophy**). **Correction of hypothyroidism and hypoadrenalism is mandatory** before labelling a patient SIADH.
12. **Causes of true SIADH.** Tumours (**bronchogenic carcinoma**, mesothelioma, thymoma, other non-pulmonary carcinoma); CNS lesions (tumour, trauma, neurosurgery, **subarachnoid haemorrhage**); pulmonary disease with raised intrathoracic pressure (**COPD**, positive-pressure ventilation); acute post-operative and post-anaesthetic states; **cerebral salt wasting**; and HIV–AIDS. In practice, an exhaustive evaluation of 50 elderly inpatients with mild-to-moderate hyponatremia linked it to **pneumonia and medication**, with **60% remaining idiopathic**.

E. Treatment (Points 13–18)

13. **The decision to treat rests on neurocognitive symptoms, not the number.** Sodium 130–135 mEq/L is usually asymptomatic and, if chronic, the brain has already adapted — it may need no therapy at all. Sodium 125–130 mEq/L with gait disturbance or cognitive impairment **does improve** with correction. Withholding causative drugs alone is often sufficient.
14. **Hypovolemic hyponatremia.** Give a trial of **1–2 litres of 0.9% saline**, withhold diuretics, and consider **oral salt 4–12 g/day in divided doses**. Restoring EABV suppresses ADH and raises sodium. **Fluid restriction is contraindicated here.**
15. **Euvolemic and hypervolemic hyponatremia. Fluid restriction 500–1500 mL/24 h** is the mainstay. **0.9% saline is usually ineffective and may worsen SIADH** — the infused sodium is quantitatively excreted in the urine while the high ADH retains the water.
16. **Severe symptomatic hyponatremia (sodium <120 mEq/L or hyponatremic encephalopathy).** Use **3% saline (513 mEq/L)**. The textbook protocols are:
    - **Continuous infusion** at **0.5–1.0 mL/kg/hour**, adjusted to urine output; or
    - **Bolus** of **100 mL of 3% saline**, with the rate then adjusted.
    - Check serum sodium **every 2 hours**; **stop the infusion if the rise exceeds 0.5 mEq/L/hour**.
    - Target a rise of only **4–8 mEq/L over 24 hours** — the goal is to remove a calculated portion of the excess free water, **not** to normalise the sodium.
17. **Osmotic demyelination syndrome (ODS) — the feared complication.** Chronic hyponatremia (>48 hours) causes the brain to extrude organic and inorganic osmoles. Correction **>8 mEq/L over 24 hours** then causes cerebral dehydration and **pontine and extrapontine demyelination**, which is **delayed in onset** and carries severe neurological morbidity and mortality.
    - **High-risk group:** serum sodium <105 mEq/L, **hypokalaemia**, alcoholism, malnutrition, advanced liver disease.
    - **If overcorrected:** re-lower with free water (dextrose) **± DDAVP**. In the bolus regimen, 14% of patients required this.
18. **Bolus versus continuous infusion.** In a historical case-control comparison, a **100 mL bolus of 3% saline was preferable to a slow 20 mL/h infusion**, with quicker restoration of the Glasgow Coma Scale. The slow-infusion group showed a trend towards higher mortality (4 of 28 died vs 0 of 22). The textbook conclusion is that it remains **unknown** which strategy is superior in real-world conditions, or whether reversing overcorrection halts established ODS.

F. Vaptans and Prognosis (Points 19–20)

19. **Vaptans (vasopressin V2-receptor antagonists).** They reliably raise serum sodium and allow fluid restriction to be stopped, but clinical benefit is modest:
    - **Tolvaptan — SALT-1 and SALT-2** (448 subjects): small overall improvement in the SF-12 quality-of-life score ($p = 0.02$), significant only in the US cohort; benefit greatest when baseline sodium was <130 mEq/L. No change in the physical component.
    - **INSIGHT trial** (107 patients with SIADH): raising sodium from 129 to 136 mEq/L did **not** improve the primary composite cognitive endpoint, only a psychomotor speed subdomain.
    - **Lixivaptan:** raised sodium by 3 mEq/L over control, with no benefit on the Trail Making Test or MOS-6 at 28 days.
    - **Systematic review:** all vaptans improve serum sodium, with **limited evidence of impact on quality of life or mortality**.
20. **Prognosis.** Hyponatremia carries a poor overall prognosis. There are probably **two temporal syndromes** in the elderly, often hard to separate: a **chronic** hyponatremia linked to underlying disease or dementia, and an **acute deterioration** manifesting as delirium. Ongoing management is to **limit thiazides and SSRIs**, avoid drugs causing orthostatic hypotension, and moderate antihypertensive intensity.

Latest Updates (2023–Present)

The 2024 treatment standard has settled the dosing of hypertonic saline

- The ERA **"Hyponatraemia — treatment standard 2024"** (*Nephrology Dialysis Transplantation*, 2024) recommends **3% saline as a 100–150 mL bolus (2–4 mL/kg) over 20–40 minutes, repeated until the target is reached**, or alternatively a continuous infusion at **0.5–1 mL/kg/hour**. It states that **rapid intermittent bolus administration is preferred** for symptomatic hyponatraemia.
- The aim of the first bolus is a **rise of about 5 mmol/L**, which is enough to reduce intracranial pressure from cerebral oedema.
- The **SALSA randomised trial** (*JAMA Internal Medicine*, 2021; 178 patients, sodium ≤125 mmol/L) found rapid

intermittent bolus and slow continuous infusion **equally effective and safe with no difference in overcorrection risk**, but bolus therapy required **less relowering treatment** and achieved target sodium within one hour more often. A 2025 Indian meta-analysis (Dutta et al., New Delhi) confirmed both are safe, with continuous infusion associated with **shorter hospital stay**.

The 8 mEq/L limit is now genuinely contested

- **MacMillan et al.** (*NEJM Evidence*, 2023; 22,858 admissions, Toronto): ODS occurred in only **0.05%** overall — fewer than **5 per 10,000** when initial sodium was <130 mmol/L and about **3 per 1,000** when <120 mmol/L. Strikingly, **7 of the 12 ODS cases had no rapid correction at all**. Rapid correction occurred in **69%** of patients with sodium <110 mmol/L despite efforts to avoid it.
- **Seethapathy et al.** (*NEJM Evidence*, 2023; 3,274 patients with sodium <120 mmol/L): **slower correction was associated with higher mortality and longer hospital stay**; 5 of 7 ODS cases had **not** exceeded 8 mmol/L in 24 hours.
- **Ayus et al. meta-analysis** (*JAMA Internal Medicine*, 2025; 16 cohorts, 11,811 patients): correction at **8–10 mEq/L per 24 h** was associated with lower in-hospital mortality (OR 0.67) and lower 30-day mortality (RR 0.55), with **no significant difference in ODS incidence**.
- **See et al. meta-analysis** (*Journal of Critical Care Medicine*, 2024; 6,032 patients): overall ODS incidence **0.48%**. Rapid correction raised ODS risk nearly four-fold (RR 3.91) *but* halved in-hospital mortality. Importantly, **89% of ODS cases had alcohol use disorder, hypokalaemia, cirrhosis or a very low baseline sodium** — risk factors matter more than rate alone.
- A large integrated health-system cohort of **13,988 patients** (*Annals of Internal Medicine*, 2026) again found faster correction associated with **lower 90-day death or delayed neurologic events**.
- **The counter-argument.** Sterns and Rondon-Berrios (*American Journal of Kidney Diseases*, 2025) argue these newer studies are **confounded** — comorbidity drives both mortality and slow correction — and that the safety limits should not be relaxed. **Guidelines have not changed; the 6–8 mEq/L target remains standard of care.**

A genuinely new drug class for SIADH

- **Empagliflozin (SGLT2 inhibitor).** Refardt et al. (*Journal of the American Society of Nephrology*, 2023) conducted a randomised, double-blind, placebo-controlled **crossover** trial of empagliflozin 25 mg/day for 4 weeks in outpatients with chronic SIAD (n = 14, median age 72). It **raised serum sodium** and possibly **improved neurocognitive function (MoCA)**. The mechanism is **glycosuria-induced osmotic diuresis with increased electrolyte-free water clearance** — entirely independent of vasopressin receptor blockade.
- An earlier trial in **87 hospitalised SIAD patients** showed 4-day empagliflozin plus fluid restriction raised sodium, with **87% vs 68%** reaching sodium ≥130 mmol/L. The larger **EMPOWER** trial in euvolemic and hypervolemic hyponatremia is ongoing.
- This is highly relevant to India: empagliflozin is **widely available and inexpensive**, whereas tolvaptan is costly and urea is poorly tolerated. Use in SIAD remains **off-label**.
- **Oral urea** and the **proactive DDAVP clamp** (scheduled desmopressin with strict free water restriction, correcting sodium deliberately with 3% saline boluses) are both increasingly used to give controlled, predictable correction and prevent inadvertent overshoot.

Current Practice Update

Issue	Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Bolus vs continuous 3% saline	"Unknown whether bolus or continuous infusions, or a hybrid, will be better in real-world conditions."	Settled by the **SALSA RCT**: both safe and effective. ERA **2024 treatment standard prefers rapid intermittent bolus** for symptomatic hyponatraemia.
Bolus dose	100 mL of 3% saline once, then rate adjusted.	**100–150 mL (2–4 mL/kg) over 20–40 minutes**, repeated as needed; first bolus targets a **5 mmol/L rise**.
Risk of ODS	Presented as the dominant hazard of correction; rate limit of 8 mEq/L/24 h is absolute.	ODS is **rarer than assumed (0.05–0.5%)** and often occurs **without** rapid correction. Several large cohorts link **slow** correction to **higher mortality**. The **limit still stands**, but risk-factor stratification (hypokalaemia, alcoholism, cirrhosis, Na <105) now matters as much as rate.

Second-line therapy for chronic SIADH	**Vaptans** — effective biochemically, modest clinical benefit.	**Empagliflozin** emerges as a promising, cheap, well-tolerated alternative (JASN 2023). **Urea** is re-established as a mainstream second-line option.
Preventing overcorrection	Re-lower with free water ± DDAVP if the limit is exceeded (reactive).	Increasing use of the **proactive DDAVP clamp** — scheduled desmopressin from the outset with controlled 3% saline boluses.

Examiner's Tip — verbatim lines that earn marks

- Open with the **three-step framework**, then follow it: "**First confirm true hypotonic hyponatremia, then assess volume status, then identify the cause.**"
- "**Serum osmolality <275 mOsm/kg confirms true hypo-osmolality and excludes pseudo-hyponatremia and hyperosmolar hyponatremia.**"
- Give the SIADH criteria as a numbered set: "**Serum osmolality <275, urine osmolality >100, urine sodium >40, clinical euvolemia, and normal thyroid and adrenal function.**"
- The single most examinable therapeutic sentence: "**0.9% saline corrects hypovolemic hyponatremia but worsens SIADH, because the infused sodium is quantitatively excreted while the elevated ADH retains the water.**"
- "**Fluid restriction is indicated in euvolemic and hypervolemic hyponatremia and is contraindicated in hypovolemic hyponatremia.**"
- State the numbers precisely: **3% saline = 513 mEq/L; infuse at 0.5–1.0 mL/kg/h; check sodium 2-hourly; stop if the rise exceeds 0.5 mEq/L/h; target 4–8 mEq/L in 24 h.**
- Name the ODS risk factors as a list — **sodium <105 mEq/L, hypokalaemia, alcoholism, malnutrition, advanced liver disease** — and say ODS is **delayed in onset**.
- A drawn **algorithm/flow chart** reliably attracts marks in this question. Draw the three volume-status branches with urine sodium as the discriminator.

Extra Points to Remember (Recurring Topic)

- **Cerebral salt wasting versus SIADH** is a favourite viva question. Both follow CNS injury and both have high urine sodium; the difference is **volume status** — cerebral salt wasting is **hypovolemic with hypotension** and needs **salt and volume replacement**, whereas SIADH is euvolemic and needs **fluid restriction**. Getting this the wrong way round is dangerous. Note that a 2014 study cited in Pathy's found post-subarachnoid haemorrhage hyponatremia was actually due to **SIAD and glucocorticoid deficiency, not cerebral salt wasting**.
- **Why urea is excluded from effective osmolality:** it crosses cell membranes freely and therefore causes no water shift. Write **"effective osmolality = 2 × Na + glucose/18"** and say why.
- **The "60% idiopathic" statistic** is worth quoting: in an exhaustive evaluation of 50 elderly inpatients with mild-to-moderate hyponatremia, no classical SIADH cause was found in 60%; the association was with **pneumonia and medication**. This justifies drug review as the highest-yield step in the elderly.
- **Correction is not just biochemical.** Renneboog's prospective study showed measurable improvement in **tandem gait on a calibrated platform** and in **attention reaction time (673 → 615 msec)** after correcting sodium from 128 to 138 mEq/L. Indian CGA data (AIIMS Rishikesh, 2023) add improvement in **HMSE, Barthel ADL, Timed Up and Go and handgrip strength**.
- **Hyponatremia and bone.** There is a plausible direct mechanism — Verbalis showed in a rat SIADH model that chronic hyponatremia causes **substantial reduction in bone mass through osteoclastic resorption**. Multiple meta-analyses link hyponatremia to osteoporosis and fracture. In a fracture-clinic setting, always check the sodium.
- **Indian framing sentence:** "In Indian geriatric practice, the commonest reversible causes are **thiazides, SSRIs and gastroenteritis**; severe hyponatremia (<125 mEq/L) accounts for over half of elderly admissions in some series and typically presents as **generalised weakness or disorientation** rather than seizures, so a low threshold for checking serum sodium in any acutely confused older patient is essential."
- **A safe closing sentence when the examiner probes the correction-rate controversy:** "Recent large cohorts suggest osmotic demyelination is rarer than previously believed and that overly slow correction may itself be harmful, but current guidelines continue to recommend **6–8 mEq/L per 24 hours**, and I would not deviate from that outside a specialist setting."

Rapid Revision Grid

NIGHT-BEFORE APPENDIX · NUMBERS, THRESHOLDS, FORMULAE, TRIALS

1. Numerical Thresholds

Parameter	Value
Normal serum osmolality	285 ± 2 mOsm/kg
ADH release threshold	280 mOsm/kg
Thirst threshold	5–10 mOsm/kg **above** the ADH threshold
Hyponatremia	<135 mEq/L; clinically significant <130; severe <120
True hypo-osmolality	<275 mOsm/kg
Hypernatremia	>145 mEq/L
Inappropriately concentrated urine	Urine osmolality >100 mOsm/kg
Urine sodium in SIADH	>40 mEq/L (may approach 100)
Urine sodium in low EABV	<20 mEq/L
Total body water	60% of weight <75 y; **50% >75 y**
GFR at which fluid homeostasis fails	30–50 mL/min
Dehydration — textbook	Weight loss ≥3% body mass, or >1 kg/day
Dehydration — ESPEN (current)	Measured osmolality ≥300 mOsm/kg; calculated osmolarity >295 mOsm/L
Daily fluid recommendation	~1.5 L/day
Obligatory free water loss	0.5–1.5 L/day

2. Correction Rates — Learn These Verbatim

Situation	Target	Complication if exceeded
Hyponatremia	Raise Na by **6–8 mEq/L / 24 h** (4–8 in the acute phase)	**Osmotic demyelination syndrome** — pontine and extrapontine, delayed onset
Hypernatremia	Lower Na by **<10 mEq/L / 24 h**	**Cerebral oedema**
Monitoring — hyponatremia	Serum Na **2-hourly**; stop if rise >0.5 mEq/L/h	—
Monitoring — hypernatremia	Serum Na **4-hourly**	—

3. Formulae

Serum osmolality = 2[Na] + glucose/18 + BUN/2.8 (mg/dL)

Effective serum osmolality = 2[Na] + glucose/18 (urea excluded — freely permeable)

Water replacement / 24 h (hypernatremia) = TBW × $[(Na_{goal}/Na_{current}) - 1]$ + ongoing losses
TBW = 0.6 × wt if <75 y; 0.5 × wt if >75 y; $Na_{goal} = Na_{current} - 10$

Calculated osmolarity (ESPEN, dehydration screening) = 1.86 × (Na + K) + 1.15 × glucose + urea + 14 (mmol/L)

4. Fluid Selection

Fluid	Sodium	Use
3% saline	**513 mEq/L**	Severe symptomatic hyponatremia. Bolus 100–150 mL (2–4 mL/kg) over 20–40 min, or infusion 0.5–1.0 mL/kg/h
0.9% saline	**154 mEq/L**	Hypovolemic hyponatremia (1–2 L trial). **Worsens SIADH.** Does not lower osmolality in hypernatremia
0.45% saline	77 mEq/L	Hypernatremia with combined water and solute loss (50% free water)
5% dextrose	0	Hypernatremia from pure water loss; also used to re-lower after overcorrection

Oral salt	—	4–12 g/day in divided doses, hypovolemic hyponatremia

5. Named Trials and Landmark Studies

Name	Message
SALT-1 / SALT-2	Tolvaptan in 448 subjects — raised sodium; only a small SF-12 quality-of-life gain, significant in the US cohort only
INSIGHT	Tolvaptan in 107 SIADH patients — sodium 129 → 136 mEq/L but **no improvement** in the primary cognitive endpoint
Renneboog et al.	Mild chronic hyponatremia causes falls, unsteadiness and attention deficits; gait and reaction time improve on correction
Verbalis (rat model)	Chronic hyponatremia causes osteoporosis via osteoclastic bone resorption
SALSA (JAMA Intern Med 2021)	Bolus vs continuous 3% saline — both safe and effective; **bolus needed less relowering therapy**
MacMillan (NEJM Evid 2023)	22,858 admissions — ODS only 0.05%; **7 of 12 cases had no rapid correction**
Seethapathy (NEJM Evid 2023)	3,274 patients — **slower correction linked to higher mortality** and longer stay
Ayus meta-analysis (JAMA Intern Med 2025)	11,811 patients — correction 8–10 mEq/L/24 h: lower in-hospital (OR 0.67) and 30-day (RR 0.55) mortality, no excess ODS
Refardt (JASN 2023)	**Empagliflozin 25 mg/day** crossover trial in chronic SIAD — raised sodium, possible MoCA improvement
ERA treatment standard 2024	3% saline **100–150 mL bolus preferred** for symptomatic hyponatraemia
AIIMS Rishikesh (BMC Geriatrics 2023)	Indian CGA data — HMSE, Barthel ADL, TUG and handgrip all **improve** with sodium correction

6. One-Line Volume-Status Discriminator

Type	Clue	Urine Na	Treatment
Hypovolemic	Orthostatic hypotension, diuretics, GI losses	**<20 mEq/L**	0.9% saline 1–2 L; oral salt. **Never fluid restrict**
Euvolemic (SIADH)	No oedema, no postural drop; drugs, pneumonia, CNS or lung lesion	**>40 mEq/L**	Fluid restriction 500–1500 mL/day; urea, vaptan, empagliflozin
Hypervolemic	Oedema — heart failure, cirrhosis, nephrotic syndrome	Usually low	Fluid restriction + treat underlying disease; loop diuretic

Final Three-Sentence Summary

- **Physiology:** ageing brings reduced thirst, reduced urinary concentrating ability, reduced free water excretion and a fall in total body water from 60% to 50% after age 75 — a narrow margin in both directions.
- **Diagnosis:** confirm true hypo-osmolality, classify by volume status using urine sodium, then review every drug and exclude hypothyroidism and adrenal insufficiency before diagnosing SIADH.
- **Treatment:** correct according to neurocognitive symptoms, not the number — up by 6–8 mEq/L per 24 hours in hyponatremia, down by less than 10 mEq/L per 24 hours in hypernatremia.

QUESTION 1 — THYROID

Treatment of Hypothyroidism

15 MARKS

High-Yield Points (Textbook Core)

A. Definition and aims

1. Hypothyroidism is deficient thyroid hormone action. In old age the commonest cause is **autoimmune (Hashimoto's) thyroiditis**, followed by earlier thyroid surgery or radioiodine given for thyrotoxicosis.
2. The three aims of treatment are: relieve symptoms and signs, **normalise TSH to an age-appropriate range**, and **avoid over-treatment**.
3. Presentation in the elderly is atypical — memory loss, lethargy, constipation, cold intolerance, fatigue, heart failure, depression, weight gain. Absence of these symptoms does **not** rule out hypothyroidism, so a high index of suspicion is needed.

B. Drug of choice

4. **Levothyroxine (LT4) sodium**, orally, once daily, on an empty stomach 30–60 minutes before breakfast.
5. Separate by at least 4 hours from **calcium, iron, proton pump inhibitors, soya, bile acid sequestrants**, which impair absorption.
6. The full replacement dose in young adults is **1.6 µg/kg/day**. In older people the requirement is **lower** — because of reduced lean body mass and the physiological age-related fall in T4 production.

C. Starting dose and titration (the key exam point)

7. Start **very low: 12.5–50 µg/day**, particularly if there is coronary artery disease, arrhythmia or multiple cardiac risk factors.
8. Increase **slowly, every 6–8 weeks**, aiming to reach the replacement dose only after **4–6 months**.
9. Thyroid hormone increases myocardial oxygen consumption — rapid replacement can precipitate **angina, myocardial infarction or cardiac arrhythmia**.
10. In heart failure or established rhythm disturbance, a deliberately **sub-replacement dose** may be the correct choice to prevent ischaemic symptoms.
11. In older patients there is a **narrow window between TSH suppression and the substitution dose**, due to increased thyrotroph sensitivity to negative feedback by T4.

D. Targets and monitoring

12. The TSH target is **shifted upward with age**: approximately **4–6 mIU/L at 70–80 years** and **6–7 mIU/L above 80 years**, especially where there is risk of arrhythmia or fragility fracture.
13. Check TSH **every 3 months during titration**; once stable, **once or twice yearly** with small dose adjustments.

E. Special situations

14. **Central (secondary) hypothyroidism** — titrate to **free T4 in the upper half of the normal range**, **never to TSH**. The European Thyroid Association has issued 34 recommendations for this uncommon but difficult condition.
15. **Myxoedema coma** — IV levothyroxine (± liothyronine), **IV hydrocortisone until adrenal insufficiency is excluded**, passive rewarming, ventilatory and fluid support, and treatment of the precipitant.
16. **Non-thyroidal illness** — do not start levothyroxine on abnormal tests during acute illness; recheck after recovery. Treat only if there is real evidence of hypothyroidism (for example TSH >20 mIU/L with low free T4, or clear history and signs).

F. Hazards of over-treatment and review of indication

17. Over-replacement causes iatrogenic thyrotoxicosis → **atrial fibrillation, osteoporosis and fragility fracture**, anxiety, muscle wasting, insomnia.
18. Warn the patient and caregiver to report new **angina, breathlessness, confusion or insomnia**.
19. Many older patients began levothyroxine when younger for inappropriate or transient indications and continue without review. In one nursing-home study, thyroid hormone was **successfully withdrawn in half the residents** — always re-examine the indication.
20. Poor adherence is the commonest cause of a persistently raised TSH despite an apparently adequate dose.

Latest Updates (2023–Present)

- **ETA 2025 guideline on levothyroxine monotherapy** — emphasises individualisation; recognises **liquid and softgel LT4 formulations** where absorption is impaired (malabsorption, PPI/coffee interference, post-bariatric surgery).
- **Age-specific reference intervals** (Jansen et al., *Thyroid* 2024) — TSH rises physiologically with age, particularly after 50 in women and 60 in men. Applying a single adult range **over-diagnoses hypothyroidism in the elderly**.
- **Over-treatment is common** — Baltimore Longitudinal Study of Aging (2023) and subsequent real-world data show 10–20% of older adults on LT4 are over-treated; iatrogenic thyrotoxicosis is significantly more frequent in **women** (Adams & Mammen, *Thyroid* 2025).
- **Deprescribing** — structured levothyroxine discontinuation trials are running in community-dwelling adults ≥60 on stable doses ≤150 µg with TSH <10 mIU/L; roughly half are expected to remain euthyroid off treatment.
- **T4/T3 combination therapy** — a pooled analysis of eleven randomised trials (*JCEM* 2024) found a consistent **patient preference** for combination therapy or desiccated thyroid extract, but no reproducible objective benefit. It remains a second-line option for persistently symptomatic patients on adequate LT4, and is **not recommended routinely in the elderly** because of arrhythmia risk.

Current Practice Update

Issue	Textbook position	Current practice (2023–present)
TSH reference range	Single adult range; higher target suggested in the very old	Formal age-specific reference intervals now published and increasingly adopted
LT4 formulation	Standard tablet	Liquid/softgel preparations recognised for malabsorption and drug interference
Duration of therapy	Review indication; withdrawal possible in many nursing-home residents	Deprescribing now an active, trial-supported strategy in older adults with TSH <10 mIU/L
T4 + T3	Not advocated	Still not routine; patient-preference signal acknowledged, objective benefit unproven

Exam One-Liners

- Start low, go slow: **12.5–50 µg**, increase every **6–8 weeks**, full dose by **4–6 months**.
- Elderly replacement dose is **below 1.6 µg/kg/day** because lean body mass falls.
- Target TSH **4–6 mIU/L at 70–80**, **6–7 mIU/L above 80**.
- Central hypothyroidism → titrate to **free T4**, not TSH.
- Over-treatment → **atrial fibrillation + osteoporotic fracture**.
- Myxoedema coma → give **hydrocortisone before or with** thyroxine.

QUESTION 2 — THYROID

Subclinical Hypothyroidism

7 MARKS

High-Yield Points

1. **Definition:** an elevated serum TSH with a **normal or low-normal free T4**. It is a biochemical, not a clinical, diagnosis.
2. **Prevalence:** 4–10% of the general population, rising to **up to 20% in women over 60**. Very common because of widespread sensitive TSH assays.
3. **Confirm before acting:** a TSH above 4.5 mIU/L must be repeated at 1–3 months, and thereafter every 6–12 months if the patient is asymptomatic.
4. **Evaluate for a cause:** past radioiodine, previous thyroid surgery, goitre, family history of thyroid disease; check **anti-thyroid peroxidase antibodies** and a lipid profile.
5. **Natural history:** progression to overt hypothyroidism is **around 5% per year (range 3–20%)**, higher with goitre and/or positive antibodies. Antibodies help predict progression but rarely change management.
6. **When to treat:** if TSH rises above **10 mIU/L**, start levothyroxine. Between 4.5 and 10 mIU/L, an individual *ex adiuvantibus* trial may be considered for subtle symptoms.
7. **TRUST trial** (Stott et al., NEJM 2017) — 737 adults aged ≥65 (mean 74.4 years, baseline TSH 6.40 mIU/L). Levothyroxine lowered TSH to 3.63 vs 5.48 mIU/L on placebo but produced **no improvement in Hypothyroid Symptoms score, Tiredness score, cognition, blood pressure, weight, Barthel index or IADL**.
8. **The cardiovascular link is age-dependent:** subclinical hypothyroidism appears detrimental in young and middle-aged people (Whickham re-analysis showed excess coronary events over 20 years), but is **harmless or possibly protective in the oldest old**. In studies of people over 73 and over 85, high TSH and/or low free T4 were associated with **lower all-cause and cardiovascular mortality**.
9. **Leiden 85-plus study:** 12% of 85-year-olds had hypothyroidism (7% overt, 5% subclinical); none of the subclinical group progressed by age 88, and a raised TSH predicted **slower decline in instrumental ADL**.
10. **Conclusion for the elderly:** do not treat minor TSH elevations in the oldest old — the risks (atrial fibrillation, fracture) outweigh benefit. Decide on **comorbidity, frailty and symptom burden**, not on a TSH cut-off alone.

Latest Updates & Current Practice (2023–Present) — 3 Points

- **Age-specific TSH reference intervals** (*Thyroid* 2024) are reducing the number of older adults labelled with subclinical hypothyroidism at all — many are simply normal for their age.
- **Systematic review and meta-analysis** (Holley et al., *Systematic Reviews* 2024, 6 studies, 3853 participants) found **no clear cardiovascular or bone-health benefit** from levothyroxine in older people with subclinical hypothyroidism — consistent with TRUST and with the pooled TRUST/IEMO 80-plus data.
- **Current practice therefore diverges from the textbook only in emphasis:** where Pathy's leaves the 4.5–10 mIU/L band open to an individual trial, guidelines now favour **watchful monitoring without treatment** in those over 70–80, and are moving towards active **deprescribing** of levothyroxine started for this indication.

Exam One-Liners

- Raised TSH + normal free T4 = subclinical hypothyroidism.
- Treat above **10 mIU/L**; individualise **4.5–10 mIU/L**; do not treat the very old.
- **TRUST** = no symptomatic benefit in those aged ≥65.
- In the oldest old, a high TSH may actually be **protective**.

QUESTION 3 — THYROID

Solitary Thyroid Nodule

7 MARKS

High-Yield Points

1. **Definition and significance:** a discrete lesion within the thyroid, radiologically distinct from surrounding parenchyma. **About 95% are benign**, but every nodule deserves evaluation because a few harbour malignancy.
2. **Epidemiology:** palpable in 3–7% of adults, but present in **around 50% on ultrasound or autopsy**. Frequency and goitre size increase with age, and nodular goitre is commoner in women and in iodine-deficient areas. In the Pescopagano (iodine-deficient) survey, goitre prevalence rose from 30% in young adults to **75% in those aged 55–65**.
3. **Key principle:** the risk of malignancy is **the same** for a solitary nodule and for a nodule within a multinodular goitre.
4. **Red flags requiring urgent referral:** rapid growth over a few weeks, **stridor, hoarseness (recurrent laryngeal nerve), cervical lymphadenopathy**, fixation, prior neck irradiation.
5. **First-line investigation:** serum **TSH plus high-resolution ultrasound**. Ultrasound is not a population screening test, but any palpable nodule must be scanned.
6. **If TSH is low or suppressed** → radioisotope scan. A **"hot" (autonomous) nodule is virtually never malignant** and is managed as hyperthyroidism — ^{131}I is the treatment of choice in old age, especially with cardiovascular disease. A **"cold"** nodule requires FNAC.
7. **If TSH is normal or high** → risk-stratify by ultrasound using **EU-TIRADS**: category 2 (pure cyst / spongiform) ≈0%; category 3 (ovoid, smooth, iso/hyperechoic) 2–4%; category 4 (mildly hypoechoic) 6–17%; **category 5 (irregular shape or margins, microcalcification, marked hypoechogenicity) 26–87%**.
8. **FNAC is the cornerstone of diagnosis**, and accuracy improves with ultrasound guidance. Perform for nodules **≥10 mm** with irregular margins, chaotic intranodular vascularity, taller-than-wide shape, or microcalcification; for nodules <10 mm only if clinical or ultrasound features are suspicious. **No ultrasound finding alone is diagnostic.**
9. **Limitation of FNAC:** inadequate or indeterminate results in **10–25%**; surgery is then usually advised for diagnosis, although most such nodules prove benign.
10. **Follow-up and treatment:** benign nodule → ultrasound at 12 months, then at 2–5 year intervals. Repeat FNA only for **>50% volume growth, ≥20% increase in two dimensions**, new suspicious features, or new symptoms. **Routine TSH-suppressive levothyroxine is NOT recommended** — harm outweighs benefit and it can cause exogenous thyrotoxicosis with cardiac and bone consequences. Malignant or suspicious → surgery; large compressive non-toxic goitre → surgery or radioiodine.

*Supporting datum: in a prospective Italian multicentre study of 992 patients (1567 benign nodules) followed 5 years, only 11.1% grew, thyroid cancer was found in 0.3%, and age ≥60 was associated with a **lower** risk of nodule growth.*

Latest Updates & Current Practice (2023–Present) — 3 Points

- **ETA 2023 thyroid nodule guideline:** minimally invasive techniques are now **first-line for symptomatic benign nodules** — ethanol ablation for cystic/predominantly cystic lesions, and thermal ablation (radiofrequency, microwave, laser, HIFU) for solid nodules, giving **57–77% volume reduction sustained at 5 years** without general anaesthesia. The ATA issued a 2023 statement on safe performance and training for these techniques.
- **ATA 2025 guidelines** now separate differentiated thyroid cancer from nodule management: **lobectomy is preferred over total thyroidectomy for unilateral cT1N0M0 tumours ≤2 cm**; active surveillance and percutaneous ablation are formally accepted alternatives for papillary microcarcinoma; molecular diagnostics have an expanded role in Bethesda III/IV nodules; and TSH suppression has been simplified to a binary target ("within" versus "below" the normal range).
- **Relevance to the older patient:** these de-escalated pathways (surveillance, lobectomy, ablation) are **particularly suited to frail elderly patients**, in whom the competing risks of thyroidectomy, hypocalcaemia and lifelong levothyroxine often outweigh the risk from an indolent tumour.

Exam One-Liners

- **TSH + ultrasound first** — scan only if TSH is low.
- Hot nodule = almost never cancer; cold nodule = FNAC.
- **FNAC is the cornerstone**; ultrasound stratifies but never diagnoses.
- Solitary nodule and MNG carry the **same** malignancy risk.
- Never use suppressive levothyroxine for a benign nodule.

QUESTION 4 — DIABETES

Evaluation and Management of Hypoglycaemia

15 MARKS

High-Yield Points (Textbook Core)

A. Definition and classification

1. Hypoglycaemia is a plasma glucose low enough to cause symptoms or harm; the conventional biochemical threshold is **<70 mg/dL**.
2. **Three levels:** Level 1 (alert value) <70 mg/dL; Level 2 (clinically significant) **<54 mg/dL**; **Level 3 (severe) — any glucose with cognitive impairment requiring external assistance**.
3. **Whipple's triad** confirms true hypoglycaemia: compatible symptoms + a documented low plasma glucose + relief of symptoms when glucose is raised.
4. Hypoglycaemia is the **critical limiting factor** in achieving glycaemic targets in older adults with diabetes.

B. Why older people are especially vulnerable

5. **Patient factors:** polypharmacy, frailty, high comorbidity burden, cognitive impairment, renal disease, low body mass, low HbA1c, erratic or reduced food intake, inability to self-administer treatment safely.
6. **Drug factors: sulphonylureas — particularly long-acting glibenclamide** — and insulin, especially twice-daily premixed and basal-bolus regimens.
7. **Non-diabetic causes to remember:** sepsis, hepatic failure, adrenal insufficiency, hypopituitarism, malnutrition and alcohol excess, insulinoma, non-islet-cell tumour hypoglycaemia (IGF-2 mediated), post-gastrectomy dumping, quinolones, quinine, and beta blockers which mask warning symptoms.

C. Clinical features

8. **Autonomic:** palpitations, tremor, sweating, hunger, anxiety.
9. **Neuroglycopaenic:** behavioural change, confusion, focal neurological deficit, seizure, coma.
10. **Autonomic warning symptoms are blunted with age → hypoglycaemia unawareness**. Presentation is often atypical — falls, delirium, “dizziness”, or a stroke mimic — and the symptomatic threshold in older people may differ from the conventional cut-off.

D. Evaluation

11. Confirm with a **laboratory glucose**, not a meter reading alone; document Whipple's triad.
12. In a person already on glucose-lowering drugs, **the medication review IS the evaluation** — no endocrine work-up is needed. Establish the pattern (nocturnal, pre-meal, post-exercise), timing relative to doses, renal function, and recent weight or appetite loss.
13. In a **non-diabetic**, take a **critical sample during the episode**: insulin, C-peptide, proinsulin, beta-hydroxybutyrate, sulphonylurea screen, cortisol.
    - High insulin + high C-peptide → **insulinoma or sulphonylurea** (differentiated by the drug screen)
    - High insulin + **low** C-peptide → **exogenous insulin** administration
    - Low insulin + low ketones → **IGF-2 mediated / non-islet-cell tumour**
    - Low insulin + high ketones → alcohol, starvation, cortisol deficiency

E. Acute management

14. **Conscious and able to swallow** — the “rule of 15”: give **15–20 g fast-acting carbohydrate** (glucose tablets or gel, 3–4 teaspoons of sugar in water, 150 mL fruit juice), recheck at 15 minutes, repeat up to three times, then give a **long-acting carbohydrate snack** to prevent recurrence.
15. **Unable to swallow or unconscious: IV 25% dextrose 75–100 mL** (or 10% dextrose 150–200 mL) via a large vein, or **IM/SC glucagon 1 mg**. **Glucagon is ineffective in alcoholic, malnourished or hepatic glycogen-depleted patients.**
16. **Sulphonylurea-induced hypoglycaemia is prolonged and relapsing** — admit, run a 10% dextrose infusion, observe for at least 24–48 hours; octreotide may be used for refractory cases. Never discharge such a patient after a single correction.
17. Always identify and treat the **precipitant**: missed meal, sepsis, worsening renal function, deliberate or accidental dose error, alcohol.

F. Prevention — the real answer in geriatrics

18. **Relax targets by health status:** healthy older adult HbA1c <7.5%; complex/intermediate health <8.0%; very complex or poor health <8.5%. Frail patients per EDWPOP: **7.6–8.5%**. **Avoid HbA1c below 7% in the frail.**
19. **Deintensify and deprescribe:** replace glibenclamide with gliclazide or a glinide if meals are irregular; simplify basal-bolus to basal-only insulin; prefer agents with no intrinsic hypoglycaemia risk — metformin, DPP4 inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists.
20. Re-evaluate the entire treatment plan after **any Level 2 or Level 3 event**; assess frailty, functional status and life expectancy at every review; educate patient and carer, give sick-day rules, and check the capacity to self-administer treatment.

Latest Updates (2023–Present)

- **ADA Standards of Care 2026** — **real-time continuous glucose monitoring (CGM) is now recommended for older adults with type 1 diabetes and for older adults with type 2 diabetes on insulin**, to improve glycaemic outcomes, reduce hypoglycaemia and reduce treatment burden. CGM is advised at diabetes onset and any time thereafter for anyone on insulin, on non-insulin agents that can cause hypoglycaemia, or where CGM aids management.
- **CGM-based hypoglycaemia targets:** time below 70 mg/dL **<4% (and <1% for older adults)**; time below 54 mg/dL **<1%**. **Failure to meet these should itself trigger deintensification** — a target-driven trigger not present in the textbook.
- **Intermittently-scanned CGM has been removed** from the ADA technology table — real-time CGM is now the recognised standard.
- CGM reduces hypoglycaemic episodes by **more than 50%** versus standard monitoring in adults over 65; ADA 2026 Scientific Sessions data (SAGE) show that pairing CGM with structured pharmacist-led education converts detection into behaviour change and facilitates **deprescribing of high-risk agents**.
- **Deintensification is now formally endorsed** for both glucose and blood pressure in older adults, including in palliative care, with growing safety and efficacy evidence.
- **JBDS-IP guidance** (Sinclair et al.) on inpatient care of the frail older adult with diabetes recommends **frailty-adjusted inpatient glycaemic targets**; audit work in 2025 confirms this reduces inpatient hypoglycaemia.
- Level 2 or 3 hypoglycaemia should also prompt **annual screening for fear of hypoglycaemia and diabetes distress**, with referral to behavioural therapy if unresolved (new for 2026).

Current Practice Update

Issue	Textbook position	Current practice (2023–present)
Detection	Symptom report + capillary glucose; hypoglycaemia unawareness recognised but hard to quantify	Real-time CGM recommended for all older adults on insulin; detects asymptomatic and nocturnal events
Metric used	HbA1c and episode counts	Time below range <1% (<70 mg/dL) for older adults, in addition to HbA1c
Trigger to change therapy	Clinical judgement after admissions	Any Level 2/3 event, or failure to meet CGM time-below-range goals
Deintensification	“Now an essential action a clinician must consider”; little guiding evidence	Evidence base established; explicit algorithms for insulin simplification and palliative de-escalation
Psychological impact	Not systematically addressed	Annual screening for fear of hypoglycaemia and diabetes distress recommended

Exam One-Liners

- **<70 / <54 / severe** = Levels 1, 2, 3.
- Whipple's triad confirms it; the **critical sample** is taken *during* the episode.
- Rule of 15: **15 g carbohydrate, recheck at 15 minutes**.
- Sulphonylurea hypoglycaemia → **admit and infuse dextrose for 24–48 hours**.
- Glucagon fails in the alcoholic and the malnourished.
- The definitive treatment of recurrent hypoglycaemia is **deintensification, not more glucose**.

QUESTION 5 — DIABETES / THERAPEUTICS

SGLT2 Inhibitors in Type 2 Diabetes Mellitus

15 MARKS

High-Yield Points (Textbook Core)

A. Agents and mechanism

1. **Agents:** empagliflozin, dapagliflozin, canagliflozin, ertugliflozin, bexagliflozin; also marketed as fixed-dose combinations with metformin and with DPP4 inhibitors.
2. **Mechanism:** inhibit the sodium–glucose co-transporter 2 in the **proximal convoluted tubule**, which normally reabsorbs **about 90% of filtered glucose** → glycosuria and a fall in plasma glucose.
3. The action is **insulin-independent**, so efficacy is preserved despite beta-cell failure and there is **no intrinsic hypoglycaemia risk** — a major advantage in the older patient.

B. Metabolic effects

4. HbA1c fall of about **0.5–1.0%**; **weight loss 2–3 kg**; systolic blood pressure fall of roughly 3–5 mmHg.
5. Beyond glucose lowering: reduced circulating insulin, reduced hepatic steatosis, improved beta-cell function, mild uricosuria, and reduced hyperkalaemia risk.

C. Cardiovascular and renal outcomes (highest-yield section)

6. In the cardiovascular outcome trials, **empagliflozin and canagliflozin significantly reduced MACE** (cardiovascular death, non-fatal MI, non-fatal stroke); **empagliflozin also reduced cardiovascular death, hospitalisation for heart failure and worsening nephropathy**. DPP4 inhibitors, by contrast, showed no cardiovascular benefit.
7. **Heart failure across the whole ejection-fraction spectrum:** HFrEF (DAPA-HF, EMPEROR-Reduced) and HFpEF (EMPEROR-Preserved, DELIVER). Benefit is independent of diabetes status and begins within days of initiation.
8. **Renal protection — the three trials to name:** CREDENCE (type 2 diabetes, eGFR >30, UACR >300 mg/g), DAPA-CKD (eGFR >25, with and without diabetes), and EMPA-KIDNEY (eGFR ≥20, including non-diabetic and non-albuminuric CKD) — EMPA-KIDNEY showed a **28% reduction** in kidney disease progression or cardiovascular death.
9. **Renal benefit is independent of glucose lowering.** Mechanism: restoration of tubuloglomerular feedback with afferent arteriolar constriction → reduced intraglomerular hypertension, plus natriuresis and reduced tubular workload and hypoxia.

D. Practical use in older adults

10. **Initiation threshold: eGFR ≥20 mL/min/1.73 m².** Once started, **continue as eGFR falls** — the glycaemic effect fades but cardiorenal protection persists — down to dialysis.
11. An acute **"eGFR dip" of up to about 10% in the first 2–4 weeks is expected and haemodynamic**; it does not predict worse outcome and is **not a reason to stop the drug**.
12. Assess volume status before starting; **reduce or hold the loop diuretic** in a euvolaemic older patient to avoid dehydration and postural hypotension.
13. Glycaemic efficacy is **diminished in older people with renal impairment**; monitor renal function more frequently in the elderly.

E. Adverse effects and cautions

14. **Genital mycotic infection** (5–10% of women, 3–5% of men), **volume depletion with symptomatic hypotension**, and urinary tract infection — all more frequent above age 75.
15. **Euglycaemic diabetic ketoacidosis** — glucose may be near-normal, so it is easily missed. Precipitants: fasting, sepsis, surgery, very low-carbohydrate diet, insulin dose reduction, alcohol. **Withhold 3 days before elective surgery** (4 days for ertugliflozin).
16. Rare: **Fournier's gangrene** (necrotising fasciitis of the perineum). Canagliflozin carried a lower-limb amputation signal in CANVAS (boxed warning later downgraded to a standard warning).
17. **Pathy's caution in frailty:** consider avoiding an SGLT2 inhibitor in the frail because of **weight loss, dehydration and toe amputation**. This must now be balanced against the strong cardiorenal benefit — see Current Practice Update.
18. **Avoid or contraindicated in:** type 1 diabetes, prior DKA, recurrent genital infection, significant volume depletion, active foot ulceration, and where oral intake is unreliable.

F. Positioning in therapy

19. Metformin remains first-line after lifestyle measures; an SGLT2 inhibitor is a standard second-step choice. However, in the presence of **established atherosclerotic disease, heart failure or CKD, an SGLT2 inhibitor is now indicated irrespective of HbA1c** — it is prescribed for organ protection, not for glucose.
20. Blood pressure and lipid targets must be addressed in parallel: systolic 130–139 mmHg in those over 65, diastolic <80 but not <70 mmHg, with LDL targets graded by cardiovascular risk.

Latest Updates (2023–Present)

- **KDIGO 2024 CKD guideline** — SGLT2 inhibitors are now a **grade 1A foundational therapy** for adults with CKD and eGFR ≥20 mL/min/1.73 m², **with or without diabetes**, alongside RAAS blockade and statins. A weaker (2B) suggestion covers eGFR 20–45 with UACR <200 mg/g.
- **ADA Standards of Care 2026** confirms initiation at eGFR ≥20 in type 2 diabetes with CKD, and positions SGLT2 inhibitors and GLP-1 receptor agonists as complementary organ-protective agents. The **FLOW trial** extended kidney protection to the GLP-1 RA semaglutide.
- **Evidence specifically in older adults** — a 2025 meta-analysis (*Drugs & Aging*) and a 2025 systematic review of nine trials in those aged ≥65 found benefit fully preserved, including in the **≥75 year subgroup (composite of heart-failure hospitalisation and cardiovascular death, HR ≈0.71)**, without an excess of serious adverse events, fractures or amputations.
- Product labelling now explicitly advises **more frequent renal monitoring in the elderly** and notes higher rates of volume depletion and urinary tract infection in patients aged ≥75.
- Label expansions have been granted for dapagliflozin and empagliflozin in **chronic kidney disease and heart failure regardless of diabetes status**; ESC guidance includes them in acute heart-failure pathways.

Current Practice Update

Issue	Textbook position	Current practice (2023–present)
Indication	A glucose-lowering agent, used at the second step	Foundational organ-protective therapy, given irrespective of HbA1c in ASCVD, HF or CKD — and in CKD/HF **without** diabetes
Renal threshold	Caution in renal impairment; efficacy diminished	Initiate at eGFR ≥20; continue to dialysis; the early eGFR dip is expected and benign
Use in frailty	"Consider avoiding" because of weight loss, dehydration, amputation	Not a blanket contraindication — benefit preserved at ≥75 years; manage risk by assessing volume status, reducing diuretics and giving sick-day rules
Heart failure	Empagliflozin reduces HF hospitalisation in diabetes	Benefit proven across HFrEF and HFpEF, independent of diabetes, apparent within days
Amputation	Cited as a class concern	Signal was canagliflozin-specific and not consistently replicated post-marketing

Exam One-Liners

- Blocks SGLT2 in the **proximal tubule**, which handles **90%** of glucose reabsorption.
- Insulin-independent → **no hypoglycaemia**; weight and blood pressure both fall.
- Name the renal trio: **CREDENCE, DAPA-CKD, EMPA-KIDNEY**.
- Start at **eGFR ≥20**; do not stop when eGFR falls.
- The early **eGFR dip is haemodynamic** — keep going.
- Beware **euglycaemic DKA** — stop 3 days before surgery.
- Fournier's gangrene is the rare but exam-favourite adverse effect.

QUESTION 6 — METABOLIC BONE / ELECTROLYTES

Hypocalcaemia

7 MARKS

High-Yield Points

1. **Definition:** corrected serum calcium below **8.5 mg/dL** (normal range 8.5–10.5 mg/dL). Always correct for albumin or measure ionised calcium — hypoalbuminaemia is very common in the frail elderly and causes **pseudo-hypocalcaemia**.
   Corrected Ca (mg/dL) = measured Ca + 0.8 × (4.0 − serum albumin in g/dL)
2. **Causes with LOW or inappropriately normal PTH (hypoparathyroidism):** post-surgical after thyroidectomy or parathyroidectomy (**the commonest, ~75–90% of chronic cases**), autoimmune, infiltrative (haemochromatosis, Wilson's, metastasis), radiation, and **hypomagnesaemia**, which impairs both PTH secretion and PTH action.
3. **Causes with HIGH PTH (secondary hyperparathyroidism): vitamin D deficiency** — extremely common in Indian older adults; chronic kidney disease; malabsorption; hungry bone syndrome after parathyroidectomy; acute pancreatitis; rhabdomyolysis and tumour lysis syndrome (hyperphosphataemia); massive blood transfusion (citrate chelation); and drugs — bisphosphonates, denosumab, cinacalcet, phenytoin, foscarnet, proton pump inhibitors.
4. **Clinical clue:** suspect vitamin D deficiency in any older person with a **borderline-low calcium and a raised alkaline phosphatase**.
5. **Clinical features — neuromuscular irritability:** perioral and acral paraesthesia, muscle cramps, carpopedal spasm, tetany, **laryngospasm and bronchospasm**, seizures, confusion. Chronic hypocalcaemia causes cataract, basal ganglia calcification, papilloedema, dry skin, brittle nails and extrapyramidal features.
6. **Signs and ECG: Chvostek's sign** (facial twitch on tapping the facial nerve — falsely positive in up to 10% of normals) and **Trousseau's sign** (carpal spasm after cuff inflation above systolic pressure for 3 minutes) — Trousseau's is the more specific. ECG shows a **prolonged QTc** with risk of torsades de pointes.
7. **Investigations:** corrected and/or ionised calcium, **magnesium**, phosphate, creatinine, alkaline phosphatase, **intact PTH**, 25(OH) vitamin D, and 24-hour urinary calcium. High phosphate + low PTH = hypoparathyroidism; low phosphate + high PTH = vitamin D deficiency.
8. **Acute symptomatic hypocalcaemia** (tetany, seizure, laryngospasm, prolonged QT): **IV 10% calcium gluconate 10–20 mL diluted, over 10–20 minutes with cardiac monitoring**, followed by an infusion delivering roughly 1 mg/kg/hour of elemental calcium. **Correct magnesium first — calcium will not respond while the patient is hypomagnesaemic.** Prefer gluconate to chloride peripherally (chloride is sclerosant).
9. **Chronic management:** oral **elemental calcium 1–2 g/day in divided doses** plus **active vitamin D (calcitriol 0.25–1 µg/day)** in hypoparathyroidism, or plain cholecalciferol where the problem is simple vitamin D deficiency. **Target calcium at the LOW end of normal (8.0–8.5 mg/dL)** — chasing a normal calcium in hypoparathyroidism produces hypercalciuria, nephrocalcinosis and renal failure, because PTH-driven renal calcium reabsorption is absent. A thiazide with a low-salt diet reduces hypercalciuria.
10. **In the older patient specifically:** stop the offending drug, treat malabsorption and renal disease, and ensure **800–1000 IU/day vitamin D with 700–1200 mg calcium** (target 25(OH)D ≥30 ng/mL) — the same regimen that reduces hip fracture and falls. Monitor calcium, phosphate, creatinine and urinary calcium on treatment.

Latest Updates & Current Practice (2023–Present) — 3 Points

- **Palopegteriparatide (TransCon PTH, Yorvipath)** — the first **long-acting once-daily PTH(1-34) prodrug**, giving continuous physiological PTH exposure over 24 hours (released hormone half-life ≈60 hours). EMA-approved November 2023 and **FDA-approved August 2024** for chronic hypoparathyroidism. The phase 3 **PaTHway** trial normalised serum calcium, phosphate and 24-hour urinary calcium with withdrawal of conventional therapy in the majority, sustained to 3 years, and normalised bone remodelling. rhPTH(1-84) (Natpara) manufacture was **discontinued worldwide at the end of 2024**.
- **Revised ESE guideline (2025) and the Parathyroid Summit best-practice recommendations (2024/2025)** retain **calcium plus active vitamin D as first-line** therapy, and reserve PTH replacement for patients with inadequate control, an unacceptable pill burden, persistent hypercalciuria, or declining renal function. Diagnosis of chronic hypoparathyroidism requires hypocalcaemia with an inappropriately low or normal PTH, and DNA analysis is now recommended in non-surgical cases.
- **Emerging agents: eneboparatide** (selective PTHR1 agonist), an oral PTH analogue, and **encaleret** (a calcilytic for autosomal dominant hypocalcaemia type 1) are in phase 2/3 development — the field is moving from calcium supplementation towards true hormone replacement.

Exam One-Liners

- Correct for albumin: **add 0.8 mg/dL per 1 g/dL fall**.
- **Check and correct magnesium first** — otherwise calcium will not rise.
- Trousseau's is more specific than Chvostek's; the ECG shows a **long QT**.
- Acute: **10% calcium gluconate IV, slowly, monitored**.
- In hypoparathyroidism, aim for calcium at the **low end of normal** to protect the kidney.
- New drug to quote: **palopegteriparatide** — the first true PTH replacement.

QUESTION 7 — REPRODUCTIVE ENDOCRINOLOGY

Hormone Replacement Therapy in the Geriatric Patient

RECURRING TOPIC

15 MARKS

High-Yield Points (Textbook Core)

A. Definition, indications and governing principle

1. **HRT / menopausal hormone therapy** = oestrogen therapy, with a **progestogen added in every woman who still has a uterus** to prevent endometrial hyperplasia and carcinoma.
2. **Licensed indications are two only:** (a) relief of vasomotor and genitourinary symptoms; (b) prevention or treatment of osteoporosis where the risk–benefit balance is favourable. **It is NOT indicated for prevention of cardiovascular disease, dementia or any other chronic condition.**
3. **Governing principle:** the **lowest effective dose, for the shortest time required**, with periodic reassessment; the decision belongs to the informed woman.

B. The "window of opportunity" — the central concept

4. The ideal age range for initiation is **50–60 years, and within 10 years of the menopause**. Beyond this the balance turns unfavourable.
5. Meta-analysis shows women who start HRT **more than 10 years after menopause have higher risks of stroke and venous thromboembolism**. A WHI post-hoc analysis found that women aged **70 or older** starting HRT for persisting vasomotor symptoms had a significantly increased risk of coronary heart disease — with oestrogen alone *and* with combined therapy.

C. Preparations, progestogen choice and route

6. **Oestrogens are of natural origin** (unlike contraceptives): estradiol (oral, transdermal patch or gel, nasal spray, vaginal), estrone, estriol, estetrol. Conjugated equine oestrogens — used in WHI — remain popular in some countries.
7. **Progestogens are not equivalent: medroxyprogesterone acetate carries the cardiovascular and breast-cancer signal**, whereas **natural micronised progesterone appears substantially gentler**.
8. **Route matters: transdermal oestrogen is essentially neutral for VTE risk** because it avoids hepatic first-pass metabolism — the preferred route in older women, in obesity, and in anyone with thrombotic risk.
9. **Alternatives:** tibolone; the SERM–oestrogen combination bazedoxifene with conjugated oestrogens. **Low-dose vaginal oestrogen** for genitourinary syndrome has negligible systemic absorption, may be continued indefinitely, and can be given alongside systemic HRT.

D. Benefits

10. HRT is the **most effective treatment for vasomotor symptoms**, which affect **70–80% of women for an average of about 7 years**; it reverses genitourinary syndrome, improves sleep, mood and quality of life.
11. **Bone:** prevents bone loss and fragility fracture; even the **ultra-low-dose 0.014 mg estradiol patch** preserves BMD, though less than a standard dose. Continuation is recommended for women at high fracture risk in whom alternative agents are unsuitable or poorly tolerated.

E. Major risks (must be enumerated)

12. **Breast cancer:** increased with combined oestrogen + progestogen therapy. Crucially, long-term WHI follow-up showed **oestrogen-only HRT was associated with reduced breast-cancer incidence and mortality** in hysterectomised women — a favourite examiner discriminator.
13. **Venous thromboembolism and stroke** — dose- and route-dependent; oral confers greater risk than transdermal.
14. **Coronary heart disease** when started late (more than 10 years post-menopause, or after 70).
15. **Dementia:** continuous combined oestrogen + progestin started in older postmenopausal women **doubled the risk of all-cause dementia** (WHIMS).
16. **Endometrial carcinoma** with unopposed oestrogen in a woman with an intact uterus.

F. Contraindications

17. Current or past **breast cancer** or high breast-cancer risk; oestrogen-dependent malignancy; **VTE or thromboembolic disease**; active cardiovascular disease; **undiagnosed postmenopausal bleeding**; active liver disease.

G. Continuing HRT beyond age 65

18. The North American Menopause Society position is that the **lowest effective dose may be continued after 65** for persistent hot flushes, quality of life or osteoporosis, provided the clinician has established that benefits outweigh risks after thorough counselling. **HRT should not be stopped on the basis of age alone.** Document the counselling and the woman's wish to continue, and review periodically.
19. This matters practically: Swedish data show **15% of women at 66 and 9% at 72 still experience hot flushes**, women over 80 continue to use HRT, and many are unwilling to discontinue — with quality-of-life and economic implications as more older women remain in the workforce.

H. Non-hormonal alternatives — the default in most women over 60

20. **Lifestyle:** dressing in layers and using a fan, cold food and drink, avoiding hot and spicy food, stopping smoking, reducing caffeine, regular exercise, relaxation techniques (paced respiration, yoga, meditation, massage). **Pharmacological: clonidine** (the only UK-licensed non-hormonal agent, reduces central noradrenergic tone); **paroxetine** (FDA-approved, the most efficacious SSRI for women not on tamoxifen); **venlafaxine** (preferred in breast-cancer survivors taking tamoxifen — it does not interfere with tamoxifen metabolism); gabapentin or pregabalin; and **menopause-specific cognitive behavioural therapy**. Phyto-oestrogen studies are of poor quality.

Latest Updates (2023–Present)

- **Fezolinetant** (NK3-receptor antagonist) — **FDA-approved May 2023**, the first targeted non-hormonal drug for moderate-to-severe vasomotor symptoms. It acts on hypothalamic **KNDy neurons** (kisspeptin/neurokinin B/dynorphin), the mechanism Pathy's identified as the basis of hot flushes. SKYLIGHT 1/2/4 and DAYLIGHT showed roughly **60% reduction** in hot-flush frequency. **FDA (September 2024) and MHRA (April 2025) issued warnings of rare serious liver injury — baseline and periodic liver function tests are mandatory.**
- **Elinzanetant** (first **dual NK1 and NK3** receptor antagonist) — approved in the UK, Canada, Australia and Switzerland in 2025 and by the **FDA on 24 October 2025**. OASIS 1–3 showed a **73.8% reduction** in moderate-to-severe vasomotor symptoms at 12 weeks versus 47% on placebo, with rapid onset and additional benefit for **sleep disturbance** and quality of life — the NK1 component makes it particularly attractive where insomnia dominates. It may be used first-line.
- **NICE NG23 (updated 2024, further revised)** — recommends menopause-specific CBT; recommends **fezolinetant when HRT is unsuitable**; advises **transdermal rather than oral HRT where VTE risk is increased, including BMI over 30 kg/m²**; offers vaginal oestrogen for genitourinary symptoms including in women already on systemic HRT; and states plainly that combined or oestrogen-only HRT should **not** be offered for prevention of cardiovascular disease or dementia.
- **2025 — the FDA removed the boxed warning** from systemic menopausal hormone therapy labels after re-evaluating WHI data in the light of age at initiation, formulation and route. This is a significant regulatory reversal that partially rehabilitates HRT for appropriately selected women.
- **Cochrane review** (19 trials, 40,410 postmenopausal women) confirms HRT is **ineffective for primary or secondary prevention of cardiovascular events** and increases stroke and venous thromboembolic events — the textbook position stands.
- Phase 3 data support neurokinin antagonists in **breast-cancer survivors on endocrine therapy** (OASIS-4), a group in whom HRT is absolutely contraindicated.

Current Practice Update

Issue	Textbook position	Current practice (2023–present)
Non-hormonal options	Clonidine, paroxetine, venlafaxine, gabapentin; phyto-oestrogens poorly evidenced	Two licensed targeted agents — **fezolinetant** (NK3) and **elinzanetant** (NK1/NK3) — acting on the KNDy pathway; CBT formally recommended
Route of oestrogen	Transdermal noted as neutral for VTE	Transdermal now formally **preferred** where VTE risk is raised, explicitly including BMI >30
Regulatory labelling	WHI-driven boxed warning on all systemic HRT	Boxed warning **removed by FDA in 2025** after age- and route-stratified re-analysis
Use after 65	NAMS 2015 — lowest effective dose acceptable; do not stop for age alone	Unchanged and reinforced; documentation of shared decision-making now expected
Chronic disease prevention	Not recommended	Unchanged — Cochrane and USPSTF confirm no preventive role
Monitoring burden	Not applicable	New: **LFT monitoring required with fezolinetant**

Extra Recall Scaffolding — Recurring Topic

Mnemonic for contraindications — "BLOCK-U":
Breast cancer (current, past or high risk) · **L**iver disease (active) · **O**estrogen-dependent tumour · **C**lot — VTE/thromboembolism · **K**nown cardiovascular disease (active) · **U**nexplained postmenopausal bleeding

Numerical anchors to quote: window **50–60 years / within 10 years** of menopause · vasomotor symptoms in **70–80%** for about **7 years** · hot flushes persist in **15% at 66** and **9% at 72** · ultra-low patch **0.014 mg estradiol** · universal advice **800 IU vitamin D + 700–1200 mg calcium** · alcohol **≤2 units/day** · elinzanetant **73.8%** VMS reduction · fezolinetant **~60%**.

Named frameworks: WHI · WHIMS (dementia) · Chlebowski JAMA 2020 (breast-cancer follow-up) · Boardman Cochrane review · NAMS/The Menopause Society position on use after 65 · NICE NG23 · SKYLIGHT and DAYLIGHT (fezolinetant) · OASIS 1–4 (elinzanetant).

Examiner traps to avoid:
• **Saying HRT prevents heart disease** — it does not; started late it *causes* it.
• **Forgetting the progestogen** in a woman with a uterus.
• **Claiming all HRT increases breast cancer** — oestrogen-alone reduced incidence and mortality in WHI.
• **Stopping HRT purely because the woman has turned 65.**
• Failing to distinguish **systemic** HRT from **low-dose vaginal** oestrogen, which is safe long-term.
• Treating all progestogens as equivalent — MPA is not micronised progesterone.

15-second answer skeleton: Define (oestrogen ± progestogen) → two licensed indications → lowest dose, shortest time → **window of opportunity 50–60 / within 10 years** → preparations, progestogen choice, transdermal route → benefits (VMS, GSM, bone) → risks (breast, VTE, stroke, CHD if late, dementia, endometrium) → contraindications (BLOCK-U) → continuing beyond 65 (NAMS — not stopped for age alone) → non-hormonal alternatives → **NK antagonists: fezolinetant and elinzanetant**.

Exam One-Liners

- **Window of opportunity: 50–60 years, within 10 years of menopause.**
- Uterus present → **always add a progestogen**.
- Transdermal oestrogen is VTE-neutral; oral is not.
- Oestrogen alone **lowered** breast cancer in WHI; combined therapy raised it.
- WHIMS: combined HRT in older women **doubles** dementia risk.
- Do not stop HRT for age alone — stop it for **risk**.
- New non-hormonal drugs: **fezolinetant (NK3)** and **elinzanetant (NK1/NK3)** acting on KNDy neurons.

QUESTION 8 — MALE ENDOCRINOLOGY

Gynaecomastia

7 MARKS

High-Yield Points

1. **Definition:** benign proliferation of **glandular** breast tissue in a male, caused by an increased ratio of **oestrogen to androgen action** on the breast. Must be distinguished from **lipomastia (pseudogynaecomastia)**, which is fat alone with no palpable disc.
2. **Clinical picture:** a **concentric, rubbery, mobile subareolar disc**, often tender during the active proliferative phase, usually bilateral but frequently asymmetrical.
3. **Why it is common in old age:** testosterone falls while **SHBG rises** (so free testosterone falls faster), and increasing adiposity raises **peripheral aromatisation of androgens to oestradiol** — shifting the oestrogen:androgen ratio.
4. **Physiological / idiopathic:** senescent gynaecomastia and obesity account for a large share of cases.
5. **Pathological causes — reduced androgen:** primary or secondary hypogonadism (including Klinefelter's presenting late), chronic kidney disease, chronic liver disease, testicular atrophy.
6. **Pathological causes — increased oestrogen:** cirrhosis (reduced oestrogen clearance and raised SHBG), thyrotoxicosis, adrenal tumours, testicular Leydig or Sertoli cell tumours, and **hCG-secreting tumours (bronchogenic carcinoma, germ cell tumours)**. Also refeeding after starvation.
7. **Drug-induced (about a quarter of cases — the dominant cause in geriatric practice): spironolactone**, digoxin, cimetidine/ranitidine, ketoconazole, calcium channel blockers, ACE inhibitors, **antiandrogens and GnRH agonists used for prostate cancer**, antipsychotics, metoclopramide, antiretrovirals, alcohol, cannabis, opioids — and **exogenous testosterone itself**, through aromatisation to estradiol.
8. **Red flags for male breast carcinoma:** a **hard, eccentric (not subareolar), fixed, unilateral** mass, skin dimpling, nipple retraction or bloody discharge, or axillary lymphadenopathy → mammography with core biopsy (triple assessment). Male breast cancer incidence rises with age, so an older man with an eccentric hard lump must never simply be reassured.
9. **Investigations:** a meticulous **drug history** and examination of testes, liver, thyroid and chest; then liver and renal function, TSH, **early-morning total testosterone, LH, estradiol, beta-hCG, prolactin and DHEAS**. Testicular ultrasound if a testicular mass is palpable or hCG is raised.
10. **Management:**
    - **Treat the cause** — stop or substitute the offending drug, treat hypogonadism, thyrotoxicosis, liver or renal disease, and reduce weight. This alone resolves most cases.
    - **Drug therapy works only in the early, painful, proliferative phase (<12 months)**: **tamoxifen 10–20 mg/day** is the best-supported option (off-label); aromatase inhibitors are less effective. After about a year, fibrosis is established and drugs rarely help.
    - **Surgery** — subcutaneous mastectomy with or without liposuction — for persistent, fibrotic or cosmetically distressing disease.
    - **Prophylaxis:** tamoxifen or low-dose breast irradiation before starting antiandrogen therapy for prostate cancer.
    - Testosterone-induced gynaecomastia in the first months of replacement is usually **transient** and resolves as testosterone antagonises estradiol at the breast; occasionally an oestrogen receptor antagonist or aromatase inhibitor is used briefly.

Latest Updates & Current Practice (2023–Present) — 3 Points

- **TRAVERSE** (Lincoff et al., NEJM 2023; 5246 men aged 45–80) recorded gynaecomastia among the adverse events of transdermal testosterone but found **no excess of prostate cancer or prostate-related events**, and non-inferiority for major adverse cardiac events — reassuring for men who develop breast tenderness on testosterone therapy.
- **Iatrogenic gynaecomastia now dominates geriatric practice** — with widespread use of **spironolactone in heart failure** (and now of mineralocorticoid receptor antagonists generally) and of **androgen-deprivation therapy for prostate cancer**, the medication list should be reviewed **before** any endocrine work-up.
- **Prophylaxis before androgen deprivation is now standard** in men expected to receive prolonged antiandrogen monotherapy — a single fraction of breast irradiation or tamoxifen substantially reduces the incidence and pain of gynaecomastia, and is far more effective given before rather than after the breast tissue has become fibrotic.

Exam One-Liners

- Gynaecomastia = **glandular** disc; lipomastia = fat only.
- The mechanism is always a **raised oestrogen:androgen ratio**.
- In an older man, **look at the drug chart first** — spironolactone, digoxin, antiandrogens.
- **Eccentric, hard, fixed lump = carcinoma until proved otherwise.**
- Tamoxifen works only in the **first 12 months**; after that, surgery.

QUESTION 9 — MALE ENDOCRINOLOGY

Andropause (Late-Onset Hypogonadism)

7 MARKS

High-Yield Points

1. **"Andropause" is a misnomer.** Unlike the menopause there is **no abrupt, universal, inevitable loss of gonadal function in men**; testosterone declines gradually and continuously throughout adulthood. The preferred term is **late-onset hypogonadism (LOH)**.
2. **Definition:** hypogonadism is a combination of **subnormal serum testosterone AND one or more attributable symptoms**. It is primary (testicular) or secondary (pituitary/hypothalamic).
3. **Physiology:** free testosterone falls about **1% per year after age 30**. In the European Male Ageing Study, between 40 and 79 years total testosterone fell **0.4% per year** and free testosterone **1.3% per year** — the free fraction falls faster because **SHBG rises with age**. Mechanisms: fewer Leydig cells, reduced Leydig cell response to LH, and reduced episodic and stimulated gonadotropin secretion.
4. **Epidemiology:** at least **30% of older men have subnormal testosterone**, but true symptomatic LOH affects only about **2–3%**. Only 5–35% of hypogonadal men are treated. Comorbidity — obesity, type 2 diabetes, chronic illness, opioids, glucocorticoids — contributes at least as much as age itself.
5. **Symptoms: low libido is the most specific**. Others: erectile dysfunction, loss of morning erections, reduced muscle mass and strength, increased body fat, reduced bone mineral density and osteoporosis, mild anaemia, breast discomfort and gynaecomastia, hot flushes, sleep disturbance, reduced vitality, poor concentration, depression and fatigue. **Most of these overlap with normal ageing and with other diseases — the central diagnostic difficulty.**
6. **Screening tools:** the **ADAM questionnaire** and the **Aging Male Symptoms (AMS) scale** are sensitive (97% and 83%) but poorly specific (30% and 39%), especially in the borderline range — useful to prompt testing, useless to confirm.
7. **Diagnosis:** two separate **fasting early-morning (before 11 am) total testosterone** measurements. If borderline, obese, or SHBG is abnormal, measure **free testosterone** by equilibrium dialysis or calculation. Then measure **LH and FSH**: raised = primary; low or inappropriately normal = secondary, which requires prolactin, iron studies, other pituitary hormones, and **pituitary MRI** if testosterone is very low or there are visual/headache symptoms.
8. **Exclude reversible causes before treating:** acute or chronic illness (non-gonadal illness suppresses testosterone), obesity, obstructive sleep apnoea, opioids, glucocorticoids, alcohol, uncontrolled diabetes. Weight loss and treating the illness may normalise testosterone without any hormone.
9. **Treatment principle:** testosterone is offered **only to older men with a genuinely low testosterone AND clinically significant symptoms — never for an asymptomatic age-related decline**. Aim for a **lower target than in young men: about 300–400 ng/dL rather than 500–600 ng/dL**, to minimise risk. Preparations: transdermal gel, intramuscular undecanoate or enanthate, buccal or nasal formulations; **oral testosterone (other than undecanoate) is avoided because of hepatotoxicity, peliosis hepatis and hepatic tumours**. **Contraindications:** prostate carcinoma (the major one), breast cancer, baseline haematocrit >48–50%, untreated severe sleep apnoea, decompensated heart failure, and any desire to father a child (testosterone suppresses spermatogenesis).
10. **Monitoring and expectations:** check testosterone, **haematocrit (keep below 55%)**, PSA and digital rectal examination at baseline, at 3–6 and 12 months, then annually. Benefits are **modest** — improved libido, sexual activity, mood, bone mineral density, anaemia and body composition — but the T-Trials showed **no benefit in vitality or walking distance**. If symptoms do not improve, **stop the testosterone and look for another cause**.

Latest Updates & Current Practice (2023–Present) — 3 Points

- **TRAVERSE** (Lincoff et al., NEJM 2023) — 5246 men aged 45–80 with symptomatic hypogonadism (two fasting testosterone levels <300 ng/dL) and pre-existing or high cardiovascular risk, randomised to 1.62% transdermal testosterone gel or placebo for a mean 22–27 months. Testosterone was **non-inferior to placebo for major adverse cardiac events (7.0% vs 7.3%) and did not increase prostate cancer or prostate-related events** — resolving the question the FDA had mandated in 2015.
- **But the substudies matter as much:** the fracture substudy (Snyder et al., NEJM 2024) found **MORE clinical fractures on testosterone (3.50% vs 2.46%)** — the opposite of expectation. There were also small excesses of atrial fibrillation, pulmonary embolism and acute kidney injury, alongside genuine benefits: a **22.5% reduction in progression from prediabetes to diabetes**, and improvements in sexual desire and activity, depressive symptoms and anaemia.
- **Practice implication: testosterone must NOT be used to treat osteoporosis in older men** — use a

bisphosphonate or denosumab instead. Counsel on falls prevention early in therapy, particularly in the frail, since increased vitality and activity may precede any skeletal benefit. EAU 2024 and the 2025 European Expert Panel (PaTeR) position statement have incorporated TRAVERSE, endorsing treatment for symptomatic hypogonadism provided these precautions and monitoring are followed.

Exam One-Liners

- **Andropause does not exist** — say “late-onset hypogonadism”.
- Free testosterone falls **1% per year** after 30 because **SHBG rises**.
- 30% have low levels; only **2–3%** have true LOH.
- Diagnose on **two fasting morning** samples plus symptoms; **low libido is the most specific** symptom.
- Aim for **300–400 ng/dL**, not the young-adult range.
- **TRAVERSE** = cardiovascular and prostate safe, but **more fractures**.
- Absolute contraindication: **prostate carcinoma**. Keep haematocrit **<55%**.

QUESTION 10 — SEXUAL HEALTH

Causes of Erectile Dysfunction and Treatment Options

15 MARKS

High-Yield Points (Textbook Core)

A. Definition and epidemiology

1. **Erectile dysfunction (ED)** is the persistent inability to attain and maintain an erection satisfactory for sexual intercourse, present for at least 3 months.
2. Prevalence rises steeply with age: about **50% of non-diabetic men over 60**, and **55–95% of diabetic men over 60**.
3. Continuation of an active sex life is **associated with longevity in both men and women**; ED must never be dismissed as normal ageing. In women the parallel problems are vaginal atrophy, low desire, depression and SSRI effects.
4. **Physiology:** erection is **parasympathetic (S2–S4)** and nitric-oxide mediated → cavernosal smooth-muscle relaxation via cGMP; **PDE5 degrades cGMP**. Detumescence is sympathetic. This is the rationale for PDE5 inhibition.

B. Causes — organic (about 80% in the elderly)

5. **Vasculogenic (commonest):** atherosclerosis, hypertension, dyslipidaemia, smoking, diabetes, **endothelial dysfunction**, venous leak, pelvic irradiation, Leriche syndrome.
6. **Neurogenic:** diabetic **autonomic neuropathy**, stroke, Parkinson's disease, multiple sclerosis, spinal cord disease, cauda equina, and pelvic or prostate surgery (radical prostatectomy, cystectomy).
7. **Endocrine / hormonal dysregulation:** hypogonadism, hyperprolactinaemia, thyroid disease, poorly controlled diabetes.
8. **Local and anatomical:** Peyronie's disease, post-priapism fibrosis, phimosis, BPH-related lower urinary tract symptoms.
9. **Drug-related — a particular problem in older patients: thiazide diuretics, spironolactone, beta blockers, cimetidine** (all four specifically named in Pathy's), plus SSRIs, antipsychotics, antiandrogens and GnRH agonists, 5-alpha-reductase inhibitors, opioids, and older centrally acting antihypertensives. **Always take an alcohol and tobacco history.**

C. Causes — psychogenic

10. Performance anxiety, depression, bereavement and loss of a partner, relationship difficulty, and lack of privacy in institutional or multigenerational settings. **Sudden onset, situational failure and preserved nocturnal or early-morning erections suggest a psychogenic component.** In practice most older men have a mixed organic and psychogenic picture.

D. Evaluation

11. **Interview the patient — and the partner where appropriate.** Take a full sexual, psychosocial and drug history, and clarify whether the problem is desire, erection, ejaculation or orgasm.
12. **Examination:** secondary sexual characteristics, penis (plaques, phimosis), testicular volume and consistency, gynaecomastia, peripheral pulses, blood pressure, digital rectal examination, and a focused neurological examination including perineal sensation and bulbocavernosus reflex.
13. **Investigations:** fasting glucose/HbA1c, lipid profile, **early-morning total testosterone**, thyroid function; add prolactin and gonadotrophins if testosterone is low. Validated assessment: the **International Index of Erectile Function (IIEF / IIEF-5)**.
14. **Specialised tests** — nocturnal penile tumescence, penile duplex Doppler, cavernosometry — are available through specialist ED clinics but **are usually avoided in older patients**, in whom extensive testing rarely changes management.

E. Treatment — a stepwise approach

15. **Step 1 — modify reversible factors:** optimise glycaemic, blood pressure and lipid control; stop smoking; reduce alcohol; weight loss and regular exercise; and **substitute the offending drug** (for example replace a thiazide or non-selective beta blocker — nebivolol and ARBs are more erection-friendly; use bupropion or mirtazapine rather than an SSRI for depression).
16. **Step 2 — psychosexual counselling** with the partner involved; general education about age-related sexual change; treat depression and address bereavement.
17. **Step 3 — oral PDE5 inhibitors (first-line pharmacotherapy):**

- **Sildenafil** 25–100 mg on demand, about 1 hour before intercourse; a fatty meal delays absorption.
- **Tadalafil** 10–20 mg on demand or **5 mg once daily**; duration up to **36 hours**, and it also improves BPH-related LUTS — often the best choice in the older man.
- **Vardenafil** and **avanafil** are alternatives.
- PDE5 inhibitors are effective in carefully selected older people with diabetes. **Start at the lower dose** in the elderly, in renal or hepatic impairment, and in men on alpha blockers.

18. **PDE5 inhibitor contraindications and cautions: absolute — any nitrate or nicorandil** (risk of profound hypotension), and riociguat. Caution with alpha blockers (separate dosing), recent myocardial infarction or stroke, unstable angina, severe aortic stenosis, hypotension, and retinitis pigmentosa. Side effects: headache, flushing, dyspepsia, nasal congestion, blue-tinged vision (sildenafil), back and muscle ache (tadalafil), and rarely **non-arteritic anterior ischaemic optic neuropathy** and sudden sensorineural hearing loss.
19. **Step 4 — testosterone replacement** where the man is genuinely hypogonadal: it improves libido and may **restore responsiveness to a previously failed PDE5 inhibitor**. It is not a treatment for ED with normal testosterone.
20. **Step 5 — second-line therapies: intracavernosal alprostadil** injection (most effective non-surgical option; warn about priapism), **intraurethral alprostadil (MUSE)**, and the **vacuum erection device** — particularly valuable in older men on nitrates or anticoagulants and after radical prostatectomy.
21. **Step 6 — penile prosthesis** (inflatable or malleable) for refractory ED, with high satisfaction rates. Penile revascularisation is reserved for younger men with isolated post-traumatic arterial insufficiency. **Low-intensity shockwave therapy, platelet-rich plasma and stem-cell "restorative" therapies remain investigational** and should not be offered as established treatment.

Latest Updates (2023–Present)

- **Princeton IV Consensus** (Kloner et al., *J Sex Med* 2024; Mayo Clin Proc 2024) — ED is formally recognised as an **ASCVD risk-enhancing factor**. Men aged 40–79 with ED and no overt cardiac disease should undergo formal 10-year ASCVD risk estimation, with **coronary artery calcium scoring as a risk modifier** in those calculated to be low risk. Sexual intercourse represents only **2–3 METs**, comparable to climbing two flights of stairs or walking 1.6 km in 20 minutes, and is safe in stable cardiovascular disease.
- **PDE5 inhibitors appear cardioprotective.** A 2023 meta-analysis of 16 cohort studies (1,257,759 subjects, median follow-up 4.3 years) found PDE5 inhibitor use associated with **reduced MACE (RR 0.78) and reduced all-cause mortality (RR 0.70)**. This reframes them as more than a symptomatic drug — though randomised confirmation is still awaited, and signals are neutral or unfavourable in HFpEF and after stroke.
- **EAU 2025 Sexual and Reproductive Health guideline** — many apparent "non-responders" are simply **inadequately treated**: verify dosing, timing and at least 4–6 adequate attempts, and try more than one molecule or schedule before declaring failure. Efficacy is lower where diabetes, obesity and cardiovascular disease are poorly controlled, so **comorbidities must be optimised concurrently**. Testosterone therapy may be used as an **initial** treatment where ED coexists with biochemical hypogonadism.
- **ICSM 2024** (Fifth International Consultation on Sexual Medicine) — choice among PDE5 inhibitors should be driven by patient preference, anticipated frequency of activity, desired duration of action, response to a therapeutic trial, partner factors and cost; **testosterone monotherapy has only a limited role in isolated ED**. A dedicated 2025/2026 ICSM statement addresses sexuality and sexual health specifically in older adults.
- Combination or dual PDE5 inhibitor regimens (daily low-dose tadalafil plus on-demand sildenafil) are being studied for on-demand non-responders, particularly in diabetes — including Indian cohort data (Lucknow, 2025).

Current Practice Update

Issue	Textbook position	Current practice (2023–present)
Meaning of ED	A complex multifactorial sexual problem	A **sentinel marker of endothelial dysfunction and an ASCVD risk-enhancing factor** — triggers formal cardiovascular risk assessment
PDE5 inhibitors	Effective symptomatic therapy in selected older diabetic men	Same, plus observational evidence of reduced MACE and all-cause mortality
Defining failure	Move to second-line if oral therapy fails	Must first confirm correct dose, timing and ≥4–6 attempts, and trial a second molecule
Testosterone	Adjunct in the hypogonadal man	May be an **initial** treatment when ED coexists with proven hypogonadism; not for isolated ED

Restorative therapies	Not discussed	Shockwave, PRP and stem-cell therapy formally reviewed and classed as **investigational**

Exam One-Liners

- Erection = **parasympathetic, nitric oxide, cGMP**; PDE5 breaks cGMP down.
- Commonest organic cause in the elderly is **vasculogenic**; commonest reversible cause is **drugs**.
- Preserved **morning erections** point to a psychogenic component.
- **Nitrates + PDE5 inhibitor = absolutely contraindicated.**
- **Tadalafil 5 mg daily** treats ED and LUTS together — ideal in the older man with BPH.
- Vacuum device is the safe option in men on nitrates or anticoagulants.
- **ED precedes coronary events by about 3–5 years** — assess cardiovascular risk in every man who presents with it.

QUESTION 11 — FEMALE ENDOCRINOLOGY / DERMATOLOGY

Hirsutism and Baldness in Elderly Women

7 MARKS

High-Yield Points

1. **Definitions: hirsutism** is excessive growth of **terminal** (coarse, pigmented) hair in a male pattern in a woman — upper lip, chin, chest, upper abdomen, back and thighs. It must be distinguished from **hypertrichosis**, which is generalised excess of vellus or terminal hair, is **not androgen-dependent**, and is usually drug-induced or familial.
2. **Why both problems appear together after the menopause:** ovarian follicles are depleted so **oestrogen production falls sharply, while ovarian stromal and thecal androgen production and adrenal androgens are relatively preserved**. The resulting rise in the **androgen:oestrogen ratio** produces facial hirsutism *and* scalp hair loss in the same woman — a classic examination point.
3. **Common causes:** idiopathic hirsutism; long-standing polycystic ovary syndrome; obesity and insulin resistance (adipose tissue is a major site of aromatisation and of altered SHBG); and drugs — glucocorticoids, danazol, testosterone and anabolic steroids cause true hirsutism, while **minoxidil, ciclosporin, phenytoin and diazoxide cause hypertrichosis**.
4. **Sinister causes that must be excluded:** androgen-secreting **ovarian or adrenal tumour**, ovarian hyperthecosis, Cushing's syndrome, non-classical congenital adrenal hyperplasia, acromegaly, hyperprolactinaemia and thyroid disease. **New or rapidly progressive hirsutism with virilisation in a postmenopausal woman is a tumour until proved otherwise.**
5. **Virilisation red flags:** onset over weeks to months, **clitoromegaly**, deepening of the voice, temporal balding, breast atrophy, increased muscle bulk, and biochemically a **total testosterone above 150–200 ng/dL** or **DHEAS above 700 µg/dL**.
6. **Assessment of hirsutism:** the **modified Ferriman–Gallwey score** — nine androgen-sensitive areas each scored 0 (no hair) to 4 (frankly virile). An abnormal score (conventionally ≥8, but **ethnicity-adjusted — lower thresholds for East Asian and higher for Mediterranean and South Asian women**) warrants androgen testing. **Investigations:** early-morning total and free testosterone, DHEAS, 17-hydroxyprogesterone, prolactin, TSH, and overnight dexamethasone suppression if Cushing's is suspected; then transvaginal ultrasound and adrenal CT if androgens are markedly raised.
7. **Female pattern hair loss (FPHL):** diffuse thinning over the crown with **widening of the central parting and preservation of the frontal hairline** (Ludwig pattern) — in contrast to the bitemporal recession of male-pattern loss. It affects **up to two-thirds of postmenopausal women**. Exclude telogen effluvium, iron deficiency, thyroid disease, and the **scarring alopecias — particularly frontal fibrosing alopecia, characteristically a postmenopausal condition with eyebrow loss and a receded, pale hairline**.
8. **Investigations for hair loss: ferritin** (aim above 40–60 ng/mL, not merely above the laboratory lower limit), TSH, vitamin D, complete blood count, and a careful drug review; clinically, the hair pull test and dermoscopy (trichoscopy) showing **hair-shaft diameter diversity**.
9. **Treatment of hirsutism:**
   - **Direct hair removal** — shaving, plucking, threading, waxing and depilatories; definitive removal by **electrolysis** or **laser/photoepilation** (most effective for dark hair on light skin; multiple sessions needed).
   - **Topical eflornithine 13.9% cream** slows facial hair growth (it inhibits ornithine decarboxylase) and is useful as an adjunct.
   - **Systemic antiandrogens** for moderate to severe disease: **spironolactone 50–100 mg/day** — **monitor potassium and renal function carefully in the elderly and avoid combining with ACE inhibitors or ARBs**; alternatives are finasteride and cyproterone acetate. **Flutamide should be avoided** because of hepatotoxicity.
   - **Allow at least 6 months before judging response**, because the hair growth cycle is slow. Contraception is not a concern in this age group, unlike in premenopausal women.
10. **Treatment of female pattern hair loss: topical minoxidil 5%** is the only FDA-approved option — expect results at 4–6 months, peak benefit at 6–12 months, and **loss of benefit if stopped**. Correct iron and thyroid deficiency first, since no topical agent compensates for an untreated nutritional or endocrine cause. Add an antiandrogen or 5-alpha reductase inhibitor for greater effect; procedural adjuncts include microneedling, platelet-rich plasma and low-level laser therapy. **Both conditions cause substantial psychological distress and a perceived loss of femininity — address body image, mood and social withdrawal explicitly, as part of the geriatric assessment.**

Latest Updates & Current Practice (2023–Present) — 3 Points

- **Low-dose oral minoxidil (0.625–2.5 mg/day)** has become a mainstream option for female pattern hair loss. A

2025 *JAAD* meta-analysis and ambulatory blood-pressure monitoring studies found **no clinically significant fall in blood pressure at these doses**, with hypertrichosis the commonest side effect. This is directly relevant to older women, who often cannot tolerate or physically apply the topical form — roughly 40% of women in one Mayo Clinic series had abandoned topical minoxidil for local side effects or adherence difficulty.

- **Antiandrogen therapy in FPHL** (*JAAD* 2025 review): **combination therapy consistently beats monotherapy**. Oral bicalutamide 25 mg/day is emerging, although a randomised trial found no clear added benefit over oral minoxidil alone within 6 months. Importantly, the androgenic contribution to FPHL is now considered **less certain than in men** — most affected women have normal androgen levels, and androgen excess in women manifests as hirsutism rather than alopecia.
- **Guidance on investigation:** the Endocrine Society hirsutism guideline (2018, still current) and SOGC Guideline No. 444 (2023) advise **against** biochemical androgen testing in women with only mild localised unwanted hair and a normal hirsutism score, recommend **pharmacological therapy plus hair removal** for patient-important hirsutism, and advise **strongly against flutamide**. A 2024 *JAMA Dermatology* systematic review confirms the efficacy of laser and light-based therapies.

Exam One-Liners

- Hirsutism = **terminal, androgen-dependent, male pattern**; hypertrichosis = generalised and androgen-independent.
- After the menopause, **oestrogen falls but androgen persists** — hence chin hair and crown thinning together.
- **Rapid hirsutism + virilisation in an older woman = androgen-secreting tumour.**
- Testosterone **>150–200 ng/dL** or DHEAS **>700 µg/dL** → image the ovaries and adrenals.
- Score it with the **modified Ferriman–Gallwey** scale (9 areas, 0–4 each).
- FPHL = **Ludwig pattern**, frontal hairline preserved; check **ferritin and TSH**.
- Spironolactone in the elderly → **watch potassium and creatinine**.

GASTROENTEROLOGY & NUTRITION

MD Geriatric Medicine — Examination Answers

Ten high-yield structured answers with current evidence to 2026

Primary textbook sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (2022); Essentials of Clinical Geriatrics, 7th edition.

Format: 15–20 numbered high-yield points for 15-mark questions; 8–10 points for 7-mark questions.

Each answer contains: textbook-based points → Latest Updates (2023–present, inline citations) → Current Practice Update comparison table → Examiner's Tip panel.

Green "Extra Points to Remember" panels mark recurring / repeatedly asked topics.

Units: Indian conventional units throughout (Hb g/dL, calcium mg/dL, creatinine mg/dL).

Prepared for Sudarsan | Revision set — Gastroenterology & Nutrition | August 2026

Contents

1. Malabsorption — etiopathogenesis, clinical features, diagnostic algorithm, management RECURS
2. Constipation in the elderly — pharmacological management and complications RECURS
3. Gastro-oesophageal reflux disease (asked twice) RECURS
4. Gastrointestinal motility disorders in the elderly
5. Approach to upper gastrointestinal bleeding
6. Haematemesis (7 marks)
7. Assessment of nutrition — methods, advantages and disadvantages
8. Mini Nutritional Assessment — components, scoring, interpretation (7 marks)
9. Total parenteral nutrition
10. Vitamin deficiencies in the elderly

A. Rapid Revision Grid — numbers, trials, formulae and named evidence

1. Etiopathogenesis, clinical manifestations, diagnostic algorithm and management of malabsorption

15 MARKS RECURRING TOPIC

Definition and Ageing Physiology

1. **Malabsorption** means defective passage of digested nutrients into the blood and lymph. It may be **global** (all nutrients) or **selective** (one nutrient, e.g. B12).
2. Distinguish **maldigestion** (failure of luminal breakdown — pancreatic or bile salt problem) from **malabsorption** (failure of mucosal uptake or lymphatic transport).
3. Healthy ageing alone does **not** cause malabsorption. Pathy's states that although brush-border enzymes fall, digestion and absorption of **carbohydrate, fat and protein remain normal** in healthy old age.
4. Age-related changes are selective: **vitamin A absorption increases**, **vitamin D absorption decreases**, **folate absorption falls slightly**, and **B12 absorption falls when hypochlorhydria is present**.
5. Small-intestinal **motility and transit are essentially preserved** with healthy ageing; therefore **bacterial overgrowth is rare in the healthy elderly**. When it occurs, look for disease, not for age.

Etiopathogenesis — Four Mechanisms

6. **Luminal (maldigestion):** pancreatic exocrine insufficiency (chronic pancreatitis, pancreatic cancer), bile salt deficiency (cholestasis, ileal resection), and **hypochlorhydria from atrophic gastritis or long-term PPI use**.
7. **Mucosal:** coeliac disease, tropical sprue, Crohn's disease, giardiasis, drug-induced enteropathy (olmesartan, NSAIDs, colchicine), amyloidosis, radiation enteritis.
8. **Post-mucosal (lymphatic/vascular):** intestinal lymphangiectasia, lymphoma, chronic mesenteric ischaemia, constrictive pericarditis, right heart failure.
9. **Stasis with bacterial overgrowth (SIBO):** Pathy's identifies the classic geriatric mechanism — **diabetes with autonomic neuropathy**, **small-intestinal diverticula**, and **reduced gastric acid** cause stasis and predispose to overgrowth, causing malnutrition and diarrhoea.
10. Post-surgical causes matter in the elderly: previous gastrectomy, blind loop, ileal resection, and short bowel after mesenteric ischaemia.
11. In **India**, always add **tropical sprue**, **intestinal tuberculosis**, **giardiasis**, **strongyloidiasis**, and **HIV enteropathy** to the differential — these are far commoner than in Western series.

Clinical Manifestations

12. **Classical picture** — chronic diarrhoea, **steatorrhoea** (bulky, pale, offensive, floating stool), weight loss, abdominal bloating and flatulence.
13. **Geriatric picture is atypical and oligosymptomatic:** presentation is often only **unexplained weight loss, anaemia, fatigue or a metabolic bone disease**, with little or no diarrhoea. Diarrhoea may even be absent.
14. **Deficiency-based clues:** iron/folate/B12 deficiency anaemia; osteomalacia and proximal myopathy (vitamin D, calcium); bruising (vitamin K); glossitis and cheilitis (B-complex); night blindness (vitamin A); oedema (hypoalbuminaemia); peripheral neuropathy (B12).
15. Fat-soluble vitamin loss (**A, D, E, K**) occurs in maldigestion and steatorrhoea, whereas isolated B12 loss suggests ileal or gastric pathology.

Diagnostic Algorithm

16. **Step 1 — Confirm malabsorption and screen:** CBC with MCV, iron studies, B12, folate, calcium, phosphate, albumin, prothrombin time, 25(OH)D, TSH. A raised INR that corrects with vitamin K is a useful bedside pointer.
17. **Step 2 — Confirm fat malabsorption:** qualitative **Sudan III stain** of stool (simple, available in India) or 72-hour faecal fat (>7 g/day). Faecal calprotectin distinguishes inflammatory from non-inflammatory causes.
18. **Step 3 — Localise the defect:**
    - **Mucosal → IgA anti-tTG plus total IgA**, then **upper GI endoscopy with 4–6 duodenal biopsies** (including bulb).
    - **Pancreatic → faecal elastase-1**; <200 µg/g suggests, <100 µg/g indicates severe exocrine insufficiency; CT/MRCP for structural disease.
    - **SIBO** → Pathy's: culture of **duodenal aspirate** or **glucose/xylose hydrogen breath test**; sensitivity and specificity vary widely, so a **negative test after antibiotics increases diagnostic certainty**.
19. **Step 4 — Imaging and exclusion of malignancy:** CT enterography, capsule endoscopy or enteroscopy for obscure cases; CT angiography if chronic mesenteric ischaemia is suspected (post-prandial pain, food fear, weight loss).

20. **Always exclude malignancy first in the elderly.** Weight loss plus altered bowel habit in an older patient requires a low threshold for colonoscopy and cross-sectional imaging before labelling anything "functional".

Management

21. **Treat the cause:** lifelong gluten-free diet for coeliac disease; pancreatic enzyme replacement for exocrine insufficiency; tetracycline plus folic acid for tropical sprue; ATT for intestinal tuberculosis.
22. **SIBO (Pathy's): metronidazole, tetracycline or quinolones, or non-absorbed rifaximin**, given for **one to four weeks**, repeated **cyclically** if recurrent — noting that Pathy's stresses there is a paucity of controlled data to guide practice.
23. **Correct deficiencies aggressively:** parenteral iron if oral is not absorbed, B12 (oral high-dose or IM), folate, calcium with vitamin D, and vitamin K where INR is prolonged.
24. **Nutritional rehabilitation:** high-energy, high-protein diet; oral nutritional supplements; MCT oil for severe steatorrhoea; lactose restriction if secondary lactase deficiency; involve a dietitian, and monitor for **refeeding syndrome** in the very depleted.
25. **Symptomatic and stewardship measures:** Pathy's notes **loperamide and clonidine** may help when no cause is found, but warns older patients are especially prone to adverse effects — constipation, urinary retention and glaucoma with loperamide; hypotension, bradycardia, sedation and dry mouth with clonidine. **Deprescribe the PPI** if the indication has lapsed, since acid suppression drives both B12 deficiency and overgrowth.

Latest Updates (2023–Present)

- **UEG 2025 guideline on malabsorption in adults** gives the first unified framework — history and drug review first, then targeted functional and endoscopic testing rather than a scattergun panel. It highlights that in autoimmune atrophic gastritis, parietal cell loss, **SIBO and iatrogenic hypochlorhydria from chronic PPI use** all aggravate B12 deficit, and that **B12 screening in the elderly matters because some neurological abnormalities reverse with supplementation** *(United European Gastroenterol J, 2025)*.
- **ACG guideline update on coeliac disease (2023)** retains **EGD with multiple duodenal biopsies** as the confirmatory standard in adults, recommends **case-finding rather than mass screening**, and requires serology and biopsy to be done **on a gluten-containing diet** *(Am J Gastroenterol, 2023)*.
- **ESsCD 2025 guidelines** conditionally permit a **no-biopsy diagnostic pathway only in adults under 45 years** with markedly raised IgA anti-tTG — meaning **older adults still require duodenal biopsy**, an important exam-relevant caveat *(United European Gastroenterol J, 2025)*.
- Coeliac disease in the elderly is increasingly recognised: a UK cohort found the proportion of coeliac diagnoses made over age 65 rose from 0% in 1990–91 to **18.7% by 2016–17**, with older patients presenting **less often with diarrhoea and more often with B12 deficiency** *(UK coeliac cohort study, 2020)*.
- Population data support routinely considering **exocrine pancreatic insufficiency** as a cause of unexplained diarrhoea and bloating in older adults, with reported prevalence around **10% by faecal elastase-1 in the elderly** *(Norwegian population data cited in current EPI literature)*.

Current Practice Update

Textbook position (Pathy's / Essentials)	Current evidence (2023–2026)
SIBO diagnosed by duodenal aspirate culture or hydrogen breath test; both with variable accuracy.	Same tests remain, but UEG 2025 emphasises a **structured stepwise work-up with drug history first** and warns against over-testing; PPI use is now formally listed as an aggravating cause.
Coeliac disease considered largely a younger-adult disease.	Now recognised as a **growing elderly diagnosis**, presenting with anaemia and B12 deficiency rather than diarrhoea; the **no-biopsy pathway is restricted to under-45s**, so biopsy remains mandatory in geriatric practice.
Little dedicated emphasis on pancreatic exocrine insufficiency as a geriatric cause.	**Faecal elastase-1** is now the routine first-line non-invasive test; <200 µg/g suggests and <100 µg/g indicates severe insufficiency.
Antibiotic courses for SIBO based on limited controlled data.	Position unchanged — **rifaximin and cyclical courses remain empirical**; high-quality RCT evidence in older adults is still awaited.

Examiner's Tip — mark-earning lines

- "Ageing itself does not cause malabsorption — Pathy's states digestion and absorption of fat, carbohydrate and protein remain normal in healthy old age; malabsorption in an older patient always signals underlying pathology."
- "In the elderly the presentation is oligosymptomatic — unexplained weight loss, anaemia or osteomalacia without diarrhoea."
- "Bacterial overgrowth is rare in the healthy elderly but common where there is stasis — diabetes, small-bowel diverticula and hypochlorhydria."
- "Exclude malignancy before diagnosing benign malabsorption in any patient over 65."

Extra Points to Remember (recurring topic)

- **D-xylose test:** abnormal in mucosal disease, normal in pure pancreatic disease — a classic viva discriminator.
- **MMA and homocysteine:** both raised in B12 deficiency; only homocysteine raised in folate deficiency.
- **Drug-induced enteropathy** to name: olmesartan (sprue-like), NSAIDs, colchicine, metformin (B12), methotrexate (folate).
- **Whipple's disease** — rare but examinable: PAS-positive macrophages, treated with ceftriaxone then long-course co-trimoxazole.
- Steatorrhoea threshold to quote: **faecal fat >7 g/day on a 100 g fat diet**.

2. Management of constipation in the elderly (including pharmacological management and complications)

15 MARKS RECURRING TOPIC

Definition, Epidemiology and Ageing

1. Constipation is defined by **Rome IV** criteria — straining, hard or lumpy stools, sensation of incomplete evacuation, anorectal blockage, need for manual manoeuvres, or fewer than three spontaneous bowel movements weekly, for at least 3 of the last 6 months.
2. Pathy's makes a key teaching point: **when comorbidities are controlled for, constipation is no commoner in the elderly than in the young, and stool frequency does not change with age**. What older people complain of is **straining and hard stools**.
3. **Laxative use, not constipation itself, rises steeply with age.** Complaints and laxative consumption are both very common in older people.
4. Age-related changes that do matter: **slower colonic peristalsis**, **reduced anal sphincter tone**, and in older women, impaired rectoanal angle and perineal descent after obstetric trauma — so **elderly women have more rectal evacuation problems than elderly men**.
5. Constipation reduces quality of life, lowers self-perceived health, worsens urinary frequency, urgency and dysuria, and its treatment improves mood, sexual function and continence.

Aetiology and Classification

6. Pathy's is explicit that **most causes relate to medication use or coexisting medical illness**, not to ageing.
7. **Commonest drugs: opiates, calcium channel blockers (verapamil worst), NSAIDs and anticholinergics**. Also iron, antipsychotics, tricyclics, antiparkinsonian drugs, diuretics.
8. **Secondary causes:** hypothyroidism, hypercalcaemia, hypokalaemia, diabetes, Parkinson's disease, stroke, dementia, depression, spinal cord lesions, colorectal cancer, strictures.
9. **Pathophysiological types:** normal-transit (commonest), **slow-transit**, and **dyssynergic defecation** (pelvic floor dyssynergia) — the last is important because it responds to biofeedback and not to laxatives.
10. Pathy's notes that **immobility and low fluid/fibre intake are often blamed but poorly supported by evidence** — increased physical activity does not reliably improve constipation.

Assessment

11. History with the **Bristol Stool Form Scale**, full drug review, and a **mandatory digital rectal examination** to detect impaction, reduced tone, and dyssynergia.
12. **Red flags demanding colonoscopy:** rectal bleeding, anaemia, weight loss, new change in bowel habit, family history of colorectal cancer, age with overdue screening.
13. Pathy's principle: **in patients with up-to-date colorectal cancer screening and no worrying symptoms, empirical treatment is appropriate**; testing is reserved for those who fail to respond.
14. Second-line testing when refractory: **colonic transit study**, **anorectal manometry with balloon expulsion**, and **defecography**. A plain abdominal radiograph helps assess stool load or confirm high impaction.

Pharmacological Management — Stepwise

15. **Step 1 — Review and remove:** stop or substitute constipating drugs; switch verapamil to another calcium channel blocker; increase dietary fibre and fluids as a universally accepted first step (though of limited evidence).
16. **Step 2 — Bulking agents: psyllium 3–6 g**, bran 4–10 g, methylcellulose 2–4 g. Pathy's warns they must be **avoided in faecal impaction, bed-bound patients and those with poor fluid intake**; side effects are bloating and flatulence.
17. **Step 3 — Osmotic laxatives: PEG (macrogol) 17–34 g** is the best tolerated overall in elders and improves both stool consistency and frequency; lactulose 10–40 g and sorbitol 70% 15–60 mL are alternatives but cause bloating and cramps through bacterial fermentation.
18. **Magnesium and saline salts should generally be avoided in the elderly** — risk of hypermagnesaemia even with normal renal function; contraindicated in renal disease, end-stage liver disease and heart failure.
19. **Step 4 — Stimulant laxatives: senna 15 mg**, **bisacodyl 5–10 mg**, **sodium picosulfate 5–10 mg**. Most commonly combined with an osmotic agent when a single drug fails.
20. **Step 5 — Second-line prescription agents: lubiprostone 8–24 µg twice daily** (chloride channel activator) is specifically endorsed by Pathy's for elders; **prucalopride**, a 5-HT4 agonist, is useful in refractory cases.
21. **Stool softeners (docusate) have no evidence base** — Pathy's records no RCT showing efficacy, one trial showing

no benefit over placebo, and psyllium proving superior. The faecal incontinence chapter states bluntly that **docusate is ineffective and should not be prescribed**.

22. **Opioid-induced constipation:** use **PAMORAs** — **naloxegol, naldemedine, methylnaltrexone** — which reverse constipation without reversing analgesia or precipitating withdrawal. Pathy's calls methylnaltrexone "an important advance", reserved for refractory cases as it is injected on alternate days.
23. **Enemas and suppositories:** small-volume tap water enemas and arachis oil retention enemas (check nut allergy) are useful; **phosphate enemas cause serious hyperphosphataemia** in renal impairment; large tap-water enemas can cause hyponatraemia; **soap-suds enemas should never be used**.
24. **Non-pharmacological and special situations: biofeedback is the mainstay for dyssynergic defecation**, effective in around **70%** over 4–6 sessions and superior to diet, exercise, laxatives or diazepam. In dementia, prevention with a regular osmotic laxative is preferred; non-verbal cues of a need to defecate include fidgeting, pacing and pulling at clothes.
25. **Refractory disease:** nearly **90% of slow-transit constipation responds to laxatives**; subtotal colectomy with ileorectal anastomosis is rarely needed and only after dyssynergia has been treated. Antegrade enemas via caecostomy are a last resort with limited evidence.

Complications

26. **Faecal impaction** — present in about **7% of institutionalised elderly** on rectal examination. **The first sign is often overflow diarrhoea and rectal incontinence**; without a rectal examination it is misdiagnosed and wrongly treated with antidiarrhoeals.
27. Further complications: **stercoral ulceration and colonic perforation** (immobile or cognitively impaired patients), faecal incontinence, urinary retention and urinary symptoms, haemorrhoids and anal fissure, rectal prolapse, sigmoid volvulus, delirium and agitation in dementia, and laxative-related electrolyte disturbance.
28. **Management of impaction:** Pathy's states the optimal treatment is not clear — oral **PEG or other osmotic laxatives with or without enemas** if tolerated; **manual disimpaction** for a hard or large rectal bolus; hyperosmotic water-soluble contrast enemas have also been used successfully. **Bulking agents must be avoided** in this group.

Latest Updates (2023–Present)

- The **first-ever joint AGA–ACG clinical practice guideline on chronic idiopathic constipation (2023)** made 10 GRADE recommendations. **Strong recommendations** were given for **polyethylene glycol, sodium picosulfate/bisacodyl, linaclotide, plecanatide and prucalopride**; conditional suggestions for fiber, magnesium oxide, lactulose, senna and lubiprostone *(Am J Gastroenterol / Gastroenterology, 2023)*.
- This guideline was the **first to endorse magnesium oxide and senna as evidence-based treatments**, and the first to include randomised data for magnesium oxide and prucalopride *(AGA/ACG joint guideline, 2023)*.
- It reaffirms that **prescription secretagogues and prokinetics should follow, not precede, over-the-counter agents**, and that fibre is first-line particularly in those with low dietary fibre intake *(AGA/ACG, 2023)*.
- **Docusate remains without support** — it was reviewed and not recommended, confirming the textbook's scepticism *(AGA/ACG, 2023)*.
- The **ASCRS 2024 guideline** on chronic constipation adds surgical-perspective guidance for refractory slow-transit disease and pelvic floor dysfunction *(Dis Colon Rectum, 2024)*.
- Non-pharmacological adjuncts continue to accumulate low-grade support in stroke survivors — **abdominal massage** and **visceral mobilisation** reduce constipation severity, though further high-quality studies are needed *(systematic review and RCT evidence, 2020–2024)*.

Current Practice Update

Textbook position (Pathy's)	Current evidence (2023–2026)
Best evidence supports psyllium, osmotic laxatives (especially PEG) and lubiprostone.	AGA/ACG 2023 **upgrades PEG, sodium picosulfate, linaclotide, plecanatide and prucalopride to strong recommendations**; lubiprostone is now only **conditional**.
Magnesium salts generally avoided in elders because of hypermagnesaemia risk.	Magnesium oxide is now a **recognised evidence-based option with RCT support** — but the geriatric caution stands: avoid in CKD, and this is the answer's key nuance.
Senna listed as a stimulant option without a strong evidence base.	**Senna formally endorsed for the first time** as an evidence-based treatment.
Stool softeners of limited value; no RCT support.	**Position confirmed and strengthened** — docusate is not recommended.
Methylnaltrexone highlighted as the advance for opioid-induced constipation.	Whole **PAMORA class** (naloxegol, naldemedine, methylnaltrexone) now supported by network meta-analysis; **oral agents preferred first** for convenience in older outpatients.

Examiner's Tip — mark-earning lines

- "Stool frequency does not change with age — older people complain of straining and hard stools, and when comorbidity is controlled for, constipation is no commoner than in the young."
- "Constipation in an older person is a drug problem until proved otherwise — opiates, calcium channel blockers, NSAIDs and anticholinergics."
- "Overflow diarrhoea in an older patient is faecal impaction until a rectal examination proves otherwise; treating it as diarrhoea is a serious error."
- "Avoid bulking agents in impaction, phosphate enemas in renal impairment, and magnesium salts in CKD."
- "Biofeedback, not laxatives, is the treatment for dyssynergic defecation — around 70% respond."

Extra Points to Remember (recurring topic)

- **Doses to quote:** psyllium 3–6 g; PEG 17–34 g; lactulose 10–40 g; senna 15 mg; bisacodyl 5–10 mg; lubiprostone 8–24 µg BD.
- **Numbers to quote:** 7% of institutionalised elderly impacted; 90% of slow-transit responds to laxatives; biofeedback effective in ~70%; median 42% prevalence in long-term care.
- **Neostigmine** — reserved for hospitalised acute colonic pseudo-obstruction (Ogilvie's); produces prompt colonic decompression.
- **Probiotics:** large RCTs have failed to show significant benefit; misoprostol and colchicine are refractory-case options limited by cramping.
- **Indian practice point:** ispaghula (isabgol) is cheap and widely available and is the psyllium of choice; PEG sachets are affordable and preferable to repeated enemas in home care.

3. Gastro-oesophageal reflux disease in the elderly

15 MARKS ASKED TWICE — RECURRING

Definition and Epidemiology

1. **GORD** is the reflux of gastric contents into the oesophagus causing troublesome symptoms or mucosal complications.
2. Pathy's records that GORD is the **sixth most common disorder among elderly people in residential care**, and that around **20% of the general population experience weekly reflux symptoms**.
3. The prevalence in the elderly is **as high as in the young**, but the disease behaves differently: it **presents atypically and is more likely to be severe**.

Pathophysiology and Age-related Changes

4. The dominant mechanism at all ages is **transient lower oesophageal sphincter relaxations**, particularly after meals — not simply low resting sphincter pressure.
5. Age-related predisposing changes listed in Pathy's: **hiatus hernia in around 60% of those over 60**; **declining LOS resting pressure and intra-abdominal length**; **increased acid exposure**; reduced salivary flow; and impaired acid clearance.
6. The **number of reflux episodes is similar to the young, but their duration is longer**, reflecting impaired clearance from reduced primary and secondary peristalsis and a less compliant oesophagus.
7. **Visceral sensation declines with age** — perception of balloon distension and of acid is reduced, and cortical evoked potentials are of lower amplitude. This explains why symptoms are milder despite worse mucosal injury.
8. The refluxate may be **less acidic** because of atrophic gastritis, but its **bile content may still injure the mucosa** and contribute to Barrett's change.

Clinical Features — the Geriatric Paradox

9. **Key examination line:** Pathy's states GORD in the elderly presents with **more severe mucosal injury — erosive oesophagitis, stricture or Barrett's oesophagus — yet symptoms are characteristically milder or qualitatively different**.
10. Consequently **dysphagia, vomiting, respiratory difficulty, weight loss and anaemia are not uncommon presenting features**, while **heartburn occurs less often than in the young**.
11. In the general population heartburn or regurgitation has a sensitivity of about **70%** for GORD but low specificity against 24-hour pH monitoring; comparable data for an ageing population are not available.
12. **Atypical/extra-oesophageal manifestations:** chronic cough, asthma, laryngitis and non-cardiac chest pain — mediated either directly by acid-pepsin or by vagal reflexes from oesophageal acid exposure.
13. **Alarm symptoms mandating prompt endoscopy:** dysphagia, anorexia, weight loss, haematemesis, anaemia. Pathy's states the **threshold for endoscopy in older patients should be lower than in the young**.

Investigations

14. **Endoscopy** is the first investigation in older patients — it grades oesophagitis (Los Angeles A–D), detects stricture, Barrett's and malignancy, and permits biopsy and dilatation.
15. **Trial of double-dose PPI for 2–8 weeks** (depending on symptom frequency) is a useful and cost-effective initial test in atypical presentations and non-cardiac chest pain, with sensitivity and specificity up to **80%**.
16. **Oesophageal manometry and ambulatory pH monitoring** are indicated when PPIs fail — manometry is particularly useful to **exclude achalasia** before considering surgery.
17. Exclude cardiac disease first in any older patient with chest pain; also consider musculoskeletal, pulmonary, pericardial, gastric and biliary causes.

Management

18. **Lifestyle:** weight reduction, head-end elevation, avoidance of late meals, smoking and alcohol; review drugs that lower LOS pressure (calcium channel blockers, nitrates, anticholinergics) and drugs causing pill oesophagitis.
19. **PPIs are the drugs of choice.** Pathy's states there is **no significant difference in healing capacity between older and younger patients**, that **PPIs retain superiority over H2 receptor antagonists**, and that **no dose adjustment is needed for age-related renal or hepatic change**.
20. Important geriatric caveat: **downward dose titration is less appropriate than in the young**, especially where the initial symptoms were mild or the GORD is complicated — because symptom severity underestimates mucosal disease.
21. **Adverse effects of long-term PPI use** (Pathy's grading of causality):
    - **Causal relationship likely:** acute interstitial nephritis, benign gastric fundic gland polyps, increased enteric

infections.
    - **Possible:** *Clostridioides difficile* infection, B12 deficiency, hypomagnesaemia/hypocalcaemia.
    - **Not supported by strong evidence:** osteoporosis and hip fracture, community-acquired pneumonia, dementia, CKD progression.
    - Clopidogrel interaction is of **minimal significance except with omeprazole**.
22. **Deprescribing principle:** PPIs are often over-prescribed and the indication for ongoing therapy should be **reviewed periodically**. H2RAs are an alternative but are less potent and can cause **mental status change in renal or hepatic dysfunction**.
23. **Prokinetics have no established role** in GORD treatment.
24. **Surgery:** laparoscopic fundoplication is an option, with outcomes and complication rates in patients over 70 comparable to those under 60. However, **patients with ineffective oesophageal motility risk post-operative dysphagia**, and long-term medical therapy is likely more cost-effective in older patients given the fewer remaining years of therapy needed.
25. **Endoscopic anti-reflux procedures have not fulfilled their initial promise** and should be restricted to clinical trials.

Latest Updates (2023–Present)

- **Lyon Consensus 2.0 (2024)** redefined conclusive evidence of GORD: **LA grade B, C or D oesophagitis** now counts as conclusive, while **LA grade A is no longer accepted as diagnostic** and requires confirmation by ambulatory reflux monitoring *(Gut, 2024)*.
- **Potassium-competitive acid blockers (P-CABs)** have entered practice. **Vonoprazan received FDA approval in November 2023** for erosive GORD and in **July 2024 for heartburn in non-erosive GORD** — the first major advance in GORD therapy in over three decades *(FDA / Pharmaceuticals, 2025)*.
- The **AGA Clinical Practice Update on integrating P-CABs (2024)** advises that P-CABs may be used for healing and maintenance in **more severe (LA grade C/D) erosive oesophagitis**, where they may be superior and act faster than PPIs — but notes that **markedly higher cost and lack of comparison with double-dose PPI mean they are not routine first-line therapy** *(Gastroenterology, 2024)*.
- P-CABs give **rapid, potent, food-independent and sustained acid suppression** without needing acid activation, and act on both resting and activated proton pumps *(Front Physiol, 2025)*.
- The **VISION study** provides the only 5-year safety data for a P-CAB: maintenance vonoprazan produced higher gastrin levels with parietal and foveolar cell hyperplasia, but **no excess malignant epithelial change or gastric neuroendocrine tumours** *(Clin Gastroenterol Hepatol, 2025)*.
- The **2025 focused update of the Seoul Consensus** recommends either a **standard-dose PPI or a P-CAB for 4–8 weeks** as initial therapy for NERD or mild erosive oesophagitis, with P-CABs offering superior healing in severe erosive disease *(J Neurogastroenterol Motil, 2025)*.
- The **ACG Clinical Guideline for GORD (2022)** remains the reference standard for diagnosis and management and continues to emphasise **de-escalation to the lowest effective dose and periodic review of PPI indication** *(Am J Gastroenterol, 2022)*.

Current Practice Update

Textbook position (Pathy's)	Current evidence (2023–2026)
PPIs are the mainstay and are superior to H2 receptor antagonists; no newer class discussed.	A new class — **P-CABs (vonoprazan, tegoprazan, fexuprazan, keverprazan, zastaprazan)** — is now available, with **superior and faster healing in LA grade C/D oesophagitis**; cost restricts routine first-line use.
Endoscopic grading of oesophagitis taken at face value.	**Lyon 2.0 (2024)**: LA grade A is no longer conclusive for GORD; only **grades B, C and D** are diagnostic, so pH monitoring is needed if grade A is the only finding.
Long-term PPI adverse effects graded as likely/possible/unsupported.	**Framework unchanged and reinforced**; guidelines now stress structured deprescribing and periodic review rather than indefinite continuation.
Fundoplication safe in over-70s but medical therapy more cost-effective.	**Position unchanged.** Endoscopic anti-reflux therapy still not recommended outside trials.
H. pylori eradication not emphasised in the reflux context.	AGA 2024 advises **P-CABs should replace PPIs in H. pylori eradication regimens for most patients** — pooled first-line eradication 92% with vonoprazan versus 80% with PPI.

Examiner's Tip — mark-earning lines

- "The geriatric paradox of GORD: **more severe mucosal injury with milder symptoms**, because visceral sensation declines with age."
- "Because symptoms underestimate disease, **the threshold for endoscopy must be lower and dose reduction is less appropriate** than in younger patients."
- "Hiatus hernia is present in around 60% of those over 60."
- "Long-term PPI risks should be graded, not recited — likely for interstitial nephritis and enteric infection, unproven for dementia and hip fracture."
- "Prokinetics have no established role in GORD."

Extra Points to Remember (asked twice — very high yield)

- **Pill oesophagitis** is a geriatric differential for odynophagia: potassium chloride, tetracyclines, aspirin, NSAIDs, quinidine, theophylline, ferrous sulfate, alendronate and now **dabigatran** (extensive mucosal sloughing). Prevent by taking tablets upright with a full glass of water.
- **Barrett's oesophagus** — intestinal metaplasia; more prevalent in elderly reflux; surveillance decisions must be individualised against life expectancy and fitness for intervention.
- **Scleroderma oesophagus** — 80% have dysmotility with very low LOS pressure and severe reflux; **high-dose PPI is often required**.
- **Extra-oesophageal GORD** is a recognised cause of chronic microaspiration, worsening asthma and fibrotic lung disease, and diffuse aspiration bronchiolitis.
- **PPI–pneumonia association:** PPI use may impart about a **1.5-fold risk of community-acquired pneumonia**, greatest in the first month after initiation — an important prescribing caution in frail elders.
- **Indian practice:** pantoprazole and rabeprazole are the cheapest and most available PPIs; vonoprazan is marketed in India but cost limits routine use.

4. Gastrointestinal motility disorders in the elderly

15 MARKS

General Principle

1. The core teaching point of Pathy's chapter is that **gastrointestinal motor function is relatively well preserved with healthy ageing, but there is a general decline in visceral sensation**.
2. **Systemic illness and medication — not age — impair gut function in the elderly.** Consequences include swallowing disorders, impaired nutrition, altered drug absorption and altered bowel habit.
3. Sensory decline is demonstrable throughout the gut: reduced perception of balloon distension in the **oesophagus, stomach and rectum**, probably from loss of intrinsic sensory enteric neurons plus altered central processing. Perception of **chemical stimuli such as acid also decreases**.

Oesophageal Motility Disorders

4. In those over 60, **upper oesophageal sphincter resting pressure is lower but shows less swallow-induced relaxation**, indicating a degree of UOS resistance; reference ranges from young subjects must not be applied to older patients.
5. **Reflex UOS contraction in response to laryngeal stimulation is impaired** — a mechanism predisposing to aspiration; the frequency but not the magnitude of the response falls, implicating the sensory limb.
6. In the distal oesophagus there is **reduced contraction amplitude and more frequent failed peristalsis**; secondary peristalsis is less easily elicited. These changes begin as early as **age 40**.
7. **Achalasia:** peak incidence is in early-to-mid adulthood, but **a second smaller peak occurs in the elderly**. It presents with dysphagia for both liquids and solids; in older patients **weight loss, regurgitation and aspiration** are prominent while **chest pain is less common**.
8. **Diagnosis of achalasia:** barium swallow shows a dilated oesophagus with **'bird's beak' or 'rat's tail' tapering**; manometry shows **absent or incomplete LOS relaxation** with type I (absent contractions), type II (pan-oesophageal pressurisation) or type III (premature spastic contractions).
9. **Always exclude pseudo-achalasia** — carcinoma of the distal oesophagus or cardia mimicking achalasia. A **short history with disproportionate weight loss** is the clue; endoscopy, and sometimes endoluminal ultrasound or CT, is mandatory in the elderly.
10. **Treatment of achalasia: pneumatic dilatation** and **laparoscopic myotomy** are the most efficacious for types I and II, each with about a **1% perforation rate**. **POEM** allows calibrated myotomy and is particularly useful in **type III**. In a consecutive series of 51 patients aged ≥65 undergoing laparoscopic myotomy there were **no deaths, few complications and a median stay of 3 days**. For the **frail elderly**, **endoscopic botulinum toxin injection into the LOS** is a safe alternative.
11. **Distal oesophageal spasm** is more commonly diagnosed over age 50 and gives a **corkscrew appearance on barium** with premature contractions on manometry.
12. **Minor disorders — ineffective oesophageal motility and fragmented peristalsis** — account for **more than one-third of presentations with dysphagia in patients over 65**. Radiographic and manometric abnormalities correlate poorly with symptoms, no specific therapy exists, and management is **acid suppression plus optimisation of nutrition**.

Gastric and Small-Intestinal Motility

13. **Only a modest slowing of gastric emptying** occurs with healthy ageing, confirmed longitudinally. However, altered perception of gastric distension and enhanced humoral responses to duodenal nutrients contribute to the **anorexia of ageing**.
14. Intraduodenal nutrients stimulate **greater cholecystokinin release** in healthy elderly, intraduodenal glucose is **more satiating**, and higher rates of *H. pylori* infection and atrophic gastritis are associated with **lower ghrelin** — a triad worth quoting for anorexia of ageing.
15. **Drug absorption:** slow emptying and altered gastric pH may affect absorption of oral medication; paracetamol absorption is slightly slower, but **benzodiazepines, tetracycline and L-dopa absorption are not significantly altered by age**.
16. **Small intestine:** MMC periodicity is preserved in the healthy elderly; phase III propagation velocity is modestly slower, and there are more propagated clustered contractions — a pattern also seen in IBS, of unclear significance. **Transit is comparable to the young**, in contrast to the delayed colonic transit characteristic of ageing.
17. **Postprandial hypotension** can legitimately be classified as a gastrointestinal motility disorder — the fall in blood pressure relates to splanchnic blood flow regulation and gut peptide release, is worst in **type 2 diabetes with autonomic neuropathy**, and is an **under-recognised cause of syncope and falls**. It is attenuated by **octreotide**,

and by measures slowing gastric emptying and carbohydrate absorption (e.g. **GLP-1 receptor agonists such as lixisenatide**, guar, acarbose).

Motility Disorders in Systemic Disease

18. **Diabetes:** gastroparesis impairs nutrient and drug absorption and destabilises glycaemia; diagnose by endoscopy first to exclude obstruction, then **scintigraphic gastric emptying**. Treat with prokinetics — **metoclopramide, domperidone or erythromycin (a motilin agonist)**. **Cisapride was withdrawn for arrhythmia risk.** Pyloric botulinum toxin is of unclear benefit and **less likely to help patients over 50**; gastric electrical stimulators lack adequate controlled evidence.
19. Up to **80% of patients with diabetic gastroparesis have abnormal small-intestinal motility**. In diabetic diarrhoea, specifically exclude **SIBO, coeliac disease and pancreatic exocrine insufficiency**.
20. **Progressive systemic sclerosis:** peak incidence in the fifth and sixth decades; GI involvement in the majority. **Oesophageal dysmotility in about 80%** with very low LOS pressure and severe reflux; gastroparesis, pseudo-obstruction, bacterial overgrowth, malnutrition, constipation and faecal incontinence may all occur. Smooth muscle atrophy and fibrosis plus **antibodies to M3 muscarinic receptors** are implicated. High-dose PPI is often needed; prokinetics help when transit is delayed.
21. **Parkinson's disease** causes dysphagia, gastroparesis and constipation, and is a major contributor to bowel dysfunction; amyloidosis and other connective tissue diseases produce similar patterns.

Functional Gastrointestinal Disorders

22. Functional disorders are defined by **Rome IV** and are often overlooked in the elderly. **10–15% of people over 70 have IBS** in community surveys; prevalence is greater in women at all ages.
23. **Organic disease must be rigorously excluded** — its prevalence is higher than in the young. Have a low threshold for colonoscopy with altered bowel habit, and remember that **mesenteric ischaemia occurs more often in patients with IBS than without**.
24. **Treatment:** low-FODMAP diet is first-line for IBS but almost unstudied in the elderly; antispasmodics (hyoscine, mebeverine, peppermint oil) and **low-dose tricyclics** have a good evidence base, with SSRIs better tolerated than tricyclics in older patients. **Placebo response is 20–70%**, so judge all therapies against it.
25. **Opiates must be avoided** for chronic abdominal pain — ineffective, and causing tolerance, opioid-induced hyperalgesia and narcotic bowel syndrome. Beware anticholinergic burden: sedation, urinary retention, postural hypotension, blurred vision and glaucoma.

Latest Updates (2023–Present)

- The **Chicago Classification v4.0** is now the manometric standard, requiring **both supine and upright swallows and provocative testing (multiple rapid swallows, rapid drink challenge)**, and re-labelling ineffective oesophageal motility with stricter criteria — reducing over-diagnosis of "minor motility disorders" in older patients *(Neurogastroenterol Motil, current standard)*.
- **Lyon Consensus 2.0 (2024)** integrates motility and reflux assessment, altering how manometric findings are interpreted alongside pH-impedance data *(Gut, 2024)*.
- The **ACG guideline on gastroparesis (2022)** confirms **4-hour scintigraphy as the diagnostic standard**, recommends metoclopramide at the lowest effective dose with attention to tardive dyskinesia risk, and does not support routine botulinum toxin — consistent with Pathy's scepticism *(Am J Gastroenterol, 2022)*.
- **GLP-1 receptor agonists** are now a widespread iatrogenic cause of delayed gastric emptying in older diabetics; this is clinically relevant both for symptoms and for **peri-endoscopic and peri-operative aspiration risk**, prompting society guidance on withholding these agents before procedures *(ASA/multisociety guidance, 2023–2024)*.
- For achalasia, contemporary comparative data continue to support **POEM for type III** and **laparoscopic Heller myotomy or pneumatic dilatation for types I and II**, with POEM carrying a higher rate of post-procedure reflux — relevant when choosing therapy in an older patient already prone to severe GORD *(contemporary achalasia literature, 2023–2025)*.

Current Practice Update

Textbook position (Pathy's)	Current evidence (2023–2026)
Chicago Classification v3.0 used for manometric diagnosis.	**Chicago v4.0** now standard — mandates upright and supine swallows plus provocative manoeuvres, and tightens criteria for ineffective oesophageal motility.
Pyloric botulinum toxin and gastric electrical stimulation of unproven value.	**Position confirmed** by ACG 2022 gastroparesis guideline; neither is recommended as routine therapy.
Postprandial hypotension attenuated by octreotide and by GLP-1 agonists slowing gastric emptying.	Same mechanism now cuts both ways — **widespread GLP-1 agonist use is itself a common cause of delayed emptying**, requiring pre-procedural withholding to reduce aspiration risk.
POEM emerging, with role yet to be defined.	**POEM established**, especially for type III achalasia; higher post-procedural reflux rates make patient selection important in the elderly.

Examiner's Tip — mark-earning lines

- "Motor function is largely preserved with healthy ageing; **it is visceral sensation that declines** — and that decline explains atypical presentations across the gut."
- "In an older patient with achalasia, always exclude pseudo-achalasia — a short history with disproportionate weight loss is the warning."
- "Minor motility disorders account for over a third of dysphagia presentations after 65, and manometric findings correlate poorly with symptoms."
- "Postprandial hypotension is a gastrointestinal cause of falls and syncope in the elderly."
- "For the frail elderly with achalasia, botulinum toxin injection is the safe option."

5. Approach to upper gastrointestinal bleeding in the elderly

15 MARKS

Definition and Significance

1. **Upper GI bleeding (UGIB)** is bleeding proximal to the ligament of Treitz, presenting as haematemesis, coffee-ground vomiting, melaena, or occasionally haematochezia when brisk.
2. Pathy's places this in context: **bleeding causes or contributes to the death of about 5% of the elderly population**, chiefly from intracranial and subarachnoid haemorrhage, ruptured aortic aneurysm, and **gastrointestinal bleeding from peptic ulcers and gastric or colonic malignancy**.
3. A crucial principle: **most bleeding in the elderly is localised and due to a specific underlying pathology, frequently malignancy** — primary haemostatic disorders are relatively rare.

Causes

4. **Peptic ulcer disease** — the commonest cause; driven in older people by **NSAIDs, aspirin, corticosteroids and *H. pylori***. Pathy's tabulates aspirin, NSAIDs (ibuprofen, diclofenac, naproxen) and corticosteroids as carrying an **enhanced risk of peptic ulceration**, and antiplatelets, DOACs, heparins and thrombolytics as carrying an **enhanced risk of bleeding**.
5. **Erosive gastritis and duodenitis** — drug-related and stress-related.
6. **Oesophageal and gastric varices** — in India a major cause, from cirrhosis and also from **non-cirrhotic portal fibrosis and extrahepatic portal venous obstruction**.
7. **Oesophagitis, including pill oesophagitis** — Pathy's notes perforation and bleeding as complications, particularly with potassium chloride, quinidine and non-steroidal drugs.
8. **Malignancy** — gastric and oesophageal carcinoma; must always be excluded in this age group.
9. **Mallory–Weiss tear, Dieulafoy lesion, angiodysplasia, GAVE (watermelon stomach), aorto-enteric fistula** after aortic graft.

Why the Elderly Do Worse

10. **Reduced physiological reserve** — blunted tachycardic response (especially on beta-blockers), so hypotension appears late and shock is under-recognised.
11. **Polypharmacy and antithrombotics** — anticoagulants and antiplatelets both increase incidence and severity; warfarin effects are enhanced by age over 80, weight loss, acute illness, heart failure, renal and hepatic impairment.
12. **Comorbidity** — ischaemic heart disease limits tolerance of anaemia; CKD limits fluid loading; cirrhosis worsens coagulopathy.
13. **Atypical presentation** — syncope, falls, confusion, angina or breathlessness may be the only manifestation, with melaena discovered only on rectal examination.

Initial Assessment and Resuscitation

14. **ABC first:** two wide-bore cannulae, crystalloid resuscitation, oxygen, protect the airway in active haematemesis or encephalopathy; hourly urine output and continuous monitoring.
15. **Bloods:** CBC, cross-match, urea and creatinine (a **disproportionately raised urea supports an upper source**), LFTs, coagulation profile, and consider troponin/ECG in older patients with ischaemic risk.
16. **Risk stratification with the Glasgow–Blatchford Score (GBS):** patients with **GBS 0–1** are at very low risk of rebleeding, death or needing intervention and may be managed as outpatients. The **Rockall score** is used for post-endoscopic risk.
17. **Transfusion:** a **restrictive strategy with a haemoglobin threshold of 7 g/dL** is recommended in haemodynamically stable patients, targeting a post-transfusion haemoglobin of **7–9 g/dL**. In those with acute or chronic **cardiovascular disease, use a more liberal threshold of 8 g/dL**.
18. **Pre-endoscopic erythromycin:** a single **250 mg intravenous dose 30–120 minutes before endoscopy** improves visualisation, reduces the need for second-look endoscopy, reduces units transfused and shortens hospital stay.
19. **Pre-endoscopic PPI:** ACG could not reach a recommendation for or against it; in practice a high-dose PPI infusion is started while awaiting endoscopy and downgrades stigmata.
20. **Antithrombotic management:** withhold vitamin K antagonists; for haemodynamic instability give **four-factor prothrombin complex concentrate** (rapid onset) rather than routine FFP, which carries volume overload and TRALI risk. Do **not routinely give vitamin K** in acute bleeding because of slow onset and later difficulty re-anticoagulating. Do **not routinely transfuse platelets**. **Do not stop aspirin used for secondary cardiovascular prevention** — cessation increases 30-day mortality; if held, restart within 3–5 days. For dual antiplatelet therapy, continue aspirin and hold the second agent, restarting preferably within 5 days.

21. **Tranexamic acid is not recommended** in acute GI bleeding.

Endoscopy and Definitive Therapy

22. **Timing:** endoscopy **within 24 hours** of presentation for admitted patients. **Very early endoscopy (<12 hours)** may be considered with persistent haemodynamic instability, in-hospital bloody emesis, or when anticoagulation cannot be interrupted.
23. **Forrest classification** guides therapy: Ia spurting, Ib oozing, IIa non-bleeding visible vessel, IIb adherent clot, IIc flat pigmented spot, III clean base. **Endoscopic therapy is indicated for Ia, Ib and IIa.**
24. **Endoscopic modalities:** combination therapy (dilute adrenaline injection **plus** a second modality) — bipolar electrocoagulation, heater probe, absolute ethanol injection, clips, argon plasma coagulation, soft monopolar coagulation. **Hemostatic powder spray (TC-325)** is suggested for actively bleeding ulcers and **over-the-scope clips** for recurrent bleeding after previous successful haemostasis.
25. **Post-endoscopic PPI: high-dose PPI continuously or intermittently for 3 days**, then twice-daily oral PPI for the first 2 weeks after endoscopy.
26. **Variceal bleeding:** resuscitate, give **terlipressin or octreotide** plus **prophylactic antibiotics (ceftriaxone)**, and perform **endoscopic band ligation**; consider early TIPS in high-risk patients. Gastric varices are treated with cyanoacrylate glue injection.
27. **Failure of endoscopic therapy:** repeat endoscopy for rebleeding; if this fails, **transcatheter arterial embolisation** is preferred to surgery in the elderly, with surgery reserved for uncontrollable bleeding or perforation.

Secondary Prevention

28. **Test for and eradicate *H. pylori*** in all ulcer bleeding, and confirm eradication. Stop NSAIDs; if they are essential, co-prescribe a PPI or use a COX-2 inhibitor with PPI cover.
29. **Re-evaluate the indication for every antithrombotic**, restart at the earliest safe time with PPI co-prescription, and biopsy or repeat endoscopy for gastric ulcers to exclude malignancy.

Latest Updates (2023–Present)

- **ACG guideline (2021)** and **ESGE guideline (2021)** remain the operative standards: GBS 0–1 for outpatient management, transfusion threshold 7 g/dL, endoscopy within 24 hours, high-dose PPI for 3 days post-haemostasis, and TC-325 / over-the-scope clips as newer haemostatic options. The **ESGE guideline is under review for update** *(Am J Gastroenterol 2021; Endoscopy 2021)*.
- A **2023 systematic review and meta-analysis** confirmed restrictive transfusion does not increase in-hospital or 30-day mortality or rebleeding, with fewer transfusion reactions and post-transfusion interventions; **thresholds above 8 g/dL may produce more untoward outcomes** *(Sci Rep, 2023)*.
- **ESGE (2022) variceal guideline** found FFP transfusion in variceal haemorrhage was associated with **significantly increased 42-day mortality**, and advises against routine platelet transfusion or a fixed platelet threshold *(Endoscopy, 2022)*.
- **Vonoprazan** has been compared with intravenous PPI for prevention of rebleeding from high-risk peptic ulcers after successful endoscopic haemostasis, with promising results — an emerging alternative where available *(comparative trial data cited in AGA P-CAB update, 2024)*.
- A **2025 network meta-analysis** examined prokinetics with or without nasogastric lavage versus lavage alone for improving endoscopic visualisation, supporting **erythromycin** as the agent of choice *(network meta-analysis, 2025)*.
- A **2025 study of 297 patients over 65** confirmed that antiplatelet, anticoagulant and NSAID use meaningfully alters transfusion need, endoscopic treatment requirement, rebleeding rates and 30-day mortality in geriatric UGIB — reinforcing structured medication review *(Medicine (Baltimore), 2025)*.
- The **ACG lower GI bleeding guideline update (2023)** reinforced the same principles for the lower tract — risk stratification for early discharge, restrictive transfusion at 7 g/dL, and **against antifibrinolytics such as tranexamic acid** *(Am J Gastroenterol, 2023)*.

Current Practice Update

Textbook position (Pathy's)	Current evidence (2023–2026)
Peptic ulcer and malignancy identified as major causes of fatal bleeding in the elderly; no scoring system detailed.	Care is now **protocolised**: GBS 0–1 permits outpatient management; Rockall for post-endoscopic risk; Forrest class dictates endoscopic therapy.
No specific transfusion threshold given.	**Restrictive strategy at Hb 7 g/dL** is standard (target 7–9 g/dL), rising to **8 g/dL with cardiovascular disease**, supported by meta-analysis to 2023.
Antithrombotic drugs listed as bleeding risks without reversal protocols.	Explicit reversal guidance: **4F-PCC over FFP** for VKA with instability; **no routine vitamin K**, **no routine platelets**, **no tranexamic acid**; **continue secondary-prevention aspirin**.
Endoscopic haemostasis described in general terms.	Newer modalities are now guideline-endorsed: **TC-325 haemostatic powder** for active ulcer bleeding and **over-the-scope clips** for recurrent bleeding.
PPI therapy for ulcer bleeding not protocolised.	**High-dose PPI for 3 days, then twice-daily oral PPI for 2 weeks** after endoscopic haemostasis; vonoprazan is an emerging alternative.

Examiner's Tip — mark-earning lines

- "Bleeding contributes to about 5% of deaths in the elderly, and most of it is localised pathology — frequently malignancy — rather than a haemostatic disorder."
- "Quote the numbers: GBS 0–1 for discharge; transfuse below 7 g/dL, or 8 g/dL with cardiovascular disease; endoscopy within 24 hours; erythromycin 250 mg IV 30–120 minutes pre-procedure."
- "Do not stop secondary-prevention aspirin — cessation increases 30-day mortality."
- "PCC, not FFP, for warfarin reversal with haemodynamic instability; no routine tranexamic acid."
- "In India, always consider variceal bleeding from cirrhosis, non-cirrhotic portal fibrosis and EHPVO alongside peptic ulcer."

6. Haematemesis

7 MARKS

1. **Haematemesis** is vomiting of frank blood or coffee-ground material, indicating bleeding proximal to the ligament of Treitz. It is **an alarm symptom mandating prompt endoscopy at any age**, and Pathy's specifically lists it among the alarm symptoms requiring urgent investigation.
2. **Distinguish from mimics:** haemoptysis (frothy, bright red, alkaline, with cough) and swallowed blood from epistaxis or oropharyngeal bleeding. Coffee-ground appearance reflects acid conversion of haemoglobin to haematin.
3. **Common causes in the elderly:** peptic ulcer (NSAIDs, aspirin, steroids, *H. pylori*), erosive gastritis, oesophageal and gastric varices, oesophagitis including pill oesophagitis, Mallory–Weiss tear, Dieulafoy lesion, angiodysplasia, and **gastric or oesophageal malignancy**.
4. **Assess severity immediately:** pulse, blood pressure, postural drop, capillary refill, urine output and mental state. Remember the blunted tachycardic response in older patients and those on beta-blockers — **shock is under-recognised**.
5. **Resuscitate first, investigate second:** two wide-bore cannulae, crystalloid, oxygen, cross-match, and airway protection with massive haematemesis or encephalopathy. Send CBC, urea and creatinine (raised urea supports an upper source), LFTs and coagulation.
6. **Risk stratify with the Glasgow–Blatchford Score** — a score of **0–1 identifies very-low-risk patients** suitable for outpatient management; all others are admitted.
7. **Transfuse restrictively** at a haemoglobin threshold of **7 g/dL** (target 7–9 g/dL), or **8 g/dL if there is cardiovascular disease**. Withhold anticoagulants, use **PCC rather than FFP** for warfarin reversal with instability, and **continue aspirin prescribed for secondary prevention**.
8. **Endoscopy within 24 hours** (earlier if unstable), preceded by **erythromycin 250 mg IV** to clear the stomach. Apply **combination endoscopic haemostasis** for Forrest Ia, Ib and IIa lesions, then **high-dose PPI for 3 days followed by twice-daily oral PPI for 2 weeks**.
9. **If variceal:** terlipressin or octreotide, prophylactic ceftriaxone, and band ligation; consider early TIPS. If endoscopy fails, proceed to **transcatheter embolisation** before surgery.
10. **Prevention:** eradicate *H. pylori*, stop NSAIDs, co-prescribe PPI where antithrombotics must continue, and **always biopsy or re-scope a gastric ulcer to exclude malignancy**.

Latest Updates (2023–Present) — concise

- **Restrictive transfusion at 7 g/dL is confirmed safe** by 2023 meta-analysis, with no excess mortality or rebleeding and fewer transfusion reactions; thresholds above 8 g/dL may worsen outcomes *(Sci Rep, 2023)*.
- **Tranexamic acid is not recommended** in acute GI bleeding, and **FFP in variceal haemorrhage is associated with increased 42-day mortality** *(ESGE, 2021–2022; ACG, 2023)*.
- **Vonoprazan** is emerging as an alternative to intravenous PPI for preventing rebleeding from high-risk ulcers after endoscopic haemostasis *(cited in AGA P-CAB Clinical Practice Update, 2024)*.

Current Practice Update

Textbook position	Current evidence
Haematemesis treated as an alarm symptom requiring prompt endoscopy.	Unchanged — but now with a **defined 24-hour window** and formal risk scoring for safe outpatient management.
No transfusion or reversal protocol specified.	**Hb 7 g/dL threshold (8 g/dL with cardiovascular disease); PCC over FFP; no routine platelets, vitamin K or tranexamic acid.**

Examiner's Tip

- "Resuscitation precedes endoscopy — but endoscopy within 24 hours changes outcome."
- "A raised urea with normal creatinine supports an upper gastrointestinal source."
- "Never discharge an older patient with haematemesis on symptom resolution alone — score them."

7. Assessment of a patient's nutrition — methods, advantages and disadvantages

15 MARKS

Principles

1. Nutritional assessment in older adults is a **two-step process**: **screening** to identify those at risk, followed by **assessment** for diagnosis and severity grading.
2. Essentials of Clinical Geriatrics states plainly that anthropometric variables **cannot provide a complete description of nutritional status and are not highly correlated with biochemical or haematological indicators** — so no single method suffices, and a combination is always required.
3. The critical questions to answer are: is there reason to suspect malnutrition; of which nutrient and to what extent; what is the pathophysiological mechanism (intake, digestion and absorption, metabolism, excretion or requirement); and what aetiology underlies it.
4. Distinguish **starvation** from **cachexia**: the hallmark of starvation is a **rapid response to refeeding**, whereas **cachexia is remarkably resistant to hypercaloric feeding**. In cachexia, appetite is suppressed early, BMI predicts mortality, albumin and transthyretin fall early, CRP is elevated and inflammatory disease is present.

Method 1 — Clinical History and Examination

5. **Content:** dietary history and 24-hour recall, unintentional weight loss, appetite, chewing and swallowing difficulty, dentition, gastrointestinal symptoms, functional ability to shop and cook, social isolation, alcohol, depression, and a full drug review.
6. **Advantages:** free, universally available, identifies the reversible cause, and detects the social and functional determinants that no laboratory test can.
7. **Disadvantages:** subjective, time-consuming, and **unreliable in dementia or delirium** where recall is impaired.

Method 2 — Anthropometry and Body Composition

8. The methods and what each measures: **weight** — global; **body mass index** — total body fat; **skin folds** — percentage fat; **waist:hip ratio** — central adiposity; **upper arm circumference** — lean body mass.
9. **Weight** is easily obtained and useful, but only **in the absence of oedema**. Serial weights are more informative than a single value.
10. **Upper arm circumference correlates with lean body mass** and is **particularly helpful in oedematous patients in whom weight is misleading** — but the effect of ageing on lean mass is so great that it remains a poor reflection of nutritional status in older adults.
11. **Calf circumference** is an accepted surrogate for muscle mass and is used in the MNA when BMI is unavailable.
12. **Height substitutes:** where standing height cannot be measured, use **knee-heel height** equations — Men = (2.02 × knee height in cm) × (0.04 × age) + 64.19; Women = (1.83 × knee height in cm) × (0.24 × age) + 84.88. For amputees, add the stated percentage for the missing part (single below knee 6.0%, at knee 9.0%, above knee 15.0%, single arm 6.5%, arm below elbow 3.6%).
13. **Advantages:** cheap, bedside, repeatable, no laboratory needed — ideal for Indian community and long-term care practice.
14. **Disadvantages:** confounded by **oedema, ascites, dehydration, kyphosis and vertebral collapse**; BMI is unreliable when height cannot be measured; observer variability with skin folds.

Method 3 — Biochemical Markers

15. **Serum albumin** is described as a practical indicator of malnutrition in older adults, **but liver disease, proteinuria and protein-losing enteropathy must be excluded**. A low albumin may indicate malnutrition; **a normal or raised albumin does not exclude it**.
16. **Thyroxine-binding prealbumin (transthyretin) and retinol-binding protein are more sensitive** than albumin and transferrin, because of their shorter half-lives.
17. **Anaemia** is one of the earliest manifestations of protein-energy malnutrition and should alert the physician to its possibility; **total lymphocyte count** may be a very good marker of nutritional problems.
18. **Advantages:** objective, numerical, prognostically useful.
19. **Disadvantages — the critical caveat:** all these proteins are **negative acute-phase reactants** and fall with inflammation regardless of nutrition. They therefore reflect **disease severity as much as nutritional state**, and must be interpreted alongside CRP.

Method 4 — Validated Screening and Assessment Tools

20. **Mini Nutritional Assessment (MNA):** developed specifically for elderly populations; the full MNA is

multidimensional and a **short form (MNA-SF) has similar performance**. It assesses body mass by either BMI or calf circumference. It was **96% sensitive and 60% specific** for body weight loss; a normal baseline score carried a **mortality risk of 0.35 (95% CI 0.18–0.66)** relative to an abnormal score. It is a powerful prognostic factor, particularly in cancer, and can assess cancer cachexia.

21. **Subjective Global Assessment (SGA):** combines history and physical signs. Both MNA and SGA predict mortality in geriatric patients; the **MNA classified fewer patients as well-nourished than the SGA, and those it called well-nourished had better 3-year survival** — making the MNA the more discriminating tool in older adults.
22. **Other tools: SNAQ** (Simplified Nutrition Assessment Questionnaire — a score below 14 signals significant risk of weight loss), **MUST**, and **NRS-2002** for hospital screening.
23. **Advantages:** validated, quick, reproducible, usable by nurses, and prognostically powerful.
24. **Disadvantages:** screening tools identify risk but **do not diagnose the cause**; the MNA requires cognitive cooperation and its specificity is modest at 60%.

Method 5 — Comprehensive Geriatric Assessment

25. Pathy's positions **comprehensive gerontological assessment as the framework** for complex cases with multimorbidity or frailty. It links nutrition to cognition (MMSE, MoCA), mood (GDS), delirium (CAM), falls risk (TUG, SPPB), function (Katz, Barthel, Lawton–Brody), morbidity, medication review, oral and swallowing assessment, constipation screening, and social and socioeconomic support.
26. The value of this approach is that it converts a measurement into an **action plan** — dental treatment, meal texture adaptation, help with shopping and meal preparation, meals-on-wheels, treatment optimisation and caregiver support.

Latest Updates (2023–Present)

- The **GLIM criteria** are now the global standard, endorsed by **ESPEN, ASPEN, FELANPE and PENSA**. Diagnosis requires **at least one phenotypic plus one etiologic criterion** after a positive screen. Phenotypic: **non-volitional weight loss (>5% in 6 months or >10% beyond 6 months), low BMI, low muscle mass**. Etiologic: **reduced food intake or assimilation, and inflammation or disease burden** *(Clin Nutr, 2019; JPEN, 2019)*.
- The **GLIM 5-year update (2025)** reviewed 2019–2024 evidence with a 43-member working group and ten systematic reviews, and has appointed working groups on **muscle mass cut-offs, inflammation assessment, screening procedures and food intake/assimilation** *(Clin Nutr 2025; JPEN 2025)*.
- GLIM and MNA are **not interchangeable**. A 2025 geriatric outpatient study found malnutrition rates of **6.6% by MNA-SF versus 21.1% by GLIM**, and a 2025 study of overweight geriatric outpatients found **58.8% of GLIM-defined malnutrition was missed by MNA-SF screening** — the practical message being that **a normal BMI or obesity does not exclude malnutrition** *(Ir J Med Sci 2025; Nutr Clin Pract 2025)*.
- **Sarcopenic obesity** is now a defined entity by the **ESPEN–EASO consensus (2022)**, with a prevalence of about **15.9%** in geriatric outpatients with BMI ≥25 — meaning muscle measurement, not weight, is what matters *(Clin Nutr 2022; Nutr Clin Pract 2025)*.
- The **ESPEN practical guideline on clinical nutrition and hydration in geriatrics** remains the operational reference, noting malnutrition prevalence generally **below 10% in independently living older people**, rising steeply with dependency and hospitalisation *(Clin Nutr, ESPEN)*.
- Critical care guidance now advises that **serum protein markers such as prealbumin and CRP are not recommended for evaluating nutritional status or goals**, though they retain value in series — confirming that these are inflammation markers first *(ASPEN/SCCM-derived practice, 2025)*.

Current Practice Update

Textbook position (Pathy's / Essentials)	Current evidence (2023–2026)
Serum albumin described as "a practical indicator of malnutrition" in older adults.	Albumin is now regarded primarily as an **inflammatory and prognostic marker, not a nutritional one**; GLIM excludes it from the diagnostic criteria and current guidance advises against using protein markers to set nutritional goals.
MNA and SGA are the principal validated tools.	These remain **screening tools**; **GLIM is now the diagnostic standard** and detects two to three times more malnutrition than MNA-SF alone in geriatric outpatients.
Body composition assessed by BMI, skin folds, waist:hip and arm circumference.	Emphasis has shifted to **muscle mass and function** — calf circumference, hand-grip strength, BIA and DXA — reflecting sarcopenia (EWGSOP2) and sarcopenic obesity (ESPEN–EASO).
Low BMI central to identifying malnutrition.	**Malnutrition frequently coexists with obesity**; GLIM identifies cases that BMI-based screening misses entirely.

Examiner's Tip — mark-earning lines

- "Nutritional assessment is a two-step process — screen, then diagnose — and no single measure is adequate."
- "A low albumin may indicate malnutrition, but a normal albumin does not exclude it; prealbumin and retinol-binding protein are more sensitive but are still acute-phase reactants."
- "Upper arm circumference is the measurement of choice when oedema makes weight misleading."
- "The MNA is 96% sensitive but only 60% specific — quote both figures."
- "State the GLIM framework explicitly: one phenotypic plus one etiologic criterion after a positive screen."

8. Mini Nutritional Assessment — components, scoring and interpretation

7 MARKS

1. The **Mini Nutritional Assessment (MNA)** was developed specifically **to assess malnutrition in elderly populations**. The full MNA is a **multidimensional tool** identifying older people who are malnourished or at risk, **whatever the cause**; a **short form (MNA-SF) has similar performance**, and a six-item version has equivalent predictive value.
2. **Structure:** the MNA-SF is a **6-item screening section scored out of 14 points**. If screening is abnormal, the full MNA (total 30 points) is completed with additional assessment items covering living situation, medication, pressure sores, meal frequency, protein and fluid intake, self-perceived health and nutrition, and mid-arm and calf circumference.
3. **The six screening components (A–F):**
   - **A — Food intake decline** over the past 3 months due to loss of appetite, digestive problems, or chewing/swallowing difficulty: 0 = severe decrease, 1 = moderate decrease, 2 = no decrease.
   - **B — Weight loss** in the last 3 months: 0 = >3 kg, 1 = does not know, 2 = 1–3 kg, 3 = no weight loss.
   - **C — Mobility:** 0 = bed or chair bound, 1 = able to get out of bed/chair but does not go out, 2 = goes out.
   - **D — Psychological stress or acute disease** in the past 3 months: 0 = yes, 2 = no.
   - **E — Neuropsychological problems:** 0 = severe dementia or depression, 1 = mild dementia, 2 = no psychological problems.
   - **F1 — Body mass index:** 0 = BMI <19; 1 = 19 to <21; 2 = 21 to <23; 3 = BMI ≥23.
   - **F2 — Calf circumference** (used **only if BMI is not available**): 0 = CC <31 cm; 3 = CC ≥31 cm. **Do not answer F2 if F1 has already been completed.**
4. **Interpretation of the screening score (maximum 14 points):**
   - **12–14 points — normal nutritional status** (no further assessment needed).
   - **8–11 points — at risk of malnutrition.**
   - **0–7 points — malnourished.**
5. **Action:** a screening score of **11 or below indicates possible malnutrition and the full MNA should be completed**; Essentials notes that where greater specificity is desired, a threshold of 10 or below may be used.
6. **Performance:** the MNA is **96% sensitive and 60% specific** for body weight loss. Subjects with a normal baseline score had a **lower mortality risk of 0.35 (95% CI 0.18–0.66)** than those with an abnormal score.
7. **Prognostic value:** those judged at risk by the MNA had **more frequent acute illness, greater need for assistance and more weight loss**. The MNA is a powerful prognostic factor across several pathologies, **particularly cancer**, and can be used to assess cancer cachexia.
8. **Advantages:** designed for and validated in older people; non-invasive, needs no blood tests; usable by nurses in wards, clinics and long-term care; incorporates **cognitive, psychological and mobility domains** that other tools omit; and offers **calf circumference as a substitute when BMI cannot be measured** — a decisive practical advantage in bed-bound, kyphotic or amputee patients.
9. **Disadvantages: specificity is only 60%**, so it over-identifies risk; it requires cognitive cooperation and is difficult in severe dementia; the acute-illness item may score positively for reasons unrelated to nutrition; and it is a **screening tool, not a diagnosis** — it does not establish the cause.

Latest Updates (2023–Present) — concise

- The MNA is now positioned as a **screening tool feeding into GLIM diagnosis**, not as a stand-alone diagnostic instrument; GLIM requires one phenotypic plus one etiologic criterion after a positive screen *(Clin Nutr 2019; GLIM 5-year update, Clin Nutr / JPEN 2025)*.
- **MNA-SF substantially under-detects malnutrition compared with GLIM**: a 2025 geriatric outpatient study reported **6.6% by MNA-SF versus 21.1% by GLIM**, and in overweight geriatric outpatients **58.8% of GLIM-defined malnutrition was not flagged as at-risk by MNA-SF** *(Ir J Med Sci 2025; Nutr Clin Pract 2025)*.
- The BMI-based item is the main limitation in **sarcopenic obesity**, now formally defined by the **ESPEN–EASO consensus** and present in about **15.9%** of geriatric outpatients with BMI ≥25 — supporting the addition of muscle mass or hand-grip measurement alongside the MNA *(Clin Nutr 2022; Nutr Clin Pract 2025)*.

Current Practice Update

Textbook position (Pathy's / Essentials)	Current evidence (2023–2026)
MNA is the validated multidimensional tool for identifying malnutrition in the elderly.	Retained as the **preferred geriatric screening tool**, but **GLIM is now the diagnostic standard**; a normal MNA-SF does not exclude malnutrition.
Body mass assessed by BMI or calf circumference within the tool.	Current practice adds **hand-grip strength and muscle mass** measurement, because BMI-based scoring misses malnutrition in overweight and sarcopenic-obese older adults.

Examiner's Tip

- Reproduce the **three cut-offs verbatim**: 12–14 normal; 8–11 at risk; 0–7 malnourished — these carry the marks.
- "Calf circumference replaces BMI only when BMI is unavailable — never score both F1 and F2."
- "96% sensitive, 60% specific: a good screen, a poor confirmatory test."

9. Total parenteral nutrition

15 MARKS

Definition and Governing Principle

1. **Total parenteral nutrition (TPN)** is the intravenous delivery of the complete nutritional requirement — water, carbohydrate, amino acids, lipid, electrolytes, vitamins and trace elements — when the gastrointestinal tract cannot be used at all. **Partial or supplemental PN** supplements inadequate enteral intake.
2. **The governing principle is "if the gut works, use it."** Pathy's records a **downward trend in the use of parenteral nutrition in critical care over recent years, chiefly because of studies showing higher morbidity with parenteral compared with enteral nutrition**.
3. In acute pancreatitis this hierarchy is explicit: **early oral feeding is preferred; enteral tube feeding (nasogastric or nasojejunal) within 72 hours if oral feeding is not tolerated; and parenteral nutrition is the last option if caloric goals cannot be met enterally** — because PN carries a **significantly higher risk of infection including bacteraemia and infected necrosis**.

Indications

4. **Non-functioning or inaccessible gut:** intestinal obstruction, high-output enterocutaneous fistula, prolonged paralytic ileus, severe short bowel syndrome, mesenteric ischaemia with extensive resection.
5. **Severe malabsorption or intestinal failure** where enteral feeding cannot meet requirements; severe inflammatory bowel disease unresponsive to enteral support; radiation enteritis.
6. **Peri-operative:** severely malnourished patients unable to be fed enterally for more than 7 days; post-operative complications preventing enteral access.
7. **In advanced disease:** Pathy's notes that in motor neuron disease, parenteral nutrition can be useful in advanced disease when gastrostomy is not feasible.
8. **General rule for older adults:** consider PN when the gut cannot be used for more than 5–7 days in a well-nourished patient, or more than 3 days in an already malnourished patient.

Access and Composition

9. **Access:** central venous access is required for full-strength TPN because of high osmolarity — a tunnelled catheter, PICC line or implanted port. **Peripheral parenteral nutrition** is possible only with low-osmolarity solutions and for short periods. Use a **dedicated lumen** with strict aseptic technique.
10. **Energy:** approximately **25–30 kcal/kg/day**, reduced to **20–25 kcal/kg/day in the acutely ill and the elderly** to avoid overfeeding.
11. **Protein:** approximately **1.0–1.5 g/kg/day** of amino acids in older adults; Essentials notes protein requirement estimates range from 0.5 to more than 1.0 g/kg/day, and that **higher protein intake is independently associated with a dose-responsive lower risk of incident frailty** in older women.
12. **Carbohydrate:** dextrose supplying about 50–60% of non-protein calories; do not exceed roughly 4–5 mg/kg/min to avoid hyperglycaemia and hepatic steatosis.
13. **Lipid:** 20–30% of total energy, providing essential fatty acids; modern olive-oil and fish-oil-containing emulsions are preferred to pure soybean-oil emulsions.
14. **Micronutrients:** daily electrolytes, trace elements (zinc, selenium, copper, chromium, manganese) and vitamins including **thiamine** must be added — deficiency states develop rapidly on PN.

Monitoring

15. **Daily initially:** capillary glucose, fluid balance, weight, and serum **potassium, phosphate and magnesium** for the first 3–5 days.
16. **Twice weekly then weekly:** urea, creatinine, sodium, calcium, liver function tests, triglycerides, full blood count and CRP; periodic trace element and vitamin levels in long-term PN.
17. **Clinical monitoring:** catheter site inspection, temperature charting, and daily reassessment of whether the gut can be used — **PN should be stopped as soon as enteral feeding is feasible**.

Complications

18. **Catheter-related mechanical:** pneumothorax, haemothorax, arterial puncture, air embolism, catheter malposition, thrombosis and occlusion.
19. **Catheter-related bloodstream infection** — the most feared complication; higher infection risk than enteral feeding is the principal reason PN use has declined.
20. **Metabolic:** hyperglycaemia (and rebound hypoglycaemia on abrupt cessation), hypertriglyceridaemia, electrolyte

disturbances, azotaemia, hypercapnia from overfeeding, and metabolic bone disease in long-term PN.

21. **Hepatobiliary:** steatosis, cholestasis, gallbladder sludge and gallstones — the last especially relevant in older adults, in whom Pathy's already notes increased biliary cholesterol and reduced gallbladder tone predispose to stone formation.
22. **Gut-related:** intestinal mucosal atrophy and bacterial translocation from disuse of the gut.
23. **Refeeding syndrome** — the most important early hazard in the malnourished older patient. Reintroduction of carbohydrate triggers an insulin surge with intracellular shift of **phosphate, potassium and magnesium**, plus thiamine depletion, causing arrhythmia, cardiac failure, respiratory failure, rhabdomyolysis, seizures, delirium and death.

Refeeding Syndrome — Prevention

24. **Identify risk:** low BMI, significant unintentional weight loss, minimal intake for several days, low baseline potassium, phosphate or magnesium, alcohol misuse, and loss of subcutaneous fat or muscle. **Electrolytes may be normal despite total-body deficiency.**
25. **Prevention protocol:** give **thiamine before any dextrose-containing solution**; start feeding at **100–150 g of dextrose or 10–20 kcal/kg in the first 24 hours**, advancing by about **33% of goal every 1–2 days**; correct severe electrolyte deficits before or alongside feeding; and monitor vital signs 4-hourly for the first 24 hours with daily weights and fluid balance.

Evidence and Ethical Considerations in the Elderly

26. Pathy's is deliberately cautious about outcomes: **the results of percutaneous parenteral feeding in subacute patients were not optimal**, and **undernourished or high-risk surgical patients did not have post-operative complications reduced to the level of well-nourished patients by either enteral or parenteral support** — suggesting factors beyond pure starvation are operating.
27. Enteral tube feeding likewise did **not affect 24-month survival in nursing home residents over 65 with severe cognitive impairment**, and aspiration pneumonia occurred at a similar rate with or without enteral feeding — the same reasoning applies with even greater force to PN in advanced dementia.
28. **Ethical framing:** artificial nutrition is a medical treatment, not basic care. Decisions require goals-of-care discussion, capacity assessment, and consideration of advance directives; in India this is framed by the Mental Healthcare Act 2017 and Supreme Court jurisprudence on advance medical directives.

Latest Updates (2023–Present)

- The **ASPEN consensus definition of refeeding syndrome** remains the reference standard, defining it by a decrease from pre-feeding serum phosphorus, magnesium or potassium of **≥10% (mild), ≥25% (moderate) or ≥50% (severe)**, with thiamine **100 mg before dextrose-based solutions** and no routine value in checking thiamine levels *(Nutr Clin Pract, 2020; validated in JPEN, 2022)*.
- Comparative work in older hospitalised patients has shown that **incidence and mortality of refeeding syndrome differ substantially depending on which of three diagnostic criteria is applied**, so the criterion used must be stated *(Clin Nutr ESPEN, 2024)*.
- **ESPEN's partially revised ICU guideline** reaffirms the hierarchy — oral diet preferred, then enteral, with low-dose PN considered only where enteral feeding is not feasible in high-risk or severely malnourished patients, **balanced against the risks of overfeeding and refeeding**; supplemental PN timing remains debated *(Clin Nutr, 2023)*.
- **ASPEN has issued expert guidance on "When Is Parenteral Nutrition Appropriate?"** together with updated guidelines on **PN ordering, order review, compounding, labelling and dispensing**, and on **selection and care of central venous access devices for adult home parenteral nutrition** *(ASPEN guidelines and standards, current)*.
- Current critical-care practice explicitly advises that **serum protein markers such as prealbumin and CRP are not recommended for evaluating nutritional status or setting nutritional goals**, and that CRP should be measured simultaneously when interpreting vitamin or mineral levels *(ASPEN/SCCM-derived protocols, 2025)*.

Current Practice Update

Textbook position (Pathy's)	Current evidence (2023–2026)
Downward trend in PN use in critical care because of higher morbidity than enteral nutrition.	**Position confirmed and formalised** — ESPEN ICU guidance places oral first, enteral second, and PN only where enteral is not feasible, weighing overfeeding and refeeding risk.
Refeeding described as a risk without formal diagnostic criteria.	**ASPEN consensus criteria** now define and grade it by percentage fall in phosphate, potassium or magnesium, with a defined calorie-advancement protocol and thiamine before dextrose.
Nutritional support judged largely by weight and biochemical response.	**Protein markers are no longer recommended** for assessing nutritional status or goals; assessment is by GLIM criteria and functional/muscle measures.
Little detail on PN safety systems.	ASPEN now publishes **prescribing, compounding, labelling and central venous access standards**, reflecting that most PN harm is preventable system error.

Examiner's Tip — mark-earning lines

- "If the gut works, use it — parenteral nutrition carries a significantly higher infection risk, and its use in critical care has fallen for exactly this reason."
- "Quote the refeeding protocol: thiamine before dextrose; start at 10–20 kcal/kg or 100–150 g dextrose in the first 24 hours; advance by about a third of goal every 1–2 days."
- "Electrolytes may be normal despite total-body depletion — normal values do not exclude refeeding risk."
- "In advanced dementia, artificial nutrition does not improve survival or reduce aspiration — this is a goals-of-care decision, not a nutritional one."

10. Vitamin deficiencies in the elderly

15 MARKS

General Principles

1. Vitamins and minerals are **micronutrients** — required in minute quantities but essential for life, functioning as hormones, antioxidants, enzyme cofactors, and in one-carbon metabolism and DNA synthesis. They cannot be synthesised in adequate quantity and must come from food, fortified food or supplements.
2. **Classification: water-soluble** (B group and vitamin C) and **fat-soluble** (A, D, E, K). Fat-soluble deficiency accompanies fat malabsorption; water-soluble deficiency develops faster because stores are small.
3. Pathy's makes the important point that the **same age-associated changes in food intake that cause protein-calorie inadequacy also cause multiple micronutrient deficiencies**, and that **inadequate intake can impair cellular and physiological function even before a classic deficiency syndrome appears**.
4. **Causes in older adults:** anorexia of ageing, reduced taste and smell, poor dentition, dysphagia, poverty and isolation, chronic disease, malabsorption, alcohol, and **polypharmacy with drug–nutrient interaction**.
5. **Nutrients of public health concern for older adults** (Pathy's): the vitamins **choline, riboflavin, thiamine, A, C, D and E**, and the minerals **calcium, magnesium, potassium and selenium**.
6. Essentials adds a corrective: **there is no general increase in vitamin requirements with age** — requirements for vitamins A, B1, B2, C, B6 and B12 do not rise with age. What changes is intake and absorption, not requirement.

Vitamin B12 (Cobalamin)

7. **Prevalence rises with age, ranging from 5% to 40% depending on the cut-off used.** In one Canadian nursing home study of 412 residents, prevalence was **13.8% on admission with a new incidence of 4% per year**.
8. **Causes: food-bound B12 malabsorption from atrophic gastritis affects 10–30% of older adults**; pernicious anaemia (lack of intrinsic factor) occurs in **1–2%**; drugs — **PPIs, H2 blockers and metformin**; gastric or ileal resection; SIBO; and strict vegetarian or vegan diets, since B12 is found only in animal products.
9. **Features:** macrocytic anaemia (which may be absent), plus **fatigue, weakness, anorexia, weight loss, numbness and tingling, balance problems, depression, confusion, dementia, poor memory and glossitis**. Subacute combined degeneration of the cord is the classic neurological syndrome.
10. **Diagnosis:** there is **no gold standard test**. Diagnosis rests on anaemia plus a low B12; **methylmalonic acid and homocysteine are both raised** and add sensitivity but are not mandatory.
11. **Treatment:** oral or intramuscular; **oral is easier, cheaper and likely as effective at high enough doses**. Recheck haemoglobin and B12 at **3 months**. Because of malabsorption of food-bound B12, those aged 50 and over should meet the RDA mainly from **fortified foods or a supplement**.

Folate (Vitamin B9)

12. **Causes:** poor intake, alcoholism, malabsorption (folate is absorbed in the jejunum by passive transport), atrophic gastritis, smoking, and **drugs — methotrexate, sulfasalazine, trimethoprim and phenytoin**.
13. **Stores are small**, so deficiency develops in weeks to months, unlike B12.
14. **Diagnosis:** low haemoglobin, raised MCV, low serum folate, low reticulocyte count. **Serum folate <2 ng/mL is deficient, 2–4 ng/mL borderline, >4 ng/mL normal.** In folate deficiency **MMA is normal and homocysteine is raised**, in contrast to B12 deficiency where both are raised. **Red cell folate** reflects status over the preceding 120 days.
15. **Treatment: folic acid 1 mg daily** orally. **Always correct B12 first** — giving folate alone in B12 deficiency can precipitate or worsen neurological damage. Correcting B12 may resolve a relative folate deficiency without supplementation.

Vitamin D

16. **Mechanism of deficiency in the elderly:** limited sunlight exposure plus a **fourfold reduction in the skin's capacity to produce vitamin D**, compounded by reduced intestinal absorption with age.
17. **Prevalence:** in the relatively healthy older Europeans of the SENECA study, **40% had serum 25(OH)D below 30 nmol/L** — itself below the proposed adequacy threshold of at least 50 nmol/L.
18. **Recommended intakes after age 50 (Pathy's):** calcium **1000–1200 mg/day** and vitamin D **800 IU (20 µg)/day**; upper limits are 2000 mg for calcium and 4000 IU (100 µg) for vitamin D.
19. **Assessment and treatment:** status is assessed by **serum 25(OH)D**; **at a minimum, concentrations below 25–30 nmol/L (10–12 ng/mL) should be treated**. Essentials adds that nursing home residents require **at least 800 IU daily — double the usual recommendation** — to maintain normal levels.

20. **Benefits:** supplementation reduces bone loss and fracture rate in both older men and women, and more recent trials indicate **improvement in sarcopenia and a decrease in falls**.

Other Vitamins and Key Minerals

21. **Thiamine (B1):** deficiency in alcohol misuse, poor intake, refeeding and diuretic use; causes wet and dry beriberi and **Wernicke's encephalopathy**. Must be given before dextrose in any at-risk patient.
22. **Vitamin B6 (pyridoxine):** dietary deficiency is rare and usually occurs with other water-soluble vitamin deficiencies; causes include alcoholism, malabsorption, dialysis and drugs acting as pyridoxine antagonists (isoniazid). Assessed by **plasma pyridoxal-5-phosphate**.
23. **Riboflavin (B2):** contributes to hyperhomocysteinaemia; not usually high-risk in those consuming adequate dairy.
24. **Hyperhomocysteinaemia:** inadequate **B2, B6, folate or B12** raises homocysteine, an independent cardiovascular risk factor also correlated prospectively with dementia and osteoporotic fracture. **Folate lowers homocysteine most effectively** — but Pathy's is explicit that **homocysteine-lowering B vitamins have been mostly unsuccessful in reducing incidence of cardiovascular disease, osteoporosis or Alzheimer's progression**.
25. **Vitamin C:** readily lost from food during storage and preparation — losses may account for about **50% of the potential dietary content**, and around 30% of subjects in European studies had inadequate intake. **Absorption is not affected by age.** Deficiency causes scurvy — perifollicular haemorrhage, gum bleeding, poor wound healing.
26. **Vitamin K:** deficiency from fat malabsorption, prolonged antibiotics and poor intake; causes prolonged prothrombin time and bruising. Note the interaction with warfarin in both directions.
27. **Vitamin A:** deficiency causes night blindness and xerophthalmia; note that **vitamin A absorption increases with age**, so excess is as relevant a hazard as deficiency in supplemented older adults.
28. **Zinc:** deficiency is seen in older people, **particularly in diabetics**; causes **anorexia through impaired taste and smell**, impaired vision, confusion and restlessness, sometimes diarrhoea, and reduced immunity, collagen synthesis and wound healing. **Cytokines dramatically reduce serum zinc**, so plasma levels are unreliable in illness — leucocyte or hair zinc may be more useful.
29. **Iron:** less prevalent in older than younger people; requirement falls sharply after the menopause. Distinguish iron deficiency from **anaemia of chronic disease** using ferritin and CRP. **When anaemia is diagnosed, chronic blood loss or folate/B12 deficiency must be considered.**
30. **Overall caution from Pathy's:** beyond general health, **the role of each micronutrient in preventing or treating specific chronic disease is unclear from clinical trial data**; given limited efficacy and potential adverse effects, supplements should be chosen to contain **no more than the recommended amounts (about 100% of recommendations)**.

Latest Updates (2023–Present)

- The **Endocrine Society Clinical Practice Guideline on vitamin D (2024)** represents the biggest shift. It **suggests empiric supplementation for the general population aged 75 and over** to lower mortality risk, but **suggests against routine 25(OH)D testing in all populations considered**, including those aged 75 and over *(J Clin Endocrinol Metab, 2024)*.
- The same guideline **advises against empiric supplementation above the DRI in healthy adults under 75**, and for people over 50 with an indication, recommends **daily lower-dose vitamin D rather than intermittent high doses**. Trial doses informing the mortality recommendation ranged from 400 to 3333 IU daily, with a weighted average of about **900 IU daily** *(J Clin Endocrinol Metab, 2024)*.
- Critically, the Endocrine Society **no longer endorses 30 ng/mL as a sufficiency target**, and states no clear evidence defines an optimal 25(OH)D level for disease prevention — a reversal of its own 2011 position that remains contested by other experts *(J Clin Endocrinol Metab 2024; Endocr Pract commentary 2024–2026)*.
- Note the scope limitation for exams: this guideline addresses **disease prevention in generally healthy people without established indications for testing or treatment**. It does **not** apply to patients with malabsorption, CKD, osteoporosis, osteomalacia or drug-induced deficiency, where **testing and treatment remain fully indicated** *(J Clin Endocrinol Metab, 2024)*.
- The **UEG 2025 malabsorption guideline** stresses that **screening for B12 in the elderly is important because some related neurological abnormalities reverse with supplementation**, and identifies chronic PPI use and SIBO as aggravating factors alongside atrophic gastritis *(United European Gastroenterol J, 2025)*.
- The **USPSTF** continues to recommend against vitamin D with or without calcium for primary fracture prevention in community-dwelling postmenopausal women and men aged 60 and over — consistent with the 2024 guideline's restraint *(USPSTF, reaffirmed in JBMR commentary 2025)*.

Current Practice Update

Textbook position (Pathy's / Essentials)	Current evidence (2023–2026)
Assess vitamin D status by 25(OH)D; treat levels below 25–30 nmol/L; adequacy often taken as ≥50 nmol/L.	Endocrine Society 2024 **suggests against routine 25(OH)D testing** in generally healthy people and **no longer endorses a numerical sufficiency target**. Testing remains indicated in malabsorption, CKD, osteoporosis and osteomalacia.
800 IU vitamin D daily recommended after age 50; nursing home residents need at least 800 IU.	**Empiric supplementation now recommended specifically from age 75** to reduce mortality, with **daily low-dose preferred over intermittent high-dose** in those over 50 — supporting the textbook dose but sharpening the age threshold and the regimen.
Homocysteine-lowering B vitamins mostly unsuccessful for CVD, osteoporosis and Alzheimer's.	**Position unchanged** — no new trial has overturned it; treat documented deficiency, not the homocysteine number.
B12 deficiency diagnosed on anaemia plus low B12, with MMA and homocysteine as adjuncts.	**Unchanged**, but UEG 2025 adds a stronger case for **proactive B12 screening in older adults**, given reversibility of neurological features and the contribution of PPIs and SIBO.
Micronutrient supplements should contain no more than about 100% of recommendations.	**Position reinforced**; USPSTF continues to advise against routine vitamin D and calcium for primary fracture prevention in community-dwelling older adults.

Examiner's Tip — mark-earning lines

- "Requirements for most vitamins do not rise with age — what changes is intake and absorption."
- "10–30% of older adults malabsorb food-bound B12; pernicious anaemia accounts for only 1–2%."
- "MMA and homocysteine both raised in B12 deficiency; only homocysteine raised in folate deficiency."
- "Always correct B12 before folate — folate alone can worsen the neurological lesion."
- "Skin capacity to synthesise vitamin D falls fourfold in the elderly; 40% of healthy older Europeans in SENECA had 25(OH)D below 30 nmol/L."
- "Homocysteine-lowering B vitamins have failed to reduce cardiovascular events, fractures or Alzheimer's progression."

Extra Points to Remember — Indian context

- **Vitamin D deficiency is highly prevalent across all Indian age groups** despite abundant sunlight, driven by skin pigmentation, indoor living, covered clothing, air pollution and low dietary intake — so the Endocrine Society's "generally healthy Western population" caveats must be applied with care in Indian practice.
- **B12 deficiency is common in Indian vegetarians** irrespective of malabsorption — a lifelong dietary cause rather than an age-related one; combine dietary counselling with supplementation.
- **ICMR-NIN dietary guidelines** for Indians provide the local RDA framework and should be quoted alongside Western figures.
- **Fortification programmes:** India's fortified staples (double-fortified salt with iron and iodine, fortified oil and milk with vitamins A and D, fortified wheat flour and rice with iron, folic acid and B12) are the population-level answer.
- **Practical Indian prescribing:** cholecalciferol 60,000 IU weekly sachets are widely used for repletion followed by daily maintenance — but note the current preference for **daily lower-dose regimens over intermittent high doses** in those over 50.

Appendix — Rapid Revision Grid

NIGHT-BEFORE REVISION

Numbers Worth Quoting

Topic	Figure
GORD prevalence	6th commonest disorder in residential care; ~20% of general population have weekly reflux; hiatus hernia in ~60% of those over 60
GORD diagnosis	Heartburn/regurgitation ~70% sensitive; double-dose PPI trial 2–8 weeks, sensitivity and specificity up to 80%
Constipation	Faecal impaction in 7% of institutionalised elderly; median 42% prevalence in long-term care; 90% of slow-transit responds to laxatives; biofeedback effective in ~70%
Laxative doses	Psyllium 3–6 g; PEG 17–34 g; lactulose 10–40 g; senna 15 mg; bisacodyl 5–10 mg; sodium picosulfate 5–10 mg; lubiprostone 8–24 µg BD
IBS in elderly	10–15% of people over 70; placebo response in functional GI disorders 20–70%
Achalasia	Perforation risk ~1% for both pneumatic dilatation and myotomy; series of 51 patients aged ≥65 — no deaths, median stay 3 days
Gastroparesis	Up to 80% of diabetic gastroparesis has abnormal small-intestinal motility; scleroderma oesophageal dysmotility ~80%
UGI bleeding	Bleeding contributes to ~5% of elderly deaths; GBS 0–1 for outpatient care; transfuse at Hb 7 g/dL (8 g/dL with CVD), target 7–9 g/dL; erythromycin 250 mg IV 30–120 min pre-scope; endoscopy within 24 h; high-dose PPI ×3 days then BD oral ×2 weeks
Malabsorption	Faecal fat >7 g/day; faecal elastase-1 <200 µg/g suggests, <100 µg/g severe EPI; SIBO antibiotics 1–4 weeks
MNA	Screening max 14 points: 12–14 normal, 8–11 at risk, 0–7 malnourished; sensitivity 96%, specificity 60%; mortality risk 0.35 (0.18–0.66) with normal score
GLIM	Weight loss >5% in 6 months or >10% beyond 6 months; needs 1 phenotypic + 1 etiologic criterion
TPN	25–30 kcal/kg/day (20–25 if acutely ill/elderly); protein 1.0–1.5 g/kg/day; refeeding start 10–20 kcal/kg or 100–150 g dextrose in first 24 h, advance ~33% of goal every 1–2 days; thiamine 100 mg before dextrose
Refeeding severity	Fall from pre-feeding phosphate, magnesium or potassium: ≥10% mild, ≥25% moderate, ≥50% severe (ASPEN)
Vitamin B12	Prevalence 5–40%; 10–30% malabsorb food-bound B12; pernicious anaemia 1–2%; nursing home 13.8% on admission, 4%/year new
Folate	<2 ng/mL deficient, 2–4 borderline, >4 normal; treat with folic acid 1 mg/day; red cell folate reflects 120 days
Vitamin D	Calcium 1000–1200 mg/day and vitamin D 800 IU/day after 50; ULs 2000 mg and 4000 IU; treat 25(OH)D below 25–30 nmol/L; SENECA — 40% below 30 nmol/L; skin synthesis reduced fourfold

Named Guidelines and Evidence by Topic

Topic	Named source
Malabsorption	UEG malabsorption guideline 2025; ACG coeliac guideline update 2023; ESsCD 2025 (no-biopsy pathway restricted to under-45s)
Constipation	Joint AGA–ACG CIC guideline 2023 (first joint guideline; PEG, sodium picosulfate, linaclotide, plecanatide, prucalopride strong); ASCRS 2024
GORD	Lyon Consensus 2.0 (Gut 2024); ACG GERD guideline 2022; AGA Clinical Practice Update on P-CABs 2024; VISION 5-year safety study 2025; Seoul Consensus focused update 2025
Motility	Chicago Classification v4.0; ACG gastroparesis guideline 2022
UGI bleeding	ACG UGIB guideline 2021; ESGE non-variceal 2021 and variceal 2022; ACG LGIB update 2023; restrictive transfusion meta-analysis (Sci Rep 2023)
Nutrition assessment	GLIM consensus 2019 and 5-year update 2025; ESPEN geriatric nutrition and hydration guideline; ESPEN–EASO sarcopenic obesity consensus 2022; EWGSOP2
Parenteral nutrition	ASPEN refeeding consensus 2020; ESPEN ICU guideline revision 2023; ASPEN PN ordering/compounding and CVAD standards
Vitamins	Endocrine Society vitamin D guideline 2024; USPSTF fracture prevention; ICMR-NIN dietary guidelines (India)

Classifications and Criteria to Name

Name	Use
Rome IV	Constipation, IBS, functional dyspepsia
Bristol Stool Form Scale	Stool consistency; target type 4–5 in faecal incontinence
Los Angeles classification A–D	Erosive oesophagitis; only B, C, D conclusive for GORD under Lyon 2.0
Chicago Classification v4.0	Oesophageal manometry; achalasia types I, II, III
Forrest classification	Ulcer stigmata; treat Ia, Ib, IIa endoscopically
Glasgow–Blatchford / Rockall	Pre-endoscopic and post-endoscopic UGIB risk
GLIM criteria	Diagnosis of malnutrition — 1 phenotypic + 1 etiologic
MNA / MNA-SF / SNAQ / MUST / NRS-2002 / SGA	Nutritional screening and assessment tools
ASPEN refeeding criteria	Grading refeeding syndrome by electrolyte fall

Indian Context — One Line per Topic

- **Malabsorption:** tropical sprue, intestinal tuberculosis, giardiasis, strongyloidiasis and HIV enteropathy must appear in every differential.
- **Constipation:** ispaghula (isabgol) is the accessible bulking agent; PEG sachets are affordable and preferable to repeated enemas at home.
- **GORD:** pantoprazole and rabeprazole are the cheapest available PPIs; vonoprazan is marketed but cost-limited.
- **UGI bleeding:** variceal bleeding from cirrhosis, non-cirrhotic portal fibrosis and EHPVO is a major cause; PCC availability is variable outside tertiary centres, so FFP may be the practical alternative.
- **Nutrition:** LASI Wave 1 data document high rates of undernutrition among older Indians; NPHCE provides the service framework.
- **Vitamins:** widespread vitamin D deficiency despite sunlight; B12 deficiency common in lifelong vegetarians; ICMR-NIN RDAs and national food fortification are the population-level responses.

MD GERIATRIC MEDICINE

Haematology in the Elderly — Compendium of High-Yield Answers

Plasma Cell Dyscrasias · Leukaemias · Myelodysplasia · Anaemia · Thrombocytopenia
Lymphomas · Transfusion Medicine · Bone Marrow Transplantation · POEMS Syndrome

Based on Pathy's Principles and Practice of Geriatric Medicine (6th ed.)
and Essentials of Clinical Geriatrics (7th ed.), supplemented with current evidence

CONTENTS

1 Plasma Cell Dyscrasias — Classification

2 Plasma Cell Dyscrasias — Presentation, Diagnostic Criteria, Progression & Treatment

3 Multiple Myeloma — Aetiology, Diagnosis & Management

4 Chronic Myeloid Leukaemia — Clinical Features & Management

5 Myelodysplasia

6 Alkylating Agents · Intramedullary vs Extramedullary Haemolysis · Dysplasia

7 Anaemia of Chronic Disease

8 Anaemia in the Elderly & Evaluation of Anaemia

9 Thrombocytopenia

10 Hodgkin Lymphoma

11 Non-Hodgkin Lymphoma — Presentation, Prognosis & Principles of Therapy

12 Anaemia of Chronic Kidney Disease — Type, Investigation & Treatment

13 Mechanisms of Drug-Induced Thrombocytopenia

14 Blood Transfusion

15 WHO Classification & Diagnostic Criteria of MDS, and its Differentials

16 Bone Marrow Transplant

17 POEMS Syndrome

Reference lists have been omitted from this compilation for concise night-before revision.

QUESTION 1

Name the various plasma cell dyscrasias

> **Textbook gap:** Pathy's has no dedicated chapter on plasma cell dyscrasias. Only incidental mentions exist in Ch. 24 (paraproteins as a cause of acquired coagulation defects — myeloma, MGUS, amyloid; inhibition of fibrin polymerisation; acquired haemophilia/vWD) and in the Anaemia chapter (MGUS grouped under "anaemia of clonal disorders" with CHIP/MDS). The classification below is sourced from WHO-HAEM5 (2022), ICC (2022) and IMWG consensus.

High-Yield Points

Definition

1. **Plasma cell dyscrasias (monoclonal gammopathies)** are disorders in which a single clone of plasma/lymphoplasmacytic cells secretes a **monoclonal immunoglobulin (M-protein)**.
2. They form a **continuous spectrum** from harmless MGUS to plasma cell leukaemia. Every myeloma is preceded by an MGUS phase.
3. **Diseases of old age**: MGUS in ~3% over 50; median myeloma diagnosis age ~69 years.

A. Premalignant precursor states

4. **MGUS** — M-protein <3 g/dL, clonal marrow plasma cells <10%, no CRAB. Progresses ~1%/year.
5. **Three MGUS subtypes:** Non-IgM (→ myeloma), IgM (→ Waldenström's), Light-chain (→ light-chain myeloma/AL amyloidosis).
6. **Smouldering (asymptomatic) myeloma** — M-protein ≥3 g/dL or plasma cells 10–60%, no end-organ damage.

B. Malignant plasma cell neoplasms

7. **Multiple myeloma (symptomatic)** — ≥10% clonal plasma cells or plasmacytoma + a myeloma-defining event (CRAB or SLiM).
8. **Variants:** non-secretory, IgD/IgE myeloma (rare, aggressive), IgM myeloma, light-chain (Bence Jones) myeloma.
9. **Solitary plasmacytoma of bone** — single lytic lesion, normal marrow, no CRAB.
10. **Extramedullary plasmacytoma** — solitary soft-tissue lesion, usually upper aerodigestive tract.
11. **Plasmacytoma with minimal marrow involvement** — <10% clonal marrow plasma cells; higher progression risk.
12. **Plasma cell leukaemia** — primary or secondary; most aggressive form.

C. Immunoglobulin deposition disorders

13. **AL amyloidosis** — misfolded light chains deposit as β-pleated fibrils in heart, kidney, liver, nerve, gut.
14. **Monoclonal Ig deposition disease (MIDD)** — non-fibrillar, Congo-red negative: LCDD, HCDD, light-and-heavy-chain forms.
15. **Monoclonal gammopathy of renal significance (MGRS)** — small non-malignant clone causing kidney damage; needs clone-directed treatment.

D. Heavy chain diseases

16. **Alpha HCD** (IPSID/Mediterranean lymphoma), **Gamma HCD** (Franklin disease), **Mu HCD** (with CLL).

E. Lymphoplasmacytic disorders

17. **Waldenström macroglobulinaemia** — IgM paraprotein, MYD88 L265P; causes hyperviscosity.
18. **Cold agglutinin disease** and **cryoglobulinaemia** (Type I monoclonal; Type II mixed).

F. Paraneoplastic gammopathies

19. **POEMS syndrome** — Polyneuropathy, Organomegaly, Endocrinopathy, Monoclonal gammopathy, Skin changes; lambda light chain, sclerotic lesions, high VEGF.
20. **Newer syndromes:** TEMPI, AESOP, Schnitzler; umbrella term **MGCS (monoclonal gammopathy of clinical significance)** — neurological, cutaneous, haemostatic forms.

Latest Updates (2023–Present)

WHO-HAEM5 (2022) restructured the group into four blocks: Monoclonal gammopathies (adds MGRS, cold agglutinin disease); Ig deposition diseases (renamed AL amyloidosis, MIDD); Heavy chain diseases; Plasma cell

neoplasms (adds TEMPI, AESOP as full entities). **ICC 2022** introduced genetic subtyping of myeloma (CCND-family, MAF-family, NSD2 translocations, hyperdiploidy vs MM-NOS). **Plasma cell leukaemia threshold lowered** to ≥5% circulating plasma cells (from >20%). **MGCS** is now formally accepted, covering MGRS (renal), MGNS (neurological), cutaneous and multisystem forms. A new **IMS–IMWG high-risk myeloma consensus (2025)** replaces R-ISS/R2-ISS. **AQUILA trial (NEJM 2025):** daratumumab in high-risk smouldering myeloma improved 5-yr PFS (63.1% vs 40.8%) and OS (93.0% vs 86.9%) — FDA-approved Nov 2025, the first therapy for a precursor state. The **IMWG Frailty Index** (and possibly the Rockwood Frailty Index) now guides treatment intensity in the elderly.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Coverage	No dedicated section	Fully classified under WHO-HAEM5/ICC 2022
New entities	Not mentioned	MGRS, cold agglutinin disease, TEMPI, AESOP formally recognised
MGCS concept	Absent	Established — small clones causing organ damage need clone-directed therapy
Plasma cell leukaemia	Not mentioned	Redefined at ≥5% circulating plasma cells
Smouldering myeloma	Not mentioned	Daratumumab approved (2025) for high-risk SMM

QUESTION 2

Plasma Cell Dyscrasias — Clinical Presentation, Diagnostic Criteria, Progression & Treatment

Textbook gap: No dedicated Pathy's content. Relevant fragments: Ch. 24 (paraprotein-related coagulation defects), Anaemia chapter (MGUS as clonal anaemia), Ch. 59 (chronic pain red flags — weight loss, fever, prior malignancy, progressive neurological deficit — directly applicable to myeloma back pain).

High-Yield Points

A. Clinical Presentation

1. MGUS/smouldering myeloma usually found incidentally on routine SPEP or a raised globulin gap/unexplained high ESR.
2. **Symptomatic myeloma = CRAB tetrad** (hyperCalcaemia, Renal impairment, Anaemia, Bone lesions) — present in ~80% at diagnosis.
3. **Bone pain** is commonest — back/rib pain, vertebral fractures, height loss, spinal cord compression (emergency).
4. **Anaemia in ~70%** — normocytic; in the elderly presents as fatigue, falls, delirium, functional decline; film shows rouleaux.
5. **Renal impairment in 20–40%** — mainly light-chain cast nephropathy, worsened by hypercalcaemia, dehydration, NSAIDs, contrast.
6. **Recurrent infection** from immune paresis (suppressed uninvolved immunoglobulins); encapsulated organisms predominate.
7. Syndrome-specific: hyperviscosity (Waldenström's), neuropathy (POEMS/anti-MAG), nephrotic syndrome/macroglossia (AL amyloidosis).
8. In the elderly, presentation is often non-specific — falls, delirium, weight loss, or a persistently raised ESR.

B. Diagnostic Criteria

9. Screening: **SPEP + serum immunofixation + serum free light chain (FLC) assay**, plus 24-hr urine electrophoresis/IFE for Bence Jones protein.
10. **Bone marrow aspirate/biopsy** with flow cytometry (CD38 bright, CD138+) and FISH (del17p, t(4;14), t(14;16), 1q gain).
11. **Imaging:** whole-body low-dose CT, whole-body MRI, or PET-CT. Plain skeletal survey is obsolete.
12. **MGUS** = M-protein <3 g/dL, marrow plasma cells <10%, no end-organ damage.
13. **Smouldering myeloma** = M-protein ≥3 g/dL (or urine ≥500 mg/24h) or plasma cells 10–60%, no MDE.
14. **Multiple myeloma (IMWG)** = ≥10% clonal plasma cells or plasmacytoma + ≥1 myeloma-defining event.
15. **MDE = CRAB + SLiM:** Ca >11 mg/dL; creatinine >2 mg/dL or CrCl <40 mL/min; Hb <10 g/dL; ≥1 lytic lesion; ≥60% plasma cells; FLC ratio ≥100; >1 MRI focal lesion.

C. Progression

17. Stepwise: normal → MGUS → smouldering myeloma → symptomatic myeloma → plasma cell leukaemia/extramedullary disease.
18. Rates: MGUS ~1%/year (lifelong); SMM ~10%/year (first 5 yrs), then ~3%, then ~1%/year.
19. Risk models: **Mayo MGUS model** (M-protein ≥1.5 g/dL, non-IgG, abnormal FLC ratio); **"20-2-20" SMM model** (plasma cells >20%, M-protein >2 g/dL, FLC ratio >20).
20. Staging: ISS → R-ISS → R2-ISS. **IMWG Frailty Index** independently predicts survival/toxicity in the elderly.

Treatment at a Glance

Condition	Standard approach
MGUS (low risk)	Observation; repeat SPEP+FLC at 6 months then 1–2 yearly
Smouldering myeloma (high risk)	Subcutaneous daratumumab (2025) or trial
Myeloma, fit/transplant-eligible	Quadruplet induction → ASCT → lenalidomide maintenance
Myeloma, transplant-ineligible	D-VRd (fit) or DRd/Isa-Rd (frail), until progression
Myeloma, frail/very old	Dose-attenuated doublet/triplet; treat to tolerability

Relapsed/refractory	BCMA CAR-T (cilta-cel, ide-cel) or bispecifics (teclistamab, elranatamab)
Supportive care	Zoledronic acid/denosumab, hydration, avoid NSAIDs/contrast, VTE prophylaxis with IMiDs
AL amyloidosis	Dara-VCd (first-line)
Waldenström's	Zanubrutinib or bendamustine-rituximab; plasmapheresis for hyperviscosity

Latest Updates (2023–Present)

CEPHEUS (Nat Med 2025): D-VRd gave MRD-negativity 60.9% vs 39.5%, 43% lower progression/death risk in transplant-ineligible myeloma. **IMROZ (NEJM 2024):** Isa-VRd gave 5-yr PFS 63% vs 45%. Both capped age at 80 and excluded frail patients — DRd/Isa-Rd remain preferred for the truly frail. **AQUILA (NEJM 2025):** daratumumab in high-risk SMM, FDA-approved Nov 2025 — shift to early interception. **IMS–IMWG 2025** redefines high-risk myeloma (~20–25% of patients): del17p/TP53, t(4;14)/t(14;16) with 1q gain, high β2-microglobulin with normal creatinine. **FDA ODAC (April 2024)** voted MRD-negative CR an acceptable endpoint for accelerated approval; **MIDAS trial (NEJM 2025)** tested whether MRD-negative patients can skip transplant. CAR-T/bispecifics now give 60–97% response in triple-class-exposed disease; bispecifics often preferred in frail elderly (off-the-shelf, no apheresis). AL amyloidosis: anti-fibril antibodies **anselamimab** and **birtamimab** in phase III. Waldenström's: **zanubrutinib** preferred over ibrutinib (ASPEN — far less AF).

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Diagnostic criteria	Absent	CRAB + SLiM biomarkers (IMWG)
Imaging	Not addressed	Skeletal survey/bone scan obsolete; WBLDCT/WB-MRI/PET-CT standard
First-line therapy	Not addressed	Quadruplets (D-VRd/Isa-VRd) fit; DRd/Isa-Rd frail
Precursor treatment	Not addressed	Daratumumab approved for high-risk SMM (2025)
Relapsed disease	Not addressed	CAR-T and bispecific antibodies

QUESTION 3

Multiple Myeloma — Aetiology, Diagnosis & Management

Textbook gap: No myeloma chapter in Pathy's. Transferable content: Ch. 24 (paraprotein coagulopathy), Anaemia chapter (clonal anaemia), Ch. 59 (spinal red flags), and — most valuably — Ch. 26/27's geriatric-oncology philosophy (CGA is standard of care; treatment must not be chosen on chronological age alone; frailty/comorbidity assessment via gait speed, SPPB, Charlson index, CRASH score, Hurria/CARG tool).

High-Yield Points

A. Definition & Epidemiology

1. **Malignant clonal plasma cell proliferation** producing M-protein and end-organ damage.
2. 10–15% of haematological malignancies; median diagnosis age 65–70; >30% of patients >75 years.

B. Aetiology & Risk Factors

3. Cause unknown; arises from a post-germinal-centre plasma cell; every case preceded by MGUS.
4. **Host factors:** age (dominant), male sex, African ancestry (~2× risk, 5–10 yrs earlier), family history (2–3×), obesity/T2DM.
5. **Environmental:** ionising radiation, benzene, pesticides/herbicides/dioxins, agriculture/woodworking/paper industry.
6. **Predisposing states:** MGUS (~1%/yr progression), smouldering myeloma (~10%/yr), solitary plasmacytoma.

C. Pathogenesis

7. **Primary genetic events** (mutually exclusive): hyperdiploidy (55–60%, better prognosis) vs IgH translocations — t(11;14)→CCND1, t(4;14)→NSD2/FGFR3, t(14;16)→MAF.
8. **Secondary events** drive progression: MYC rearrangement, RAS mutations, del(17p)/TP53 loss, 1q21 gain.
9. **Marrow microenvironment:** IL-6, IGF-1, VEGF from stroma; bone disease from ↑RANKL/MIP-1α + ↓osteoprotegerin (osteoclast activation) and DKK1/IL-3 suppressing osteoblasts — purely lytic lesions, bone scan is falsely negative.

D. Diagnosis

10. SPEP + immunofixation + serum FLC + 24-hr urine IFE.
11. Marrow biopsy with flow cytometry and FISH (del17p, t(4;14), t(14;16), t(14;20), 1q gain).
12. Imaging: WBLDCT/WB-MRI/PET-CT (skeletal survey/bone scan obsolete).
13. **IMWG criteria:** ≥10% clonal plasma cells or plasmacytoma + ≥1 myeloma-defining event (CRAB + SLiM).

E. Staging & Management Principles

14. ISS → R-ISS → R2-ISS; **IMWG Frailty Index** independently predicts survival/toxicity.
15. Four rules: treat only symptomatic disease; decide transplant eligibility by fitness not age; CGA/frailty assessment before intensity; supportive care equally important.

Management at a Glance

Setting	Approach
Transplant-eligible	Quadruplet induction (D-VRd/Isa-VRd) → ASCT (melphalan 200 mg/m²) → lenalidomide ± daratumumab maintenance
Transplant-ineligible/older	D-VRd (fit, ≤80) or DRd/Isa-Rd (frail), until progression
Frail/very elderly	Dose-attenuated; SC bortezomib weekly; reduce dexamethasone to 20 mg weekly
Relapsed	Carfilzomib, pomalidomide, isatuximab, elotuzumab, or cilta-cel CAR-T
Triple-class-exposed	BCMA CAR-T or bispecifics (teclistamab, elranatamab, talquetamab)
Bone disease	Zoledronic acid 4mg IV monthly (avoid if eGFR<30) or denosumab 120mg SC monthly
Renal impairment	Hydration ~3L/day; stop NSAIDs/ACEi/contrast; urgent bortezomib-based therapy
Cord compression	Emergency — urgent MRI + high-dose dexamethasone + radiotherapy/surgery

Latest Updates (2023–Present)

PERSEUS (NEJM 2024): D-VRd + Dara-R maintenance gave 4-yr PFS 84.3% vs 67.7% (VRd) — new standard for transplant-eligible. **CEPHEUS/IMROZ:** quadruplets now standard for transplant-ineligible too (age capped at 80, excludes frail). **AURIGA:** Dara-R maintenance boosts MRD-negative conversion in post-transplant MRD-positive patients. **IMS–IMWG 2025** redefines high-risk myeloma. **FDA ODAC (2024)** accepts MRD-negative CR as regulatory endpoint; **MIDAS (2025)** tests transplant omission if MRD-negative. CAR-T/bispecifics transform relapsed disease — bispecifics favoured in frail elderly. **AQUILA (2025):** daratumumab approved for high-risk SMM. Frailty subgroup analyses of MAIA/IMROZ confirm anti-CD38 benefit persists in frail patients but quadruplets tolerated poorly.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Aetiology/diagnosis	No content at all	Fully defined by IMWG/WHO-HAEM5
First-line therapy	Not addressed	Quadruplets (D-VRd/Isa-VRd) fit; DRd/Isa-Rd frail
Transplant	Not myeloma-specific; RIC principle for MDS/AML transfers	ASCT melphalan 200mg/m², increasingly deferred if MRD-negative
Role of CGA	Strongly endorsed for haematological malignancy	Formalised as IMWG Frailty Index with frailty-adapted dosing

QUESTION 4

Chronic Myeloid Leukaemia — Clinical Features & Management

Textbook gap: Pathy's mentions CML only once — Ch. 24, Table 24.2 — as a myeloproliferative disorder causing acquired platelet dysfunction (bleeding paradoxically more common when platelets >10,00,000/µL). Everything else is externally sourced (ELN 2025, WHO-HAEM5).

High-Yield Points

A. Definition & Epidemiology

1. Myeloproliferative neoplasm defined by **Philadelphia chromosome t(9;22)** → **BCR::ABL1** fusion, a constitutively active tyrosine kinase.
2. ~15% of adult leukaemias. Indian series show younger median age (30s–40s) with bulkier/more advanced disease at diagnosis.
3. TKIs reduced annual mortality from 10–20% to ~1%; 10-yr survival now 82–87%; prevalence rising steeply.

B. Clinical Features

4. Nearly half asymptomatic — found on routine leucocytosis.
5. Constitutional symptoms: fatigue, weight loss, low-grade fever, night sweats.
6. **Splenomegaly** is the most consistent sign, may be massive; splenic infarction causes sudden pleuritic pain with rub.
7. Significant lymphadenopathy is rare in chronic phase — suggests blast phase if present.
8. **Leukostasis** at WCC >1,00,000/µL — priapism, blurred vision, tinnitus, confusion, stroke (emergency).
9. Hyperuricaemia/gout; characteristically **high serum B12**.
10. Blood picture: leucocytosis with full left shift, "myelocyte bulge", **basophilia** (near-universal clue), eosinophilia, thrombocytosis, low LAP score.

C. Phases, Diagnosis & Management

11. **WHO 2022 abolished "accelerated phase"**; blast phase = ≥20% blasts (older ELN definition was >30%).
12. Diagnosis: marrow morphology + cytogenetics + RT-PCR (transcript type e13a2/e14a2) for additional chromosomal abnormalities.
13. **ELTS score** replaces Sokal/Euro/EUTOS for prognosis.
14. Initial management: hydroxyurea, hydration, allopurinol, then start TKI once diagnosis confirmed.
15. **Six first-line TKIs:** imatinib, dasatinib, nilotinib, bosutinib, asciminib (2024), radotinib. Generic imatinib remains most cost-effective in India.
16. **Monitoring:** RT-qPCR (International Scale) 3-monthly. Milestones: BCR::ABL1(IS) ≤10% at 3mo, ≤1% at 6mo, ≤0.1%(MMR) at 12mo.

Response Milestones

Response	Definition
Complete cytogenetic (CCyR)	No Ph+ metaphases ≈ BCR::ABL1(IS) ≤1%
Major molecular (MMR/MR3)	BCR::ABL1(IS) ≤0.1%
MR4 / MR4.5	≤0.01% / ≤0.0032%

Treatment Algorithm

Situation	Approach
Toxicity in responder	Reduce dose rather than switch drugs
Resistance	Check adherence/interactions first, then BCR::ABL1 kinase mutation analysis
Second line	After imatinib → any 2GTKI. After 2GTKI → ponatinib or asciminib
T315I mutation	Ponatinib, high-dose asciminib, or olverembatinib
Blast phase	Intensive chemo + potent TKI → allogeneic SCT

Allo-SCT	Resistance to ponatinib/asciminib; RIC and haploidentical donors widen access in elderly

Latest Updates (2023–Present)

WHO-HAEM5 abolished accelerated phase; blast phase = ≥20%. **Asciminib** (STAMP inhibitor, binds myristoyl pocket) — **ASC4FIRST (NEJM 2024)**: MMR at 48wk 67.7% vs 49% with investigator-chosen TKI; FDA-approved first-line 2024. **ELN 2025** renamed milestones "favourable/warning/unfavourable" (no switch on a single PCR result). Older/comorbid patients: "failed" milestones still had ~80% 10-yr survival (German CML-IV, MDACC) — more conservative approach supported, but not based on age alone. **Dose reduction preferred over switching** for toxicity — low-dose dasatinib 50mg or 20mg (DAVLEC, age ≥70) reduces effusions. **EURO-SKI final analysis (JCO 2024):** MMR maintained in 46% at 12 months after stopping TKI (TFR). **Olverembatinib** effective after ponatinib/asciminib failure. EBMT: transplant outcome determined by disease stage/Karnofsky score, not number of prior TKI lines — haploidentical donors and RIC have widened access in the elderly.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Coverage	One line — platelet dysfunction only	Comprehensive ELN 2025/WHO-HAEM5
Disease phases	Not addressed	Biphasic; blast phase ≥20%; accelerated phase abolished
First-line therapy	Not addressed	Six TKIs; asciminib added first-line 2024
Toxicity management	Not addressed	Dose reduction preferred over switching
Older patients	Endorses CGA generally	ELN 2025 advises individualised, often conservative management

QUESTION 5

Myelodysplasia

Well covered: Pathy's Ch. 26 ("Myelodysplasia") and Ch. 27 ("Management of MDS and AML in the Elderly") cover this topic in genuine depth — this answer is largely textbook-derived.

High-Yield Points

A. Definition & Epidemiology

1. Heterogeneous **clonal haematopoietic stem cell disorders** — cytopenia from dysplastic, ineffective production, with variable risk of AML transformation.
2. **Most common haematological neoplasm in the elderly** — median diagnosis age 75–76; 86% occur ≥60 years. Incidence 75/1,00,000 over 65; 70/1,00,000/yr over 85.
3. Age is the primary risk factor — accumulating stem cell DNA mutations.

B. Aetiology

4. **Secondary (therapy-related) MDS: 10–20%**, 5–10 years after alkylating agents/radiation/benzene. Alkylator exposure → loss of chromosome 5/7.
5. Inherited predisposition: Down syndrome, Fanconi anaemia, Bloom syndrome, ataxia-telangiectasia, NF1.

C. Pathophysiology

6. Clonal myeloid precursor abnormality → excess intramedullary apoptosis → peripheral cytopenias despite a **hypercellular marrow** (the hallmark paradox).
7. **Aberrant hypermethylation** silences tumour suppressor genes (TET2, DNMT3A, EZH2, ASXL1 mutations) — basis for hypomethylating agent therapy.
8. **SF3B1** mutation → ring sideroblasts, favourable prognosis. **TP53** (5–20%) → higher-risk, therapy-related disease.

D. Clinical Features

9. Non-specific; macrocytic anaemia predominates — dyspnoea, fatigue, angina.
10. **Infection is a primary cause of death** — neutrophil dysfunction (impaired chemotaxis/killing), T-cell function intact so viral/mycobacterial infection uncommon.
11. Bleeding may occur despite normal platelet count (dysfunctional platelets). **Splenomegaly unusual — suggests CMML.**
12. **"MDS may easily be overlooked in the elderly"** — presents simply as chronic macrocytic anaemia; tendency to "leave well enough alone".

E. Diagnosis

13. Blood: macrocytic anaemia (90%), thrombocytopenia (10%), neutropenia (20–30%). Film: hypogranular/hypolobated neutrophils, **pseudo-Pelger-Huët cells** ("pince-nez").
14. Marrow: dysplastic lineage = >10% of cells abnormal. **Perls' stain** for ring sideroblasts (≥5 iron granules around ≥1/3 nucleus in >15% erythroblasts).
15. Cytogenetics essential — 60% normal karyotype; trisomy 8, del(5q/7q/11q/13q/20q); complex karyotype (≥3) = poor prognosis.
16. Exclude reactive causes: B12/folate deficiency, hypothyroidism, EBV/HIV, alcohol, chemotherapy, benzene.

IWG/NCCN Diagnostic Criteria

Two prerequisites: (1) stable cytopenia ≥6 months (or ≥2 months with specific karyotype/bilineage dysplasia); (2) exclusion of other causes.
Plus ≥1 of three: dysplasia ≥10% of a lineage; blast count 5–19%; MDS-associated karyotype (del5q, del20q, +8, −7/del7q).

WHO 2016 Classification (Pathy's)

Subtype	Key features
MDS-SLD	1 dysplastic lineage, 1–2 cytopenias, RS <15%, blasts <5%

MDS-RS	RS ≥15% (or ≥5% if SF3B1+)
MDS-MLD	2–3 dysplastic lineages
MDS-EB-1 / EB-2	Blasts 5–9% / 10–19% or Auer rods
MDS with isolated del(5q)	Normal/high platelets, hypolobated megakaryocytes
MDS-U	1% PB blasts on ≥2 occasions, or defined by cytogenetics alone

Prognostic Scoring

IPSS: Low/Int-1/Int-2/High by blast%, cytopenias, cytogenetics. **IPSS-R** uses 5 cytogenetic groups + blasts/Hb/platelets/neutrophils. CGA and comorbidity indices (MDS-CI, ACE-27, Charlson) add prognostic value in the elderly.

Management

Risk	Approach
Lower-risk	Watchful waiting; ESAs first-line (epoetin alfa preferred); G-CSF synergy; transfusion + iron chelation (start after 20–50 units or ferritin >1000–2500 ng/mL); lenalidomide for del(5q); luspatercept post-ESA failure
Higher-risk	Azacitidine 75 mg/m² SC × 7 days/28-day cycle, ≥4–6 cycles before failure; continue indefinitely if responding
Curative	Allogeneic HSCT — the only cure; RIC feasible to 70–75; CGA crucial for selection
Very frail	Best supportive care

Latest Updates (2023–Present)

WHO 2022/ICC 2022 renamed "myelodysplastic neoplasms" — split into genetically defined (**MDS-5q, MDS-SF3B1** [RS ≥15% criterion removed], **MDS-biTP53** [new]) and morphologically defined (MDS-LB, **MDS-h** [hypoplastic, new formal entity], MDS-IB1/IB2, MDS-f). ICC creates separate "MDS/AML" for 10–19% blasts. **IPSS-M** (31-gene molecular score, 6 categories) supersedes IPSS-R. **COMMANDS (Lancet Haematol 2024):** luspatercept superior to epoetin alfa as first-line in ESA-naïve lower-risk MDS — FDA-approved first-line, though benefit limited in RS-negative patients. **Imetelstat** (telomerase inhibitor, FDA June 2024) — 8-week transfusion independence ~40% vs 15% placebo after ESA failure. **VERONA trial (2025):** azacitidine + venetoclax showed NO survival benefit in higher-risk MDS — single-agent azacitidine remains standard.

Current Practice Update

Domain	Pathy's (WHO 2016)	WHO-HAEM5 (2022)
Nomenclature	Myelodysplastic syndromes	Myelodysplastic neoplasms
Ring sideroblasts	≥15% RS defines MDS-RS	SF3B1 mutation alone defines the entity
TP53	Poor-prognosis mutation, no category	MDS-biTP53 — distinct entity
Prognostic score	IPSS/IPSS-R	IPSS-M is the new reference standard
Post-ESA anaemia	Lenalidomide (del5q), luspatercept (RS/SF3B1)	Luspatercept now first-line; imetelstat added (2024)
Higher-risk MDS	Single-agent azacitidine	Unchanged — VERONA confirms venetoclax adds no benefit

QUESTION 6

Alkylating Agents · Intramedullary vs Extramedullary Haemolysis · What is Dysplasia

Part A — Alkylating Agents

1. **Alkylating agents** attach an alkyl group directly to DNA (usually N7 of guanine), causing **intra- and inter-strand cross-linking** that blocks replication/transcription → apoptosis.
2. **Cell-cycle non-specific** — kill dividing and resting cells; hence toxic to normal stem cells and a classic cause of secondary MDS/AML.

Class	Drugs
Nitrogen mustards	Cyclophosphamide, ifosfamide, chlorambucil, melphalan, bendamustine
Nitrosoureas	Carmustine, lomustine (cross blood-brain barrier)
Alkyl sulfonates	Busulfan
Triazenes	Dacarbazine, temozolomide, procarbazine
Platinum compounds	Cisplatin, carboplatin, oxaliplatin — **NOT true alkylators**, correctly called "platinating agents"

Toxicities: myelosuppression, alopecia, infertility (class-wide); cyclophosphamide/ifosfamide → haemorrhagic cystitis (prevent with mesna); busulfan/carmustine → pulmonary fibrosis; cisplatin → nephro/ototoxicity.

Alkylators vs Topoisomerase II Inhibitors — Therapy-Related Neoplasms

Feature	Alkylating agents/radiation	Topoisomerase II inhibitors
Latency	5–10 years	1–3 years
MDS prodrome	Yes	No — direct AML
Cytogenetics	Unbalanced losses: −5/del5q, −7/del7q	Balanced translocations: 11q23, 21q22

Part B — Intramedullary vs Extramedullary Haemolysis

Intramedullary = precursor dies inside the marrow before reaching blood = **ineffective erythropoiesis** (Pathy's: "dyserythropoiesis with intramedullary abortion"). **Extramedullary** = mature red cell dies after entering circulation (extravascular in spleen/liver, or intravascular in vessels).

The single best discriminator: reticulocyte count. True (extramedullary) haemolysis → HIGH reticulocytes. Intramedullary haemolysis → LOW/inappropriately normal reticulocytes, despite raised LDH, raised indirect bilirubin, low haptoglobin.

Feature	Intramedullary	Extravascular	Intravascular
Site	Inside bone marrow	Spleen/liver macrophages	Within blood vessels
Reticulocytes	**LOW**	HIGH	HIGH
Haptoglobin	Low	Low	**Absent**
Free plasma Hb	Absent	Absent	**Present**
Haemoglobinuria	Absent	Absent	**Present**
Film	Dysplastic cells	Spherocytes	Schistocytes
Examples	MDS, B12/folate deficiency, thalassaemia	AIHA, hereditary spherocytosis	PNH, MAHA, prosthetic valve

Bedside rule: "Haemolysis picture + LOW reticulocytes = the problem is INSIDE the marrow."

Part C — What is Dysplasia

1. **Dysplasia** = disordered growth/maturation of cells within a tissue — abnormal size/shape/arrangement, **NO invasion**, potentially reversible.
2. Distinguish: Hyperplasia (↑number) / Hypertrophy (↑size) / Metaplasia (mature→mature type change) / Dysplasia (disordered maturation) / Anaplasia (loss of differentiation, malignant).
3. **Pathy's definition:** "A lineage is dysplastic when qualitative cytological abnormalities are observed on >10% of the cells of the lineage."

Lineage	Dysplastic features
Dyserythropoiesis	Megaloblastoid change, nuclear budding, internuclear bridging, ring sideroblasts
Dysgranulopoiesis	Hypogranular neutrophils, pseudo-Pelger-Huët cells, Auer rods (if excess blasts)
Dysmegakaryopoiesis	Micromegakaryocytes, hypolobated nuclei

Critical caveat: Pathy's states dysplasia alone is NOT sufficient for MDS diagnosis — must exclude reactive causes: B12/folate deficiency, hypothyroidism, copper deficiency, EBV/HIV, alcohol, chemotherapy, benzene, certain antibiotics.

Latest Updates (2023–Present)

WHO-HAEM5 replaced "therapy-related myeloid neoplasm" with **"myeloid neoplasm post cytotoxic therapy (MN-pCT)"**, now including PARP inhibitors, excluding methotrexate. Modern understanding: alkylators/radiation mostly **select pre-existing clonal haematopoiesis** (TP53/PPM1D-mutant clones resistant to DNA damage) rather than creating new mutations — TP53 mutations found in up to 40% of MN-pCT. Morphological dysplasia has poor inter-observer reproducibility; WHO 2022/ICC 2022 have moved toward **genetic definition** of subtypes (MDS-SF3B1 by mutation, not RS%; MDS-biTP53, MDS-5q by genetics).

QUESTION 7

Anaemia of Chronic Disease

Well covered: Pathy's Ch. 22, under "Inflammatory Anaemias", with Figures 22.3 and 22.5.

High-Yield Points

A. Definition & Epidemiology

1. Anaemia from inflammation with excess cytokine production — a **functional iron deficiency** (stores normal/high, but unavailable for erythropoiesis).
2. **Commonest anaemia in older adults** — up to 70% of hospitalised elderly. Also common in obesity.

B. Causes

3. Chronic infection (TB, endocarditis), inflammatory disease (RA, SLE, IBD), malignancy, chronic organ disease (CKD, HF, COPD, liver disease), obesity, "inflammaging".

C. Pathophysiology — Four Mechanisms

4. **Cytokines** (IL-6, TNF) are the trigger.
5. **Functional iron deficiency via HEPCIDIN** — the central mechanism. Hepcidin (liver peptide, acute-phase reactant) is over-produced by IL-6; it blocks **ferroportin** on enterocytes/macrophages/hepatocytes, blocking gut iron absorption and trapping iron in macrophage/ferritin stores.
6. **Decreased EPO production/response** — cytokines damage EPO-producing renal cells and down-regulate EPO receptors.
7. **Shortened RBC lifespan and suppressed erythropoiesis** — cytokine-mediated apoptosis of precursors and mature cells.

D. Diagnosis

8. **Normocytic, normochromic** anaemia.
9. Iron pattern: low-normal iron/transferrin/saturation, but **normal-to-ELEVATED ferritin**.
10. Ferritin <30 ng/mL → IDA; >100 ng/mL → probable ACD; 30–100 → equivocal, use **soluble transferrin receptor (sTfR)** — HIGH in IDA, NORMAL in ACD, unaffected by inflammation.
11. Reticulocytes LOW; CRP/ESR elevated.

E. Management

12. Treat the underlying disease — cornerstone but often difficult in frail elderly.
13. **Iron NOT recommended unless true concomitant deficiency** — avoid if ferritin >100 ng/mL (futile; iron just locked in RE system).
14. **ESAs** — FDA-approved only for cancer chemotherapy or HIV myelosuppression; check iron first (ESAs often precipitate absolute iron deficiency); target Hb 11–12 g/dL; monitor 2–4 weekly.

IDA vs ACD vs CKD Anaemia

Parameter	IDA	ACD	CKD anaemia
Ferritin	Low (<30)	Normal-high (>100)	Normal-high
TIBC	High	Low-normal	Normal-high
sTfR	HIGH	Normal	Normal
MCV	Microcytic	Normocytic	Normocytic

Latest Updates (2023–Present)

Term **"anaemia of inflammation"** now preferred over "anaemia of chronic disease". **WHO 2024** reaffirmed Hb cutoffs (<13 g/dL men, <12 g/dL women); haemoglobin should **NOT be adjusted for inflammation** (adjust only for altitude/smoking). **HIF-prolyl hydroxylase inhibitors** (roxadustat, daprodustat, vadadustat, desidustat) raise endogenous EPO AND suppress hepcidin — work despite inflammation, unlike ESAs; approved for CKD anaemia (daprodustat FDA 2023). Treatment framing has shifted from "downstream replacement" (iron, ESAs) to "upstream pathway-level" approaches (HIF-PHIs, anti-hepcidin antibodies).

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Terminology	Anaemia of chronic disease	"Anaemia of inflammation" preferred
Pathophysiology	Four mechanisms — hepcidin central	Unchanged, now validated as therapeutic target
New drug class	Not mentioned	HIF-PHIs — raise EPO and lower hepcidin simultaneously

QUESTION 8

Anaemia in the Elderly & Evaluation of Anaemia

Well covered: Pathy's Ch. 22 (Figures 22.1, 22.3, 22.4) — largely textbook-derived.

High-Yield Points

1. **Definition:** Hb <13 g/dL men, <12 g/dL women — but also track the **trend** from the patient's own baseline.
2. **Anaemia is NOT normal ageing** — signifies disease; associated with mortality, disability, hospitalisation.
3. Prevalence: 10–25% over 65, up to 50% over 80 and in nursing homes.
4. **Causes (Bach et al., quoted in Pathy's):** ACD 62.1%, CKD anaemia 11.3–45.1%, multifactorial 28.1%, iron deficiency 14.4%, clonal disorders 10%, folate 6.7%, B12 2%.
5. Associated with impaired ADLs, frailty, cognitive decline, depression, fractures; higher RDW independently predicts mortality.
6. **MCV unreliable in the elderly** — B12 deficiency may be normocytic; concurrent diseases can cancel each other's MCV effect.
7. Presentation often a **geriatric syndrome** — falls, delirium, syncope — not a haematological complaint.

Stepwise Evaluation

Step	Action
1	History: bleeding, diet, alcohol, drugs (PPIs/H2 blockers, metformin, NSAIDs)
2	Examination: pallor, jaundice, glossitis, koilonychia, splenomegaly, neuro exam for SACD
3	CBC + indices + reticulocyte count + **blood film** (single most informative test)
4	Reticulocytes LOW → hypoproliferative; HIGH → haemolysis/blood loss
5	Iron studies: ferritin <30 → IDA; >100 → ACD; 30–100 → add sTfR
6	B12/folate: B12 <200 pg/mL deficient; 200–350 equivocal → add MMA + homocysteine
7	Renal/liver/thyroid function, CRP/ESR
8	**GI evaluation mandatory** for IDA in an older adult — endoscopy top and bottom
9	Marrow biopsy if macrocytic + other cytopenias + low reticulocytes (clonal disorder red flags)

Treatment by Cause

Cause	Treatment
Iron deficiency	Oral iron once daily; IV if malabsorptive/intolerant; continue 3–6 months after correction
B12 deficiency	Oral 2000 mcg daily as effective as IM; IM 1000 mcg weekly then monthly if severe
Folate deficiency	Folic acid 1 mg daily
ACD	Treat underlying disease; iron only if concomitant deficiency

Latest Updates (2023–Present)

WHO 2024 reaffirmed Hb cutoffs; adjust for altitude/smoking, NOT inflammation or ethnicity; no separate elderly-specific cutoff yet. **Oral iron dosing changed:** alternate-day, single-morning dosing (60–120mg elemental iron) increases fractional absorption ~33% with fewer GI side effects — now recommended by ACG and EHA (2024). **AABB 2023:** restrictive transfusion threshold Hb<7 g/dL generally (<7.5 cardiac surgery, <8 orthopaedic/CVD) — but **MINT trial (2023)** in acute MI showed higher 6-month cardiac mortality with restrictive strategy; 2025 AABB now suggests **liberal threshold <10 g/dL in acute MI**. "Unexplained anaemia of the elderly" increasingly reclassified as **CCUS/clonal haematopoiesis** on molecular testing.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Oral iron dosing	Once daily only, never divided	Alternate-day single morning dose now preferred

Transfusion	Not discussed in detail	Restrictive generally; LIBERAL (<10g/dL) in acute MI
Unexplained anaemia	Recognised as a category	Increasingly reclassified as CCUS/clonal haematopoiesis

QUESTION 9

Thrombocytopenia

Well covered: Pathy's Ch. 24 ("Disorders of Platelet Number"), supplemented by Ch. 23 (DIC).

High-Yield Points

1. **Definition:** platelet count <1,50,000/µL. **Platelet count does NOT change with normal ageing** — a low count always signifies disease.
2. Haemostasis normal above 80,000/µL. **Spontaneous haemorrhage (incl. ICH) doesn't occur until <20,000/µL.**
3. **Three mechanisms:** decreased production, increased destruction (consumption/immune), splenic pooling. **Always consider drugs as a cause.**

Immune Thrombocytopenia (ITP)

4. Adult ITP: insidious onset, chronic course (unlike childhood ITP which is acute, post-viral, self-limiting).
5. Autoantibody against GPIb/GPIIb-IIIa; platelet survival falls from 7–10 days to hours.
6. **Always repeat count + check film first** to exclude pseudothrombocytopenia (EDTA-clumping/clotted sample).
7. Treatment ladder: prednisolone 1mg/kg or IVIg 1g/kg×2 days (first line) → TPO-RAs/romiplostim/eltrombopag (second line) → splenectomy (third line, needs pre-op vaccination) → azathioprine/cyclophosphamide (last resort).

Drug-Induced & Other Causes

8. Two mechanisms: direct marrow suppression, or immune-mediated. Common culprits: aspirin, paracetamol, antibiotics, anticonvulsants, diuretics, quinine, quinidine.
9. **HIT is the exception — causes THROMBOSIS not bleeding.** Mortality ~30% if untreated. Treatment: stop heparin, start argatroban (acute) then fondaparinux. **Warfarin worsens acute HIT.**

DIC vs TTP

Test	DIC	TTP
Coagulation screen	**Grossly abnormal**	Normal/mild
Fibrinogen	Low (<100 mg/dL)	Normal
D-dimer	>1000 ng/mL	Normal/mild ↑
Key feature	Multi-organ failure from microthrombosis	Pentad: fever, thrombocytopenia, neuro, renal, MAHA
Treatment	Treat cause + product support	Plasma exchange + steroids/rituximab

Two Geriatric Pearls

10. In MDS, platelet dysfunction coexists with thrombocytopenia — bleeding/infection are commonest causes of death.
11. In myeloproliferative disorders, bleeding is **paradoxically MORE common at very high platelet counts** (>10,00,000/µL).

Latest Updates (2023–Present)

Rilzabrutinib (oral BTK inhibitor) — FDA-approved Aug 2025 for persistent/chronic ITP; dual mechanism (blocks autoantibody production AND FcγR-mediated platelet phagocytosis) — **LUNA3 trial**. **Splenectomy moved far down the ladder** — ASH now recommends TPO-RAs/rituximab first; delay splenectomy ≥12 months. ITP renamed "immune thrombocytopenia", threshold now <1,00,000/µL. **TTP:** ISTH 2025 update — recombinant ADAMTS13 (apadamtase alfa) now preferred over FFP in congenital TTP; caplacizumab confirmed standard in immune TTP alongside plasma exchange. **HIT** now part of a family of "anti-PF4 disorders" (autoimmune HIT, spontaneous HIT, VITT); **DOACs now accepted alternatives** to argatroban/fondaparinux in stable HIT.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
ITP later	Splenectomy, then	Splenectomy deferred ≥12 months; rilzabrutinib (2025) major new

lines	azathioprine/cyclophosphamide	option
HIT	Classic heparin-triggered; argatroban→fondaparinux	Part of anti-PF4 spectrum including VITT; DOACs accepted
TTP	Plasma exchange + steroids/rituximab	Adds caplacizumab; recombinant ADAMTS13 first choice in congenital TTP

QUESTION 10

Hodgkin Lymphoma

Textbook gap: No Hodgkin lymphoma chapter. Only link: Ch. 26 — actuarial risk of therapy-related MDS/AML is 6–9% after Hodgkin's treatment (vs 17% after myeloma treatment). Geriatric-oncology philosophy from Ch. 26/27 transfers directly.

High-Yield Points

A. Definition & Epidemiology

1. B-cell derived lymphoid malignancy; malignant cells only 1–2% of tumour mass, surrounded by reactive infiltrate.
2. **Bimodal age distribution** — peaks at 15–35 and after 55–60 years; 20–25% of cases occur >60 years.
3. Elderly HL behaves worse: more advanced stage, more B symptoms, more mixed-cellularity, higher EBV positivity. 5-yr survival falls from >90% (young) to 40–60% (>60).

B. Classification (WHO-HAEM5)

Subtype	Frequency	Features
Nodular sclerosis	~70%	Young adults, mediastinal mass
Mixed cellularity	20–25%	Older patients, HIV, EBV+
Lymphocyte-depleted	<1%	Worst prognosis — elderly, HIV, EBV+

4. **Immunophenotype:** classic RS cells — CD30+, CD15+, CD45−, CD20 weak/neg. NLPHL "popcorn" cells — CD20+, CD45+, CD30−, CD15− (mirror image).
5. 9p24.1 amplification → **PD-L1/PD-L2 overexpression** — basis for checkpoint inhibitor efficacy.

C. Clinical Features

6. Painless, rubbery cervical/supraclavicular lymphadenopathy ± mediastinal mass.
7. **Spreads contiguously** node-group to node-group (unlike NHL's unpredictable spread).
8. B symptoms (fever >38°C, night sweats, weight loss >10%) in 25–30%, more frequent in elderly.

D. Diagnosis & Staging

9. **Excisional lymph node biopsy mandatory** — FNA inadequate.
10. Staging: PET-CT, Lugano/Ann Arbor (I–IV, A/B suffix); bone marrow biopsy usually omitted.
11. **IPS score** (advanced disease): albumin <4 g/dL, Hb <10.5 g/dL, male, age ≥45, stage IV, WCC ≥15,000, lymphocytes <600/µL.

Management

Setting	Approach
Early favourable	2 cycles ABVD + 20 Gy involved-site RT, or PET-adapted chemo alone
Advanced, fit	Nivolumab-AVD (new standard, S1826), or BrECADD, or A+AVD
Advanced, ≥60 years	**Nivolumab-AVD now preferred**; bleomycin lung toxicity mortality up to 25% in >60 — avoid
Frail/unfit	Sequential BV→AVD→BV, or attenuated regimens (VEPEMB, PVAG)
Relapsed	Salvage → ASCT (fit); checkpoint inhibitors for transplant-ineligible

Late effects: secondary MDS/AML (6–9%, per Pathy's), anthracycline cardiomyopathy, radiation-related breast/lung cancer, hypothyroidism, bleomycin pulmonary fibrosis.

Latest Updates (2023–Present)

WHO-HAEM5 repositioned HL among B-cell neoplasms. ICC renamed NLPHL as "NLPBL" — WHO retained NLPHL. **SWOG S1826 (older-patient subset, ≥60, JCO 2025):** nivolumab-AVD vs BV-AVD — 2-yr PFS 89% vs 64% (HR 0.24), 2-yr OS 96% vs 85%; fewer sepsis episodes and less neuropathy. Contrast with ECHELON-1 where BV-AVD showed NO benefit over 60 — **nivolumab-AVD is a genuine breakthrough for older patients. GHSG HD21 (BrECADD):** comparable PFS in 61–75 age group but febrile neutropenia 54% vs 13% with nivolumab-AVD — decisive

difference in frail elderly.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Coverage	None — only late-effect MDS/AML risk	Fully covered by WHO-HAEM5/ESMO/NCCN
Advanced-stage therapy	Not addressed	Nivolumab-AVD (S1826) preferred, especially ≥60 yrs
Late effects	Correctly states 6–9% secondary MDS/AML risk — still valid	Confirmed; termed MN-pCT under WHO 2022

QUESTION 11

Non-Hodgkin Lymphoma — Presentation, Prognosis & Principles of Therapy

Textbook gap: No NHL chapter. Only links: Ch. 24 (lymphoma causing marrow infiltration/thrombocytopenia, acquired FVIII inhibitors); Ch. 26 (lymphoma treatment as MDS/AML risk). Geriatric-oncology philosophy transfers directly — median NHL diagnosis age is 65–70.

High-Yield Points

A. Definition, Epidemiology & Classification

1. Heterogeneous clonal lymphoid proliferations — 85–90% B-cell. WHO-HAEM5 recognises >60 entities. **5–6× commoner than Hodgkin lymphoma.**
2. Risk factors: age (dominant), immunosuppression, autoimmune disease, infections (EBV, HTLV-1, *H. pylori*→gastric MALT, HCV), pesticides.

Group	Examples	Behaviour
Indolent	Follicular (1–2), marginal zone, SLL/CLL	Incurable but long survival; watch and wait
Aggressive	**DLBCL (commonest, 30–40%)**, mantle cell	Fatal in months untreated, but curable 50–60%
Very aggressive	Burkitt, lymphoblastic	Rapidly fatal untreated, highly curable

B. Clinical Presentation

4. Painless, generalised lymphadenopathy; **non-contiguous, unpredictable spread** — most present stage III/IV.
5. **Extranodal disease in 25–40%** (far commoner than HL) — stomach, bowel, Waldeyer's ring, CNS, testis, skin.
6. B symptoms in 30–40%. Marrow involvement common (40–70% in indolent NHL).
7. Oncological emergencies: SVC obstruction, cord compression, tumour lysis syndrome.
8. In the elderly: often atypical — weight loss, falls, recurrent infection, or simply raised LDH.

C. Diagnosis & Prognosis

9. **Excisional biopsy essential** — FNA inadequate. PET-CT staging (Lugano).

IPI (mnemonic "APLES"), one point each: Age >60, **P**erformance status ECOG≥2, **L**DH above normal, **E**xtranodal sites ≥2, **S**tage III/IV. In rituximab era, 5-yr OS ranges 90% (low risk) to ~50% (high risk). NCCN-IPI uses age bands and specific extranodal sites for better discrimination in the elderly.

Principles of Therapy

10. Treatment dictated by **subtype, stage and fitness — never age alone.**
11. Indolent NHL: watch and wait legitimate until GELF/BNLI criteria met.
12. Aggressive NHL: potentially curable — treat promptly with curative intent where tolerated.
13. **Anti-CD20 antibody (rituximab/obinutuzumab) added to chemotherapy** for all CD20+ B-cell NHL.
14. Geriatric assessment BEFORE choosing intensity — first decision is curative vs palliative intent.

Treatment at a Glance

Setting	Approach
DLBCL, advanced, fit	R-CHOP×6 or Pola-R-CHP×6
DLBCL, ≥80 or frail	**R-miniCHOP** — 2-yr PFS ~47%, OS ~59%
Gastric MALT	*H. pylori* eradication alone cures 60–80%
Relapsed, fit	Salvage → ASCT, or CD19 CAR-T (now 2nd line)
Relapsed, CAR-T ineligible	CD20×CD3 bispecifics (glofitamab, epcoritamab), polatuzumab-BR

Latest Updates (2023–Present)

POLARIX (NEJM 2022): Pola-R-CHP improved 2-yr PFS to 76.7% vs 70.2% (trial capped age at 80). **POLAR BEAR trial** (Nordic, patients ≥80 or ≥75+frail): R-pola-mini-CHP had MORE serious/fatal adverse events than R-miniCHOP — **R-miniCHOP remains a sound standard in the very old. Bispecific antibodies** (glofitamab, epcoritamab — FDA 2023) transformed relapsed disease, especially valuable in older patients ineligible for CAR-T — off-the-shelf, no apheresis delay. **ZUMA-7/TRANSFORM:** CD19 CAR-T now superior to salvage+ASCT in early relapse; **PILOT trial** shows liso-cel effective in transplant-ineligible second line.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Coverage	None	Fully covered by WHO-HAEM5/NCCN/ESMO
First-line DLBCL	Not addressed	R-CHOP or Pola-R-CHP; R-miniCHOP for ≥80/frail
Relapsed disease	Not addressed	CAR-T (2nd line); bispecifics for CAR-T-ineligible

QUESTION 12

Anaemia of Chronic Kidney Disease — Type, Investigation & Treatment

Well covered: Pathy's Ch. 22, dedicated CKD section with Figure 22.3.

High-Yield Points

A. Type & Epidemiology

1. **Normocytic, normochromic, HYPOPROLIFERATIVE anaemia** — reticulocytes low for the degree of anaemia.
2. 45–70% of adults over 75 meet CKD criteria (GFR<90); 51–60% of CKD nursing-home residents also anaemic. Hb<8 g/dL carries 2× mortality risk vs 10–11 g/dL.

B. Pathophysiology — Five Mechanisms

3. **EPO deficiency** — dominant mechanism, most severe once CrCl<30 mL/min.
4. **Hepcidin excess — HIGHER than ordinary ACD** because of reduced renal clearance of the peptide.
5. Shortened RBC lifespan — uraemic toxins cut survival from 120 to 30–40 days.
6. Increased blood loss — uraemic platelet dysfunction + dialysis/phlebotomy losses.
7. Concurrent true iron deficiency very common.

C. Investigation

8. Work up when Hb <12 g/dL (men), <11 g/dL (women) — per NKF.
9. Serum EPO of limited value — may be normal/slightly high but **inappropriately low** for the anaemia.
10. Same ferritin/sTfR algorithm as ACD; exclude B12/folate, TSH, PTH, occult bleeding.

D. Treatment

11. **Correct iron FIRST, then give ESA** — enough free iron must be available for marrow use.
12. Maintain ferritin ~200 ng/mL, TSAT >20% in dialysis; no benefit above ferritin ~500 ng/mL.
13. Target Hb 11–12 g/dL — **normal range must NOT be targeted** (increased mortality from thrombosis).
14. 10–20% are ESA-hyporesponsive; ESAs linked to malignancy progression — do not treat the underlying disease.

Latest Updates (2023-Present) — KDIGO 2026

Pathy's cites KDOQI 2000/2006 — **fully superseded.** New terminology: **"iron-restricted erythropoiesis"** replaces "functional iron deficiency"; "systemic iron deficiency" replaces "absolute". **Haemoglobin target LOWERED to BELOW 11.5 g/dL** (Level 1 recommendation) — lower than Pathy's 11–12 g/dL. ESA initiation at Hb ≤9.0–10.0 g/dL in dialysis. Formal iron thresholds: start IV iron in HD if ferritin ≤500 ng/mL AND TSAT ≤30%; withhold if ferritin >700 ng/mL or TSAT ≥40%. **HIF-PHIs now addressed but as SECOND-line** (never combined with ESA); daprodustat FDA-approved 2023 with boxed thrombotic warning; roxadustat FDA-rejected. **Transfusion now symptom-based, not threshold-based**; avoid in transplant candidates.

Current Practice Update

Domain	Pathy's (KDOQI-era)	KDIGO 2026
Target haemoglobin	11–12 g/dL	**Below 11.5 g/dL** — lowered
Terminology	"Functional iron deficiency"	"Iron-restricted erythropoiesis"
New drug class	Not mentioned	HIF-PHIs — second-line only
Transfusion	Not detailed	Symptom-based; avoid in transplant candidates

QUESTION 13

Mechanisms of Drug-Induced Thrombocytopenia

Covered briefly: Pathy's Ch. 24 gives the two-mechanism framework and HIT in detail; the six-antibody subdivision below is externally sourced.

High-Yield Points

1. **Pathy's rule:** "Prescription drugs should ALWAYS be considered as a possible cause in any case of thrombocytopenia."
2. Two broad mechanisms: **direct marrow suppression**, or **induction of an immune response.**

Non-Immune Mechanisms

3. Dose-dependent marrow suppression (cytotoxics, alcohol, chloramphenicol).
4. Idiosyncratic marrow aplasia (gold, phenylbutazone, carbamazepine, thiazides).
5. Direct platelet/megakaryocyte toxicity (linezolid, valproate, daptomycin, bortezomib).
6. Drug-induced thrombotic microangiopathy (quinine, gemcitabine, clopidogrel).

Immune Mechanisms — Six Types

Mechanism	How it works	Prototype drugs
1. Hapten-dependent	Covalent binding → neo-antigen	Penicillins, cephalosporins
2. Quinine-type	**Tri-molecular complex** — drug alters antibody CDR → binds GPIIb/IIIa or GPIb/IX	Quinine, quinidine, sulfonamides, vancomycin, rifampicin
3. Fiban-type	Binds RGD site → exposes LIBS neoepitope; onset within HOURS	Tirofiban, eptifibatide
4. Chimeric antibody	Antibody against murine CDR3	Abciximab
5. Autoantibody induction	True autoantibody, drug-independent, may persist	Gold, procainamide, checkpoint inhibitors
6. Immune complex	**PF4-drug complex → IgG → FcγRIIa → platelet ACTIVATION**	Heparin (HIT), VITT

HIT — The Special Case

9. Unlike other DIT causing bleeding, **HIT causes THROMBOSIS** via platelet activation. Mortality ~30% if untreated. More common with UFH than LMWH.
10. Management: stop heparin, start argatroban (acute) then fondaparinux. **Warfarin worsens acute HIT.**

Timing Clues

Mechanism	Onset
Classic (quinine-type) DITP	5–10 days first exposure; hours on re-exposure
Fiban/abciximab-type	Within hours, even first exposure
HIT	5–10 days (or hours if heparin in prior 100 days)

Latest Updates (2023–Present)

HIT now part of a family of "anti-PF4 disorders": classic HIT, autoimmune HIT, spontaneous HIT (no heparin exposure, post-infection/surgery), and **VITT** (adenoviral-vector COVID vaccines). **DOACs (rivaroxaban, apixaban) now accepted alternatives** to argatroban/fondaparinux in stable HIT. VITT treatment: non-heparin anticoagulation + high-dose IVIg. **Immune checkpoint inhibitors** (pembrolizumab, nivolumab) recognised as an important autoantibody-type cause — may persist after stopping, often needs steroids/IVIg. Refined "antibody-first" model for quinine-type binding confirmed structurally.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
GPIIb/IIIa inhibitors	Not mentioned	Fiban-type and abciximab-type mechanisms — hours to onset

HIT	Heparin-triggered only	Part of anti-PF4 spectrum including VITT; DOACs accepted
Culprit drugs	Aspirin, paracetamol, quinine, quinidine	Expanded — linezolid, checkpoint inhibitors, ADCs

QUESTION 14

Blood Transfusion

Partial coverage: No dedicated transfusion chapter, but elderly-specific PRACTICE is discussed substantially across Ch. 22 (CKD), Ch. 23 (DIC), Ch. 24 (platelet thresholds) and Ch. 26/27 (MDS transfusion support — the most detailed section).

High-Yield Points

1. **Ageing does NOT change platelet count or coagulation tests** — a low count/deranged clotting always reflects disease.
2. **CKD:** Hb<8 g/dL carried 2× mortality risk vs 10–11 g/dL — but do not normalise the target (thrombotic risk).
3. **MDS/malignancy:** threshold generally 8 g/dL, raised to **9–10 g/dL with cardiac/other comorbidities.**
4. **Transfusion SPEED should be SLOW** to avoid volume overload — explicit Pathy's point.
5. Platelets: spontaneous ICH risk below 20,000/µL; MDS prophylactic threshold <10,000/mm³; curative-intent transfusion preferred over routine prophylaxis (alloimmunisation risk).
6. Leukoreduced and irradiated products recommended to reduce isoimmunisation, infection, febrile reactions.
7. Phenotyped RBCs for chronically transfused patients; 10–15% develop alloantibodies in MDS.

Iron Overload (detailed in Pathy's)

8. Each unit contains ~250 mg iron. Chelation indicated after **20–50 units AND ferritin >1000–2500 ng/mL.**
9. Monitor with hepatic/cardiac MRI annually; deferoxamine SC or oral deferasirox; check ferritin 3-monthly.

Transfusion in DIC

10. Transfusion prevents death from bleeding, but **not from multi-organ failure** (microvascular thrombosis is the usual cause of death). ABO-incompatible transfusion is itself a rare DIC trigger.

Blood Products (supplemented)

Product	Main indication
Packed red cells	Symptomatic anaemia
Platelet concentrate	Thrombocytopenia with bleeding or prophylaxis <10,000/µL
FFP	DIC, warfarin reversal, massive transfusion
Cryoprecipitate	Hypofibrinogenaemia, DIC

Latest Updates (2023–Present)

AABB 2023: restrictive Hb<7 g/dL generally, <7.5 cardiac surgery, <8 orthopaedic/CVD; **2025 update suggests LIBERAL <10 g/dL in acute MI** (MINT trial). **TACO is now the LEADING cause of transfusion death** (34–41% of fatalities); **age ≥70 is a formally recognised independent risk factor**, alongside CHF and renal failure. **MHRA/SHOT Patient Safety Alert (April 2024):** mandatory pre-transfusion TACO risk assessment for patients ≥70; **"Code R7" mandates single-unit transfusion strategy** for stable non-bleeding patients — reassess after each unit before ordering a second. Patient Blood Management now the global WHO/AABB standard framework. Iron overload monitoring refined with cardiac/hepatic T2* MRI.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Dedicated coverage	No transfusion chapter	AABB 2023 guidelines; formal PBM frameworks
TACO	Not discussed at all	**Leading cause of transfusion death; age ≥70 a formal risk factor**
Transfusion rate	"Slow to avoid volume overload" — explicit	Validated — now formalised as core TACO mitigation
Single-unit policy	Implicit in "personalise threshold"	Explicitly mandated (2024) for TACO-risk patients

QUESTION 15

WHO Classification & Diagnostic Criteria of MDS, and its Differentials

Exceptionally well covered: Pathy's Ch. 26/27, Tables 26.1–26.4 and 27.1 — directly quotable.

High-Yield Points

Cytopenia Thresholds (Table 26.1)

Parameter	Threshold
Haemoglobin	<10 g/dL
Platelets	<1,00,000/µL
ANC	<1800/µL

WHO 2016 Classification — Full Table

Subtype	Dysplastic lineages	Ring sideroblasts	Blasts
MDS-SLD	1	<15% (<5% if SF3B1+)	PB<1%, BM<5%
MDS-RS	1–3	≥15% (≥5% if SF3B1+)	PB<1%, BM<5%
MDS-MLD	2–3	Variable	PB<1%, BM<5%
MDS-EB-1	0–3	Any	PB 2–4% or BM 5–9%
MDS-EB-2	0–3	Any	PB 5–19% or BM 10–19%, or Auer rods
MDS del(5q)	1–3	Any	PB<1%, BM<5%

Blast-count denominator redefined (2016) to include ALL nucleated marrow cells. **≥20% blasts defines AML** (vs MDS-EB-2's ceiling of 19%). **5q− syndrome:** macrocytic anaemia with NORMAL/INCREASED platelets, hypolobated megakaryocytes.

IWG/NCCN Diagnostic Criteria

Two prerequisites: (1) stable cytopenia ≥6 months (or ≥2 with specific karyotype/bilineage dysplasia); (2) exclusion of other causes.
Plus ≥1 of: dysplasia ≥10% of a lineage; blasts 5–19%; MDS-associated karyotype (del5q, del20q, +8, −7/del7q).

Differential Diagnosis

"Dysplasia in the marrow is NOT sufficient to establish myelodysplasia" (Pathy's, verbatim). Exclude: B12/folate deficiency, hypothyroidism, EBV/HIV, ethanol, chemotherapy, benzene.

Feature	CHIP	ICUS	CCUS	MDS
Cytopenias	No	Yes	Yes	Yes
Dysplasia	No	Minimal	Minimal	>10% of a lineage
Somatic mutations	Yes (VAF≥2%)	No	Up to 36%	Up to 85%
5-yr progression	0.5–1%/yr	Up to 10%	Up to 80%	—

Splenomegaly is unusual in MDS — suggests **CMML** if present. Other differentials: PNH, aplastic anaemia, congenital neutropenia, marrow infiltration by carcinoma/lymphoma.

Latest Updates (2023-Present)

WHO-HAEM5 (2022) renamed "myelodysplastic neoplasms" — two groups:

Group	Entity	Key criteria
Genetically defined	MDS-5q	del(5q) alone or +1 other (except −7/del7q)
	MDS-SF3B1	**SF3B1 mutation ALONE defines it — RS threshold removed**
	MDS-biTP53 (NEW)	≥2 TP53 mutations, or 1 + copy-number loss/cnLOH

Morphologically defined	MDS-LB	<5% BM, <2% PB blasts
	MDS-h (NEW)	Hypoplastic marrow
	MDS-IB1/IB2	Replaces MDS-EB-1/EB-2
	MDS-f (NEW)	Increased blasts + fibrosis

NPM1-mutated cases now reclassified as AML regardless of blast count. ICC creates separate "MDS/AML" for 10–19% blasts (WHO calls this MDS-IB2). **IPSS-M** (31-gene molecular score) supersedes IPSS-R.

Current Practice Update

Domain	Pathy's (WHO 2016)	WHO-HAEM5 (2022)
Ring sideroblasts	≥15% defines MDS-RS	SF3B1 mutation alone defines the entity
Hypoplastic MDS	Morphological variant, 15–20%	MDS-h — formal WHO category
NPM1-mutated	Classified by blast %	Automatically AML regardless of blast count
Prognostic score	IPSS/IPSS-R	IPSS-M is the reference standard

QUESTION 16

Bone Marrow Transplant

No standalone chapter, but Ch. 27 discusses allogeneic HSCT in real depth, framed around age eligibility — directly quotable.

High-Yield Points

1. **Definition:** conditioning regimen + infusion of HLA-compatible stem cells. Allogeneic (curative, immune graft-vs-leukaemia effect) vs autologous ("autografting" — harder in elderly due to mobilisation difficulty).
2. **Donor–versus–leukaemia effect vs GVHD** — same donor immune cells that kill leukaemia can attack gut/skin/liver.
3. Donor sources: related, unrelated, cord blood, **haploidentical.**
4. **Myeloablative conditioning:** mortality 20–50%; age was historically a contraindication because of this.
5. **Reduced-intensity/non-myeloablative (RIC)** maximises graft-vs-leukaemia while minimising toxicity — low short-term mortality up to age 70–75, OS comparable to ablative (offset by higher relapse).
6. US registry: 1106 patients ≥70; proportion rose 0.1%(2000)→3.85%(2013); **2-yr OS improved 26%→39%**; **2-yr TRM unchanged at 33–35%.**
7. **HCT-CI** (Sorror) and **Karnofsky performance status** are independent predictors of survival.
8. **CGA is "crucial in selecting candidates for transplantation"** — Pathy's explicit refrain.
9. MDS: only potential cure. AML: consolidation after CR for intermediate/unfavourable risk.
10. Autologous mobilisation becomes progressively more difficult with age.

Latest Updates (2023–Present)

Post-transplant cyclophosphamide (PTCy) has transformed GVHD prophylaxis — **BMT CTN 1703 update specifically in patients ≥70 (Blood Adv 2025):** GVHD-free/relapse-free survival 67.1% vs 29.5% with Tac/MTX, lower NRM. Authors conclude allo-HCT is **underutilised in ≥70** and PTCy should prompt greater consideration. **Haploidentical transplant with PTCy now feasible over 70** (Johns Hopkins: 2-yr OS 53%, 180-day NRM 14%). **PTCy dose reduced to 80 mg/kg** specifically improves elderly outcomes (vs 100 mg/kg). **Donor AGE, not donor type, is now the dominant variable** — younger haploidentical donor may be preferable to an older matched donor. **Letermovir CMV prophylaxis extended to 200 days** (ASTCT 2025) — particularly relevant given older recipients' higher CMV seroprevalence.

Current Practice Update

Domain	Pathy's (2022)	Current evidence
Age ceiling	RIC "rarely completed after 70"	PTCy-based transplant established into late 70s
GVHD prophylaxis	Not specified	**PTCy now preferred platform**, proven benefit in ≥70
Donor selection	Four types listed, no hierarchy	Donor age now more important than donor type
CMV prophylaxis	Not addressed	Letermovir extended to 200 days

QUESTION 17

POEMS Syndrome

Complete textbook gap. Only tangential link: the standard peripheral neuropathy work-up algorithm (Essentials of Clinical Geriatrics, Fig. 13-3) includes SPEP/UPEP/IPEP for any acquired demyelinating neuropathy — the pathway that would uncover POEMS' paraproteinaemia, though the syndrome itself is never named.

High-Yield Points

1. **POEMS** = Polyneuropathy, Organomegaly, Endocrinopathy, M-protein, Skin changes — paraneoplastic syndrome from a low-tumour-burden, **LAMBDA-restricted** clonal plasma cell neoplasm.
2. **VEGF drives the phenotype** — increased vascular permeability → oedema, increased endoneural pressure, capillary leak.
3. Distinctive marrow: combined plasma cell, lymphoid and megakaryocytic changes.

Diagnostic Criteria (Dispenzieri, updated 2023)

Category	Criteria
Mandatory major (both)	Polyradiculoneuropathy + clonal plasma cell disorder (lambda-restricted)
Additional major (≥1)	Castleman disease, sclerotic bone lesions, elevated VEGF
Minor (≥1)	Organomegaly, endocrinopathy, skin changes, papilledema, extravascular volume overload, thrombocytosis

Mnemonics: "POEMS" (2 mandatory + 3 minor); "PEST" (Papilledema, Extravascular overload, Sclerotic lesions, Thrombocytosis). **Serum VEGF** is the key diagnostic AND monitoring biomarker, independent of M-protein size.

Clinical Features

4. Polyradiculoneuropathy — symmetric, ascending, demyelinating — **mimics CIDP** (commonest cause of diagnostic delay).
5. Extravascular volume overload (oedema, effusions, ascites) and thrombocytosis **distinguish it from ordinary CIDP.**
6. Skin: hyperpigmentation, hypertrichosis, **glomeruloid haemangiomata** (near-pathognomonic).
7. Also: restrictive lung disease, pulmonary hypertension, increased stroke/thrombosis risk.
8. Untreated → death from neuropathic exhaustion or cardiopulmonary failure.

Management

Disease extent	First-line approach
Localised (≤2 lesions, no marrow involvement)	Radiotherapy 30–54 Gy ± lenalidomide-dexamethasone; ~82% cure
Disseminated, transplant-eligible	Induction chemo → **autologous stem cell transplant (ASCT)** — best CR/PFS rates
Transplant-ineligible	Lenalidomide + dexamethasone, or daratumumab + Len + dex (Dara-Rd)
Rapidly deteriorating	Corticosteroids as a bridge

IVIg gives only short-term benefit — reliance on it (as if treating CIDP) is a recognised trap that delays correct diagnosis. Anti-VEGF therapy (bevacizumab) proved largely ineffective.

Latest Updates (2023–Present)

Diagnostic criteria formally updated (Dispenzieri, 2023). **"Capillary leak phenotype"** identified (Leukemia, Dec 2024) as an independent major cause of death. **Daratumumab-based regimens (Dara-Rd)** emerging for transplant-ineligible patients, including reports in patients in their 70s. First **CAR-T and BCMA×CD3 bispecific trials** for relapsed POEMS opened 2024–2025. Comprehensive **2025 ASH review** (Dispenzieri) is now the reference source.

Current Practice Update

Domain	Pathy's	Current evidence
Coverage	Not mentioned at all	Full Mayo Clinic diagnostic/management framework

Mortality mechanism	Not addressed	Capillary leak phenotype now recognised (2024)
Transplant-ineligible therapy	Not addressed	Daratumumab-based triplets — relevant to older patients

— End of Compendium —

Compiled for night-before revision. Reference lists omitted per request; consult original chat threads for full citations.

MD Geriatric Medicine

High-Yield Answer Set — Haematology & Oncology in the Older Adult

CONTENTS

1. **Myelodysplastic Syndrome** — WHO classification, diagnostic criteria and differential diagnosis
2. **Bone Marrow Transplantation** — types, indications, procedure, complications and the older recipient
3. **POEMS Syndrome** — clinical features, laboratory investigations and treatment
4. **Hormone Therapy in Malignancy** — principles, agents, indications and adverse effects

HOW EACH ANSWER IS BUILT

- **15–20 high-yield points** in simple sentences, arranged in logical exam sequence, with keywords in bold
- **Latest Updates (2023–present)** — recent trials and guideline changes, named inline
- **Current Practice Update** — textbook position contrasted with current evidence
- **Exam one-liners** — condensed rapid-recall summary
- All laboratory values in **Indian conventional units** (calcium mg/dL, sodium mEq/L, creatinine mg/dL, haemoglobin g/dL)

Primary source: *Pathy's Principles and Practice of Geriatric Medicine*, 6th edition, supported by *Kane's Essentials of Clinical Geriatrics* and current international guidelines (WHO 2022, ICC 2022, NCCN, EBMT, ASH, SIOG). Prepared for postgraduate examination revision.

1. Myelodysplastic Syndrome

> *Describe the WHO classification and diagnostic criteria of myelodysplastic syndrome. Discuss its differential diagnosis. (15 marks)*

Definition, Epidemiology and Pathophysiology

1. **Definition.** Myelodysplastic syndromes are **clonal disorders of the haematopoietic stem cell**. The marrow is **cellular but ineffective** — it produces cells that die before they leave the marrow. The result is a paradox that defines the disease: **a hypercellular marrow with a peripheral blood cytopenia**. There is a variable risk of progression to acute myeloid leukaemia.
2. **A disease of old age.** The **median age at diagnosis is around 70–75 years**, and incidence rises steeply after 60. It is **the commonest acquired cause of marrow failure in the elderly**. Because it presents as tiredness and a low haemoglobin, it is very frequently mislabelled as "anaemia of ageing" or "anaemia of chronic disease".
3. **Two mechanisms drive the disease.** First, **somatic mutations** in a haematopoietic stem cell give it a growth advantage. Second, an **abnormal marrow microenvironment with excessive apoptosis** destroys the maturing progeny. Mutations cluster in four functional groups — **RNA splicing (SF3B1, SRSF2, U2AF1, ZRSR2)**, **DNA methylation (TET2, DNMT3A, IDH1/2)**, **chromatin/transcription (ASXL1, EZH2, RUNX1)**, and **DNA damage response (TP53)**.
4. **Primary versus secondary.** Most cases are **primary (de novo)**. **Secondary or therapy-related MDS** follows exposure to **alkylating agents, topoisomerase II inhibitors, radiotherapy, benzene or tobacco**, typically 5–7 years after treatment, and carries a much worse prognosis with a higher rate of complex karyotype and TP53 mutation.
5. **Clinical presentation is non-specific and easily missed.** Around **80–90% have anaemia** — fatigue, breathlessness, angina, falls, worsening heart failure or confusion. **Neutropenia** causes recurrent infection and **thrombocytopenia** causes bruising and mucosal bleeding. About **20% have splenomegaly**. In an older patient the presentation is often simply **functional decline with an unexplained macrocytic anaemia that does not respond to haematinics**.

Diagnostic Criteria

6. **The three requirements.** A diagnosis of MDS needs all three: **(a) a persistent cytopenia** in one or more lineages; **(b) morphological dysplasia in ≥10% of cells of at least one lineage, or an increase in blasts, or an MDS-defining genetic lesion**; and **(c) exclusion of every other cause** of cytopenia and dysplasia.
7. **Cytopenia thresholds (in Indian conventional units). Haemoglobin <13 g/dL in men and <12 g/dL in women; absolute neutrophil count <1,800/µL; platelet count <1,50,000/µL.** The cytopenia must be **persistent for at least 4–6 months** unless a defining cytogenetic abnormality or excess blasts are present.
8. **Essential investigations. Complete blood count with reticulocyte count and a peripheral smear**; **bone marrow aspirate with iron stain (Perls) plus trephine biopsy**; **conventional karyotyping** (abnormal in about 50%); **FISH** if metaphases fail; **flow cytometry**; and now **next-generation sequencing of a myeloid gene panel**. Always send **serum vitamin B12, folate, ferritin, thyroid function, copper, HIV, hepatitis serology and serum erythropoietin** before labelling a patient as having MDS.
9. **Morphological features to name in the exam. Dyserythropoiesis** — megaloblastoid change, nuclear budding and bridging, ring sideroblasts. **Dysgranulopoiesis** — **pseudo-Pelger–Huët cells (bilobed "pince-nez" nuclei)**, hypogranular neutrophils. **Dysmegakaryopoiesis** — **micromegakaryocytes and non-lobated or multiple separated nuclei**. The presence of **Auer rods** automatically places the case in a higher-risk category.
10. **Blast percentage is the single most important morphological number.** Blasts must be counted on a **500-cell marrow differential and a 200-cell blood differential**. **Under 5% marrow blasts = low blasts; 5–19% = increased blasts; 20% or more = acute myeloid leukaemia.**

WHO 2022 Classification (5th edition) — Myelodysplastic Neoplasms

The 5th edition renamed the group **"myelodysplastic neoplasms"**, retaining the abbreviation MDS, and split it into **genetically defined** and **morphologically defined** categories — a fundamental shift from counting cells to identifying the driver lesion.

Category	Defining criteria	Key exam point
A. MDS WITH DEFINING GENETIC ABNORMALITIES		
MDS with low blasts and isolated del(5q) — MDS-5q	Blood blasts <2%, marrow blasts <5%; isolated del(5q), or with one other abnormality except −7/del(7q)	**The "5q− syndrome"** — elderly woman, macrocytic anaemia, **normal or high platelets**, hypolobated micromegakaryocytes. **Best prognosis; responds to lenalidomide**
MDS with low blasts and SF3B1 mutation — MDS-SF3B1	Blood blasts <2%, marrow blasts <5%; **SF3B1 mutation**. **≥15% ring sideroblasts may substitute** where mutation testing is unavailable	**Replaces the old "MDS with ring sideroblasts".** Favourable prognosis. Practically important in India, where the morphological surrogate is still permitted
MDS with biallelic TP53 inactivation — MDS-biTP53	Marrow blasts <20%; **two or more TP53 mutations, or one mutation with loss of the other allele** (17p deletion or copy-neutral LOH)	**New category and the worst prognosis of all** — median survival about **10 months**, usually with complex karyotype. **Overrides every other**

		subtype
B. MDS DEFINED MORPHOLOGICALLY		
MDS with low blasts — MDS-LB	Blood blasts <2%, marrow blasts <5%	Replaces the old single- and multi-lineage dysplasia categories
MDS, hypoplastic — MDS-h	Marrow cellularity ≤25% (age-adjusted)	**New entity.** Must be separated from **aplastic anaemia**; often responds to **immunosuppressive therapy**
MDS with increased blasts 1 — MDS-IB1	Blood blasts 2–4% **or** marrow blasts 5–9%	Higher-risk disease; consider hypomethylating agents
MDS with increased blasts 2 — MDS-IB2	Blood blasts 5–19% **or** marrow blasts 10–19% **or Auer rods present**	**Auer rods alone make it IB2 regardless of blast count**
MDS with fibrosis — MDS-f	Blood blasts 2–19% or marrow blasts 5–19% **with grade 2–3 reticulin fibrosis**	**New entity.** Poor prognosis — median survival about 15 months. Aspirate is often a "dry tap", so **trephine is essential**

The parallel ICC 2022 classification — know the three differences

- The **International Consensus Classification** was published in the same year and is used alongside WHO. It requires **SF3B1 with a variant allele frequency ≥10%, and excludes del(5q), monosomy 7, complex karyotype and RUNX1 mutation**, whereas WHO permits ring sideroblasts as a surrogate.
- ICC created a new transitional category, **"MDS/AML" for 10–19% marrow blasts**, replacing "excess blasts-2" and signalling proximity to acute leukaemia. WHO keeps these cases as **MDS-IB2**.
- ICC groups TP53 cases as **"myeloid neoplasms with mutated TP53"** spanning MDS and MDS/AML, while WHO confines **MDS-biTP53** to under 20% blasts.

Prognostic Assessment

1. **IPSS-R (Revised International Prognostic Scoring System).** Scores **cytogenetic risk group, marrow blast percentage, haemoglobin, platelet count and absolute neutrophil count** into five categories — **very low, low, intermediate, high and very high**. The practical division is **"lower-risk" (very low, low, and part of intermediate) versus "higher-risk"**, because this decides whether treatment aims at **improving blood counts** or at **altering the natural history**.
2. **IPSS-M (Molecular IPSS, 2022).** Adds **31 gene mutations** to the IPSS-R variables and produces **six risk strata**. It **restratifies about 46% of patients** compared with IPSS-R, moving roughly a quarter upward and a fifth downward. **SF3B1 is favourable; TP53 multi-hit, RUNX1, EZH2, ASXL1, U2AF1 and NRAS are adverse.**
3. **Geriatric assessment adds independent prognostic value. Age, ECOG performance status, comorbidity (CIRS-G or Charlson), ADL/IADL dependence, frailty and transfusion burden** all predict survival independently of IPSS-R. **A frail patient with lower-risk MDS may fare worse than a fit patient with higher-risk disease.**

Differential Diagnosis — the core of this question

> **Principle:** MDS is a **diagnosis of exclusion**. Dysplasia is a morphological appearance, not a disease — many reversible conditions produce identical marrow changes. **Every reversible cause must be excluded before a lifelong clonal diagnosis is made in an older person.**

Group	Conditions	How to distinguish
Nutritional deficiency	**Vitamin B12 deficiency, folate deficiency, copper deficiency** (including after zinc excess or bariatric surgery)	Megaloblastic change with **hypersegmented neutrophils**; low B12/folate/copper; **corrects fully with replacement**. **Copper deficiency is the classic mimic — it produces ring sideroblasts and vacuolated precursors**
Toxins and drugs	**Alcohol**, isoniazid, chloramphenicol, linezolid, methotrexate, azathioprine, mycophenolate, valproate, lead, arsenic	Careful drug and alcohol history; changes reverse on withdrawal. **Alcohol and lead both cause ring sideroblasts**
Infection	**HIV, hepatitis B and C, parvovirus B19, tuberculosis, visceral leishmaniasis (kala-azar)**	Serology and marrow examination. **In India, kala-azar and disseminated tuberculosis are important causes of pancytopenia with marrow dysplasia**
Other marrow failure	**Aplastic anaemia**, **paroxysmal nocturnal haemoglobinuria**, pure red cell aplasia	**Hypoplastic MDS versus aplastic anaemia is the hardest distinction** — look for dysplasia, blasts and a clonal cytogenetic lesion. **Send flow cytometry for PNH clone in every case**
Other clonal myeloid disease	**Acute myeloid leukaemia** (≥20% blasts), **chronic myelomonocytic leukaemia**, MDS/MPN overlap, **primary myelofibrosis**, atypical CML	**CMML requires persistent monocytosis >1,000/μL and ≥10% monocytes.** Myelofibrosis shows leucoerythroblastic blood with teardrop cells and marked splenomegaly
Pre-clonal states	**ICUS** (idiopathic cytopenia of undetermined	**CHIP = mutation without cytopenia; ICUS =**

	significance), **CHIP** (clonal haematopoiesis of indeterminate potential), **CCUS** (clonal cytopenia of undetermined significance)	**cytopenia without mutation or dysplasia; CCUS = both mutation and cytopenia, but no diagnostic dysplasia.** These require surveillance, not treatment
Systemic and autoimmune disease	Chronic kidney disease, hypothyroidism, chronic liver disease, SLE, rheumatoid arthritis, Felty syndrome, **large granular lymphocytic leukaemia**	Renal and thyroid profile, autoantibodies, T-cell clonality studies
Marrow infiltration	Metastatic carcinoma, **lymphoma**, **multiple myeloma**	**Trephine biopsy is far more sensitive than aspirate**. Send serum protein electrophoresis and free light chains in every older patient

Outline of Management

14. **Treatment is decided by risk group, not by age.** In **lower-risk disease** the aim is to **improve quality of life and reduce transfusion dependence**; in **higher-risk disease** the aim is to **delay leukaemic transformation and prolong survival**.
15. **Lower-risk disease.** Observation if asymptomatic. For anaemia with **serum erythropoietin below 500 mU/mL**, use an **erythropoiesis-stimulating agent** with or without G-CSF. **Lenalidomide for del(5q)**. **Luspatercept** for ring-sideroblast-positive or SF3B1-mutated disease. **Immunosuppressive therapy (ATG plus ciclosporin)** for hypoplastic MDS in younger patients with HLA-DR15. Transfusion support as required.
16. **Iron overload matters in the transfusion-dependent patient.** Each unit of packed cells contains about 200–250 mg of iron. Consider **iron chelation with deferasirox** once the patient has received **more than 20–25 units** or the **serum ferritin exceeds 1,000 ng/mL**, provided life expectancy and risk category justify it.
17. **Higher-risk disease. Hypomethylating agents are the standard of care — azacitidine 75 mg/m² for 7 days every 28 days**, or decitabine. Response takes **4–6 cycles**, so treatment must not be abandoned early. **Allogeneic stem cell transplantation is the only curative option** and, with reduced-intensity conditioning, is now offered to selected fit patients into their **early seventies**.
18. **Supportive care underpins everything. Transfusion targets should be symptom-based rather than number-based**; platelet transfusion for counts below 10,000/µL or for bleeding; prompt antibiotics for febrile neutropenia; **avoid aspirin and NSAIDs**; vaccination; and attention to **falls risk from anaemia and to bleeding risk from concurrent anticoagulation**.
19. **Prognosis.** Median survival ranges from **almost 9 years in very-low-risk disease to under 10 months in very-high-risk disease**. Roughly **30% transform to acute myeloid leukaemia**; the remainder die of the consequences of marrow failure — **infection and bleeding** — or of unrelated comorbidity.
20. **The geriatric bottom line.** MDS in an older person is frequently **underdiagnosed** (dismissed as ageing) and then **undertreated** (dismissed as too old). Both errors are avoidable: the diagnosis needs a marrow, and the treatment decision needs a comorbidity and function assessment, not a birth certificate.

Latest Updates (2023–present)

Classification has shifted from morphology to genetics

- The **WHO 5th edition (2022)** and the **ICC (2022)** both now place **genetically defined categories first**. Validation in the **Düsseldorf MDS Registry** (5,010 patients, median age 71) confirmed that **TP53 mutational status and multilineage dysplasia are independently associated with poor outcome**, and that **MDS-biTP53 and MDS-f carry the highest risk of leukaemic transformation and the poorest survival**.
- Reclassification studies show the **2022 WHO criteria stratify patients more effectively than the 2017 criteria** (C-index 0.705 versus 0.681). Median survival for **MDS-biTP53 was 10 months and for MDS-f 15 months**, against 45 months for MDS overall.
- A practical caveat now recognised: **TP53 mutational burden matters**. Cases with a **variant allele frequency below 10%** behave better — lower IPSS-R scores, more favourable cytogenetics, more SF3B1 mutations and longer survival — supporting the ICC's 10% cut-off.

IPSS-M has become the reference prognostic tool

- Comparative work confirms that **IPSS-M risk is highest in biallelic/multi-hit TP53 disease and lowest in MDS-SF3B1**, with **median leukaemia-free survival of only 0.7 years in multi-hit TP53** and not reached in MDS with low blasts. Roughly **70% of patients are still classified morphologically and 30% genetically** under both systems.
- Importantly for practice, **response to hypomethylating agents was not associated with IPSS-M risk category** — so a high IPSS-M score predicts poor survival but does not predict failure of azacitidine.

Two new drugs for anaemia in lower-risk disease

- **COMMANDS** established **luspatercept as superior to epoetin alfa** in ESA-naïve, transfusion-dependent lower-risk MDS, moving it into the **first line** rather than after ESA failure.
- **IMerge**, the first phase 3 trial of a **telomerase inhibitor**, tested **imetelstat 7.5 mg/kg intravenously every 4 weeks** in transfusion-dependent non-del(5q) lower-risk MDS relapsed after or refractory to ESAs (median age 72–73 years). **40% achieved 8-week red cell transfusion independence**, with longer duration of independence and a

greater rise in haemoglobin than luspatercept achieved in MEDALIST — and notably this included **ring-sideroblast-negative patients**. **FDA approval followed in June 2024.**

- **NCCN now recommends imetelstat** as **category 1 second-line therapy after ESAs or luspatercept where serum erythropoietin is ≤500 mU/mL**, and as **category 2A first-line therapy where erythropoietin exceeds 500 mU/mL**. Sequencing after front-line luspatercept remains poorly defined — in IMerge, of the few patients previously given luspatercept, **86% had a reduction in transfusion burden but none achieved transfusion independence**.

Transplantation has extended into the eighth decade

- Reduced-intensity conditioning with modern graft-versus-host disease prophylaxis has made allogeneic transplantation feasible for fit patients with higher-risk MDS **into their early seventies** — see Topic 2.

Current Practice Update

Area	Textbook position	Current practice (2023–2026)
Nomenclature	Myelodysplastic syndromes	**Myelodysplastic neoplasms** (WHO 2022), abbreviation MDS retained
Classification basis	Morphology — lineage dysplasia, ring sideroblasts, blast count	**Genetics first** — del(5q), SF3B1, biallelic TP53; then morphology
Ring sideroblasts	"MDS with ring sideroblasts" is a defined entity	Replaced by **MDS-SF3B1**; **≥15% ring sideroblasts is now only a surrogate** for the mutation
New entities	Not described	**MDS-biTP53, MDS-h (hypoplastic), MDS-f (with fibrosis)**
Blasts 10–19%	MDS with excess blasts-2	**WHO: MDS-IB2. ICC: a new "MDS/AML" category**
Prognostic score	IPSS-R	**IPSS-M** — adds 31 mutations, six strata, restratifies about 46% of patients
Lower-risk anaemia	ESAs; lenalidomide for del(5q); transfusion	Add **luspatercept first-line (COMMANDS)** and **imetelstat (IMerge, approved 2024)**
Transplantation	Allogeneic transplant mentioned for higher-risk disease	**Reduced-intensity transplant now offered to fit patients into their early seventies**
Pre-clonal states	CHIP and CCUS noted	**Formally defined and separated from MDS**; surveillance, not treatment

Exam one-liners

- **MDS = hypercellular marrow with peripheral cytopenia** — ineffective haematopoiesis, not underproduction.
- **Three things must be present:** persistent cytopenia + dysplasia (or excess blasts, or a defining mutation) + exclusion of everything else.
- **Blast thresholds:** <5% low, 5–19% increased, ≥20% acute myeloid leukaemia. **Auer rods = IB2 regardless of count.**
- **Three genetic categories:** del(5q) — best; SF3B1 — favourable; **biallelic TP53 — worst (about 10 months)**.
- **Three new morphological entities:** hypoplastic (MDS-h), with fibrosis (MDS-f), and the renamed low-blast group.
- **Before diagnosing MDS, always exclude B12, folate, copper, alcohol, drugs, HIV, kala-azar and PNH.**
- **Copper deficiency is the great mimic** — it reproduces ring sideroblasts and vacuolated precursors, and it is completely reversible.
- **IPSS-R for counts and karyotype; IPSS-M when a mutation panel is available.**
- **Lower-risk = treat the anaemia. Higher-risk = treat the disease.**
- **Azacitidine needs 4–6 cycles** before response — never stop early.

2. Bone Marrow Transplantation

> *Discuss the types, indications, procedure and complications of bone marrow transplantation, with emphasis on the older patient. (15 marks)*

Definition and Types

1. **Definition.** Bone marrow transplantation — more accurately **haematopoietic stem cell transplantation (HSCT)** — is the **intravenous infusion of haematopoietic stem cells to re-establish marrow function** in a patient whose marrow has been damaged, is defective, or has been deliberately destroyed by high-dose therapy.
2. **Autologous transplantation.** The patient's **own** stem cells are collected, stored, and returned after high-dose chemotherapy. Here the transplant is simply a **rescue procedure** that permits a chemotherapy dose which would otherwise be lethal to the marrow. **There is no graft-versus-host disease and no graft-versus-tumour effect**, and **no donor is required**.
3. **Allogeneic transplantation.** Stem cells come from **another person** — an HLA-matched sibling, a matched or mismatched unrelated donor, a **haploidentical (half-matched) family member**, or umbilical cord blood. The therapeutic benefit comes from two sources: the **conditioning chemotherapy** and, crucially, the **graft-versus-tumour effect** of donor immune cells. The price of that effect is **graft-versus-host disease** and the need for prolonged immunosuppression.
4. **Sources of stem cells. Peripheral blood stem cells** mobilised with G-CSF (with or without plerixafor) are now used in over 90% of adult transplants — collection is by apheresis, engraftment is faster, but chronic GVHD is commoner. **Bone marrow** harvested from the posterior iliac crest under anaesthesia gives slower engraftment but less chronic GVHD. **Umbilical cord blood** permits greater HLA mismatch but has a limited cell dose and slow engraftment.
5. **Conditioning regimens — the key concept in geriatrics.**
   - **Myeloablative conditioning** (for example busulfan–cyclophosphamide, or cyclophosphamide with total body irradiation) destroys the marrow irreversibly. It is **too toxic for most patients over 55–60**.
   - **Reduced-intensity conditioning (RIC)** — typically **fludarabine with melphalan or busulfan** — relies mainly on the **graft-versus-tumour effect** rather than on the chemotherapy. **This is the single development that made transplantation possible in older adults.**
   - **Non-myeloablative regimens** (fludarabine with low-dose total body irradiation) are gentler still and can be given largely as an outpatient.

Indications

Autologous	Allogeneic	Comment for the older patient
Multiple myeloma (commonest indication worldwide); **relapsed/refractory diffuse large B-cell lymphoma**; relapsed Hodgkin lymphoma; germ-cell tumours; **POEMS syndrome**; some autoimmune disease	**Acute myeloid leukaemia** (intermediate/adverse risk); **higher-risk myelodysplastic syndrome**; acute lymphoblastic leukaemia; **myelofibrosis**; CML failing multiple TKIs; **aplastic anaemia**; thalassaemia and sickle cell disease; primary immunodeficiency	**Autologous transplant is far better tolerated** and, with melphalan dose reduced to 140 mg/m², is routinely performed up to about **age 75**. **Allogeneic transplant is the only curative option in higher-risk MDS and AML** and is now offered selectively into the early seventies

The Procedure — Six Steps

6. **Step 1 — Patient evaluation.** Confirm the disease and its risk category; assess **cardiac function (echocardiogram), pulmonary function with DLCO, renal and hepatic function**; screen for **HIV, hepatitis B and C, CMV, EBV and tuberculosis**; dental review; and calculate the **HCT-CI (Haematopoietic Cell Transplantation Comorbidity Index)**. Perform a **full geriatric assessment** in anyone over 60.
7. **Step 2 — Donor selection. High-resolution HLA typing at A, B, C, DRB1 and DQB1**. Preference order: matched sibling → 10/10 matched unrelated donor → mismatched unrelated donor or **haploidentical relative** → cord blood. Match **CMV serostatus** where possible. **The availability of haploidentical donors has effectively abolished the "no donor" barrier** — highly relevant in India, where unrelated donor registries are small and most patients have an available parent, sibling or child.
8. **Step 3 — Stem cell collection.** Mobilisation with **G-CSF 10 µg/kg daily for 4–5 days**, then apheresis targeting **a CD34+ cell dose of at least 2 × 10^6/kg** (ideally 4–5 × 10^6/kg) of recipient body weight.
9. **Step 4 — Conditioning.** Given over roughly **days −7 to −1**. Choice of intensity is the single most important determinant of non-relapse mortality in an older patient.
10. **Step 5 — Infusion (day 0)** and the **aplastic phase**. Cells are infused through a central line. Expect **neutrophil engraftment (ANC >500/µL) at about day +12 to +21** and **platelet engraftment at about day +20 to +30**. During this period the patient is profoundly pancytopenic and needs protective isolation, irradiated leucodepleted blood products, and antimicrobial prophylaxis.
11. **Step 6 — GVHD prophylaxis and long-term follow-up.** Traditional prophylaxis is **calcineurin inhibitor (tacrolimus or ciclosporin) plus methotrexate**. The modern standard is **post-transplant cyclophosphamide with tacrolimus and mycophenolate mofetil**. Long-term care covers immune reconstitution, revaccination from 6–12 months, endocrine

and bone surveillance, and screening for **second malignancies**.

Complications

Timing	Complication	Notes
Early (0–30 days)	**Mucositis**, nausea and vomiting, **febrile neutropenia**, bacterial and fungal sepsis, **haemorrhagic cystitis** (cyclophosphamide, BK virus), **sinusoidal obstruction syndrome** (formerly veno-occlusive disease), **engraftment syndrome**, **graft failure**	**Mucositis is the commonest and most distressing complication**, and in older patients precipitates dehydration, delirium and malnutrition. **Sinusoidal obstruction syndrome** — weight gain, tender hepatomegaly, jaundice — is treated with **defibrotide**
Intermediate (30–100 days)	**Acute GVHD**; **CMV reactivation**; **Pneumocystis jirovecii**; invasive aspergillosis; idiopathic pneumonia syndrome	**Acute GVHD affects skin, gut and liver** — maculopapular rash, secretory diarrhoea, cholestatic jaundice; graded I–IV; first-line treatment is **methylprednisolone 2 mg/kg/day**. **Ruxolitinib is the standard for steroid-refractory disease**
Late (>100 days)	**Chronic GVHD**; late infection with encapsulated organisms; **bronchiolitis obliterans**; **cataract, hypothyroidism, hypogonadism, infertility**; **osteoporosis and avascular necrosis**; iron overload; **secondary malignancy**; relapse of the original disease	**Chronic GVHD is the leading cause of late non-relapse mortality** and resembles an autoimmune disease — sicca syndrome, scleroderma-like skin change, lichenoid oral lesions, and lung involvement. It is a major cause of poor quality of life

The Older Transplant Recipient

12. **Why age was historically a barrier.** Reduced marrow and organ reserve, more comorbidity, higher infection risk, slower immune reconstitution and greater treatment-related mortality. Traditional upper limits of **55 years for allogeneic and 65 for autologous transplant** excluded the very patients in whom AML and MDS are commonest.
13. **What changed. Reduced-intensity conditioning**, **better supportive care and antimicrobial prophylaxis**, **haploidentical donors**, and **modern GVHD prophylaxis** have together shifted the question from "how old is the patient?" to **"what is the patient's comorbidity and functional reserve?"**
14. **Selecting the older candidate — four tools.**
    - **HCT-CI (Sorror index)** — the transplant-specific comorbidity score; higher scores predict non-relapse mortality.
    - **Comprehensive geriatric assessment** — **ADL/IADL, gait speed, cognition (Mini-Cog), nutrition (MNA), polypharmacy, social support and depression** all independently predict outcome.
    - **Performance status** — Karnofsky **≥70%** is the usual threshold.
    - **Disease risk index** — the likelihood of relapse must justify the risk of the procedure.
15. **Two practical points that dominate the geriatric transplant ward.** First, **caregiver availability is a hard requirement** — the patient needs a competent 24-hour caregiver for at least 100 days, and lack of one is a common reason older patients are declined. Second, **delirium is markedly commoner in older transplant recipients** and independently predicts mortality; it should be actively prevented and screened for.
16. **Prognosis.** Historical **one-year non-relapse mortality in patients aged 70 and above was around 25%**. With current conditioning and prophylaxis this has fallen substantially, and **outcomes in fit older patients now approach those of patients in their sixties**. The dominant predictors are **comorbidity, performance status and disease risk — not chronological age**.

Latest Updates (2023–present)

BMT CTN 1703 has changed GVHD prophylaxis

- This phase 3 trial randomised **431 adults** undergoing allogeneic transplantation with a matched related or matched/7-of-8 mismatched unrelated donor after **reduced-intensity conditioning** to either **post-transplant cyclophosphamide with tacrolimus and mycophenolate mofetil** or **tacrolimus with methotrexate**. The primary endpoint was **GVHD-free, relapse-free survival at one year**, with events defined as grade III–IV acute GVHD, chronic GVHD requiring systemic treatment, relapse or death.
- **Post-transplant cyclophosphamide was significantly superior**, and this regimen is now the standard prophylaxis after reduced-intensity conditioning.
- **The subgroup analysis in patients aged 70 and above is the geriatric headline.** Of the 431 patients enrolled, **96 were aged 70 or over**. Despite the concern that older adults would experience more treatment-related toxicity and GVHD, **post-transplant cyclophosphamide produced markedly better results in this group as well**, published in *Blood Advances* in 2025.
- The authors note that allogeneic transplantation **remains underutilised in adults aged 70 and above**, and that **morbidity driven by GVHD is considered the major barrier to its use** — a barrier this trial directly addresses.

Age itself is not the driver of GVHD

- A **2025 systematic review and meta-analysis of outcomes in patients aged 70 and above** reported that **graft source and prophylaxis regimen, rather than advancing age, determine GVHD incidence**. Peripheral blood stem cell grafts and tacrolimus-based prophylaxis increased GVHD, with **similar incidence across the 60–64, 65–69 and 70-and-above age groups**.

- The same review identifies **post-transplant cyclophosphamide as the principal strategy for reducing non-relapse mortality in older patients**.

Real-world feasibility in the elderly

- A ten-year single-centre series of **allogeneic transplantation for AML at a median age of 68** found it feasible and safe: **65% received grafts from a 10/10 or 9/10 matched unrelated donor, 14% from a matched sibling and 20% from a haploidentical donor**; **all received reduced-intensity conditioning** and **98% received peripheral blood stem cells**. **Acute GVHD occurred in 44%** (grade III–IV in 5 patients) and **CMV reactivation in 39% by day +100**.
- Registry work continues to show that older transplant candidates are a **frailer population overall**, reinforcing the case for formal geriatric assessment rather than age cut-offs.

Other developments worth naming

- **Ruxolitinib** is now standard for steroid-refractory acute and chronic GVHD, with **belumosudil** and **axatilimab** as further options in chronic disease.
- **Letermovir** prophylaxis has substantially reduced clinically significant CMV reactivation.
- A dedicated trial (NCT06799195) is now enrolling **adults aged 60 and older with Karnofsky performance status ≥70% receiving reduced-intensity conditioning** to optimise GVHD prophylaxis specifically in this population — the first study designed around the older recipient rather than including them incidentally.

Current Practice Update

Area	Traditional position	Current practice (2023–2026)
Upper age limit	Allogeneic 55 years; autologous 65 years	**No fixed limit** — allogeneic transplant into the **early seventies**, autologous to about **75**, decided by comorbidity and function
Conditioning	Myeloablative	**Reduced-intensity conditioning is standard in older adults**
GVHD prophylaxis	Calcineurin inhibitor + methotrexate	**Post-transplant cyclophosphamide + tacrolimus + MMF (BMT CTN 1703)**, including in patients ≥70
Donor availability	Matched sibling or unrelated donor only	**Haploidentical transplantation has removed the donor barrier**
Patient selection	Chronological age and performance status	**HCT-CI plus comprehensive geriatric assessment**
Steroid-refractory GVHD	Second-line immunosuppression, poor outcome	**Ruxolitinib**; belumosudil and axatilimab in chronic GVHD
CMV	Pre-emptive monitoring and treatment	**Letermovir prophylaxis**
Stem cell source	Bone marrow harvest	**Peripheral blood stem cells in over 90%** of adult transplants

Exam one-liners

- **Autologous = rescue** from high-dose chemotherapy. **Allogeneic = replacement plus a graft-versus-tumour effect.**
- **Myeloma is the commonest indication for autologous, AML and higher-risk MDS for allogeneic transplant.**
- **Reduced-intensity conditioning is what made transplantation possible in the elderly** — it borrows its efficacy from the donor immune system, not from the chemotherapy.
- **Aim for a CD34+ dose of at least 2 × 10^6/kg.** Neutrophils engraft around day +14, platelets around day +21.
- **Acute GVHD = skin, gut, liver, within 100 days. Chronic GVHD = an autoimmune-like multisystem illness** and the leading cause of late non-relapse mortality.
- **Post-transplant cyclophosphamide is now standard prophylaxis — and BMT CTN 1703 showed it works in patients aged 70 and above too.**
- **Age is not the risk factor; comorbidity is.** Use the **HCT-CI plus a geriatric assessment**, not the birth certificate.
- **No caregiver, no transplant** — 24-hour support for 100 days is a hard requirement.
- **Haploidentical donors mean almost every Indian patient now has a donor.**

3. POEMS Syndrome

> *Describe the clinical features, laboratory investigations and treatment of POEMS syndrome. (15 marks)*

Definition and Pathogenesis

1. **Definition.** POEMS syndrome is a **rare multisystem paraneoplastic disorder caused by an underlying clonal plasma cell disorder**. The acronym stands for **Polyneuropathy, Organomegaly, Endocrinopathy, Monoclonal gammopathy and Skin changes**. It is also called **osteosclerotic myeloma**, **Crow–Fukase syndrome** or **Takatsuki syndrome**.
2. **The acronym is incomplete and misleading.** It omits several of the most useful diagnostic features, which are captured by the second acronym **PEST — Papilloedema, Extravascular volume overload, Sclerotic bone lesions, and Thrombocytosis/erythrocytosis**. Candidates who quote only POEMS lose the features that actually make the diagnosis.
3. **Central pathogenic mechanism.** A **small, almost always lambda-restricted clonal plasma cell population** drives **markedly elevated vascular endothelial growth factor (VEGF)**. VEGF increases **vascular permeability and angiogenesis**, and explains most of the clinical picture — **oedema, effusions, organomegaly, papilloedema, skin haemangiomata and neuropathy**. Other cytokines (IL-1, IL-6, TNF-alpha) contribute.
4. **Why it matters in geriatric practice. Median age at presentation is around 50, but a substantial minority present in the sixties and seventies.** The diagnosis must be considered in what would otherwise be called a **monoclonal gammopathy of undetermined significance** when **unusual features appear — peripheral neuropathy, thrombocytosis and extracellular volume overload**. In an older patient the neuropathy is routinely blamed on **diabetes, alcohol, B12 deficiency or ageing**, and the oedema on **heart failure** — which is why diagnosis is so often delayed by years.

Clinical Features

5. **P — Polyneuropathy (present in essentially 100%; it is the dominant symptom).** A **chronic, symmetrical, ascending, distal, sensorimotor polyneuropathy**. It begins with **tingling, numbness and coldness of the feet**, then progresses to **severe motor weakness** that may confine the patient to a wheelchair. It is **predominantly demyelinating with axonal loss**, and is **painful in only a minority** — a useful clue, since it is otherwise easily mistaken for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP).
6. **O — Organomegaly. Hepatomegaly, splenomegaly and lymphadenopathy.** Enlarged nodes may show **Castleman disease** on biopsy — a recognised and important association.
7. **E — Endocrinopathy.** Present in about **two-thirds**. The commonest are **hypogonadism** (erectile dysfunction, gynaecomastia, amenorrhoea), then **hypothyroidism**, **diabetes mellitus**, and **adrenal insufficiency**. Hypogonadism is the most frequent single endocrine abnormality. **Diabetes and hypothyroidism alone are too common in the elderly to count towards diagnosis.**
8. **M — Monoclonal plasma cell disorder.** Almost invariably **IgG or IgA with a lambda light chain**. The **M-protein is characteristically small** and may be missed on routine electrophoresis — **immunofixation of serum and urine is mandatory**.
9. **S — Skin changes. Hyperpigmentation** (commonest), **haemangiomata and glomeruloid angiomata** (highly characteristic), **hypertrichosis**, **acrocyanosis and plethora**, **white nails**, sclerodermatous thickening and **clubbing**.
10. **P — Papilloedema.** Present in about **one-third**. It is often **asymptomatic**, so **fundoscopy must be performed in every suspected case**; its presence strongly supports the diagnosis.
11. **E — Extravascular volume overload. Peripheral oedema, ascites, and pleural or pericardial effusions.** In an older patient this is almost always first attributed to **heart failure, nephrotic syndrome or liver disease**, and the true diagnosis emerges only when these are excluded.
12. **S — Sclerotic bone lesions.** Present in about **95%** and **virtually diagnostic in this clinical context**. They may be purely sclerotic, or sclerotic-rimmed lucencies with a **"soap-bubble" appearance**. **They are frequently missed because a bone scan is normal and a skeletal survey is often reported as unremarkable** — dedicated CT or PET-CT is needed.
13. **T — Thrombocytosis and erythrocytosis. Thrombocytosis occurs in about half**. This is a critical negative discriminator: **anaemia and thrombocytopenia point to multiple myeloma or amyloidosis, not POEMS**.
14. **Other features and the major hazard. Pulmonary hypertension, restrictive lung disease, reduced DLCO, weight loss, fatigue, clubbing and a hypercoagulable state. Arterial and venous thrombotic events — stroke, myocardial infarction, peripheral arterial occlusion — occur in roughly 10–20% and are a leading cause of death**, an especially important consideration in older patients who already have vascular risk factors.

Diagnostic Criteria (Dispenzieri)

Diagnosis requires **both mandatory major criteria**, plus **one other major criterion**, plus **at least one minor criterion**.

Mandatory major criteria (both required)	Other major criteria (one required)	Minor criteria (one required)

1. Polyneuropathy — typically demyelinating **2. Monoclonal plasma cell proliferative disorder** — almost always lambda	**3. Castleman disease** **4. Sclerotic bone lesions** **5. Elevated VEGF**	**Organomegaly** (spleen, liver, lymph nodes) **Extravascular volume overload** (oedema, effusion, ascites) **Endocrinopathy** (adrenal, thyroid, pituitary, gonadal, parathyroid, pancreatic) — **excluding diabetes and hypothyroidism alone** **Skin changes** **Papilloedema** **Thrombocytosis or polycythaemia**

Laboratory Investigations

Category	Test	Expected finding / purpose
Plasma cell clone	Serum and **24-hour urine protein electrophoresis with immunofixation**; **serum free light chain assay**; **bone marrow aspirate and trephine with immunohistochemistry and flow cytometry**	**Small IgG or IgA lambda M-protein.** Marrow usually shows **<5–10% clonal plasma cells**. **The free light chain ratio is frequently normal and therefore uninformative** — a recognised pitfall
The key biomarker	**Serum or plasma VEGF**	**Markedly elevated — usually more than three to four times the upper limit of normal.** It is the **single most useful diagnostic test** and also the **best marker for monitoring response**. Serum values run higher than plasma values, so use the same medium throughout follow-up
Neurological	**Nerve conduction studies and EMG**; CSF examination; sural nerve biopsy if needed	**Demyelinating pattern with axonal loss**, more marked in the lower limbs, with **less temporal dispersion and less conduction block than CIDP**. CSF shows **albuminocytological dissociation** — raised protein with normal cell count
Skeletal imaging	**Whole-body low-dose CT or FDG PET-CT**. Plain skeletal survey only if CT is unavailable	**Sclerotic or mixed sclerotic-lucent lesions**, commonly in **spine, pelvis and ribs**. **A bone scan is typically normal and does not exclude the diagnosis**
Haematology	Complete blood count	**Thrombocytosis and/or erythrocytosis. Anaemia and thrombocytopenia argue against POEMS**
Endocrine	Thyroid function; **testosterone (ng/dL)**, LH, FSH, prolactin; fasting glucose and HbA1c; morning cortisol; **calcium (mg/dL)** and PTH	Screens all six axes named in the criteria
Organ assessment	**Echocardiography with pulmonary artery pressure**; pulmonary function with DLCO; abdominal ultrasound or CT; **fundoscopy**; renal function (creatinine mg/dL) and urinalysis	Detects **pulmonary hypertension, effusions, organomegaly and papilloedema**
To exclude alternatives	**Congo red staining of fat pad or marrow**; vitamin B12; HIV, hepatitis B and C; HHV-8; ANA and vasculitis screen	**Amyloidosis is the principal differential** and must be actively excluded
Lymph node	**Excision biopsy of any enlarged node**	To identify **Castleman disease**, which is a major criterion

Differential Diagnosis

- **CIDP** — the commonest misdiagnosis. CIDP has **no M-protein, no VEGF elevation, no bone lesions and no systemic features**, and it responds to steroids and IVIG, which POEMS does not.
- **AL amyloidosis** — also a lambda-restricted plasma cell disorder with neuropathy, but features **autonomic failure, macroglossia, nephrotic syndrome, restrictive cardiomyopathy and lytic-free bones**, with **normal VEGF** and **positive Congo red**.
- **Multiple myeloma** — **lytic** lesions, hypercalcaemia (calcium >10.6 mg/dL), **anaemia**, renal failure and a large M-spike; neuropathy is not a defining feature.
- **MGUS with incidental neuropathy**, **Waldenström macroglobulinaemia**, **diabetic and alcoholic neuropathy**, **vasculitic neuropathy**, **hypothyroid myopathy** and **TAFRO syndrome**.

Treatment

> **Governing principle:** Treat the **clonal plasma cell population**, not the VEGF. Experience consistently shows better outcomes from **plasma-cell-directed therapy** than from targeting VEGF directly with anti-VEGF antibodies. The therapeutic armamentarium is **borrowed from multiple myeloma and light chain amyloidosis**, since randomised trials in POEMS are essentially absent.

16. **Step 1 — Decide whether the disease is localised or disseminated.** This single decision determines the entire treatment plan and depends on **whether the marrow contains clonal plasma cells and how many bone lesions are present**.

17. **Localised disease** — **one to three sclerotic bone lesions with no clonal plasma cells in the marrow.** Treat with **radiotherapy, 40–50 Gy to the lesion**. **Response is slow, taking 3–6 months or longer**, but is achieved in the majority, and **roughly half are cured by radiotherapy alone**. Surgical excision is an alternative for a solitary accessible lesion.

18. **Disseminated disease — the transplant-eligible patient. High-dose melphalan with autologous stem cell transplantation is the treatment of choice** and remains the favoured therapy on the basis of case series, producing **durable remissions even without maintenance therapy**. Typical outcomes are a **complete haematological response in about 60% and a complete VEGF response in about 50%**, with **5-year progression-free survival around 75% and 5-year overall survival around 90%**. Induction with a few cycles before transplant is often given.

19. **Disseminated disease — the transplant-ineligible or older patient.** Options are **lenalidomide with dexamethasone**, **melphalan with dexamethasone**, or a **bortezomib-based regimen**. In a phase 2 trial of **12 cycles of lenalidomide and dexamethasone in 41 patients**, the **complete haematological response rate was 46%, the neurological response rate 95% and the VEGF response rate 83%**, with **estimated 3-year overall survival of 90% and progression-free survival of 75%**. **Lenalidomide and dexamethasone is therefore the practical first choice in an older, frail or transplant-ineligible patient**, with **thromboprophylaxis mandatory**.

20. **Supportive care is not optional — it determines function. Intensive physiotherapy and occupational therapy**, **ankle-foot orthoses and gait aids**, **falls prevention** (this neuropathy is a major falls risk in an older patient), **neuropathic pain management**, **diuretics for volume overload**, **hormone replacement for the identified endocrinopathy**, and **thromboprophylaxis** given the recognised hypercoagulable state. **Steroids and IVIG do not work in POEMS** — persisting with them wastes months.

21. **Monitoring and prognosis.** Follow **VEGF, the M-protein, neurological function (ONLS or similar score), and volume status**. **Neurological recovery lags months behind the haematological and VEGF response**, so patients must be counselled not to expect early improvement in walking. Prognosis has transformed: **median survival was under 3 years in early series and 10-year overall survival now exceeds 50–60%**, even before the availability of monoclonal antibodies, bispecific T-cell engagers and CAR-T. **Adverse prognostic factors are age over 50, pulmonary hypertension, effusions, low albumin and reduced eGFR.**

Latest Updates (2023–present)

- The **ASH Education Program review (December 2025)** reframes the diagnostic approach around a single practical message: POEMS **"must be considered in the context of what might otherwise be believed to be a monoclonal gammopathy of undetermined significance, with unusual features including, but not limited to, peripheral neuropathy, thrombocytosis and extracellular volume overload."** It reaffirms that **autologous stem cell transplantation is still a favoured therapy with durable remissions even without maintenance**, and reports that **10-year overall survival was already favourable even before the era of therapeutic monoclonal antibodies, bispecific T-cell engagers and CAR-T**.
- The same review makes a point of direct examination relevance: the **free light chain ratio is normal for most of the disease course and is therefore uninformative**, whereas **VEGF tracks disease activity closely** — high at diagnosis and before second-line therapy, and not necessarily elevated before every subsequent line. **Rising creatinine with unmanageable oedema marks the terminal phase.**
- A **2025 review** confirms the current framework: diagnosis rests on the **Dispenzieri major and minor criteria**, with **VEGF an important biomarker both for diagnosis and for monitoring treatment response**; **radiotherapy for localised bone lesions**; **systemic therapy for widespread disease** using **lenalidomide, thalidomide or bortezomib-based regimens**; and **autologous transplantation for long-term remission in suitable patients**.
- A large single-centre comparison of **347 newly diagnosed patients** treated with autologous transplantation, melphalan–dexamethasone or lenalidomide–dexamethasone found that **patients receiving lenalidomide and dexamethasone had the shortest progression-free survival and a trend toward shorter overall survival** — though those undergoing transplantation had the lowest-risk disease to begin with, so the comparison is confounded. **Peri-engraftment syndrome occurs in 12–50% of transplanted patients**, and POEMS patients have a **higher-than-expected transfusion requirement** compared with myeloma patients; **splenomegaly predicts a complicated peri-transplant course**.
- **Anti-VEGF therapy remains unproven.** The effects of **bevacizumab have been described as ambiguous**, and current practice continues to direct therapy at the plasma cell clone rather than at VEGF alone.
- **Daratumumab** is under formal evaluation in POEMS, with endpoints including **plasma cell response by IMWG criteria, VEGF reduction and duration of improvement in the ONLS neurological score**. Its low toxicity would make it particularly attractive in older, transplant-ineligible patients.
- **Thrombosis is now recognised as a defining hazard** — a retrospective evaluation of **230 patients** has characterised its frequency and risk factors, reinforcing routine thromboprophylaxis, particularly with immunomodulatory drugs.

Current Practice Update

Area	Classical teaching	Current practice (2023–2026)
Diagnostic framing	Recognise the POEMS acronym	**Suspect it in any "MGUS" with neuropathy, thrombocytosis or volume overload**; remember **PEST** as well as POEMS
Key test	M-protein and bone lesions	**VEGF is the central diagnostic and monitoring biomarker**; free light chain ratio is often normal and unhelpful
Bone imaging	Skeletal survey; bone scan	**Whole-body low-dose CT or FDG PET-CT**; a normal bone scan does not exclude the diagnosis
Localised disease	Radiotherapy	**Unchanged and still correct** — 40–50 Gy, response over 3–6 months, about half cured
Fit patient	High-dose melphalan with autologous transplant	**Unchanged and reaffirmed in 2025** — durable remission without maintenance
Unfit or older patient	Alkylator plus steroid	**Lenalidomide with dexamethasone** — neurological response about 95%, VEGF response about 83%
Anti-VEGF antibody	Theoretically attractive	**Ambiguous results; not recommended as sole therapy**
Emerging	—	**Daratumumab under evaluation**; monoclonal antibodies, bispecifics and CAR-T on the horizon
Thrombosis	Noted as an association	**A leading cause of death; thromboprophylaxis is routine**

Exam one-liners

- **POEMS = a lambda-restricted plasma cell clone driving very high VEGF.**
- **Learn PEST as well as POEMS** — Papilloedema, Extravascular volume overload, Sclerotic bones, Thrombocytosis.
- **Two mandatory criteria: polyneuropathy + monoclonal plasma cell disorder.** Then one more major and one minor.
- **The three "other major" criteria: Castleman disease, sclerotic bone lesions, raised VEGF.**
- **Diabetes and hypothyroidism alone do not count** as the endocrinopathy — they are too common.
- **Thrombocytosis, not thrombocytopenia.** Anaemia and a low platelet count point to myeloma or amyloid instead.
- **Sclerotic bones with a normal bone scan** — image with CT or PET-CT, not a bone scan.
- **Fundoscopy in every suspected case** — papilloedema is present in a third and usually asymptomatic.
- **Steroids and IVIG do not work** — this is not CIDP.
- **Localised → radiotherapy. Fit and disseminated → autologous transplant. Older or unfit → lenalidomide with dexamethasone.**
- **Nerves recover months after the VEGF falls** — counsel the patient accordingly.
- **Thrombosis kills** — prophylax, especially on immunomodulatory drugs.

4. Hormone Therapy in Malignancy

> *Discuss the principles, agents, indications and adverse effects of hormone therapy in malignancy, with emphasis on the older patient. (15 marks)*

Principle

1. **The governing statement.** A number of cancers prevalent in the elderly, **including breast cancer and prostate cancer, are hormonally responsive**. Medications aimed at blocking these hormonal pathways can result in the **prevention of recurrence or prolongation of survival**.
2. **Why hormone therapy is the geriatrician's most valuable oncological tool.** It is **oral or depot, non-myelosuppressive, does not cause alopecia, and is given in the outpatient setting**. It does not require the marrow reserve that cytotoxic chemotherapy demands. Its toxicity is not acute but **cumulative and metabolic — falling on bone, muscle, blood vessel and brain**, which is precisely why it needs geriatric supervision.
3. **Five mechanisms of hormonal manipulation. Block synthesis** (aromatase inhibitors, abiraterone); **block the receptor** (tamoxifen, bicalutamide, enzalutamide); **degrade the receptor** (fulvestrant, elacestrant, imlunestrant); **suppress the pituitary–gonadal axis** (GnRH agonists and antagonists); and **ablate the gland** (orchidectomy, oophorectomy — now largely historical).

Breast Cancer — Anti-oestrogen Therapy

4. **Tamoxifen.** This selective oestrogen receptor modulator **reduces the risk of recurrence by 40% and the risk of breast cancer mortality by 31%** after primary treatment of oestrogen receptor positive breast cancer. It is an **antagonist in the breast but an agonist in bone and endometrium** — which is why it **protects bone but causes endometrial hyperplasia and carcinoma**.
5. **The CYP2D6–paroxetine interaction — a classic examination point. Tamoxifen is converted by cytochrome P450 2D6 into the more potent anti-oestrogen endoxifen.** Women who receive the potent 2D6 inhibitor **paroxetine** together with tamoxifen are at **increased risk of death from breast cancer**, because less tamoxifen is converted to the active form. **This interaction is not seen with other SSRIs.** The practical rule: **never prescribe paroxetine, fluoxetine or bupropion with tamoxifen** — use venlafaxine, citalopram or escitalopram for hot flushes or depression.
6. **Aromatase inhibitors.** In postmenopausal women, **letrozole, anastrozole and exemestane are the preferred anti-oestrogen therapy**. They **block the conversion of adrenal androgens to oestrogens by the enzyme aromatase**. NICE recommends an aromatase inhibitor in postmenopausal women at **medium or high risk of recurrence**, reserving tamoxifen for **low risk, or where an aromatase inhibitor is contraindicated or not tolerated**. **Aromatase inhibitors cause arthralgia and increase the risk of osteoporosis.** They work only in postmenopausal women.
7. **The comparative toxicity table — memorise this.**

Feature	Tamoxifen	Aromatase inhibitor
Efficacy	Standard for over 25 years	**Superior** — BIG 1-98: 5-year disease-free survival **84.0% versus 81.4%**; event HR **0.81**; distant recurrence HR **0.73**
Characteristic harms	**Thromboembolism, endometrial carcinoma, vaginal bleeding**, cataract, hot flushes	**Skeletal (fracture) and cardiac events, hypercholesterolaemia**, arthralgia, vaginal dryness
Effect on bone	**Protective** (agonist at bone)	**Harmful** — accelerates bone loss
Second cancers at 10 years (ATAC)	More **endometrial (24 versus 6), melanoma (19 versus 8), ovarian (28 versus 17)**	More **colorectal (66 versus 44) and lung (51 versus 34)**
Geriatric choice	Prefer in **severe osteoporosis** or intolerable arthralgia	Prefer in a woman with a **uterus, previous DVT or stroke**

8. **Adherence is the hidden problem in the elderly. One-quarter of women are incompletely adherent to their adjuvant hormonal regimen**, and **older age and an increasing number of co-medications are independent risk factors for non-adherence**. An unswallowed tablet has zero efficacy, so adherence must be asked about at every visit rather than assumed.
9. **Duration and extended therapy. Distant recurrences continue at a steady rate for at least 15 years after stopping 5 years of endocrine therapy.** The **ATLAS** trial showed that continuing tamoxifen to **10 rather than 5 years reduced recurrence (RR 0.84) and overall mortality (639 versus 722 deaths)**. **NICE and SIOG therefore recommend considering extension with an aromatase inhibitor after 5 years of tamoxifen**, discussing the continuing risk of **menopausal symptoms, bone density loss and musculoskeletal pain**.
10. **Primary endocrine therapy is not a substitute for surgery.** In the Cancer Research UK trial in women over 70, the **5-year risk of local progression was 8% after mastectomy, 18% after breast conservation, but 64% with tamoxifen alone**; **10-year survival was 37.7% with surgery plus tamoxifen versus 28.8% with tamoxifen alone**. **Primary endocrine therapy should only be offered to women with ER-positive tumours who are unfit for or refuse surgery.**

Prostate Cancer — Androgen Deprivation Therapy

11. **Principle. Testosterone fuels prostate cancer growth**, so **androgen deprivation therapy is the cornerstone of first-line therapy for metastatic prostate cancer**, although over time the cancer becomes **insensitive to anti-androgen therapy**. **Surgical castration was used historically; medical castration is now preferred.** The castrate level is **testosterone below 50 ng/dL**.
12. **GnRH agonists and the tumour flare — the most important practical point.** The agonists **leuprolide and goserelin initially cause release of FSH and LH with a rise in serum testosterone** before suppressing gonadotropin secretion. That initial surge may cause **increased pain from bone metastases, urinary obstruction, or spinal cord compression if it is already impending**. **The flare is prevented by giving an androgen receptor antagonist for two weeks before starting the GnRH agonist.** In a man with vertebral metastases, omitting this step can cause paraplegia.
13. **Antagonists and receptor blockers.** The GnRH antagonist **degarelix causes rapid suppression of testosterone without a flare**. Androgen receptor antagonists — **bicalutamide, flutamide and nilutamide** — were traditionally added after failure of first-line androgen deprivation.
14. **Immediate side effects. Hot flushes, erectile dysfunction, gynaecomastia and anaemia**, with an **increased risk of osteoporosis**.
15. **The four long-term geriatric harms of androgen deprivation.**
    - **Bone** — bone loss is **1–4.6% per year** on androgen deprivation, with **fracture risk increasing by up to 45% over the long term**. Seek osteoporosis risk factors (family history, low weight, previous fracture, alcohol, smoking, glucocorticoids, low vitamin D) and **prescribe calcium and vitamin D**. **Bisphosphonates are not recommended routinely — only in established osteoporosis.**
    - **Muscle** — hormone therapy causes an **increase in fat mass and sarcopenia**, which in the elderly leads to **loss of autonomy, falls and fractures**.
    - **Metabolic and cardiovascular** — **altered lipid profile, increased insulin resistance and diabetes, and increased prevalence of metabolic syndrome**, with increased cardiovascular risk demonstrated in RTOG 92-02.
    - **Cognitive** — **executive cognitive impairment**, alongside documented deficits in physical performance and increased falls.

    Prevention is explicit: modification of diet and lifestyle — walking, an adapted diet and smoking cessation — is needed to reduce the metabolic and cardiovascular impact of hormone therapy.

Other Hormone-Responsive Malignancies

16. **Endometrial carcinoma. High-dose progestins (medroxyprogesterone acetate, megestrol acetate)** and increasingly **aromatase inhibitors** are used in **low-grade, receptor-positive advanced or recurrent disease**. This is a well-suited option for the frail older woman who cannot tolerate chemotherapy.
17. **Differentiated thyroid carcinoma. TSH suppression with levothyroxine** after thyroidectomy removes the growth stimulus to residual thyroid tissue. **In the elderly this must be risk-adapted**, because over-suppression causes **atrial fibrillation, osteoporosis and heart failure**.
18. **Cancer cachexia. Megestrol acetate and medroxyprogesterone** improve appetite and weight, but the weight gained is largely fat rather than muscle, they carry a **thromboembolic risk**, and they do not improve survival.
19. **Two cautions on hormones that cause malignancy.**
    - **HRT and breast cancer (Million Women Study, 1,084,110 women)** — current users had **RR 1.66**; the risk was highest for **combined oestrogen plus progestogen (RR 2.0)**, then **oestrogen alone (RR 1.3)** and **tibolone (RR 1.45)**, with a **dose–response relationship rising to RR 2.31 after 10 or more years**. **Some excess risk persisted for more than 10 years after stopping.**
    - **Testosterone replacement** — the effects of long-term replacement on benign prostatic hypertrophy and prostate cancer **remain unclear**. It is **contraindicated in known prostate carcinoma**, and supplementation **may increase cardiovascular events in those aged 65 and above, especially during the first year**. **Monitoring of prostate size, PSA and haematocrit is mandatory.**
20. **A checklist before starting any endocrine therapy in an older patient.**
    - **Before an aromatase inhibitor:** DEXA and FRAX; **calcium (mg/dL) and vitamin D (ng/mL)** with supplementation; **lipid profile (mg/dL)**; baseline joint symptoms.
    - **Before tamoxifen:** history of venous thromboembolism, stroke, cataract or abnormal vaginal bleeding; **screen the drug chart for CYP2D6 inhibitors**.
    - **Before androgen deprivation:** DEXA, falls and fracture history; **calcium and vitamin D routinely**; **lipids, fasting glucose or HbA1c, blood pressure and ECG**; **baseline cognition (Mini-Cog), gait and grip strength**.

> **The five rules.** (1) **Confirm receptor status before prescribing** — older women are three times more likely to have receptor testing omitted. (2) **Never start a GnRH agonist in a man with impending cord compression without two weeks of anti-androgen cover.** (3) **Never combine tamoxifen with paroxetine.** (4) **Every patient on an aromatase inhibitor or androgen deprivation needs calcium, vitamin D and a bone-density plan.** (5) **Hormone therapy replaces chemotherapy in the frail — it does not replace surgery in the fit.**

Latest Updates (2023–present)

Oral SERDs — a new class in breast cancer

- **Elacestrant** was approved on **27 January 2023** for ER and/or PR-positive, HER2-negative metastatic breast cancer harbouring an **ESR1 missense mutation** after at least one line of endocrine therapy, on the basis of the phase 3 **EMERALD** trial (progression-free survival hazard ratio **0.70**). It is a **dose-dependent mixed ER agonist/antagonist**, only **11% bioavailable**, and **primarily metabolised by CYP3A4** — an important interaction consideration in polypharmacy.
- **Imlunestrant** was approved on **25 September 2025** — the third SERD after fulvestrant and elacestrant, and the second oral one. Unlike fulvestrant it **crosses the blood–brain barrier**, so it may be effective against brain metastases. The dose is **400 mg orally once daily on an empty stomach**. Among 256 patients with ESR1-mutated disease, **response was 14.3% with imlunestrant versus 7.7% with fulvestrant**; the **Guardant360 CDx assay** was approved simultaneously as the companion diagnostic.
- In **EMBER-3**, **imlunestrant with abemaciclib gave a median progression-free survival of 9.4 months versus 5.5 months with imlunestrant alone (HR 0.57)** — the first regimen to break the 6-month barrier after CDK4/6 inhibitor failure. **Elacestrant with abemaciclib** gave **14.3 versus 8.3 months**, irrespective of ESR1 mutation status.

From "treat on progression" to "treat on molecular signal"

- **ASCO now recommends routine ESR1 mutation testing at recurrence or progression**, since identifying these patients allows a switch to a more effective agent. The **SERENA-6** trial went further, using **ctDNA monitoring every 2–3 months** in patients on a first-line aromatase inhibitor plus a CDK4/6 inhibitor and switching the endocrine component to **camizestrant** on detection of an emergent ESR1 mutation, **before any clinical or radiographic progression**.
- **Geriatric relevance:** this allows a change of tablet rather than an escalation to chemotherapy — exactly the de-escalation an older patient needs.

Endocrine therapy is no longer given alone in high-risk early breast cancer

- **Adjuvant CDK4/6 inhibitors** are now added to endocrine therapy — **abemaciclib for 2 years (monarchE criteria: ≥4 positive nodes, or 1–3 nodes with grade 3 disease, tumour ≥5 cm or Ki-67 ≥20%)**, or **ribociclib 400 mg daily for 3 years (NATALEE criteria: anatomic stage II or III)**. Where a patient meets both, **ASCO favours abemaciclib**. Toxicity is real — in monarchE, **46% had grade 3 adverse events versus 15% on endocrine therapy alone, with 61% requiring dose interruption**.

Prostate — androgen receptor pathway inhibitors have moved earlier

- **Four ARPIs are now approved: abiraterone, apalutamide, darolutamide and enzalutamide**, and they are used **upfront with androgen deprivation** rather than only after failure.
- On **16 November 2023**, **enzalutamide was approved for non-metastatic castration-sensitive prostate cancer with biochemical recurrence at high risk of metastasis**, based on **EMBARK**. High risk was defined as a **PSA doubling time of 9 months or less, with PSA ≥2 ng/mL above nadir after radiotherapy or ≥1 ng/mL after prostatectomy**.
- EMBARK showed **metastasis-free survival hazard ratios of 0.42 for enzalutamide plus leuprolide and 0.63 for enzalutamide monotherapy**. The **final overall survival analysis published in 2025 showed 8-year overall survival of 78.9% versus 69.5% (HR 0.60) for the combination**, whereas **enzalutamide monotherapy did not significantly improve overall survival (HR 0.83)**.
- **A feature of major geriatric importance:** EMBARK used **intermittent therapy** — treatment for 36 weeks, then **suspension at week 37 if PSA was undetectable (below 0.2 ng/mL)**, restarting only if PSA rose to protocol-defined thresholds. **This offers a practical way to limit cumulative bone, metabolic and cognitive toxicity in older men.**
- A **Young-SIOG global drug review (2023)** cautions that the **landmark phase 3 data for ARPIs in older adults are limited to those with excellent performance status**, and that their **role in unfit older patients remains to be established**.

Current Practice Update

Area	Textbook position	Current practice (2023–2026)
Breast — agents	Tamoxifen; aromatase inhibitors; fulvestrant	Add **oral SERDs — elacestrant (2023) and imlunestrant (2025)** for ESR1-mutant disease
Breast — testing	ER and PR status	Add **ESR1 mutation testing at progression**; also PIK3CA, AKT1, PTEN
Breast — adjuvant	Endocrine therapy with or without chemotherapy	**Endocrine therapy plus a CDK4/6 inhibitor** in high-risk disease
Breast — monitoring	Clinical and radiological progression	**ctDNA monitoring with a pre-emptive switch (SERENA-6)**
CYP2D6 interaction	Avoid paroxetine with tamoxifen	**Unchanged and still correct**
Prostate — GnRH antagonist	Degarelix, "place remains to be determined"	**Established; oral relugolix now available** — no flare, better cardiac safety

Prostate — receptor blockers	Bicalutamide, flutamide, nilutamide, after first-line failure	**Second-generation ARPIs and abiraterone used upfront with androgen deprivation**
Biochemical recurrence	Not addressed	**Enzalutamide plus leuprolide (EMBARK), approved November 2023**; 8-year overall survival 78.9% versus 69.5%
ADT schedule	Continuous, or intermittent by PSA response	**PSA-guided intermittent therapy formalised** (EMBARK week-37 suspension)
Bone protection	Calcium and vitamin D; bisphosphonate only in established osteoporosis	**Unchanged, but denosumab is now preferred where creatinine clearance is below 30 mL/min**

Summary Table of Agents

Cancer	Target	Agents	Key toxicity in the elderly
Breast (ER-positive)	Oestrogen receptor / aromatase	**Tamoxifen; letrozole, anastrozole, exemestane; fulvestrant, elacestrant, imlunestrant**	**Tamoxifen** — VTE, endometrial carcinoma. **Aromatase inhibitor** — fracture, arthralgia, dyslipidaemia
Prostate	Androgen axis	**Leuprolide, goserelin; degarelix, relugolix; bicalutamide; enzalutamide, apalutamide, darolutamide; abiraterone**	**Osteoporosis, sarcopenia, falls, diabetes, cardiovascular events, cognitive decline**
Endometrial	Progesterone receptor	**Medroxyprogesterone, megestrol; aromatase inhibitors**	Thromboembolism, weight gain
Differentiated thyroid	TSH	**Levothyroxine suppression**	Atrial fibrillation, osteoporosis, heart failure
Cancer cachexia	Appetite	**Megestrol, medroxyprogesterone**	Thromboembolism; fat rather than muscle gain

Exam one-liners

- **Hormone therapy is the geriatrician's favourite oncological treatment** — a tablet or an injection that spares the marrow entirely.
- **Its price is paid slowly in bone, muscle, vessel and brain** — so calcium, vitamin D, a bone-density plan and a cardiometabolic review accompany every prescription.
- **Tamoxifen protects bone but threatens the endometrium; aromatase inhibitors protect the endometrium but threaten bone.**
- **Paroxetine plus tamoxifen increases breast cancer mortality** — other SSRIs do not.
- **Aromatase inhibitors work only after the menopause.**
- **Two weeks of anti-androgen before a GnRH agonist** — otherwise the flare can cause cord compression.
- **Castrate testosterone is below 50 ng/dL.**
- **ADT causes 1–4.6% bone loss per year and up to a 45% rise in fracture risk.**
- **Bisphosphonates in ADT only for established osteoporosis** — calcium and vitamin D for everyone.
- **Tamoxifen alone gave a 64% five-year local progression rate versus 8% after mastectomy** — endocrine therapy is not a substitute for surgery in a fit woman.
- **One-quarter of women are non-adherent, and older age plus polypharmacy predict it** — ask every visit.

MD GERIATRIC MEDICINE

Infections in the Elderly & Preventive Immunisation

Examination-Oriented High-Yield Answers

Six Questions · 15-Mark and 7-Mark Formats

Textbook Content with Evidence Updates to 2026

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition · Essentials of Clinical Geriatrics, 7th edition

Supplemented by: IDSA/SHEA, ACG, ACIP/CDC, WHO, API Indian Consensus Guidelines on Adult Immunization, Indian Academy of Geriatrics, and peer-reviewed trial evidence published up to mid-2026.

Structure of each answer: High-yield numbered points → Latest Updates (2023–present) → Current Practice Update comparison → Examiner's Tip. Recurring topics carry an additional "Extra Points to Remember" panel.

Prepared for Sudarsan · Postgraduate Revision Series

CONTENTS

No.	Question	Format	Recurs
1	Approach to pyrexia / fever of unknown origin in older adults	15 marks	—
2	Atypical presentations of infections in the elderly	15 marks	—
3	Herpes zoster in the elderly — aetiology, clinical features, management	15 marks	**Yes**
4	*Clostridioides difficile* colitis	7 marks	—
5	Vaccines / vaccinations for the elderly	15 marks	**Yes**
6	Influenza vaccination	7 marks	—

How to use this document the night before

Read the numbered points first — they are the marks. Then read only the orange Examiner's Tip boxes and the Rapid Revision Grid. The "Latest Updates" sections are what separate a distinction answer from a pass answer; quote one or two named trials per answer, not all of them.

Q1. Approach to Pyrexia / Fever of Unknown Origin (FUO) in Older Adults

15-mark answer · 18 high-yield points

Definition and Classification

1. **Classical FUO (Petersdorf and Beeson, 1961)** means fever above **38.3°C** on several occasions, lasting **more than 3 weeks**, with no diagnosis after **1 week of hospital investigation**.
2. **Durack and Street (1991) revision** is the version used today: fever above 38.3°C for more than 3 weeks, undiagnosed after **3 days of inpatient work-up or 3 outpatient visits**. Four subtypes exist: **classical, nosocomial, neutropenic and HIV-associated**.
3. **Inflammation of unknown origin (IUO)** is a related entity — prolonged raised acute-phase reactants **without fever**. It is common in older people and is investigated the same way as FUO.
4. In the elderly the definition of fever itself must be lowered. Textbook criteria for long-term care residents are a **single oral temperature above 100°F (37.8°C)**, **repeated oral temperature above 99°F**, or **a rise of more than 2°F above the patient's own baseline**.

Why Older Adults Differ

5. Older people have a **lower baseline body temperature** and may show **no diurnal rise**, so a "normal" reading can conceal significant infection.
6. **Fever is blunted or absent in roughly one-third of elderly patients** with serious bacterial infection, and typically defined fever is absent in **more than half of long-term care residents** with serious infection.
7. Conversely, when fever **is** present in a very old patient it is more likely to indicate **bacterial rather than viral** illness — it carries greater diagnostic weight, not less.
8. **Hypothermia is an ominous sign** and predicts higher mortality than fever in elderly sepsis. Absence of leucocytosis also does not exclude bacterial infection.

Aetiology — Four Diagnostic Categories

9. **Infections:** tuberculosis (miliary and extrapulmonary), infective endocarditis, occult abscess (hepatic, subphrenic, perinephric, dental, prostatic), urinary sepsis, osteomyelitis, infected prosthesis or pacemaker lead. **Nearly 50% of infective endocarditis occurs in older adults**, usually on degenerative or prosthetic valves.
10. **Non-infectious inflammatory disease:** in the elderly this group is proportionally larger than in the young. **Giant cell arteritis and polymyalgia rheumatica are the single most important treatable causes**; also adult-onset Still's disease, vasculitis and sarcoidosis.
11. **Malignancy:** lymphoma (especially non-Hodgkin), renal cell carcinoma, hepatic metastases, atrial myxoma, myelodysplastic syndrome.
12. **Miscellaneous: drug fever** (antibiotics, allopurinol, phenytoin, methyldopa), venous thromboembolism, subacute thyroiditis, haematoma, and factitious fever. In India also consider **malaria, enteric fever, visceral leishmaniasis, amoebic liver abscess, brucellosis, scrub typhus and dengue**.
13. **Key geriatric principle:** FUO in an older person is usually **an atypical presentation of a common disease, not a rare disease**. In elderly series, TB, endocarditis, GCA/PMR and lymphoma account for the majority.

Clinical Approach

14. **Repeated history and repeated full examination** are the highest-yield "investigations." Undress the patient fully: examine the **sacrum and heels for pressure sores**, temporal arteries, oral cavity and dentition, joints, and do a rectal and genital examination.
15. Suspect infection in any older person with **functional decline, new confusion, falls, incontinence, reduced oral intake or failure to cooperate with staff**, even without fever. Also review the drug chart at every step — steroids, paracetamol and NSAIDs mask fever.
16. **First-line tests:** complete blood count with differential, ESR and CRP, renal and liver function, urinalysis and urine culture, **three sets of blood cultures off antibiotics**, chest radiograph, sputum for AFB/CBNAAT, HIV serology, and abdominal ultrasound. A **WBC above 14,000/mm³ or left shift above 6%** warrants careful assessment for bacterial infection.
17. **Second-line tests:** contrast CT chest/abdomen/pelvis, echocardiography (transthoracic then transoesophageal), temporal artery ultrasound or biopsy in anyone above 50 with raised ESR, autoantibodies, protein electrophoresis, and bone marrow examination if cytopenias are present.

Management Principles

18. **Avoid blind antibiotics** — they sterilise cultures and obscure the diagnosis. Exceptions are haemodynamic instability, neutropenia and strong suspicion of endocarditis. **Do not give an empirical steroid trial before excluding TB and malignancy.** Choose empirical cover with gram-negative organisms in mind, adjust all doses to renal function, and

monitor aminoglycoside levels. When repeated evaluation is unrevealing, "**suspect tuberculosis when an older patient is inexplicably failing**."

Latest Updates (2023–Present)

- **FDG PET-CT has become the pivotal second-line test.** A 2025 systematic review in *Journal of Clinical Medicine* and an AJR Expert Panel narrative review both conclude that FDG PET-CT is now the nuclear-medicine test of choice for FUO and IUO, superseding gallium-67 and labelled leucocyte scanning.
- **Elderly-specific data now exist.** A dedicated study of patients aged 75 and above (*Diagnostics*, 2025) found FDG PET-CT contributed to a definitive diagnosis in **30.8%** of cases and changed treatment in **38.8%**, but produced **false positives in 15.2%** — from atherosclerosis, degenerative change and recent infection. An accompanying 2025 commentary in *Journal of Cellular Immunology* stresses that scans in frail patients need multidisciplinary interpretation and careful patient selection.
- **Diagnostic yield across all ages.** A 2025 retrospective cohort of 284 FUO patients (*Frontiers in Medicine*) reported non-infectious inflammatory disease in 26.8%, malignancy in 23.2%, infection in 18.7%, and **31.3% still undiagnosed** — confirming that a large undiagnosed fraction persists despite modern imaging. A 2026 Italian multicentre study of 929 patients (*Journal of Nuclear Medicine*) further supports routine early use.
- **Known false-negative traps** for PET-CT include SLE, CMV, toxoplasmosis, urinary infection and pyelonephritis. Conversely PMR shows a highly characteristic pattern — uptake at **shoulders, hips, greater trochanters, ischial tuberosities and interspinous bursae** — which is now an important recognised diagnostic clue in older patients.
- **A negative FDG PET-CT is itself useful**, carrying a high negative predictive value, excluding focal disease and predicting a favourable prognosis — supporting watchful waiting rather than escalating invasive tests in a frail patient.
- **Vital-sign evidence refined.** A 2025 systematic review and meta-analysis in *Age and Ageing* examined whether older adults truly show different vital signs in bacterial infection, confirming that blunted responses are real but heterogeneous — some older patients present identically to younger ones.

Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Definition applied	Petersdorf/Durack criteria; fever thresholds emphasised	FUO and **IUO treated as one diagnostic problem** with the same algorithm; age-adjusted fever thresholds formally endorsed
Imaging strategy	Stepwise conventional imaging; radionuclide scanning peripheral	**FDG PET-CT as early second-line, sometimes first-line** modality; gallium and labelled leucocyte scans obsolete
Yield expectation	Not quantified for older adults	Diagnosis established in ~31% of over-75s by PET-CT; treatment altered in ~39%; false positives ~15%
Role of a negative scan	Not addressed	Negative scan has **high NPV and favourable prognosis** — supports de-escalation in frailty
Undiagnosed proportion	Implied to fall with better tests	Remains high at **~30%** even with modern imaging

Practical limitation in the Indian setting

FDG PET-CT costs roughly ₹20,000–30,000 and is confined to tertiary centres. In practice, exclude **tuberculosis, malaria, enteric fever, HIV and amoebic liver abscess** thoroughly and cheaply first — CBNAAT, peripheral smear/rapid antigen, blood culture, HIV serology and abdominal ultrasound — before requesting PET-CT. State this cost-consciousness explicitly in your answer; examiners reward it.

Examiner's Tip — verbatim lines to write

• "In older adults, FUO is usually an **atypical presentation of a common disease**, not a rare disease."
• "Fever in the elderly is defined as a single oral temperature above 100°F, a repeated temperature above 99°F, or a rise of more than 2°F above baseline."
• "**Giant cell arteritis is the most important treatable cause** of FUO in patients over 50 and must be actively excluded."
• "Hypothermia in an infected older patient carries a worse prognosis than fever."
• "I would not start blind antibiotics or an empirical steroid trial before excluding tuberculosis and malignancy."
• Draw a simple algorithm: **History and repeated examination → first-line tests → CT and echocardiography → FDG PET-CT → targeted biopsy.**

Q2. Atypical Presentations of Infections in the Elderly

15-mark answer · 18 high-yield points

Definition and Importance

1. **Atypical presentation** means an infection that presents without its classical localising or systemic features, and instead declares itself through **non-specific geriatric syndromes**.
2. It matters because **atypical presentation delays diagnosis and treatment, and is independently associated with higher mortality**. Underreporting of symptoms, impaired communication, coexisting disease and altered physiological responses all contribute.

Mechanisms — Why Presentations Change

3. **Immunosenescence:** thymic involution reduces T-cell production and function; **cell-mediated immunity falls markedly, humoral immunity to a lesser degree**; B-cell numbers and phagocytic and complement function are relatively preserved. Adaptive immunity is affected far more than innate immunity.
4. **Inflammageing:** chronic low-grade inflammation with raised IL-6 and TNF raises the baseline CRP and blunts the incremental acute-phase response, so a "modest" CRP rise may represent severe illness.
5. **Impaired thermoregulation:** reduced pyrogenic cytokine production, lower muscle mass, blunted vasoconstriction and a lower baseline temperature together produce the blunted febrile response.
6. **Loss of barrier and reserve:** impaired cough reflex, reduced mucociliary clearance and decreased mucus secretion predispose to aspiration; prostatic obstruction predisposes men to urinary infection; skin thinning and pressure sores create portals of entry.
7. **Comorbidity masking:** existing chronic disease conceals acute infection. Septic arthritis characteristically occurs in an already abnormal joint, so **synovial fluid must be aspirated whenever an older patient has an "acute exacerbation" of joint disease**.

The Classical Atypical Syndromes

8. **Delirium or acute confusion** — the single commonest atypical presentation. Infections not involving the CNS routinely cause confusion in the elderly, particularly with pre-existing dementia.
9. **Falls and unexplained loss of mobility** — a fall in a previously ambulant older person should prompt a search for infection.
10. **Acute functional decline** — sudden inability to perform activities of daily living. "Acute unexplained functional deterioration should alert the physician to a potential acute infectious process."
11. **New or worsening incontinence**, **anorexia and reduced oral intake**, **generalised weakness and fatigue**, and **failure to cooperate with carers**.
12. **Absence of fever** in one-third of cases, and frank **hypothermia**, which predicts mortality. **Absence of leucocytosis does not exclude bacterial infection.**
13. **Decompensation of a chronic condition** — new atrial fibrillation, worsening heart failure, or hyperglycaemic crisis may be the only presentation of sepsis.

Site-Specific Atypical Patterns

14. **Pneumonia:** fever and cough are **absent in 30–40%** of elderly cases. Look instead for tachypnoea above 30/min, tachycardia above 110/min, confusion or falls. Pneumonia remains the commonest infective cause of death in geriatric patients.
15. **Urinary tract infection:** presents as altered mental status rather than dysuria; over a quarter of over-70s with bacteraemic UTI present with confusion. **Do not send urine culture in an asymptomatic resident** — asymptomatic bacteriuria is common and should not be treated in the absence of obstructive uropathy.
16. **Intra-abdominal sepsis:** appendicitis and diverticulitis present without guarding or rigidity; failure to seek medical attention contributes to the higher morbidity and mortality of appendicitis in older adults.
17. **Tuberculosis:** presents as weight loss, anorexia and failure to thrive rather than haemoptysis; reactivation is favoured by malnutrition and comorbidity. A useful rule — **suspect tuberculosis when an older patient is inexplicably failing**. Rates are higher in long-term care than in the community.
18. **COVID-19 and respiratory viruses:** Pathy's records that **delirium and falls are common atypical presentations of COVID-19** in older people, with delirium in around 30% of hospitalised cases and up to 70% in severe disease. Atypical presentation should trigger testing, not reassure.

Practical Rules for the Ward

- Use an **age-adjusted fever threshold** and always compare against the patient's own baseline.
- **Undress and examine fully** — sacrum, heels, perineum, feet, oral cavity, intravenous and catheter sites.
- Change from baseline over **hours to a day** is the alarm signal, not the absolute value of any single observation.

- Pulse oximetry if respiratory rate is above 25; chest radiograph if hypoxaemia is documented or suspected; blood cultures in nursing-home residents have low yield and rarely change therapy.

Latest Updates (2023–Present)

- **The blunted-response doctrine has been refined, not overturned.** A 2025 systematic review and meta-analysis in *Age and Ageing* examined vital signs in adults hospitalised with bacterial infection and found blunted responses are real but **heterogeneous** — a substantial proportion of older patients present with entirely typical vital signs. The clinical implication: an atypical presentation should never be assumed, and a typical presentation should never be discounted.
- **Sepsis screening tools underperform in this population.** A 2024 review in *Geriatric Care* and a 2026 narrative review in *Anaesthesia Critical Care and Pain Medicine* both confirm that SIRS criteria, qSOFA and fever-based screens have reduced sensitivity and specificity in older adults, and describe interest in a **geriatric-adapted qSOFA** incorporating frailty and functional decline.
- **Fever absence quantified more precisely.** Contemporary reviews place absence of fever in older patients with serious infection at **30–50%**, with hypothermia carrying a distinct and worse prognostic signature than fever in elderly sepsis.
- **Biomarkers are increasingly favoured over vital signs.** Current reviews advocate procalcitonin and lactate for early identification because they are less blunted by immunosenescence than temperature and white cell count, and remain informative after antibiotics have been started.
- **Frailty is now formally recognised as an effect modifier** rather than a background variable — Pathy's itself notes that frailty acts synergistically to increase both susceptibility and severity, and current literature builds on this by recommending frailty scoring at the point of sepsis triage.

Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Blunted febrile response	Fever blunted or absent in a substantial minority	Confirmed at **30–50%**, but explicitly **heterogeneous** — many older patients present typically
Screening tools	Not addressed for geriatrics	SIRS/qSOFA **less sensitive and specific** in older adults; geriatric-qSOFA proposed
Diagnostic markers	WBC above 14,000/mm³ or left shift above 6%	Increasing reliance on **procalcitonin and lactate**, which are less blunted by immunosenescence
Frailty	Described as a risk factor	Treated as a **formal effect modifier** to be scored at triage
Delirium as a presentation	Recognised, mechanism undefined	Confirmed and quantified; routine delirium screening advocated as an infection-detection strategy

Examiner's Tip — verbatim lines to write

• "In the elderly, the **geriatric syndromes are the symptoms of infection** — delirium, falls, functional decline, incontinence and anorexia."
• "Fever is absent in 30–50% of older patients with serious infection, and **hypothermia carries a worse prognosis than fever**."
• "Absence of leucocytosis does not exclude bacterial infection."
• "Any acute unexplained functional deterioration is an infection until proven otherwise."
• "Standard sepsis screening tools are less sensitive in older adults, so I would rely on **change from the patient's own baseline** together with lactate and procalcitonin."
• Close with the classical Osler quotation in your own words: in old age pneumonia may be latent, with slight cough, ill-defined signs, and constitutional symptoms out of all proportion.

Q3. Herpes Zoster in the Elderly — Aetiology, Clinical Features and Management

*15-mark answer · 19 high-yield points · **Recurring topic***

Definition and Aetiology

1. **Herpes zoster (shingles)** is a localised, painful vesicular eruption caused by **reactivation of latent varicella-zoster virus (VZV)** from dorsal root and cranial nerve ganglia, where it has lain dormant since primary chickenpox.
2. The trigger for reactivation is **a decline in VZV-specific cell-mediated immunity**, which occurs with ageing (immunosenescence) and with immunosuppression from disease or therapy.
3. **Risk factors:** increasing age, malignancy (especially lymphoproliferative), HIV, chemotherapy, corticosteroids and other immunosuppressants, transplantation, diabetes, chronic kidney disease, and physical or psychological stress.

Epidemiology

4. Incidence rises sharply with age. In a prospective vaccine trial the incidence in those over 60 was **11.8 cases per 1000 persons per year**, against an all-age rate of **1.2–3.4 per 1000 per year**.
5. **Zoster occurs in up to half of all individuals surviving to age 85.**
6. **Increasing age is the strongest risk factor for postherpetic neuralgia (PHN)**, which affects **more than 40% of those over 60** who develop zoster.
7. In India, an ICMR estimate places zoster incidence at about **3.3 cases per 1000 persons per year**, and seroprevalence studies show **over 90% of Indians are VZV-seropositive by age 40** — so essentially the entire older Indian population is at risk.

Clinical Features

8. **Prodromal phase (2–7 days):** pain, itching, tingling or burning in a dermatome, often with malaise and low-grade fever. In the elderly this is frequently **misdiagnosed as myocardial infarction, renal colic, cholecystitis or a disc lesion**.
9. **Eruptive phase:** grouped vesicles on an erythematous base in a **unilateral dermatomal distribution that does not cross the midline**; vesicles become pustular, crust in 7–10 days and heal over 2–4 weeks.
10. **Commonest sites:** thoracic dermatomes (about half of cases), followed by the ophthalmic division of the trigeminal nerve.
11. **Herpes zoster ophthalmicus:** V1 involvement. **Hutchinson's sign** — vesicles on the tip or side of the nose (nasociliary branch) — predicts ocular involvement and mandates urgent ophthalmology referral; complications include keratitis, uveitis, acute retinal necrosis and blindness.
12. **Ramsay Hunt syndrome (herpes zoster oticus):** geniculate ganglion involvement causing **ipsilateral facial palsy, vesicles in the external auditory canal or on the palate, vertigo and sensorineural deafness**. Recovery of the palsy is poorer than in Bell's palsy.
13. **Disseminated zoster:** more than 20 vesicles outside the primary dermatome, with possible visceral involvement (pneumonitis, hepatitis, encephalitis). Suggests significant immunosuppression — investigate for occult malignancy or HIV.
14. **Postherpetic neuralgia:** defined as pain persisting **90 days or more after rash onset**. It is **neuropathic pain** — burning, lancinating or electric-shock in character, with allodynia and hyperalgesia. It causes insomnia, depression, weight loss and social withdrawal, and is the principal driver of the disease burden in older people.
15. **Other complications:** zoster sine herpete (dermatomal pain without rash), segmental motor palsy, myelitis, meningoencephalitis, VZV vasculopathy causing stroke, and bacterial superinfection.

Diagnosis

16. The diagnosis is **clinical** in the vast majority. Confirmation, where needed, is by **VZV PCR of vesicle fluid or a swab of the base of a de-roofed lesion** — the most sensitive test. Tzanck smear shows multinucleate giant cells but cannot distinguish HSV from VZV. Direct fluorescent antibody testing is an alternative.

Management

17. **Antiviral therapy must be started within 72 hours of rash onset. Aciclovir, famciclovir and valaciclovir all reduce acute pain and shorten the duration of chronic pain** when started within this window. Beyond 72 hours, still treat if new vesicles are still forming or if there is ophthalmic, motor or disseminated involvement.
    - Valaciclovir **1 g three times daily for 7 days** — preferred for compliance
    - Famciclovir **500 mg three times daily for 7 days**
    - Aciclovir **800 mg five times daily for 7–10 days** — cheapest and most available in India
    - **All doses must be reduced for creatinine clearance below 30 ml/min**; inadequate dose reduction causes aciclovir neurotoxicity presenting as delirium, which is easily mistaken for the infection itself
    - Intravenous aciclovir 10 mg/kg 8-hourly for disseminated, ophthalmic-severe, or CNS disease

18. **Acute pain control:** analgesia is important. Paracetamol and NSAIDs for mild pain; **those with moderate to severe pain may require opioids**. Add **gabapentin or corticosteroids if pain persists**. Keep lesions clean and dry, and use non-adherent dressings.
19. **Treatment of established PHN: topical lidocaine patch, gabapentin and pregabalin are the FDA-approved agents**; **nortriptyline and opioids have also been shown to be of benefit**, and combination therapy may be necessary. In older adults, start low and titrate slowly; avoid amitriptyline in favour of nortriptyline because of anticholinergic burden, and reduce gabapentinoid doses in renal impairment.

Critical negative to state in the answer

Corticosteroids have NOT been shown to reduce the incidence of postherpetic neuralgia in the elderly. They may be used for acute pain relief or for specific complications such as Ramsay Hunt syndrome, but they must not be offered as PHN prophylaxis. This is a favourite examiner trap.

Prevention

20. Two vaccines exist. **Zostavax**, the live attenuated vaccine (FDA 2006), is only about **30% protective** and reduced zoster incidence with a hazard ratio of 0.45, ophthalmic zoster HR 0.37 and zoster hospitalisation HR 0.35. **Shingrix**, the recombinant adjuvanted vaccine (FDA 2016), is about **90% protective**.
21. **ACIP recommends two doses of Shingrix for all adults aged 50 and above**, given 2–6 months apart, **regardless of prior chickenpox and regardless of prior Zostavax**. Those who previously received Zostavax should still receive Shingrix.

Latest Updates (2023–Present)

- **Zoster vaccination and dementia — the major development of this cycle.** A landmark **natural experiment in Wales published in *Nature* (2025)** exploited an age cut-off for vaccine eligibility and found herpes zoster vaccination reduced dementia incidence by approximately **20%** over 7 years — the strongest causal-inference evidence available.
- A parallel ***JAMA* (2025)** analysis of Australian data using the same natural-experiment design reproduced the association, as did a ***Nature Medicine* (2024)** study showing the recombinant vaccine gave a **17% increase in diagnosis-free time** over 6 years compared with the live vaccine.
- Cohort data are consistent. A *Vaccine* (2025) study of 4.5 million people found two doses of RZV associated with dementia hazard ratio **0.68**; a *Nature Communications* (2026) Kaiser Permanente study found a **51% lower risk**; and an *Annals of Internal Medicine* (2026) target-trial emulation in skilled-nursing residents found a **24% relative and 6% absolute reduction** in 4-year dementia risk.
- **Zoster infection itself is a dementia risk factor.** The same *Vaccine* (2025) analysis found a zoster diagnosis before vaccination raised dementia hazard to **1.47**, while **antiviral treatment of zoster was protective (HR 0.42)**. *Nature Medicine* (2025) confirmed a consistent association between VZV reactivation and dementia in large-scale health records.
- **The evidence is not unanimous.** A 2025 systematic review and meta-analysis in *Human Vaccines and Immunotherapeutics* found an overall 32% dementia risk reduction with zoster vaccination, but some earlier meta-analyses showed no significant benefit. **The first randomised trial is now under way** — **DAN-ZOSTER**, a pragmatic RCT in adults aged 65 and above testing RZV against major adverse cardiovascular events and dementia, began recruiting in 2026 with completion expected 2029. *Results awaited.*
- **Real-world effectiveness confirmed.** A 2026 *Clinical Infectious Diseases* study confirmed sustained effectiveness of the adjuvanted recombinant vaccine in US adults aged 50 and above.
- **India-specific:** GSK launched **Shingrix in India in April 2023** for adults aged 50 and above. It is available privately at roughly **₹8,000–12,000 per dose (₹16,000–24,000 for the two-dose course)**, is not in any government programme, and requires 2–8°C cold chain. The **API Indian Consensus Guidelines on Adult Immunization (2024, updated 2026)** include herpes zoster vaccination for older adults.

Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Preferred vaccine	Both listed; Shingrix noted as 90% protective vs Zostavax 30%	**Zostavax withdrawn** in the US and many countries since 2020; RZV is the only vaccine in use
Non-zoster benefit	Not described	**~20% reduction in dementia incidence** (*Nature* 2025 natural experiment), replicated across multiple designs; RCT (DAN-ZOSTER) ongoing
Zoster as a disease risk	Complications limited to PHN, ocular, neurological	Zoster infection itself associated with **increased dementia risk (HR 1.47)**; antiviral treatment protective (HR 0.42)
Antiviral window	Within 72 hours of rash onset	Unchanged, but treat beyond 72 h if new vesicles forming, or ophthalmic/motor/disseminated disease

Steroids for PHN prevention	Not shown to reduce PHN incidence	**Unchanged** — still not recommended for PHN prophylaxis
Indian availability	Not addressed	Shingrix available since April 2023; **cost is the principal barrier**; included in API 2024 consensus guidelines

Extra Points to Remember — recurring topic

1. The three complications that must never be missed: herpes zoster ophthalmicus with Hutchinson's sign, Ramsay Hunt syndrome, and disseminated zoster signalling occult immunosuppression.

2. Aciclovir neurotoxicity in renal impairment presents as delirium, myoclonus and hallucinations — and is routinely mistaken for the infection itself. Always calculate creatinine clearance before prescribing.

3. Zoster sine herpete — dermatomal neuropathic pain with no rash. Diagnosed by VZV PCR of CSF or blood, or by serology. Consider it in unexplained unilateral segmental pain in an older person.

4. VZV vasculopathy is an under-recognised cause of stroke in older adults, particularly after ophthalmic zoster, and is one mechanism proposed to link zoster with dementia.

5. Zoster in the immunocompromised: Shingrix is non-live and therefore **safe in immunocompromised adults** (licensed from age 18 in this group) — the key practical advantage over Zostavax.

6. Nortriptyline over amitriptyline in older people. Tricyclics are on the Beers list; nortriptyline has a substantially lower anticholinergic burden.

7. Infectivity: zoster transmits VZV to non-immune contacts causing chickenpox, not zoster. Localised zoster requires standard precautions with lesions covered; disseminated or immunocompromised zoster requires airborne plus contact precautions.

Examiner's Tip — verbatim lines to write

• "Herpes zoster results from reactivation of latent VZV in the dorsal root ganglia due to **waning VZV-specific cell-mediated immunity**."
• "**Age is the strongest risk factor for postherpetic neuralgia**, which affects over 40% of patients above 60."
• "Antivirals must be started **within 72 hours of rash onset**, with dose reduction if creatinine clearance is below 30 ml/min."
• "**Corticosteroids do not reduce the incidence of postherpetic neuralgia.**"
• "Two doses of the recombinant adjuvanted vaccine are recommended for all adults above 50, regardless of previous chickenpox or previous live vaccine."
• The distinction line for a top answer: "A 2025 *Nature* natural experiment in Wales showed zoster vaccination reduced dementia incidence by about 20%, with a randomised trial, DAN-ZOSTER, now under way."

Q4. *Clostridioides difficile* Colitis

7-mark short note · 10 high-yield points

High-Yield Points

1. **Definition:** antibiotic-associated colitis caused by toxin-producing *Clostridioides difficile*, a spore-forming anaerobic gram-positive bacillus. Disease is mediated by **toxin A (enterotoxin) and toxin B (cytotoxin)**; the hypervirulent **NAP1/BI/027 ribotype** causes more severe disease.
2. **Why the elderly:** age above 65 is an independent risk factor. Contributory factors are **recent antibiotics** (clindamycin, cephalosporins, fluoroquinolones, co-amoxiclav), **proton pump inhibitor use**, hospitalisation or long-term care residence, tube feeding, comorbidity and reduced gut microbiota diversity. Pathy's notes a possible causal relationship between PPI therapy and *C. difficile* infection, and that frail and institutionalised older people have less diverse microbiota.
3. **Clinical features:** watery diarrhoea (three or more unformed stools in 24 hours), lower abdominal cramps, fever, and leucocytosis. In older adults it may present **atypically as delirium, dehydration or unexplained leucocytosis**. Essentials states that if a resident has severe fever, abdominal cramps or diarrhoea with or without blood or leucocytes in stool, **initial evaluation for *C. difficile* should be performed**.
4. **Severe and fulminant disease:** severe disease is defined by **WBC above 15,000 cells/µl or serum creatinine at or above 1.5 mg/dl**. Fulminant disease adds hypotension, shock, ileus or toxic megacolon. **Paradoxical cessation of diarrhoea with abdominal distension signals ileus or toxic megacolon, not improvement.**
5. **Diagnosis:** test only **unformed stool from symptomatic patients**. A two-step algorithm is standard — a sensitive screen (GDH antigen or NAAT/PCR) followed by a specific toxin EIA. **NAAT positivity with toxin negativity may indicate colonisation rather than disease.** Never perform a test of cure. Abdominal CT for suspected megacolon; flexible sigmoidoscopy shows **pseudomembranes**.
6. **First principles of management: stop the inciting antibiotic** wherever possible, **stop the PPI if not clearly indicated**, correct fluid and electrolyte losses, and **avoid antimotility agents such as loperamide** in acute severe disease.
7. **Treatment of an initial episode: fidaxomicin 200 mg twice daily for 10 days** is now first-line; **oral vancomycin 125 mg four times daily for 10 days** is an acceptable alternative. **Metronidazole is no longer preferred** and should be reserved for settings where neither is available.
8. **Fulminant disease: oral vancomycin 500 mg four times daily** (plus vancomycin per rectum if ileus) **with intravenous metronidazole 500 mg 8-hourly**. Early surgical review for subtotal colectomy or diverting loop ileostomy with colonic lavage.
9. **Recurrence:** occurs in **15–25%** after a first episode and rises to 40–60% after subsequent episodes. First recurrence — fidaxomicin (standard or extended-pulsed) or tapered-pulsed vancomycin. Multiple recurrences — tapered-pulsed vancomycin, vancomycin followed by rifaximin, or **faecal microbiota transplantation, reserved for those who have had appropriate antibiotic therapy for at least two recurrences**.
10. **Infection control: contact precautions with gowns and gloves; soap-and-water handwashing because alcohol rub does not kill spores**; single room; sporicidal (chlorine-based) environmental cleaning; dedicated equipment; and antimicrobial stewardship as the single most effective preventive measure.

Latest Updates (2023–Present) — three points

- **Fidaxomicin is firmly first-line.** The **IDSA/SHEA 2021 focused update** and the **ACG 2021 guideline** both place fidaxomicin above vancomycin for initial and recurrent non-fulminant disease, based on lower recurrence: **NNT of 10** to prevent one recurrence at 4 weeks for an initial episode, and **NNT of 7 at 30 days** for recurrent disease. Real-world data (*Open Forum Infectious Diseases*, 2024 and 2025) confirm reduced recurrence, including in immunocompromised hosts, though a 2024 IDSA Emerging Infections Network survey showed uptake is still limited by cost.
- **Bezlotoxumab was discontinued in January 2025** and is no longer available — a change every candidate should know, since older textbooks and guidelines still list it. It had been recommended for those with recurrence in the preceding 6 months, with an FDA warning against use in congestive heart failure.
- **Microbiome therapeutics have replaced conventional FMT in many settings.** Two FDA-approved live biotherapeutics are now in use — **Rebyota (faecal microbiota, live-jslm; rectal)** and **Vowst (faecal microbiota spores, live-brpk; oral)** — for prevention of recurrence after antibiotic treatment. The **AGA 2024 guideline** restricts FMT to adjunctive use after standard-of-care antibiotics, or as a last resort in fulminant disease not responding to therapy. A 2025 Norwegian open-label RCT in *Annals of Internal Medicine* tested FMT enema as **first-line** therapy against vancomycin in primary infection — an area of active investigation, *with wider confirmation awaited.*

Current Practice Update

Aspect	Textbook Position	Current Evidence (2021–2026)
First-line drug	Metronidazole/vancomycin era; specific regimens not detailed	**Fidaxomicin first-line**; vancomycin acceptable alternative; **metronidazole not preferred**

Monoclonal antibody	Not addressed	Bezlotoxumab was recommended 2021–2024 but **discontinued January 2025**
Microbiome therapy	Not addressed	**Rebyota and Vowst** FDA-approved; FMT positioned as adjunct or last resort (AGA 2024)
Diagnostic strategy	"Initial evaluation for *C. difficile* should be performed"	Two-step algorithm mandatory; **test only symptomatic patients with unformed stool**; no test of cure
PPI association	Causal relationship described as "possible"	Association sustained; **PPI deprescribing is now a standard part of treatment**

Indian practical reality

Fidaxomicin is expensive and of limited availability in India. **Oral vancomycin 125 mg QID for 10 days remains the realistic first-line choice** in most Indian hospitals, with metronidazole reserved for where vancomycin is unavailable. Standardised FMT services and licensed live biotherapeutics are not routinely accessible. Say this explicitly — it demonstrates applied judgement rather than recitation.

Examiner's Tip

- "The three cornerstones are **stop the offending antibiotic, stop the PPI, and start targeted therapy**."
- "Severe disease is defined by a **WBC above 15,000/µl or creatinine at or above 1.5 mg/dl**."
- "**Alcohol hand rub does not kill spores** — soap and water handwashing is mandatory."
- "Cessation of diarrhoea with abdominal distension indicates **ileus or toxic megacolon**, not recovery."
- "Fidaxomicin is preferred over vancomycin because of lower recurrence, with a number needed to treat of 10."

Q5. Vaccines / Vaccinations for the Elderly

*15-mark answer · 19 high-yield points · **Recurring topic***

Rationale

1. **Immunosenescence** — thymic hypoplasia with reduced T-cell production and function, reduced mucosal barrier function, and preserved B-cell numbers — means **adaptive immunity is greatly affected while innate immunity is little affected**. This increases both infection and malignancy in the elderly.
2. **Inflammageing** compounds this with an excessive proinflammatory state, and vaccine responses are correspondingly weaker in older than in younger adults, which is why **higher-antigen, adjuvanted and conjugate formulations** have been developed for this age group.
3. Vaccination is **the single most cost-effective preventive intervention in geriatric medicine**, and belongs in every comprehensive geriatric assessment. Pathy's assessment schedule asks directly: "Have you been vaccinated for flu, pneumonia and tetanus?"

Influenza Vaccine

4. **Annually, for patients in all categories** — robust, frail, demented and end-of-life. **More than 90% of deaths attributed to pneumonia and influenza during epidemics occur in people aged 65 and over.**
5. It reduces hospitalisation rates, is cost-effective, and reduces influenza-associated mortality. In the nursing home it is **only about 40% effective at preventing clinical illness but more effective at preventing pneumonia, hospitalisation and death**; **vaccinating more than 80% of residents prevents outbreaks**.
6. Pathy's also records reductions of about **50% in influenza risk and 70% in influenza mortality**, and recommends **adjuvanted vaccine for the institutionalised and chronically ill**, plus **annual vaccination of healthcare personnel, family and regular visitors**.

Pneumococcal Vaccine

7. Although less effective at producing protective antibody in older than younger adults, it still **reduces pneumococcal bacteraemia in high-risk patients**. Textbook position: **one dose of PCV13 followed by PPSV23 one year later after age 65**; if PPSV23 was given first, only PCV13 is needed; no recommendations exist on re-immunisation.
8. Supporting trial evidence quoted in Pathy's: the **CAPiTA** randomised trial in community-dwelling adults over 65 found PCV13 reduced pneumococcal pneumonia by **45%**, and a large Japanese nursing-home randomised trial found PPSV23 markedly reduced pneumonia incidence and mortality.

Herpes Zoster Vaccine

9. Zoster occurs in up to half of individuals aged 85 or older and PHN affects more than 40% of those over 60. **Zostavax (2006) is only 30% protective; Shingrix (2016) is 90% protective.**
10. **ACIP recommends a two-dose Shingrix series for all adults aged 50 and above, regardless of prior chickenpox, and including those who previously received Zostavax.**

Tetanus, Diphtheria and Pertussis

11. **Over half of all tetanus cases occur in people aged 60 or older.** All adults should complete a primary series of Td — 0.5 ml intramuscularly, repeated at 2 and 6 months — if the history is incomplete or uncertain.
12. **Booster every 10 years**, with **at least one booster given as Tdap** to cover pertussis, because pertussis immunity wanes. In tetanus-prone wounds, boost every 5 years.

Other Vaccines and Screening in the Elderly

13. **SARS-CoV-2 vaccination** according to current guidelines. Pathy's records that safe and effective vaccines available since January 2021 reduce severe disease and mortality, and are indicated for adults over 65, healthcare professionals and family contacts.
14. **Hepatitis C:** not a vaccine, but the CDC recommends **one-time anti-HCV antibody testing for all adults born 1945–1965** — up to 85% are asymptomatic and at least 50% have normal liver function tests.
15. **Hepatitis B** for those with diabetes, chronic kidney or liver disease, or on haemodialysis; **travel vaccines** as indicated by destination.

Special Considerations in Long-Term Care

16. **All residents and staff with close resident contact should be vaccinated annually against influenza.** Zoster vaccination once for selected residents; pneumococcal vaccine once; tetanus booster every 10 years, or every 5 years with tetanus-prone wounds.
17. **Outbreak control:** at the onset of a suspected respiratory viral outbreak, obtain nasopharyngeal wash or swab for virus isolation and rapid influenza testing. During a confirmed influenza outbreak, give **oseltamivir or zanamivir within 24–48 hours to residents and staff throughout the outbreak**, vaccinate unvaccinated residents and staff,

restrict visits and movement, suspend group activities, reinforce hand hygiene and mask symptomatic individuals.

18. **Frailty-tailored approach:** Pathy's stratifies preventive care into **robust, frail, moderately demented and end-of-life** categories. Influenza vaccine is given yearly in **all four**; pneumococcal vaccine once, or considered once at end of life; tetanus primary series is not pursued at end of life.
19. **Contraindications and cautions:** live vaccines (Zostavax, MMR, yellow fever) are contraindicated in significant immunosuppression; acute febrile illness defers vaccination; anaphylaxis to a previous dose or component is an absolute contraindication. **Age itself is never a contraindication.**

Latest Updates (2023–Present)

Pneumococcal — the schedule has changed substantially

- **PCV21 (Capvaxive) was FDA-approved in June 2024** and recommended by ACIP as an option wherever PCV is indicated in adults. It covers up to **84–86% of invasive pneumococcal disease** in older adults versus roughly 58–59% for PCV20, but notably **does not cover serotype 4**.
- **In October 2024 ACIP lowered the age for routine pneumococcal conjugate vaccination from 65 to 50 years.**
- Current schedule for a PCV-naive adult aged 50 or above: **a single dose of PCV20 or PCV21 alone**, or **PCV15 followed by PPSV23 at least 1 year later** (minimum 8 weeks if immunocompromised, cochlear implant or CSF leak). **PPSV23 is not required after PCV20 or PCV21.** Conjugate vaccines are preferred because they trigger memory B-cell production and greater long-term immunity. Higher-valency (24- and 31-valent) vaccines are in advanced development.

RSV — an entirely new vaccine category

- Three RSV vaccines are licensed for adults aged 50 and above: **Arexvy (GSK), Abrysvo (Pfizer) and mResvia (Moderna)**, with no stated preference between them.
- CDC recommends **a single dose for all adults aged 75 and above**, and for **adults aged 50–74 at increased risk** — ACIP lowered this risk-based threshold from 60 to 50 years in April 2025. Risk conditions include COPD, asthma, cardiovascular disease, heart failure, diabetes, immunocompromise, frailty, and residence in a long-term care facility.
- **It is currently a one-time dose, not annual**, and is best given in late summer or early autumn. Guillain-Barré syndrome risk with the subunit vaccines was reviewed by ACIP and remains under surveillance.

Zoster

- **Zostavax has been discontinued in the US since 2020** and RZV is the only zoster vaccine in use. Beyond zoster prevention, a 2025 *Nature* natural experiment in Wales showed roughly a **20% reduction in dementia incidence**, replicated in *JAMA* (2025), *Nature Medicine* (2024) and multiple large cohorts. The **DAN-ZOSTER** randomised trial (started 2026, completion 2029) is testing this prospectively. *Results awaited.*

Influenza

- ACIP has since 2022 **preferentially recommended high-dose, adjuvanted or recombinant vaccines for adults aged 65 and above** over standard-dose vaccine.
- **DANFLU-2** (*NEJM*, 2025), the largest individually randomised influenza vaccine trial ever conducted with **332,438 participants**, found high-dose vaccine did **not significantly reduce the primary endpoint** of influenza or pneumonia hospitalisation, but pooled with the harmonised **GALFLU** trial (466,320 randomised in total) showed significant reductions in influenza or pneumonia, cardiorespiratory, laboratory-confirmed influenza and all-cause hospitalisation. See Q6 for detail.

Indian context

- The **API Indian Consensus Guidelines on Adult Immunization** were released in 2024 by the Association of Physicians of India with 13 collaborating societies, and updated in 2026 — the first unified Indian adult schedule, covering influenza, pneumococcal, hepatitis B and herpes zoster with emphasis on the elderly and those with chronic disease. India's population aged 50 and above is projected to reach about 23% within the next decade.
- **Coverage remains the central problem.** A 2024 *Indian Journal of Medical Research* review reports **under 2–3% adult vaccination coverage** for most vaccines. A 2026 *Journal of the Indian Academy of Geriatrics* position statement on vaccination for older adults in India identifies the barriers as **absence of a national adult immunisation schedule, low awareness, cost, accessibility and ageism**, and proposes evidence-based recommendations for those aged 60 and above.
- **India lacks a national adult immunisation programme** equivalent to the paediatric Universal Immunisation Programme. **NPHCE does not currently fund adult vaccines**, so all vaccination is out-of-pocket in the private sector.

Current Practice Update

Vaccine	Textbook Position	Current Recommendation (2024–2026)
Pneumococcal	PCV13 then PPSV23 one year later, from age 65; no re-immunisation guidance	**From age 50**: single dose PCV20 **or PCV21** alone, or PCV15 then PPSV23 ≥1 year later. **PCV13 superseded**
Zoster	Zostavax (30%) or Shingrix (90%), from age 50	**RZV only**; Zostavax withdrawn. Emerging **dementia-prevention signal** (~20%, *Nature* 2025)
Influenza	Annual standard vaccine; adjuvanted for institutionalised/chronically ill	**High-dose, adjuvanted or recombinant preferred for all aged 65+** (ACIP since 2022)

RSV	Not covered	**New category.** Single dose for all aged 75+, and 50–74 if at risk. Not annual
COVID-19	Vaccinate adults over 65 and contacts per current guidance	US policy shifted in 2025 toward **shared clinical decision-making** for older adults
Tetanus/Tdap	Td every 10 years, at least one dose as Tdap	**Unchanged**
Indian schedule	Not addressed	**API Consensus Guidelines 2024** (updated 2026); Indian Academy of Geriatrics position statement 2026; **coverage under 3%**

Extra Points to Remember — recurring topic

1. The four-vaccine minimum for every Indian patient above 60: annual influenza, pneumococcal conjugate, herpes zoster (two doses), and Td/Tdap every 10 years. Add RSV where available and affordable, and COVID-19 per current guidance.

2. Conjugate before polysaccharide, always. Giving PCV first produces a better antibody response to shared serotypes. If PPSV23 was inadvertently given first, give a PCV at least 1 year later.

3. Co-administration is safe. Influenza, pneumococcal, RSV and zoster vaccines may be given at the same visit at separate sites — use every clinical contact, because a missed opportunity in a frail older adult is rarely recovered.

4. The healthcare-worker argument. Vaccinating staff in long-term care reduces respiratory infection and overall mortality among residents even where resident coverage is already high — a strong point to raise in a policy-flavoured question.

5. Vaccine efficacy versus effectiveness. Efficacy falls with age, but **absolute benefit rises** because baseline risk is so much higher. Never use "the vaccine works less well in the elderly" as an argument against vaccinating them.

6. Live vaccines are the ones to be careful with. Zostavax, MMR and yellow fever are contraindicated in significant immunosuppression. Shingrix, being non-live, is safe and is the reason immunocompromised adults can now be protected against zoster.

7. Frailty stratification matters. In the end-of-life category, influenza vaccine is still given yearly for symptom burden, pneumococcal vaccine may be considered, but the tetanus primary series is not initiated. Frame this as goal-concordant care.

8. The Indian policy gap is a ready-made discussion point. India has a world-class paediatric Universal Immunisation Programme but **no national adult immunisation schedule**; NPHCE does not fund adult vaccines; coverage is under 3%. Recommending integration of adult immunisation into NPHCE is a high-scoring closing sentence.

Examiner's Tip — verbatim lines to write

• "Immunosenescence affects **adaptive immunity far more than innate immunity**, which is why conjugate, adjuvanted and high-dose formulations were developed for older adults."
• "More than **90% of pneumonia and influenza deaths during epidemics occur in those aged 65 and over**."
• "Vaccinating more than 80% of nursing home residents prevents influenza outbreaks."
• "ACIP **lowered the age for routine pneumococcal conjugate vaccination from 65 to 50 in October 2024**, and a single dose of PCV20 or PCV21 now suffices without PPSV23."
• "RSV vaccination is a new category — a **single, non-annual dose** for all adults aged 75 and above."
• Close with: "In India the principal barrier is not evidence but implementation — adult vaccination coverage is under 3%, and **integrating adult immunisation into NPHCE** would be the single highest-yield policy intervention."
• Draw a two-column table: **Vaccine | Schedule in the elderly**. It is the fastest way to earn structural marks.

Q6. Influenza Vaccination

7-mark short note · 10 high-yield points

High-Yield Points

1. **Burden:** influenza causes an enormous burden in the elderly. **More than 90% of deaths attributed to pneumonia and influenza during epidemics occur in people aged 65 and over**, and US hospitalisation rates reach **1195 per 100,000 in those over 85**. Global estimates are 291,243–645,832 influenza deaths annually.
2. **Definition of influenza-like illness (WHO):** an acute respiratory infection with onset within the last 10 days, **measured fever of at least 38°C, and cough**. Other viruses causing ILI include RSV, parainfluenza, adenovirus, rhinovirus, human coronaviruses and metapneumovirus; **RSV causes morbidity and mortality similar to influenza** in hospitalised older adults.
3. **Indication and timing: annual vaccination for everyone aged 65 and above**, given in **early autumn** before the season. Pathy's specifies it should be done yearly for patients in **all frailty categories** — robust, frail, moderately demented and end-of-life.
4. **Benefit:** it reduces influenza risk by about **50%** and influenza mortality by about **70%**. In the community, vaccination over 10 seasons was associated with reduced hospitalisation for pneumonia or influenza (**hazard ratio 0.75**) and reduced death (**hazard ratio 0.52**).
5. **Nursing-home specifics:** effectiveness is **only about 40% against clinical illness but higher against pneumonia, hospitalisation and death**, and **vaccinating more than 80% of residents prevents outbreaks**.
6. **Formulations:** the **adjuvanted vaccine** contains a substance that enhances immunogenicity and is **particularly valuable in institutionalised elderly or those weakened by chronic disease** such as diabetes, heart failure or respiratory failure. High-dose and recombinant formulations serve the same purpose of overcoming immunosenescence.
7. **Vaccinate the ring around the patient: annual vaccination of healthcare personnel in long-term care reduces respiratory infection and overall mortality among residents, even where resident coverage is already high**. Employers should offer free easy-access vaccination, and the same protection is logically recommended for regular visitors, family members and volunteers.
8. **Safety:** the vaccine is **well tolerated and rarely causes minor local reactions and systemic reactions**. It is an inactivated vaccine, therefore **safe in immunocompromised older adults**. The only absolute contraindication is anaphylaxis to a previous dose or component; acute febrile illness defers vaccination. **Age is not a contraindication.**
9. **Outbreak management in an institution:** confirm the virus by nasopharyngeal swab; give **neuraminidase inhibitors (oseltamivir preferred, within 24–48 hours) to both cases and contacts** to stop the outbreak; vaccinate unvaccinated residents and staff; restrict visits and movement; suspend group activities; reinforce hand hygiene; mask symptomatic residents and staff. **Oral oseltamivir is preferred over inhaled zanamivir** in elderly patients because administration is easier; reduce the dose if creatinine clearance is below 30 ml/min.
10. **Vaccine remains protective even when breakthrough occurs** — influenza pneumonia can still occur in vaccinated patients, so vaccination status must never be used to exclude the diagnosis.

Latest Updates (2023–Present) — three points

- **Enhanced vaccines are now preferentially recommended.** Since 2022 **ACIP has preferentially recommended high-dose, adjuvanted or recombinant influenza vaccine over standard-dose vaccine for all adults aged 65 and above**. A 2026 test-negative design study in *Open Forum Infectious Diseases* found **comparable effectiveness between adjuvanted and high-dose quadrivalent vaccines**, so either is acceptable — the recommendation is for an enhanced vaccine, not for one specific brand.
- **DANFLU-2 — the definitive trial, with a nuanced result.** Published in *NEJM* (2025), this pragmatic registry-based randomised trial of **332,438 Danish adults aged 65 and above** across three seasons is the largest individually randomised influenza vaccine trial ever conducted. High-dose vaccine **did not significantly reduce the primary endpoint** of hospitalisation for influenza or pneumonia. However, prespecified secondary analyses showed lower cardiorespiratory hospitalisation (2.25% vs 2.38%), driven by cardiovascular hospitalisation (1.30% vs 1.40%), and reduced myocarditis and pericarditis (relative effectiveness 45.7%). Benefit was consistent irrespective of diabetes status (*JAMA Internal Medicine*, 2026) and atrial fibrillation (*JACC*, 2025).
- **Pooled and meta-analytic data favour high-dose.** Pooled with the methodologically harmonised **GALFLU** trial from Galicia, Spain — **466,320 individually randomised older adults in total** — there were significant reductions in hospitalisation for influenza or pneumonia, cardiorespiratory illness, laboratory-confirmed influenza and all causes. A 2026 systematic review and meta-analysis in *JAMA Network Open* of 8 trials and 605,098 participants confirmed **high-dose vaccine reduced hospitalisations for influenza, laboratory-confirmed influenza, pneumonia or influenza, cardiorespiratory disease and all causes** compared with standard dose.

Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Which formulation	Standard vaccine; adjuvanted particularly	**High-dose, adjuvanted or recombinant**

	valuable in institutionalised and chronically ill	**preferentially recommended for all aged 65+** (ACIP since 2022); adjuvanted and high-dose comparable
Strength of evidence for high-dose	Not addressed	DANFLU-2 **neutral on primary endpoint**, but pooled DANFLU-2 + GALFLU (466,320) and 2026 meta-analysis (605,098) **favour high-dose**
Cardiovascular benefit	Not described	Signal for reduced **cardiovascular hospitalisation, myocarditis and pericarditis** — exploratory, from a neutral primary trial
Availability in India	Not addressed	Standard quadrivalent widely available; **high-dose and adjuvanted formulations largely unavailable** — standard-dose annual vaccination remains the practical recommendation

Examiner's Tip

• "More than **90% of pneumonia and influenza deaths during epidemics occur in those aged 65 and over**."
• "In nursing homes the vaccine is only about **40% effective against clinical illness but far more effective against pneumonia, hospitalisation and death**."
• "**Vaccinating over 80% of nursing home residents prevents outbreaks**, and vaccinating staff independently reduces resident mortality."
• The distinction line: "**DANFLU-2**, the largest randomised influenza vaccine trial ever conducted, was neutral on its primary endpoint, but pooled with GALFLU and in 2026 meta-analysis, high-dose vaccine reduced influenza, cardiorespiratory and all-cause hospitalisation."
• Close with the practical point: "In India, where enhanced formulations are largely unavailable, the priority is not which vaccine but **achieving any vaccination at all**, given coverage under 3%."

Rapid Revision Grid

Numbers, criteria and named evidence — the last-hour page

Definitions and Diagnostic Criteria

Entity	Criterion
Classical FUO (Petersdorf/Beeson 1961)	>38.3°C on several occasions, >3 weeks, undiagnosed after 1 week inpatient work-up
FUO (Durack/Street 1991) — current	>38.3°C, >3 weeks, undiagnosed after 3 days inpatient or 3 outpatient visits
IUO	Prolonged raised acute-phase reactants **without** fever
Fever in long-term care (elderly)	Single oral >100°F, **or** repeated oral >99°F, **or** rise >2°F above baseline
WHO influenza-like illness	Acute respiratory infection, onset <10 days, measured fever ≥38°C, and cough
Postherpetic neuralgia	Pain persisting ≥90 days after rash onset
Disseminated zoster	>20 vesicles outside the primary dermatome
Severe *C. difficile* infection	WBC >15,000 cells/µl **or** serum creatinine ≥1.5 mg/dl
Fulminant *C. difficile*	Severe disease plus hypotension, shock, ileus or megacolon
Diarrhoea	≥3 unformed stools in 24 hours
Infection suspicion in LTC	WBC >14,000 cells/mm³ **or** left shift >6%

Key Numbers

Fact	Figure
Fever absent in older adults with serious infection	**30–50%** (>50% in LTC residents)
Fever and cough absent in elderly pneumonia	**30–40%**
Zoster incidence, age >60	**11.8 per 1000 per year** (all ages 1.2–3.4)
Zoster incidence, India (ICMR)	**~3.3 per 1000 per year**; >90% VZV-seropositive by age 40
Lifetime zoster risk by age 85	**Up to 50%**
PHN in those >60 with zoster	**>40%**
Shingrix vs Zostavax efficacy	**90% vs 30%**
Antiviral window in zoster	**72 hours** from rash onset
C. difficile recurrence after first episode	**15–25%** (40–60% thereafter)
Fidaxomicin NNT vs vancomycin (initial episode)	**10** at 4 weeks; **7** at 30 days for recurrence
Influenza deaths in those ≥65 during epidemics	**>90%** of all pneumonia/influenza deaths
Influenza vaccine benefit	**~50%** risk reduction; **~70%** mortality reduction
Influenza vaccine effectiveness in nursing homes	**~40%** against clinical illness; higher against death
Nursing-home coverage preventing outbreaks	**>80%** of residents
PCV21 vs PCV20 IPD serotype coverage in adults	**~84–86% vs ~58–59%**
Indian adult vaccination coverage	**<2–3%** for most vaccines
FDG PET-CT in over-75s with FUO/IUO	Diagnosis in **30.8%**; treatment changed **38.8%**; false positive **15.2%**

Named Trials and Guidelines

Name	What it showed / what it changed
DANFLU-2 (*NEJM* 2025)	332,438 adults ≥65; high-dose vs standard influenza vaccine. **Neutral on primary endpoint** (influenza/pneumonia hospitalisation); secondary reductions in cardiorespiratory and cardiovascular hospitalisation
GALFLU (*NEJM* 2025)	Galicia, Spain; harmonised with DANFLU-2. Pooled total **466,320** randomised — significant reductions in influenza/pneumonia, cardiorespiratory, lab-confirmed influenza and all-cause hospitalisation

DANFLU-1	Pilot trial; post-hoc analyses by frailty score and atrial fibrillation (2025)
CAPiTA	PCV13 in community-dwelling adults >65 reduced pneumococcal pneumonia by **45%**
Shingles Prevention Study (Oxman, *NEJM* 2005)	Original Zostavax trial; incidence of zoster in >60s 11.8/1000/year
Nature 2025 Welsh natural experiment (Eyting et al.)	Herpes zoster vaccination reduced dementia incidence by **~20%** over 7 years — strongest causal evidence
JAMA 2025 (Pomirchy et al.)	Australian natural experiment replicating the dementia finding
Nature Medicine 2024 (Taquet et al.)	RZV vs live vaccine: **17% increase in dementia diagnosis-free time** over 6 years
DAN-ZOSTER	Pragmatic RCT of RZV for MACE and dementia in adults ≥65; started 2026, completion 2029. **Results awaited**
IDSA/SHEA 2021 focused update	Fidaxomicin first-line for initial and recurrent *C. difficile*; metronidazole not preferred
ACG 2021 / AGA 2024	ACG guideline on *C. difficile*; AGA restricts FMT to adjunct or last resort
ACIP October 2024	Routine pneumococcal conjugate vaccination age **lowered from 65 to 50**
ACIP April 2025	RSV vaccination risk-based age **lowered from 60 to 50**
API Indian Consensus Guidelines 2024 (updated 2026)	First unified Indian adult immunisation schedule; 13 collaborating societies
JIAG position statement 2026	Indian Academy of Geriatrics recommendations for vaccination in adults ≥60

Drug Doses to Quote

Indication	Regimen
Herpes zoster — valaciclovir	1 g three times daily × 7 days
Herpes zoster — famciclovir	500 mg three times daily × 7 days
Herpes zoster — aciclovir	800 mg five times daily × 7–10 days (reduce if CrCl <30 ml/min)
Severe/disseminated zoster	IV aciclovir 10 mg/kg 8-hourly
Established PHN	Topical lidocaine patch, gabapentin or pregabalin (FDA-approved); nortriptyline or opioids as alternatives
C. difficile — initial episode	Fidaxomicin 200 mg BD × 10 days, **or** oral vancomycin 125 mg QID × 10 days
C. difficile — fulminant	Oral vancomycin 500 mg QID (+ PR if ileus) **plus** IV metronidazole 500 mg 8-hourly
Influenza outbreak in institution	Oseltamivir within 24–48 h to cases and contacts throughout outbreak; reduce dose if CrCl <30 ml/min
Tetanus primary series (adult)	Td 0.5 ml IM, repeated at 2 and 6 months; booster every 10 years, at least one as Tdap
Zoster vaccine (RZV)	Two doses IM, 2–6 months apart, from age 50
Pneumococcal, PCV-naive adult ≥50	Single PCV20 or PCV21 alone; **or** PCV15 then PPSV23 ≥1 year later

The five statements most likely to earn or lose you marks

1. Fever in the elderly is defined at a lower threshold and against the patient's own baseline — not 38.3°C.
2. Corticosteroids do **not** reduce the incidence of postherpetic neuralgia.
3. Alcohol hand rub does **not** kill *C. difficile* spores.
4. Asymptomatic bacteriuria in older adults should **not** be tested for or treated in the absence of obstructive uropathy.
5. ACIP has lowered **both** pneumococcal (Oct 2024) and risk-based RSV (Apr 2025) vaccination ages to 50 — the schedule you memorised from the textbook is out of date.

Geriatric Pharmacotherapy & Perioperative Medicine

MD Geriatric Medicine — Structured Examination Answers

Five questions • 15-mark and 7-mark formats

Primary sources: *Pathy's Principles and Practice of Geriatric Medicine* (6th ed.) and *Essentials of Clinical Geriatrics* (7th ed.)

Supplemented with evidence and guidelines to 2026

Contents

Q	Topic	Format
1	Principles of drug therapy in the elderly	15 marks (+ Extra points)
2	Rational drug prescribing in older adults	15 marks
3	Polypharmacy — definition and prevention	15 marks (+ Extra points)
4	Drug holiday	7 marks (short note)
5	Perioperative assessment and management in older people	15 marks (+ Extra points)

Each answer follows the same architecture: high-yield numbered points from the textbooks → **Latest Updates (2023–present)** with inline citations → **Current Practice Update** comparison table → **Examiner's Tip**. Recurring topics carry an additional **Extra Points to Remember** panel. A Rapid Revision Grid appears at the end.

Question 1. Principles of drug therapy in the elderly 15 MARKS

A. Why drug therapy is different in old age

1. **Definition of the problem.** Drug therapy in old age is the art of matching a drug to a body whose **handling of and response to drugs has changed**, in a patient who usually has several diseases and takes several drugs at once.
2. **Scale of the problem.** Older people are the largest consumers of drugs. **Adverse drug reactions (ADRs) account for a large share of emergency hospital admissions** in this age group and are largely preventable (Pathy, Ch. 10).
3. **Frail elders are excluded from trials.** Frail older people are rarely included in large drug trials, so results from younger patients are often **wrongly extrapolated** to them (Pathy, Ch. 11).
4. **The therapeutic window narrows with age.** The gap between a therapeutic dose and a toxic dose becomes smaller, so the more aggressive the treatment, the greater the chance of harm (Essentials, Fig. 5-2).
5. **Non-pharmacological factors matter more than pharmacology.** Most of the steps that make drug therapy safe — correct diagnosis, correct choice, correct taking of the drug — come **before** pharmacokinetics ever apply (Essentials, Fig. 14-1).

B. Age-related pharmacokinetic changes (ADME)

6. **Absorption — least affected.** Splanchnic blood flow, absorptive surface and motility fall and gastric pH rises, but **no clinically important change in absorption occurs** unless there is gut disease (e.g. diabetic gastroparesis).
7. **Distribution — protein binding.** Serum albumin falls in illness and malnutrition (a **negative acute-phase reactant**); **highly protein-bound drugs** therefore have a higher free (active) fraction. Reported "therapeutic ranges" were defined in younger subjects and may mislead.
8. **Distribution — volume of distribution (Vd).**
   - ↓ Total body water and lean mass → **↓ Vd for water-soluble drugs** → higher plasma levels, toxicity with **early** doses: *digoxin, aminoglycosides, atenolol, sotalol, theophylline, hydrochlorothiazide, lithium, alcohol.*
   - ↑ Total body fat → **↑ Vd for fat-soluble drugs** → prolonged half-life, toxicity **after steady state**: *amiodarone, diazepam, desipramine, haloperidol.*
9. **Metabolism.** Liver blood flow, enzyme activity and enzyme inducibility all fall. **Phase I reactions (oxidation, reduction, hydrolysis) decline** — more so in men; **Phase II (conjugation, acetylation, glucuronidation) is relatively preserved**. First-pass metabolism is reduced. Normal liver function tests do **not** mean normal drug metabolism.
10. **Excretion — the most predictable change.** Renal blood flow, GFR and tubular secretion all decline. Renally cleared drugs accumulate, with longer half-lives and higher steady-state levels.
11. **Serum creatinine is misleading.** Muscle mass falls with age, so creatinine production falls; **a "normal" creatinine may hide substantially reduced renal function**. Estimate clearance (Cockcroft–Gault / eGFR), but remember there is **wide interindividual variation** — average declines must not be applied blindly to an individual.

C. Pharmacodynamic changes (tissue sensitivity)

12. **Sensitivity may rise or fall.** Receptor number and affinity, second-messenger function and nuclear responses all alter. Older patients are **more sensitive** to benzodiazepines, opioids, anticholinergics and other psychotropics, but **less sensitive** to beta-adrenergic agonists and antagonists.
13. **Reduced homeostatic reserve.** Blunted baroreflex, thermoregulation and thirst mean drugs more readily cause **postural hypotension, falls, hypothermia and dehydration**.

D. Practical prescribing principles

14. **Make the diagnosis first.** Symptoms are under-reported, vague, multiple and often atypical; treating a symptom with a drug instead of evaluating it is the commonest route into polypharmacy.
15. **"Start low and go slow" — but do not under-treat.** Begin with the lowest effective dose of the most cost-effective agent and titrate slowly; still increase to the maximum appropriate dose if the response requires it.
16. **One drug at a time; simplify.** Use as few drugs as possible, prefer **once-daily dosing**, keep all drugs on the same schedule and tie doses to a daily routine.
17. **Treat every new symptom as a possible ADR.** Never treat a symptom with a new drug before considering stopping the offending one — this avoids the **prescribing cascade**.
18. **Consider drug–disease as well as drug–drug interactions** (Essentials, Table 14-4): diuretics → incontinence and dehydration; beta-blockers → masked hypoglycaemia, bronchospasm; anticholinergics → retention, glaucoma, constipation; NSAIDs → heart failure; antipsychotics → worsening parkinsonism.
19. **Support adherence actively.** Barriers include poor vision and hearing, low literacy, memory impairment, transport, cost, and child-proof containers. Use pill boxes and drug calendars, involve family and pharmacists, and **reconcile medicines at every hospital discharge**.

20. **Review, record and prune.** Keep an updated medication record reviewed at each visit; ask patients to bring all bottles ("brown-bag" review); **each time a drug is added, ask whether one can be stopped**. **Never be the first to use a new drug in an older person, and never the last to abandon an old unsafe one.**

Latest Updates (2023–Present)

- **AGS Beers Criteria 2023 update** (*J Am Geriatr Soc*, 2023) reviewed evidence from 2017–2022 and retained the five-table structure. Headline changes: **aspirin for primary prevention** moved to "avoid — consider deprescribing"; **warfarin** to be avoided as initial therapy for VTE/non-valvular AF unless a DOAC is contraindicated; **rivaroxaban** to be avoided for long-term AF/VTE because of bleeding; **low-dose doxepin** removed as a PIM; new caution entries including SGLT2 inhibitors.
- **AGS Beers Alternatives panel** (*J Am Geriatr Soc*, 2025) published, for the first time, a companion list of **safer pharmacological and non-pharmacological alternatives across 21 common conditions** — e.g. CBT-I for insomnia, exercise for Parkinson's disease, dietary measures for constipation and reflux.
- **WHO "Medication Without Harm"**, the Third Global Patient Safety Challenge, continues to name **polypharmacy in older people** as one of its three priority action areas.
- Deprescribing is now regarded as an integral part of prescribing rather than an optional extra (*Annual Review of Medicine*, 2024).

Current Practice Update

Textbook position (Pathy 6th ed. / Essentials 7th ed.)	Current evidence and practice (2023–2026)
Beers Criteria cited as the **2019** version with 88 potentially inappropriate medications.	**2023 AGS update** is current; aspirin for primary prevention and rivaroxaban moved to "avoid"; doxepin at very low dose removed; SGLT2 inhibitors added with caution.
Anticoagulation in older people framed largely around warfarin and INR control.	**DOACs are first-line**; warfarin only where DOACs are contraindicated (Beers 2023). Relevant to Indian practice where INR monitoring access is variable.
Beers criteria do not suggest safer treatment alternatives.	The **2025 Beers Alternatives** document explicitly supplies pharmacological *and* non-pharmacological substitutes.
Creatinine clearance estimated by Cockcroft–Gault or MDRD.	**CKD-EPI 2021 (race-free)** is now the standard eGFR equation; Cockcroft–Gault is still preferred for **drug dosing** of narrow-therapeutic-index agents such as digoxin and DOACs.

Examiner's Tip

Earn marks with these verbatim lines:

- "Absorption is the pharmacological parameter **least affected** by ageing; **renal excretion is the most predictable change**."
- "A normal serum creatinine in an older person does **not** mean normal renal function, because creatinine production falls with declining muscle mass."
- "Phase I metabolism declines with age; **Phase II conjugation is relatively preserved** — hence lorazepam, oxazepam and temazepam are preferred benzodiazepines."
- "Consider **every new symptom in an older patient as a possible adverse drug reaction** until proved otherwise."
- Close with the aphorism: "*Never be the first to use a new drug in an older person, and never the last to abandon an old, unsafe one.*"

Extra Points to Remember (recurring topic)

- **Water-soluble vs fat-soluble mnemonic:** water-soluble drugs cause **early** toxicity (high peak level); fat-soluble drugs cause **late** toxicity (accumulation at steady state).
- **Indian context:** free over-the-counter availability of NSAIDs, benzodiazepines and antibiotics; concurrent AYUSH and traditional preparations; multiple prescribers without a shared record; and out-of-pocket cost driving intermittent dosing. A "brown-bag" review at every visit is even more valuable here. There is no validated India-specific PIM list in routine use, so **Beers and STOPP/START are applied with local adaptation**.
- **Drugs needing dose reduction by renal function:** digoxin, metformin, DOACs, aminoglycosides, gabapentin/pregabalin, allopurinol, sulphonylureas (glibenclamide should be avoided altogether).
- **Anticholinergic burden** is measured by the **Drug Burden Index** or the Anticholinergic Cognitive Burden scale; a high burden predicts functional decline and falls.
- **Time-to-benefit** is an essential concept: a preventive drug whose benefit takes 3–5 years to appear is inappropriate for a patient whose life expectancy is shorter.

Question 2. Rational drug prescribing in older adults 15 MARKS

A. Concept and definition

1. **Definition.** Rational prescribing means giving the **right drug, in the right dose, by the right route, for the right duration, to the right patient, at the lowest cost**, with an explicit indication and a plan for review.
2. **Two errors, not one.** Inappropriate prescribing includes both **over-prescribing / mis-prescribing** (potentially inappropriate medications, PIMs) and **under-prescribing** (potential prescribing omissions, PPOs). Withholding a beneficial drug purely because of age is a form of **ageism**.
3. **Why it matters.** Inappropriate prescribing is associated with ADRs, falls, frailty, disability, hospitalisation and mortality, and should be assessed at **every single medical encounter** (Pathy, Ch. 10, Key Points).

B. The prescribing sequence

4. **Step 1 — Confirm the diagnosis.** Atypical presentation and symptom overlap make this the commonest failure point; treating an undiagnosed symptom is irrational by definition.
5. **Step 2 — Define the therapeutic goal with the patient.** Ask what matters to them. Frail elders commonly prioritise **function, cognition, independence and relief of suffering** over length of life.
6. **Step 3 — Try non-pharmacological treatment first** where evidence supports it (exercise, physiotherapy, sleep hygiene and CBT-I, dietary measures, compression stockings, continence training).
7. **Step 4 — Select the drug.** Before writing, ask:
   - **Efficacy** — will this make a real difference, and what is the evidence in *this* age group?
   - **Cost** — is there an equally effective cheaper option?
   - **Timing** — can a once-daily regimen be used?
   - **Dose** — what is the lowest effective dose here?
   - **Side effects** — how well will this person tolerate it?
   - **Interactions** — any drug–drug or drug–disease contraindication?
8. **Step 5 — Prescribe, educate, document**: one drug at a time, written instructions in large print, explanation to patient and caregiver, and an entry in an updated medication record.
9. **Step 6 — Monitor and review.** Set a review date and an explicit stopping rule; assess both efficacy and toxicity; **periodically deprescribe**.

C. Explicit and implicit prescribing tools (Pathy, Table 10.3)

Tool	Origin	What it does	Main limitation
Beers Criteria	USA, 1991; AGS steward since 2011	Explicit list of PIMs in 5 categories: PIMs in all older adults; PIMs with specific diseases; drugs to use with caution; harmful drug–drug combinations; renal dosing. Plus a table of strongly anticholinergic drugs.	Does not address **under-prescribing**; US-centric formulary; not for hospice/end-of-life care
STOPP / START	Europe, 2008	Organ-system based. **STOPP** = PIMs, **START** = prescribing omissions. Designed to be used together.	Needs fuller medical history; suggests no safer alternatives
Medication Appropriateness Index (MAI)	USA, 1992	10 implicit questions per drug (indication, effectiveness, dose, directions, practicality, drug–drug and drug–disease interaction, duplication, duration, cost); scored A/B/C, max 18.	~10 min per drug; needs expertise; does not prioritise which drug to stop
Pill Pruner	New Zealand, 2009	Pocket card of 13 commonly prescribed drug groups based on STOPP; reduces discharge medication counts, sustained at 90 days	Studied only in hospitalised patients ≥75; no tapering guidance
Drug Burden Index (DBI)	2007	Measures cumulative **anticholinergic and sedative** exposure; high DBI predicts functional decline and falls	Covers only two drug classes
TRIM	US VA, 2016	EHR-based algorithm using Beers + STOPP to flag PIMs and generate clinician feedback	Validated only in the US VA system
FORTA	Germany, 2008	First tool to give **positive and negative labels** together (A–D classification)	Requires clinical judgement of indication

D. Aids to memory in daily practice (Pathy, Table 10.4)

10. **SAIL:** keep it **S**imple — know **A**dverse effects — identify the **I**ndication — **L**ist every drug and dose.

TIDE: allot **T**ime at each visit for medicines — **I**ndividual response — avoid **D**rug/drug and drug/disease interactions — **E**ducate the patient.

11. **ARMOR: A**ssess → **R**eview pharmacokinetics/pharmacodynamics → **M**inimise → **O**ptimise doses → **R**eassess. Focused on function and quality of life; useful in post-acute and long-term care.
12. **ERASE: E**valuate diagnoses by considering **R**esolved conditions, **A**geing normally, and **S**electing appropriate targets, to **E**liminate unnecessary diagnoses — i.e. **"un-diagnosing to prevent over-prescribing"**.
13. **AVOID TOO MANY:** Alternatives, Vague symptoms, OTC drugs, Interactions, Duration, Therapeutic vs preventive, Once daily, Other doctors, Money, Adverse effects, Needs still?, Yes/no — is the patient actually taking it?

E. Barriers and system measures

14. **Treatment burden** — the effort the patient must expend to follow the regimen — is reduced by shared decision-making and by involving pharmacists, nurses and social workers.
15. **Prescribing inertia** (continuing a drug simply because it is on the list) and **multiple prescribers** are the two commonest system failures; medication reconciliation at every transition of care is the antidote.

Latest Updates (2023–Present)

- **STOPP/START version 3** (*European Geriatric Medicine*, 2023) is the current version: **190 criteria — 133 STOPP and 57 START**, a 66.7% increase over version 2's 114 criteria. Validated by an 11-member Delphi panel from 8 European countries. Criteria are now presented **by drug class rather than individual drug name** to improve international applicability. Roughly 41% of STOPP.v3 and 42% of START.v3 criteria are new.
- **AGS Beers Criteria 2023** remains the current US standard (see Q1 for key changes), with the **2025 Alternatives** companion supplying safer substitutes.
- **Trial evidence is mixed on hard outcomes.** Single-centre trials of STOPP/START showed reduced polypharmacy, ADRs, falls and cost; but the large multicentre **SENATOR**, **OPERAM** and **OPTICA** trials did not show significant reductions in ADRs, mortality, drug-related readmissions or quality of life (*Expert Review of Clinical Pharmacology*, 2023).
- **Usability work** has produced a validated 3-page single-entry table of STOPP/START v3 for bedside use (*European Geriatric Medicine*, 2025), addressing the criticism that 190 criteria are impractical in a busy clinic.
- **STOPPFrail** remains the tool of choice for frail patients with limited life expectancy, where standard criteria are inappropriate.

Current Practice Update

Textbook position	Current evidence and practice (2023–2026)
STOPP/START **version 2 (2015)**, 114 criteria (80 STOPP + 34 START).	**Version 3 (2023)**: **190 criteria (133 + 57)**, class-based rather than drug-based, with expanded cardiovascular, diabetes and COPD sections.
STOPP/START application within 72 hours of admission reduces ADRs by ~9% and length of stay by ~3 days.	These **single-centre findings were not replicated** in SENATOR, OPERAM or OPTICA. Present the tools as improving **prescribing quality**, with hard clinical endpoints still unproven.
Beers criteria give no alternatives.	**2025 AGS Alternatives** list now covers 21 conditions and emphasises non-pharmacological options.
Tools presented as broadly interchangeable.	Current practice is **tool-plus-judgement**: an explicit tool (Beers/STOPP) to screen, an implicit tool (MAI) to judge, and a patient-centred goals discussion to decide.

Examiner's Tip

- Open with the two-sided definition: "*Rational prescribing corrects both over-prescribing and under-prescribing — STOPP addresses the first, START the second.*"
- Quote the current numbers: **"STOPP/START version 3 (2023) contains 190 criteria — 133 STOPP and 57 START."**
- Name at least **four tools with their country and year**; this single sentence often separates a distinction answer.
- Add the honest caveat: "*These tools reliably improve prescribing quality; large multicentre trials have not yet shown a mortality benefit.*"
- Always mention **time-to-benefit** and **life expectancy** as determinants of rationality.

Question 3. What is polypharmacy and how would you prevent it? 15 MARKS

A. Definition

1. **No single agreed definition.** Polypharmacy has been defined in about **24 different ways**, which has made it hard to measure and to compare studies (Pathy, Ch. 10).
2. **Numerical definition.** The most widely used cut-off is **the concurrent use of five or more medications**; **hyperpolypharmacy** is ten or more. The five-drug threshold identifies community-dwelling older men at risk of adverse outcomes.
3. **Qualitative (and more accurate) definition.** The most precise definition is **"the use of multiple medications, and more than are medically necessary"**. This allows the essential distinction between **appropriate polypharmacy** (many drugs, all indicated, e.g. in heart failure) and **inappropriate polypharmacy**.
4. **Regulatory definition.** The **Omnibus Budget Reconciliation Act (OBRA) 1987** in the USA first brought polypharmacy in nursing homes under regulatory scrutiny.

B. Epidemiology

5. **Rising everywhere.** In Scotland, use of ≥5 drugs rose from ~11% to 20% between 1995 and 2010, and ≥10 drugs from ~1.5% to almost 6%; by 2010, **13% of older patients were exposed to a potentially serious drug interaction**.
6. **Comparable trends elsewhere:** Sweden 18% → 42% (1992–2002); Italy 43% → 53% (2000–2010).
7. **Indian context.** Polypharmacy in India is driven by multimorbidity in a rapidly ageing population (LASI), fragmented care across multiple prescribers, unrestricted OTC sales, concurrent AYUSH and home remedies, and the absence of a shared electronic medication record. **NPHCE** geriatric clinics are the logical place to embed structured medication review.

C. Causes

8. **Patient factors:** multimorbidity, chronic disease, under-reporting of symptoms, expectation of a prescription, OTC and supplement use.
9. **Prescriber factors:** treating symptoms rather than evaluating them, single-disease guideline adherence in a multimorbid patient, prescribing inertia, and failure to review.
10. **System factors:** multiple doctors each prescribing without a complete list, transitions of care, direct-to-consumer advertising, and pressure from patients or families.
11. **The prescribing cascade** — an ADR is misread as a new disease and treated with another drug — is the single most important self-perpetuating mechanism.

D. Consequences

12. **Clinical:** ADRs, drug–drug and drug–disease interactions (notably **CYP450-mediated**), **falls**, **frailty**, disability, cognitive impairment and delirium, malnutrition, urinary incontinence, sarcopenia and **increased mortality**.
13. **Practical:** reduced adherence, greater treatment burden, higher cost, more hospital admissions and readmissions, and more medication errors — the incidence of medication error in UK nursing home residents has been reported as high as **69.5%** (Pathy, Ch. 11).

E. Prevention — a stepwise approach

14. **Prevent at the point of prescribing.** Apply the rational prescribing sequence (Q2): correct diagnosis → non-drug options first → lowest effective dose → explicit review date. **Each time a drug is added, consider whether one can be stopped.**
15. **Obtain an accurate, complete medication list.** "Brown-bag" review at first assessment; include OTC, herbal and traditional preparations; maintain and update the record at every visit; **reconcile medicines at admission, transfer and discharge**.
16. **Screen with a validated tool** — Beers, STOPP/START, MAI, Pill Pruner, DBI or FORTA. Be proficient in at least one.
17. **Deprescribe systematically.** Deprescribing is **"a patient-centred, systematic optimisation of a person's medication list through the reduction, tapering or stopping of medications that are not indicated or are causing real or potential harm"** (Scott et al.).
    - **Scott's five-step protocol:** (i) compile a complete, accurate medication list; (ii) assess overall risk of drug-induced harm; (iii) determine each drug's discontinuation potential; (iv) prioritise drugs for discontinuation; (v) establish a monitoring plan.
    - **Barnett's seven steps** begin with the patient's needs and goals and end with a long-term communication and monitoring plan.
    - The **Deprescribing Rainbow** places the patient at the centre and considers clinical, psychological, social, financial

and physical determinants.

18. **Taper, do not stop abruptly**, for benzodiazepines, opioids, SSRIs, beta-blockers, corticosteroids, levodopa and antiepileptics — abrupt withdrawal causes **adverse drug withdrawal events**.
19. **Avoid under-prescribing at the same time.** Use START criteria so that deprescribing does not become age-based rationing; apply ERASE to remove unnecessary diagnoses.
20. **Work as a team and educate.** Clinical pharmacists, nurses, family caregivers and structured patient education are the interventions most consistently shown to work. Documented benefits of systematic deprescribing include **fewer falls, improved cognitive and psychomotor function, reduced mortality and reduced healthcare utilisation, without an increase in adverse outcomes**.

Latest Updates (2023–Present)

- **Deprescribing is safe and effective at reducing drug counts, but benefit on hard endpoints is unproven.** A meta-analysis of 32 RCTs including 18,670 patients aged ≥60 confirmed reductions in PIMs (*JAMDA*, 2023). An updated systematic review of 259 studies found **no significant reduction in mortality** from deprescribing polypharmacy (*British Journal of Clinical Pharmacology*, 2024).
- **Long-term care evidence.** A meta-analysis of 38 studies (22 RCTs) in long-term care facilities showed sustained reductions in the number of drugs per resident and in PIMs at ≥12 months (*Age and Ageing*, 2026).
- **Pharmacist-led review works for medication outcomes but not quality of life.** A cluster-randomised trial in patients ≥75 with hyperpolypharmacy found significantly more medications stopped or reduced with a deprescribing-focused clinical medication review (2.5 vs 1.7 per patient), but **no change in health problems or health-related quality of life at 6 months** (*Age and Ageing*, 2026).
- **Polypharmacy and sarcopenia.** A 2023 systematic review and meta-analysis confirmed an association between polypharmacy and sarcopenia, possibly mediated by malnutrition — strengthening the case for medication review as part of sarcopenia management.
- **Structural change.** WHO's **Medication Without Harm** challenge explicitly targets polypharmacy, and deprescribing is now embedded in national quality frameworks in several countries.

Current Practice Update

Textbook position	Current evidence and practice (2023–2026)
Systematic deprescribing is associated with **reduced mortality** and reduced healthcare utilisation.	Larger and more recent syntheses are **more cautious**: deprescribing reliably reduces drug counts and PIMs and is **safe**, but a 2024 review of 259 studies found **no significant mortality benefit**. Present it as safe and quality-improving rather than life-prolonging.
Screening tools quoted at 2015/2019 versions.	**STOPP/START v3 (2023)** and **Beers 2023** with the **2025 Alternatives** list are current.
Emphasis is on identifying and stopping inappropriate drugs.	Equal emphasis now on **implementation** — who does the review, how often, and how changes are communicated across transitions. Pharmacist-integrated workflows and patient activation are the components most associated with success.
Quality of life expected to improve after deprescribing.	Repeated trials show **no measurable change in HRQoL** at 6–12 months; existing QoL instruments may simply be insensitive to medication burden.

Examiner's Tip

- Never give only the numerical definition. Say: "*Polypharmacy has been defined in about 24 ways; the commonest numerical cut-off is five or more drugs, but the most precise definition is the use of more medications than are medically necessary.*"
- Make the **appropriate vs inappropriate polypharmacy** distinction explicitly — examiners look for it.
- Reproduce the **Scott five-step deprescribing protocol** as a numbered list; it is the single highest-yield block in this answer.
- Name the **prescribing cascade** and give one example (e.g. metoclopramide → parkinsonism → levodopa).
- Finish with the balanced current position: "*Deprescribing is safe and reduces inappropriate medication use; a mortality benefit has not been demonstrated.*"

Extra Points to Remember (recurring topic)

- **Classic prescribing cascades to quote:** metoclopramide/prochlorperazine → drug-induced parkinsonism → levodopa; amlodipine → ankle oedema → furosemide; NSAID → hypertension → antihypertensive; cholinesterase inhibitor → urinary urgency → oxybutynin (which then worsens cognition).
- **Fall-risk-increasing drugs (FRIDs):** benzodiazepines, Z-drugs, antipsychotics, antidepressants, antihypertensives, alpha-blockers, anticholinergics, opioids, antiepileptics. Withdrawal of psychotropics reduces falls requiring treatment.
- **Highest-risk drug classes in hospital** (Pathy, Ch. 11): **anticoagulants, opiates and centrally acting drugs**. Remember that **oxygen and intravenous fluids are drugs too** and are frequently given without the same caution.
- **Illustrative textbook vignette:** the 88-year-old woman on 21 medications whose regimen was reduced to 9 — she remained living independently with improved function and no further falls at 6 months.
- **A quotable image:** Pathy contrasts the "cornucopia" of plenty with the **Chimera** — polypharmacy looks like abundance but is a dangerous hybrid.

Question 4. Drug holiday 7 MARKS — SHORT NOTE

High-yield points

1. **Definition.** A drug holiday is a **planned, temporary, supervised interruption of a drug in a patient who is expected to resume it**, undertaken for a defined purpose and with a defined monitoring plan.
2. **Distinguish it from three other things.** It is **not** deprescribing (which is intended to be permanent), **not** non-adherence (which is unplanned), and **not** a dose reduction (the drug is stopped completely for a period).
3. **Purposes.** (i) To reduce cumulative toxicity from long-term exposure; (ii) to **test whether the drug is still needed**; (iii) to unmask an adverse effect wrongly attributed to disease; (iv) to allow recovery of receptor sensitivity or tolerance; (v) to permit a procedure or investigation.
4. **The principal current indication is the bisphosphonate drug holiday.** Bisphosphonates are retained in bone with a long terminal half-life, so anti-fracture protection persists after stopping, while the rare harms of prolonged use — **atypical femoral fracture (AFF)** and **osteonecrosis of the jaw (ONJ)** — are exposure-dependent.
5. **Practical bisphosphonate rule.** Reassess fracture risk after **5 years of oral** or **3 years of intravenous** therapy. If risk is low to moderate (no prior hip/vertebral fracture, hip T-score better than −2.5), offer a holiday of about **2–3 years**. If risk remains high, continue to **10 years oral / 6 years intravenous**. Restart if BMD falls significantly, bone turnover markers rise, or a fracture occurs.
6. **Critical exception — denosumab.** A drug holiday must **never** be taken with denosumab: cessation causes **rebound bone loss with multiple vertebral fractures**. Denosumab must always be followed by a bisphosphonate or another antiresorptive.
7. **Other situations where the term is used.** Gradual dose reduction and trial withdrawal of **antipsychotics in dementia** and of **benzodiazepines/hypnotics**; brief withdrawal of a **statin** to test whether myalgia is drug-related; periprocedural interruption of anticoagulants and antiplatelets; and short interruptions of some immunosuppressants and stimulants.
8. **An abandoned practice worth knowing.** The **levodopa drug holiday** in Parkinson's disease, once used to restore responsiveness, is now **contraindicated** because abrupt withdrawal precipitates a neuroleptic-malignant-like syndrome, aspiration, deep vein thrombosis and death.
9. **Risks of any drug holiday:** relapse of the treated disease, drug withdrawal syndromes, patient confusion about whether to restart, and being lost to follow-up so that the "holiday" silently becomes permanent.
10. **Good practice.** Document the **indication, the planned duration, the monitoring plan and the criteria for restarting** in the notes and in the patient's own record; agree it with the patient and family; and set a review appointment before the holiday begins.

Latest Updates (2023–Present) — three points

- **Duration is drug-specific, not one-size-fits-all.** The offset of effect differs between agents: alendronate has the longest residual protection, **risedronate the shortest** (holiday of ~1–2 years, with reassessment before 2 years), and zoledronic acid an intermediate 3–5 years. A large Ontario cohort found a higher hip fracture risk after 2 years off risedronate than off alendronate (*Annals of Internal Medicine*).
- **Individualisation is now the stated standard.** Commentaries and reviews (*J Clin Endocrinol Metab*, 2024–2025; *Current Osteoporosis Reports*, 2025–2026) conclude that holiday duration must be modified by total prior bisphosphonate exposure, agent used, hip BMD, falls risk, sex and body weight — **"one size does not fit all"**. AFF risk falls rapidly (~72% per year) after stopping.
- **Very old and very-high-risk patients are increasingly advised not to take a holiday at all,** because absolute hip fracture risk far exceeds the very low AFF risk (AFF accounts for fewer than 5 per 1000 hip fractures). ACP's living guideline and ACOG (2023) accept a holiday of 2–4 years but only after risk reassessment.

Current Practice Update

Textbook position (Essentials 7th ed.)	Current evidence and practice (2023-2026)
"The ultimate duration of bisphosphonate therapy is still not established... for many patients 3 to 5 years of treatment may suffice, but those at highest risk (including older patients) may benefit from longer treatment."	This remains directionally correct but is now operationalised: **formal reassessment at 5 years oral / 3 years IV**, holiday only for low-to-moderate risk, continuation to **10 years oral / 6 years IV** in high risk, with explicit restart criteria.
Drug withdrawal is discussed generically under deprescribing and tapering, without a structured "drug holiday" framework.	The drug holiday is now a **distinct, protocolised concept** with defined duration and restart rules, most fully developed for bisphosphonates and applied cautiously to antipsychotics and hypnotics.
Denosumab discussed as an antiresorptive option without a stopping rule.	**Absolute contraindication to a holiday** — rebound vertebral fracture risk mandates sequential antiresorptive therapy after stopping.

Examiner's Tip

- Open with the one-line definition and immediately separate it from deprescribing — **"planned and temporary, with the intention to resume."**
- State the numbers: **"5 years oral, 3 years intravenous, then reassess; holiday 2–3 years in low risk; continue to 10 years oral / 6 years IV in high risk."**
- Never omit: "*A drug holiday is contraindicated with denosumab because of rebound vertebral fractures.*"
- Mention the **levodopa drug holiday as an abandoned and dangerous practice** — this shows historical depth and is a common viva follow-up.

Question 5. Perioperative assessment and management in older people 15 MARKS

A. Principles and risk

1. **Age alone is not a contraindication.** Patients over 70 have higher rates of major perioperative complications and mortality after major non-cardiac surgery, but **mortality remains low even beyond 80**. Outcome is determined far more by **the presence and severity of systemic illness and whether surgery is elective or emergency** than by chronological age (Essentials, Table 3-18).
2. **Emergency surgery carries a much higher risk** than the same elective operation; wherever possible, convert an emergency into a semi-elective, optimised procedure.
3. **The first question is not "can he survive it?" but "should it be done?"** The appropriateness and risk–benefit ratio of the proposed operation must be considered explicitly, in the light of the patient's goals and life expectancy.

B. Preoperative assessment — systematic evaluation

4. **Optimise underlying conditions before non-emergency surgery** (Essentials, Table 3-18): cardiovascular disease especially **heart failure**; pulmonary status; renal function; **diabetes mellitus**; **thyroid disease, which is often occult**; anaemia; nutrition; and hydration/volume status, particularly in patients on diuretics.
5. **Identify high-risk cardiac conditions.** Substantially increased risk is conferred by **myocardial infarction within 6 months, pulmonary oedema, angina (especially unstable) and severe aortic stenosis**.
6. **Estimate cardiac risk formally.** Factors predicting perioperative cardiac complications in non-cardiac surgery are **ischaemic heart disease, congestive heart failure, diabetes mellitus, cerebrovascular disease and renal insufficiency** (Revised Cardiac Risk Index, Lee et al.).
7. **Assess functional capacity.** Exercise tolerance is more informative than laboratory testing — classically, **the ability to climb one flight of stairs**.
8. **Investigate selectively.** Order tests only if the result will change management. **Preoperative pulmonary function tests and arterial blood gases are rarely of prognostic value**; reserve them for respiratory symptoms, obesity, chest deformity (kyphoscoliosis), abnormal chest radiograph, or planned thoracic/upper abdominal surgery. Measure creatinine clearance where renal function is borderline or nephrotoxic/renally excreted drugs are used.
9. **Assess frailty — the geriatric addition to standard risk scoring.** Frailty (unintentional weight loss, weak grip, exhaustion, low physical activity, slow gait) **independently predicts postoperative complications, length of stay and discharge to a care facility** (Makary et al.). Frailty confers a **two- to fourfold increase in operative mortality** in cardiac surgery (Pathy, Ch. 35), and markers include Katz ADL ≤4/6, 5-metre walk ≥6 s, 6-minute walk <150 m, and Timed Up-and-Go ≥15 s.
10. **Predict 6-month mortality.** Preoperative **impaired cognition, recent falls, low albumin, greater anaemia, functional dependence and increased comorbidity** are associated with higher mortality at 6 months (Robinson et al.).
11. **Predict delirium.** Four independent preoperative predictors: **prior stroke or TIA, low MMSE score, abnormal serum albumin, and a high Geriatric Depression Scale score** (Rudolph et al.).
12. **Perform a comprehensive geriatric assessment** where time allows: medication review, functional assessment, cognition, nutrition, social and caregiver support, and **discussion of advance directives** before the patient goes to theatre.

C. Perioperative medical management

13. **Plan the medication regimen deliberately.** Some drugs must be continued, some withheld, and some dose-adjusted. Review against Beers/STOPP; inappropriate medication use in older surgical patients is common.
14. **Prophylaxis.** Give **venous thromboembolism prophylaxis** and **appropriate antimicrobial prophylaxis** according to procedure-specific protocols.
15. **Beta-blockade (textbook position).** Patients at high or intermediate cardiac risk with negative non-invasive tests should receive perioperative beta-blockade; those at low risk need none; positive non-invasive tests should prompt consideration of revascularisation. *See the Current Practice Update — this position has changed.*
16. **Revascularisation is not a licence for surgery.** Coronary artery bypass grafting or PCI should be limited to patients with an indication **independent of the need for non-cardiac surgery**.
17. **Anaesthetic technique should be individualised.** Regional anaesthesia is often favoured, but may require supplementary sedation and can itself cause significant cardiovascular change; **neither DVT incidence nor blood loss is substantially reduced** compared with general anaesthesia. Decide on patient factors, the procedure and the surgical team's preference.
18. **Postoperative care is geriatric care.** Prevent delirium (orientation, sensory aids, sleep hygiene, hydration, early mobilisation, avoid restraints and unnecessary catheters), give adequate analgesia, avoid bed rest, attend to nutrition and bowels, and start rehabilitation early. Functional decline in hospital may be irreversible — **one-third of older**

inpatients lose at least one ADL by discharge.

Latest Updates (2023–Present)

- **2024 AHA/ACC multisociety perioperative guideline for non-cardiac surgery** (*JACC / Circulation*, 2024) supersedes the 2014 guideline. It sets out a **stepwise algorithm**, urges **judicious and targeted** preoperative testing, and formalises functional assessment using **METs and the Duke Activity Status Index**. Key recommendations: **continue statins** perioperatively (Class 1) and initiate them in statin-eligible patients; **delay elective surgery for at least 3 months after stroke or TIA**; screen for **obstructive sleep apnoea** with validated questionnaires; use **emergency-focused cardiac ultrasound** for unexplained haemodynamic instability; and it names **myocardial injury after non-cardiac surgery (MINS)** as a distinct entity that must not be ignored.
- **New drug-class guidance. SGLT2 inhibitors should be stopped 3–4 days before surgery** to prevent euglycaemic ketoacidosis (2024 AHA/ACC). For **GLP-1 receptor agonists**, the 2024 multisociety guidance (ASA/AGA/ASMBS/ISPCOP/SAGES) advises that **most patients may continue the drug**, with a **24-hour clear liquid diet** before the procedure for those at higher risk of delayed gastric emptying (dose-escalation phase, high dose, GI symptoms, gastroparesis, Parkinson's disease) — replacing the earlier ASA 2023 advice to withhold weekly agents for 7 days.
- **ESAIC 2025 preoperative assessment guideline** (*Eur J Anaesthesiol*, 2025) **recommends frailty testing as an effective predictor of postoperative outcomes, particularly delirium (Grade 1C)**, and specifically the **Clinical Frailty Scale** when the examination suggests a frailty phenotype.
- **ESAIC 2024 postoperative delirium guideline** (*Eur J Anaesthesiol*, 2024): 13 recommendations, 5 of them strong — assess preoperative POD risk factors, optimise the preoperative condition, discuss prevention strategies, deliver a **non-pharmacological multicomponent intervention** in at-risk patients, and weigh risk/benefit before prophylactic dexmedetomidine. It mandates **screening in all patients ≥60 years**, delirium assessment with a validated tool **daily for at least 3 days starting in recovery**, and **EEG-based depth-of-anaesthesia monitoring**. Routine haloperidol prophylaxis, cholinesterase inhibitors and biomarker screening are **not** recommended; haloperidol is reserved for treatment when non-pharmacological measures fail.
- **2025 ASA Practice Advisory for perioperative care of older adults scheduled for inpatient surgery** (*Anesthesiology*, 2025) recommends **expanded preoperative evaluation** with cognitive and frailty screening, and states that **neither neuraxial nor general anaesthesia is superior for preventing postoperative delirium** — the choice should be by shared decision-making, and either TIVA or inhalational anaesthesia is acceptable.
- **Multicomponent prevention works.** A meta-analysis of 11 RCTs (3857 patients) found multicomponent interventions reduced postoperative delirium in older adults undergoing elective surgery by **29% (RR 0.71, 95% CI 0.59–0.85)** (2026). A network meta-analysis of drug interventions to prevent delirium after surgery in adults over 60 was published in the *BMJ* (2026).
- **Newly identified modifiable risk factors:** intraoperative hypotension, and **residual neuromuscular blockade** — the delirium risk associated with non-depolarising neuromuscular blockers disappeared when blockade was properly reversed with neostigmine or sugammadex (*Anesthesia & Analgesia*, 2025).
- **Prehabilitation** — structured preoperative exercise, nutritional supplementation, anaemia correction, smoking and alcohol cessation, and medication optimisation — is now an explicit part of the pathway wherever the interval before surgery permits.

Current Practice Update

Textbook position	Current evidence and practice (2023–2026)
Perioperative beta-blockade should be started in high- and intermediate-risk patients with negative non-invasive tests (Auerbach & Goldman, 2002).	**Substantially revised.** Since POISE, beta-blockers are **continued** in patients already taking them but **not started within 1 day of surgery** because of excess stroke, hypotension and death. Statins have replaced beta-blockers as the Class 1 perioperative drug recommendation.
Risk assessment based on comorbidity indices (RCRI) and exercise tolerance.	RCRI retained, but supplemented by **formal frailty testing (ESAIC 2025, Grade 1C)**, cognitive screening, and structured functional assessment (METs/DASI). **Frailty is now a mandated domain, not an optional extra.**
Perioperative delirium noted as an area of "growing awareness" with four predictors.	A fully protocolised field: **ESAIC 2024** and **ASA 2025** mandate screening ≥60 years, daily validated assessment for 3 days, multicomponent non-pharmacological bundles, and EEG-guided anaesthetic depth.
Regional anaesthesia "often favoured" but with stated disadvantages; decision individualised.	Confirmed and strengthened by trial data: **no superiority of neuraxial over general anaesthesia** for preventing delirium (ASA 2025). Individualisation remains correct.
Medication management described generally as continue / withhold / adjust.	Now drug-class specific: **continue statins and beta-blockers already prescribed; stop SGLT2 inhibitors 3–4 days before; in most cases continue GLP-1 agonists with a 24-hour clear liquid diet in higher-risk patients.**
Preoperative optimisation described as correcting individual organ deficits.	Reframed as **prehabilitation** — a bundled programme of exercise, nutrition, anaemia correction, glycaemic control, and deprescribing delivered in the weeks before surgery.

Examiner's Tip

- Open with the governing principle: "*Age above 70 increases risk, but comorbid conditions — especially cardiovascular — and emergency status are more important risk factors than age per se.*"
- Name the **four high-risk cardiac conditions** as a block: MI within 6 months, pulmonary oedema, unstable angina, severe aortic stenosis.
- Say clearly: **"Preoperative pulmonary function tests and arterial blood gases are rarely of prognostic value"** — a frequently rewarded negative statement.
- Quote the four delirium predictors (**prior stroke/TIA, low MMSE, abnormal albumin, high GDS**) and the frailty markers (**Katz ≤4/6, TUG ≥15 s, 5-m walk ≥6 s**).
- Flag the guideline reversal explicitly: "*The textbook recommendation to initiate perioperative beta-blockade has been superseded; since POISE, beta-blockers are continued but not started immediately before surgery.*"
- Close with the geriatric point: "*The operation is only half the treatment — delirium prevention, early mobilisation and rehabilitation determine functional outcome.*"

Extra Points to Remember (recurring topic)

- **Indian context.** A high proportion of older surgical patients present as emergencies (hip fracture, obstructed hernia, perforation), leaving little time for optimisation; undiagnosed diabetes, anaemia, hypothyroidism, tuberculosis and rheumatic valvular disease are common incidental findings at preoperative assessment. **Hip fracture surgery within 48 hours** and a formal **orthogeriatric co-management model** are the highest-yield service interventions. Access to DOACs, sugammadex and processed EEG monitoring is variable, so bridging and reversal plans must be made locally.
- **Cardiac surgery specifics (Pathy, Ch. 35):** risk is estimated by **EuroSCORE II** (Europe) or the **STS score** (USA). Crude in-hospital mortality in patients over 80 is approximately **5–9% for isolated CABG, 5–7% for isolated valve surgery and 8–11% for combined procedures**; five-year survival in patients ≥75 is about **80%**. Perioperative **stroke** is the complication of greatest concern, and **late referral** independently worsens both operative risk and late outcome.
- **TAVI vs SAVR:** frailty predicts postoperative mortality and disability after TAVI; survival curves stratify clearly by Katz ADL score. Decisions are made by a **Heart Team**.
- **Drugs to withhold vs continue — a quick list.** Continue: beta-blockers, statins, most antihypertensives, inhalers, antiepileptics, levodopa, thyroxine, steroids (with stress dosing). Withhold: ACE inhibitors/ARBs on the morning of surgery (hypotension), SGLT2 inhibitors 3–4 days, NSAIDs, metformin on the day, diuretics on the morning, and anticoagulants/antiplatelets per bleeding risk.
- **Postoperative complications specific to older people:** delirium, MINS, atrial fibrillation, aspiration pneumonia, urinary retention and catheter-associated infection, constipation and ileus, pressure injury, functional decline and new institutionalisation.

Appendix — Rapid Revision Grid

For the night before the examination. Numbers, named criteria, trials and guidelines by topic.

1. Numbers to quote

Item	Figure
Polypharmacy definitions in the literature	~24 different definitions
Polypharmacy / hyperpolypharmacy cut-offs	≥5 drugs / ≥10 drugs
Scotland trend, 1995→2010	≥5 drugs 11%→20%; ≥10 drugs 1.5%→6%; serious interaction exposure 13% (2010)
Sweden (1992→2002); Italy (2000→2010)	18%→42%; 43%→53%
Medication errors, UK nursing home residents	69.5% incidence
Beers Criteria 2019 / 2023	88 PIMs (2019); 5 categories retained in 2023; >3 dozen drugs to avoid, 40+ disease-specific
STOPP/START v2 (2015) / v3 (2023)	114 (80+34) / **190 (133+57)** — a 66.7% increase
Medication Appropriateness Index	10 items, 3-point Likert, maximum score 18
Pill Pruner	13 drug groups, pocket card, effects sustained at 90 days
Bisphosphonate holiday	Reassess at 5 y oral / 3 y IV; holiday 2–3 y (low risk); continue 10 y oral / 6 y IV (high risk); AFF risk falls ~72%/year after stopping
Frailty and operative mortality	2- to 4-fold increase; Katz ≤4/6, TUG ≥15 s, 5-m walk ≥6 s, 6-min walk <150 m
Cardiac surgery mortality, age >80	CABG 5–9%; isolated valve 5–7%; combined 8–11%; 5-year survival ≥75 y ≈ 80%
Functional decline in hospital	One-third of older inpatients lose ≥1 ADL by discharge
Multicomponent delirium prevention	RR 0.71 (95% CI 0.59–0.85) — 29% relative risk reduction
Deprescribing meta-analyses	32 RCTs / 18,670 patients (JAMDA 2023); 259 studies, no mortality benefit (BJCP 2024)
Pharmacist-led deprescribing CMR	2.5 vs 1.7 medications stopped/reduced per patient at 6 months; no HRQoL change
SGLT2 inhibitors before surgery	Stop **3–4 days** preoperatively
Elective surgery after stroke/TIA	Delay **≥3 months**
Postoperative delirium screening	All patients **≥60 years**; validated tool **daily for ≥3 days** from recovery

2. Named criteria, tools and mnemonics

Name	Content
Beers (1991, AGS)	5 categories + anticholinergic table; 2023 update; 2025 Alternatives companion
STOPP / START (2008, Europe)	PIMs / prescribing omissions; v3 2023, 190 criteria, class-based
STOPPFrail	For frail patients with limited life expectancy
MAI (1992, USA)	10 implicit criteria per drug
DBI (2007)	Cumulative anticholinergic + sedative exposure
FORTA (2008, Germany)	A–D labels; first tool to combine positive and negative labelling
TRIM (2016, US VA)	EHR algorithm using Beers + STOPP
SAIL / TIDE	Simple, Adverse effects, Indication, List / Time, Individual response, Drug interactions, Educate
ARMOR	Assess, Review, Minimise, Optimise, Reassess
ERASE	Resolved conditions, Ageing normally, Selecting targets → Eliminate unnecessary diagnoses
AVOID TOO MANY	12-item medication review checklist
Scott 5-step	List → assess harm → discontinuation potential → prioritise → monitor
Barnett 7-step / **Deprescribing Rainbow**	Goals-first process / clinical, psychological, social, financial and physical determinants
RCRI (Lee)	IHD, CHF, diabetes, cerebrovascular disease, renal insufficiency, high-risk surgery
EuroSCORE II / STS score	Cardiac surgical operative mortality prediction
Rudolph delirium rule	Prior stroke/TIA, MMSE, abnormal albumin, GDS
Clinical Frailty Scale	Recommended preoperatively by ESAIC 2025 (Grade 1C)
DASI / METs	Functional capacity assessment, 2024 AHA/ACC guideline

3. Guidelines and evidence, 2023–2026

Source	Key message
AGS Beers Criteria, JAGS 2023	Aspirin for primary prevention → avoid; warfarin and rivaroxaban → avoid as initial therapy; doxepin removed; SGLT2i caution
AGS Beers Alternatives, JAGS 2025	Safer pharmacological and non-pharmacological alternatives across 21 conditions
STOPP/START v3, Eur Geriatr Med 2023	190 criteria; class-based; 41–42% new criteria
SENATOR / OPERAM / OPTICA	No significant reduction in ADRs, mortality, readmissions or QoL
JAMDA 2023; BJCP 2024; Age Ageing 2026	Deprescribing is safe and reduces PIMs; no mortality or QoL benefit demonstrated
2024 AHA/ACC multisociety perioperative guideline	Stepwise algorithm; targeted testing; statins Class 1; delay elective surgery ≥3 months after stroke; OSA screening; MINS recognised; stop SGLT2i 3–4 days
ESAIC preoperative assessment, EJA 2025	Frailty testing recommended (1C); Clinical Frailty Scale; WHODAS 2.0 in high-risk patients
ESAIC postoperative delirium, EJA 2024	13 recommendations, 5 strong; screen ≥60 y; multicomponent non-pharmacological bundle; EEG depth monitoring; dexmedetomidine risk–benefit; haloperidol only if non-pharmacological measures fail
ASA Practice Advisory, Anesthesiology 2025	Expanded preoperative evaluation of older inpatients; neuraxial and general anaesthesia equivalent for delirium risk
GLP-1 multisociety guidance, 2024	Continue in most patients; 24-hour clear liquid diet if higher risk; supersedes 7-day withholding of weekly agents
WHO Medication Without Harm	Third Global Patient Safety Challenge; polypharmacy is a named priority action area

Five statements that must not be got wrong

1. **Absorption is the pharmacological parameter least affected by ageing; renal excretion is the most predictable change.**
2. **A normal serum creatinine does not mean normal renal function in an older person.**
3. **A drug holiday is absolutely contraindicated with denosumab** because of rebound vertebral fractures; the **levodopa drug holiday is an abandoned, dangerous practice**.
4. **Do not start beta-blockers immediately before surgery** — continue them if already prescribed. This reverses the older textbook recommendation.
5. **Deprescribing is safe and reduces inappropriate medication use, but no mortality benefit has been demonstrated** — state this rather than overclaiming.

Textbook content drawn from *Pathy's Principles and Practice of Geriatric Medicine* (6th ed.) and *Essentials of Clinical Geriatrics* (7th ed.). Updates cited inline by journal or guideline and year, current to 2026.

MD GERIATRIC MEDICINE

Examination Answer Module

Immobility, Pressure Injuries, Rehabilitation & Geriatric Pruritus

Questions 1–7 | 15-mark and 7-mark formats

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th ed.

Kane's Essentials of Clinical Geriatrics

With Latest Updates (2023–present) and Indian clinical & policy context

Prepared for Dr. Sudarsan · Written Examination Preparation

Contents

1.	Assessment and management of chronic pressure ulcers in the elderly RECURS	15 marks
2.	Prevention of pressure sores RECURS	7 marks
3.	Immobility RECURS	15 marks
4.	Rehabilitation team	7 marks
5.	Role of physiotherapy in the elderly	7 marks
6.	Role of the occupational therapist in the life of an elderly person with mobility issues and an ageing spouse	15 marks
7.	How would you deal with constant itching (pruritus) in an elderly patient?	15 marks

How to use this module

Each answer runs in the same four blocks: **High-Yield Points** (textbook core) → **Latest Updates 2023–present** → **Current Practice Update** (textbook vs. current evidence, in table form) → **Exam One-Liners**. Questions marked RECURS carry an additional purple **Rapid Recall Box** with a mnemonic, numerical anchors, examiner traps and a 15-second answer skeleton. All laboratory values are in Indian conventional units.

Question 1. Assessment and management of chronic pressure ulcers in the elderly [15 MARKS]

High-Yield Points

Definition and terminology

1. A **pressure injury** is localised damage to the skin and underlying tissue, usually over a **bony prominence** such as the sacrum or heel. Pathy's prefers "pressure **injury**" over "pressure ulcer" because not every lesion is an open ulcer.
2. A **chronic** pressure ulcer is one that fails to progress through orderly healing. A useful benchmark: the wound should be **20–40% smaller by week 4** if it is going to heal by week 12. Failure to shrink means the diagnosis and the underlying factors must be re-examined.
3. Three mechanical forces produce the injury: **pressure**, **shear** (head-of-bed elevation makes the torso slide and drags subcutaneous tissue over the sacrum) and **friction**. **Moisture** from sweat, urine and faeces compounds all three. More than **90% occur in the lower body** – sacrum and coccyx, ischial tuberosities, greater trochanter and heels.

Epidemiology and risk

4. Incidence varies widely by setting: **acute care 0.4–38%**, **long-term care 2.2–23.9%**, **home care 0–17%**. About **25% of pressure ulcers are acquired intra-operatively**, because neither position nor duration of surgery can be altered.
5. **Advanced age is NOT an independent risk factor.** The risk comes from the impairments that cluster in old age – immobility, poor nutrition and fragile skin. This is a favourite examiner point.
6. Established risk factors: bed- or chair-bound, **unable to reposition without help**, difficulty with ambulation, **history of stroke**, **faecal incontinence**, low body weight, **lymphopenia**, difficulty with independent feeding, impaired nutritional intake, **non-blanchable erythema of intact skin (a Stage 1 injury)**, and **dry sacral skin**.
7. Risk-assessment tools in use: **Braden, Norton and Waterlow** scales. The recommendation is to apply a tool **on admission and repeat regularly**. Evidence that the scales themselves improve outcomes remains uncertain – they supplement, not replace, structured skin inspection.

Clinical staging — NPIAP system

8. **Stage 1**: intact skin with non-blanchable erythema. **Stage 2**: partial-thickness loss with exposed dermis – blister, abrasion or shallow ulcer. **Stage 3**: full-thickness loss into subcutaneous fat, down to but not through fascia, often with undermining. **Stage 4**: extends through deep fascia – muscle, tendon or bone visible, undermining and sinus tracts common. Use **Arabic numerals**, not Roman.
9. Two additional categories when depth cannot be seen: **Unstageable** – base obscured by slough or eschar (stage it once debrided); and **Deep tissue pressure injury (DTPI)** – skin intact but deep red, purple or maroon, or a haemorrhagic blister, indicating damage in deeper tissue.
10. **Medical device–related pressure injuries** (urinary catheter, rectal tube, oxygen tubing) **conform to the shape of the device** and **are staged**. **Pressure injuries on mucous membranes are documented but NOT staged.**

Assessing the chronic ulcer

11. **Never reverse-stage.** A healing Stage 4 does not become a Stage 2 – the lost tissue is replaced by scar, not by fat and muscle. Monitor healing instead with the **PUSH tool** (Pressure Ulcer Scale for Healing), which scores three components – **size, exudate amount and tissue type** – and is validated and sensitive to change.
12. Document every ulcer under seven headings: (i) type, duration and setting in which it arose; (ii) **length × width × depth in cm**; (iii) colour as percentages – red granulation, yellow slough, black eschar; (iv) exudate – serous, serosanguinous, sanguineous or purulent; (v) odour, assessed only **after** thorough cleaning; (vi) periwound skin – viable, macerated, inflamed or hyperkeratotic; (vii) **undermining and sinus tracts**. Add a pain score.
13. **Diagnosing infection in a chronic wound**: **increasing pain is the single best clinical predictor (likelihood ratio 11–20)**. The "classic signs" – purulent exudate, erythema, heat, oedema – and foul odour do **not** reliably predict infection. When infection is suspected, take a **quantitative swab using the Levine technique**: rotate the swab over a **1 × 1 cm** area for **five seconds** with enough pressure to express fluid from within the tissue. A positive result gives LR 6.3; a negative result LR 0.47.
14. Suspect **osteomyelitis** in any non-healing Stage 4 ulcer: probe-to-bone, plain radiograph, MRI. **Bone or deep tissue biopsy culture** – including anaerobic culture – directs therapy far better than surface swabs.

Management

15. **Managing the underlying contributing factors matters more than any dressing or adjunctive therapy.** Offload pressure, correct nutrition, control incontinence, treat pain, restore mobility, review sedatives and restraints. Most trials unfortunately study dressings, not causes.
16. **Support surfaces and repositioning**: reposition at least **2-hourly on a standard mattress** and at least **4-hourly on a pressure-redistributing mattress**. Powered mattresses have **not** been shown to heal ulcers better than non-powered ones despite far greater cost; a disciplined turning schedule is a cheaper alternative.
17. **Local wound care**: no single dressing has been shown superior to another in well-designed trials. Standard care of a

healable ulcer must satisfy three criteria – **moisture balance, bacterial balance and debridement**. Choose the dressing on cost, ease of use, goals of care and patient comfort.

18. **Debridement** of necrotic tissue by autolytic, enzymatic/chemical, mechanical, sharp or surgical means; irrigate two to three times daily; undermine and remove eschar that conceals infected tissue. **Exception**: leave stable, dry, adherent **heel eschar** alone in a limb with peripheral arterial disease – it is a biological dressing.
19. **Antibiotic discipline**: do not treat colonisation. In **Stage 3**, treat only proven **cellulitis, osteomyelitis, bacteraemia or sepsis**; routine surface cultures are unhelpful because they grow mixed flora and miss anaerobes, and reflect colonisation. In **Stage 4**, systemic antimicrobials are often required; for a septic patient use broad-spectrum cover for **anaerobes, Gram-negative organisms and *Staphylococcus aureus***, then de-escalate on tissue culture.
20. **Nutrition**: refer to a dietitian. Targets are **30–35 kcal/kg/day energy**, **1.0–1.5 g/kg/day protein** and **1 mL fluid per kcal**. Supplementation improves healing chiefly in those who are already malnourished; protein supplements may help long-term-care residents. Check haemoglobin (g/dL) and serum albumin (g/dL) as markers of the overall nutritional state.
21. **Adjunctive therapies** – negative-pressure wound therapy, hyperbaric oxygen, laser, electrotherapy, electromagnetic therapy, therapeutic ultrasound: **no good evidence that any of these improve pressure injury healing.** Platelet-derived growth factor has some supporting evidence but not enough for routine use.
22. **Surgery**: plastic surgical consultation for selected Stage 4 lesions – flap or graft closure – but only when the patient is fit, nutrition is corrected and, above all, the **cause has been removed**, otherwise the flap breaks down.
23. **Non-healable ulcers and skin failure**: not all pressure injuries are preventable. Where the underlying conditions are irreversible or the goals of care are comfort, shift the aim from healing to **reducing infection risk and controlling pain**. Wounds that appear and worsen over bony prominences during overall terminal decline are termed **skin failure** rather than pressure injury.
24. **Pain is managed at every stage** – background pain and procedural pain at dressing change. Use topical anaesthesia, pre-emptive analgesia and the WHO ladder with geriatric dose adjustment.

Latest Updates (2023-present)

1. **International Guideline, 4th edition (2025)** – NPIAP / EPUAP / Pan Pacific Pressure Injury Alliance, edited by Emily Haesler, replacing the 2019 third edition. Built with **GRADE and evidence-to-decision frameworks** by more than 240 clinical experts and consumer representatives, and released as **staged online chapters** (prevention chapters first from February 2025, treatment recommendations from late 2025) rather than a single printed book.
2. **Sub-epidermal moisture (SEM) measurement and skin temperature** are now recommended as **adjuncts to visual skin assessment** for detecting Stage 1 injury and deep tissue injury before they are visible, particularly at the sacrum. This matters especially in **darkly pigmented skin**, where non-blanchable erythema is easily missed – highly relevant to Indian practice.
3. **Prophylactic dressings** have moved into guideline recommendations: a **soft silicone adhesive multilayered foam dressing** is suggested as an adjunct to heel elevation and repositioning for heel injuries, and over the sacrum and trochanters in at-risk hospitalised patients (BORDER trial lineage). NPIAP/EPUAP have launched the **Prophylactic Dressing Standards Initiative (PDSI)** because no accepted standard yet exists for testing dressings used on *intact* skin.
4. **SPIPP** (Standardized Pressure Injury Prevention Protocol) – a five-item checklist now widely used as an audit tool: validated risk assessment, prophylactic dressings, beds and support surfaces, repositioning systems, and skin care.
5. Device-related injuries have their own 2025 chapter, extending the concept beyond medical devices to **non-medical items** – phones, remote controls, call bells, jewellery, spectacles and bed clutter left in contact with skin.
6. Wound Canada 2025 Best Practice Recommendations reinforce the **20–40% area reduction at week 4** benchmark and formal reclassification of a stalled wound as **non-healing or non-healable** by the interprofessional team.

Current Practice Update

Domain	Textbook position	Current practice (2023-present)
Guideline reference	2019 third edition International Guideline; NPUAP 2016 revised staging	**Fourth edition, 2025**, GRADE-based, released as living online chapters
Early detection	Visual inspection plus a risk scale	Add **SEM scanner and skin temperature**; explicit caution about missing Stage 1 in dark skin
Prophylactic dressings	Barely mentioned	**Multilayer silicone foam** over sacrum, heels and trochanters as an adjunct; PDSI standards in development
Repositioning	Fixed 2-hourly / 4-hourly rule	**Individualised frequency** based on risk, tissue tolerance and support surface, documented on a turning chart
Nutrition	"Supplements may be beneficial; unclear which nutrients"	Structured screening plus **high-protein oral nutrition supplements enriched with arginine, zinc and antioxidants** for Stage 2 and above in

		malnourished patients
Adjunctive therapy	No good evidence for any	**NPWT** accepted as an adjunct in large Stage 3/4 cavities to reduce volume and exudate and prepare for surgery – still not proven to achieve closure
Non-healing wounds	Concept of skin failure introduced	Formalised: **unavoidable pressure injury** and **Kennedy terminal ulcer** as recognised end-of-life entities, with a documented prevention protocol required before the label is used

Indian Context

1. **NPHCE** provides geriatric wards at district hospitals and regional geriatric centres, where pressure injury prevention should be an audited quality indicator.
2. **Kerala's community palliative care network** – ward-level nurse-and-volunteer home-care teams under the state palliative care policy – remains India's best-developed model for the bedbound elderly, and pressure sore care is one of its core deliverables. **Vayomithram** mobile units add urban outreach.
3. **AB-PMJAY** and the **Ayushman Vay Vandana Card** (universal for those aged 70 and above) cover hospitalisation, debridement and flap surgery, but not chronic outpatient dressings.
4. **Rashtriya Vayoshri Yojana** and **ADIP–ALIMCO** supply wheelchairs, walkers, commodes and other assistive devices free or subsidised to eligible senior citizens – central to offloading and mobilisation.
5. Practical realities: alternating-pressure mattresses are frequently unavailable; **disciplined 2-hourly turning by a trained family caregiver, cotton draw sheets, a well-padded water or air mattress, and daily heel inspection** deliver most of the benefit. Vegetarian diets often fall short of the 1.0–1.5 g/kg protein target – counsel on dal, curd, paneer, eggs and locally affordable protein sources against the **ICMR-NIN 2024** reference values.

Rapid Recall Box — Recurring Topic

Mnemonic for the wound bed: "DIME" – **D**ebridement, **I**nfection/inflammation control, **M**oisture balance, **E**dge of wound advancing. (Pathy's three criteria – moisture balance, bacterial balance, debridement – map directly onto D, I and M.)

Numerical anchors: 2-hourly / 4-hourly turning · 30–35 kcal/kg · 1.0–1.5 g/kg protein · 1 mL fluid per kcal · 20–40% area reduction by week 4 · increasing pain LR 11–20 · Levine swab 1 × 1 cm for 5 seconds, LR 6.3 positive / 0.47 negative · 25% acquired intra-operatively · more than 90% in the lower body · acute care incidence 0.4–38%.

Examiner traps: (i) Saying "old age is a risk factor" – it is *not* independent. (ii) Reverse-staging a healing ulcer. (iii) Staging a mucosal injury. (iv) Sending a routine surface swab and starting antibiotics for a Stage 3 ulcer. (v) Claiming powered mattresses heal better than non-powered. (vi) Debriding dry stable heel eschar in an ischaemic limb. (vii) Forgetting that *all* pressure injuries are not avoidable, and that skin failure is a distinct end-of-life entity.

15-second answer skeleton: Define → pressure, shear, friction, moisture → NPIAP Stages 1–4 plus unstageable and DTPI, device-related staged, mucosal not staged → assess with the seven documentation headings, PUSH tool, never reverse-stage → infection = increasing pain plus Levine swab → management = correct the underlying cause first, then offload, nutrition, DIME wound bed, selective antibiotics, surgery for selected Stage 4 → non-healable ulcer and skin failure with palliative goals → 2025 fourth-edition guideline, SEM scanning, prophylactic silicone foam → Indian context.

Exam One-Liners

1. "Pressure injury" is preferred over "pressure ulcer" because not all lesions are open ulcers.
2. Advanced age is **not** an independent risk factor for pressure injury development.
3. Dry sacral skin and lymphopenia are both recognised independent risk factors.
4. Deep tissue pressure injury = intact skin that is deep red, purple or maroon, or a haemorrhagic blister.
5. Unstageable = base hidden by slough or eschar; stage it after debridement.
6. Mucous membrane pressure injuries are documented but never staged.
7. Reverse staging is inaccurate; use the PUSH tool (size, exudate, tissue type).
8. The best clinical predictor of infection in a chronic wound is **increasing pain**.
9. Levine technique: rotate a swab over 1 × 1 cm for 5 seconds with pressure enough to express tissue fluid.
10. No single dressing is superior; aim for moisture balance, bacterial balance and debridement.
11. Adjunctive therapies including hyperbaric oxygen have no good evidence of improving healing.
12. About one-quarter of pressure ulcers are acquired in the operating theatre.
13. Skin failure describes wounds appearing over bony prominences during terminal decline.
14. The 2025 fourth-edition International Guideline is a GRADE-based, staged online release.

Question 2. Prevention of pressure sores [7 MARKS]

> **Note on overlap:** This question shares its evidence base with Question 1 but is answered **purely as prevention**. Do not repeat staging, wound-bed preparation or antibiotic policy here – the pivot is risk identification, offloading, skin and moisture care, nutrition, and the avoidability question.

High-Yield Points

1. **Identify risk on day one.** Apply a validated tool – **Braden, Norton or Waterlow** – on admission to any facility and **repeat regularly**, combined with a structured head-to-toe skin inspection that specifically includes the **heels, sacrum and skin under every device**.
2. **Redistribute pressure.** Reposition at least **2-hourly on a standard mattress** and at least **4-hourly on a pressure-redistributing mattress**. Use a **30° lateral tilt** rather than full side-lying, keep head-of-bed elevation to **30° or less** to limit sacral shear, and **float the heels completely off the bed** with a pillow under the calf or a heel-suspension boot.
3. **Choose a support surface.** Non-powered surfaces are mattresses or overlays filled with air, water, gel or foam; powered surfaces mechanically vary the pressure and cost far more. **Specialised foam and sheepskin overlays reduce incidence compared with a standard hospital mattress**; the choice between powered and non-powered is not settled. **Overlays on the operating table reduce postoperative pressure injuries** and should be routine for long operations in the elderly.
4. **Reduce shear and friction.** Use slide sheets, hoists and two-person lifts rather than dragging; keep linen taut and wrinkle-free; avoid loose folded skin, which is common in the elderly from loss of subcutaneous fat and dehydration.
5. **Control moisture and incontinence.** Clean promptly after every episode with a pH-balanced cleanser, dry gently, and apply a barrier film or cream. Recognise and treat **incontinence-associated dermatitis** as a separate entity – it is frequently misclassified as a Stage 2 injury.
6. **Moisturise dry skin. Dry sacral skin is itself a risk factor**, so regular emollient application is a reasonable preventive measure. No topical agent has been shown superior to any other.
7. **Nutrition and hydration.** Refer at-risk patients to a dietitian for a full nutritional assessment. Targets: **30–35 kcal/kg/day**, **protein 1.0–1.5 g/kg/day**, **fluid 1 mL/kcal**. Nutritional supplements may help but it is not clear which nutrients matter most.
8. **Attack immobility itself.** Avoid excessive bed rest, get the patient up for meals, optimise and encourage function, avoid over-sedation, minimise **physical restraints, restrictive siderails, catheters and lines** – every one of these enforces immobility.
9. **Device care.** Inspect the skin under and around all medical devices at least twice daily, reposition or rotate the device, and consider a protective dressing beneath it. Suspect a device-related injury whenever the wound shape mirrors the device.
10. **Multifactorial, multidisciplinary bundles work** – exactly as for falls and delirium prevention. But **not all pressure injuries are avoidable, particularly at the end of life**; a documented prevention protocol must be in place before any injury is declared unavoidable.

> **Latest Updates (2023–present) — three key points**
>
> 1. **Fourth edition International Guideline (NPIAP/EPUAP/PPPIA, 2025)** – the prevention chapters were released first as living online documents using GRADE methodology; the **SPIPP checklist** distils prevention into five auditable practices: validated risk assessment, prophylactic dressings, support surfaces, repositioning systems and skin care.
> 2. **Prophylactic soft silicone multilayered foam dressings** are now suggested as an **adjunct** to heel elevation and repositioning (and over sacrum and trochanters) where resources permit – not a replacement for turning. The NPIAP/EPUAP **Prophylactic Dressing Standards Initiative** is developing performance standards for dressings applied to intact skin.
> 3. **Sub-epidermal moisture (SEM) and skin temperature measurement** are recommended as adjuncts to visual skin assessment, detecting damage before it is visible – of particular value in **darkly pigmented skin**, where Stage 1 erythema is frequently missed and injuries are therefore diagnosed later and at a higher stage.

Current Practice Update

Domain	Textbook position	Current practice
Skin assessment	Visual inspection plus risk scale	Plus **SEM and temperature**; specific protocols for dark skin tones (colour change relative to surrounding skin, boggy or firm texture, warmth)
Dressings	Used only on established wounds	**Prophylactic dressings on intact skin** as a recognised preventive intervention
Repositioning	Fixed schedule	Individualised and documented; supported by **patient repositioning systems** as a named SPIPP element

Avoidability	Not all are avoidable	Unavoidable pressure injury now a defined, defensible category, provided a prevention protocol is documented

Indian Context

Under **NPHCE**, pressure sore prevention is best delivered as **structured family-caregiver training**, since most bedbound elderly in India are cared for at home. **ASHA and ANM home visits**, and in Kerala the **ward-level palliative home-care nurse**, are the practical delivery route. Low-cost, culturally acceptable measures carry most of the benefit: a two-hourly turning chart kept on the wall, water or air mattress where affordable, cotton draw sheets, coconut or sesame oil as an emollient for dry sacral skin, immediate cleaning after incontinence, and daily heel checks. **Rashtriya Vayoshri Yojana / ADIP–ALIMCO** supply wheelchairs, walkers and commodes free to eligible elderly, which supports getting the person out of bed – the most effective preventive measure of all.

Exam One-Liners

1. Prevention rests on identifying risk, offloading pressure, and controlling moisture, friction and nutrition.
2. Turn at least 2-hourly on a standard mattress, 4-hourly on a pressure-redistributing mattress.
3. Limit head-of-bed elevation to 30° to reduce sacral shear.
4. Heels must be floated completely off the surface, not merely cushioned.
5. Specialised foam and sheepskin overlays reduce incidence versus a standard hospital mattress.
6. Theatre-table overlays reduce postoperative pressure injuries.
7. Dry sacral skin is a risk factor – moisturising is a legitimate preventive intervention.
8. Incontinence-associated dermatitis is not a Stage 2 pressure injury.
9. Prophylactic silicone foam dressings are an adjunct to, never a substitute for, repositioning.
10. An unavoidable pressure injury can only be declared after a documented prevention protocol has been applied.

Question 3. Immobility [15 MARKS]

High-Yield Points

Definition

1. **Immobility** is the restriction of time spent out of bed or chair, imposed by **medical orders, restrictive devices, chemical restraints such as antipsychotics, lack of mobility aids, or lack of human assistance and encouragement**. It is therefore as much an **iatrogenic and environmental** problem as a disease.
2. **Functional decline or "deconditioning"** is the loss of ability to perform basic activities of daily living, attributed primarily to **forced bed rest, immobilising devices such as catheters and lines, restraint use, and lack of encouragement of independence in self-care**.

Epidemiology — why it matters

3. As many as **one-third of older hospitalised patients are restricted to bed rest or chair rest**. Between **15% and 76%** show diminished performance in at least one ADL at discharge.
4. Of those who decline at discharge, **only half recover function by three months**, and for many the decline results in **permanent loss of independent living**.
5. Functional decline is a **profound marker of morbidity and mortality**, producing longer length of stay, greater cost and increased nursing-home placement.

Causes (Kane's classification)

6. **Musculoskeletal**: arthritides, osteoporosis, fractures (especially hip and femur), podiatric problems, Paget's disease.
7. **Neurological**: stroke, Parkinson's disease, neuropathies, normal-pressure hydrocephalus, dementias, cerebellar dysfunction.
8. **Cardiovascular and pulmonary**: severe congestive cardiac failure, coronary disease with frequent angina, peripheral arterial disease with claudication, severe COPD – all limiting endurance rather than strength.
9. **Sensory**: visual impairment, decreased kinaesthetic sense, decreased peripheral sensation.
10. **Drugs**: sedatives and hypnotics (drowsiness, dizziness, delirium, ataxia); **antipsychotics, especially typical agents** (rigidity, extrapyramidal effects); antihypertensives (orthostatic hypotension, bradycardia).
11. **Psychological**: depression, apathy, lack of motivation, **fear of falling**, and the health belief that **"rest and immobility aid recovery"**.
12. **Environmental and social**: forced immobility in hospitals and nursing homes, inadequate mobility aids, cluttered rooms, uneven surfaces, badly shaped or low chairs and beds, stairs – and, crucially, **well-meaning caregivers who bathe, dress and wheel an elder who is capable of doing it themselves**, which directly produces deconditioning.
13. **Others**: acute and chronic pain (a major cause, creating a vicious cycle of pain → less movement → more pain), malnutrition, severe systemic illness such as widespread malignancy, and deconditioning after prolonged bed rest for acute illness.

Complications — system by system

System	Complications of immobility and bed rest
Skin	Pressure injuries (immobility plus low serum albumin markedly increases risk)
Musculoskeletal	Muscle atrophy with loss of strength and endurance; reduced fibre size, diameter and capillarity; **contractures** (fixation of both muscle and joint in flexion, permanently reducing range of motion – the classic nursing-home consequence); **disuse osteoporosis** from increased resorption and decreased formation, with **hypercalcaemia**; degenerative joint disease
Cardiovascular	Deconditioning, decreased plasma volume, decreased maximal stroke volume and aerobic capacity; **orthostatic hypotension** (impairs rehabilitation and predisposes to falls, stroke and myocardial infarction); **deep vein thrombosis and pulmonary embolism**
Respiratory	Reduced tidal volume, atelectasis, and – with the supine position – **aspiration and hypostatic pneumonia**
Gastrointestinal	Anorexia, constipation, **faecal impaction with overflow incontinence**
Genitourinary	Urinary retention (inability to void lying down, or impaction obstructing flow), infection, bladder calculi, functional incontinence
Metabolic	**Negative nitrogen and calcium balance**, impaired glucose tolerance, altered drug pharmacokinetics from reduced plasma volume
Psychological	Sensory deprivation, **delirium**, depression and anxiety

Assessment

14. **History**: explore the **patient's and the caregiver's perceived cause** of the immobility, not just the medical one. Cover medical conditions, treatments including intravenous lines and catheters, pain, mood, motivation, and health beliefs.

15. **Nutrition**: assess protein status and **25-hydroxyvitamin D**, both associated with muscle weakness, poor physical performance, balance problems and falls. Check haemoglobin (g/dL) and albumin (g/dL).
16. **Environment**: assess both the physical and the social environment, **particularly caregiving interactions** – any of these factors can reduce the person's willingness to engage in activity.
17. **Examination**: grade muscle strength (MRC 0–5), joint range of motion and contractures, skin over all pressure points, postural blood pressure, gait and balance (Timed Up and Go, Short Physical Performance Battery), vision, feet and footwear.

Management

18. **Treat the reversible causes** – relieve pain, deprescribe sedatives and antipsychotics, treat depression, correct vitamin D and protein deficits, manage orthostasis, optimise cardiac and respiratory disease.
19. **Adopt a restorative philosophy of care** (Kane's basic principles): optimise treatment of underlying disease, nutrition, hydration and the psychosocial situation; optimise the physical environment (handrails, open access) and the care environment so care is not merely task-focused; **prevent secondary disabilities**; treat primary disabilities; set realistic, individualised, measurable functional goals; emphasise functional independence; enhance residual capacity; provide adaptive tools; adapt the environment to the patient; attend to motivation of patient *and* caregivers; and use a **team approach**.
20. **Progressive exercise programme** – passive and active range of motion, bed and chair exercises, sitting and standing balance, transfers, then assisted and independent ambulation; lower-limb resistance training with flexibility and balance work; correctly fitted cane, walker or wheelchair with training in its use.
21. **Prevent the complications actively**: 2-hourly turning, VTE prophylaxis, upright positioning with chest physiotherapy and breathing exercises, a bowel and bladder regimen, adequate nutrition and hydration, and **early removal of catheters and lines**.
22. **Minimise physical restraints and restrictive siderails.** Tinetti and Ginter described **"spiralling immobility"** – the older person perceived to be at risk of falling is restrained to prevent falls, and then becomes unable to walk safely because of the immobilising consequences of the restraint. Restraints are associated with numerous negative outcomes including **strangulation and asphyxiation**, and research demonstrates they can be **safely eliminated**.
23. Rehabilitation may be delivered in the acute hospital, a rehabilitation unit, a skilled nursing facility, an outpatient clinic or at home; ongoing **motivation of the older person and the caregiver is critical** to success.

Latest Updates (2023–present)

1. **"New horizons in hospital-associated deconditioning" (Age and Ageing, 2024;53:afae241)** reframes deconditioning as **a global condition of body and mind**: physical deconditioning drives secondary sarcopenia, and **cognitive deconditioning** – delayed mental processing on a spectrum with frank delirium – is equally common. The paper cautions that the word "deconditioning" wrongly implies easy reversibility, and recommends implementation of a **Frailty Care Bundle** targeting **mobilisation, nutrition and cognitive engagement** together.
2. A 2025 *Age and Ageing* editorial ("75 years after Marjorie Warren, the know-do gap around hospital-associated functional decline is as wide as ever") makes the point that the evidence is settled and the failure is one of **implementation**, not knowledge.
3. **In-hospital multicomponent exercise reverses functional decline** in acutely hospitalised very elderly patients (Martínez-Velilla, *JAMA Internal Medicine* 2019) – still the landmark trial, now replicated and extended. A **2025 systematic review and meta-analysis (European Geriatric Medicine)** shows that **progressive mobilisation and multicomponent interventions improve participation and reduce functional decline in hospitalised people living with dementia**, a group previously excluded from such programmes.
4. Implementation campaigns now define the standard of care: **#EndPJparalysis**, **"Sit up, Get dressed, Keep moving"** (British Geriatrics Society deconditioning hub), **"Get up, Get dressed, Get moving"**, and **MOVE ON** (Ontario multisite implementation). The **American Academy of Nursing Choosing Wisely** recommendation is explicit: "*Don't let older adults lie in bed or only get up to a chair during their hospital stay.*"
5. The **AGS White Paper on mobility assessment** argues for **daily measurement of mobility as a vital sign** in hospitalised older adults, using tools such as **DEMMI** (de Morton Mobility Index) or **AM-PAC "6-clicks"**, so that immobility becomes visible in the record rather than invisible.
6. Timelines to quote: functional decline is measurable by **day 2** of admission; **10 days of bed rest in healthy older adults** produces significant loss of lean mass and strength (Kortebein); recovery takes far longer than the decline.
7. **WHO ICOPE, 2nd edition (2025)** makes **locomotor capacity** one of the six intrinsic-capacity domains screened at primary-care level, with **multicomponent exercise** as the core intervention – moving immobility management upstream into the community.

Current Practice Update

Domain	Textbook position	Current practice (2023–present)
Concept of bed rest	"The bed is a very dangerous place for an older	Operationalised into ward-level campaigns (**End PJ**

	person"; complications listed	**Paralysis**) with measurable targets, and formally named **hospital-associated deconditioning**
Scope of harm	Physical deconditioning, with delirium listed separately	**Physical and cognitive deconditioning as one continuum** (2024 New Horizons paper)
Delivery model	Referral to physiotherapy; restorative philosophy of care	**Frailty Care Bundle**: mobilisation + nutrition + cognitive engagement, delivered by the whole ward team, not by therapists alone
Measurement	Functional status assessed at admission and discharge	**Daily mobility measurement** (DEMMI, AM-PAC 6-clicks) as a vital sign
Dementia	Little specific guidance	2025 meta-analysis supports progressive mobilisation for **hospitalised people with dementia**
Restraints	Reduce use; safe elimination is possible	**Restraint-free care** as the default standard, with accreditation-level audit indicators; chemical restraint scrutinised as closely as physical
Community	Exercise for prevention	**WHO ICOPE 2nd ed. 2025** screens locomotor capacity in primary care and triggers multicomponent exercise

Indian Context

1. **LASI Wave-1 (2017–18)**: roughly **one in four** Indians aged 60 and above report difficulty with at least one ADL, and close to **half** report difficulty with at least one IADL – the population burden of immobility is therefore enormous and largely community-based.
2. **India Ageing Report 2023 (UNFPA–IIPS)**: the 60+ population, about 10.5% in 2022, is projected to reach roughly 20.8% by 2050 – immobility and disability will scale accordingly.
3. **NPHCE** district geriatric units and regional geriatric centres provide physiotherapy and rehabilitation, but coverage is thin below district level; the family remains the main mobilising agent.
4. **Rashtriya Vayoshri Yojana** and **ADIP–ALIMCO** supply walking sticks, tripods, walkers, wheelchairs and commodes free to eligible senior citizens – the single most practical intervention against environmental immobility in a poor household.
5. Culture-specific contributors worth naming in an Indian answer: the strong belief that a sick elder should be given complete rest; floor-level living and squat toilets that become impossible with knee osteoarthritis; absent handrails and wet, slippery bathroom floors; and adult children who take over all tasks as an expression of respect, producing rapid deconditioning.
6. The **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** is relevant where neglect, confinement or restraint of an immobile elder is suspected.

Rapid Recall Box — Recurring Topic

Mnemonic for complications – "BEDREST":
Bone loss – disuse osteoporosis and hypercalcaemia · **E**mbolism – DVT and pulmonary embolism · **D**ecubitus ulcer · **R**etention of urine, constipation and impaction · **E**rosion of muscle – atrophy, weakness and contractures · **S**ensory deprivation → delirium and depression · **T**oppling blood pressure – orthostatic hypotension (plus atelectasis and aspiration pneumonia).

Numerical anchors: one-third of hospitalised elders confined to bed or chair · 15–76% decline in at least one ADL at discharge · only 50% of those recover by three months · decline measurable by day 2 · 10 days of bed rest causes measurable loss of lean mass and strength · roughly 1–1.5% of muscle strength lost per day of strict bed rest (classical teaching figure) · LASI: ~25% ADL and ~48% IADL difficulty in 60+.

Examiner traps: (i) Listing only physical complications and forgetting **delirium, depression and hypercalcaemia**. (ii) Forgetting that **chemical restraint (antipsychotics) counts as a cause of immobility**. (iii) Missing the **caregiver-generated** immobility of the over-helpful family. (iv) Not naming **Tinetti's spiralling immobility**. (v) Treating deconditioning as inevitable ageing rather than a preventable, largely iatrogenic syndrome. (vi) Omitting fear of falling and health beliefs.

15-second answer skeleton: Define immobility as restriction of time out of bed by orders, devices, drugs or lack of help → one-third of inpatients affected, half never recover → causes by system: musculoskeletal, neurological, cardiopulmonary, sensory, drugs, psychological, environmental → complications by system using BEDREST → assessment: perceived cause, drugs, pain, mood, nutrition and vitamin D, environment, strength and gait → management: treat cause, restorative philosophy, progressive exercise, prevent complications, eliminate restraints → 2024 hospital-associated deconditioning of body and mind, Frailty Care Bundle, End PJ Paralysis, ICOPE 2025 → Indian context.

Exam One-Liners

1. Immobility is restriction of time out of bed or chair by orders, devices, chemical restraint, absent aids or absent human assistance.
2. Up to one-third of hospitalised older patients are restricted to bed or chair rest.
3. Only half of those who decline functionally in hospital recover by three months.
4. Contracture describes fixation of both muscle and joint, and is the hallmark consequence of immobility in long-term care.
5. Immobility causes negative nitrogen and calcium balance and impaired glucose tolerance.
6. Disuse osteoporosis from immobility can produce hypercalcaemia.
7. Reduced plasma volume plus deconditioned reflexes produces orthostatic hypotension.
8. Spiralling immobility (Tinetti and Ginter): restraining a faller makes them permanently unable to walk.
9. Antipsychotics act as chemical restraints and are a direct cause of immobility.
10. Deconditioning is measurable by day two of hospital admission.
11. Hospital-associated deconditioning is now understood as a condition of both body and mind.
12. The Frailty Care Bundle combines mobilisation, nutrition and cognitive engagement.
13. Choosing Wisely: do not let older adults lie in bed or only get up to a chair during their hospital stay.
14. WHO ICOPE 2nd edition (2025) screens locomotor capacity as one of six intrinsic-capacity domains.

Question 4. Rehabilitation team [7 MARKS]

High-Yield Points

1. **Rehabilitation** is a goal-directed, time-limited, multidisciplinary process that reduces **impairment**, **activity restriction** and **participation restriction**, and restores the person to the highest function their condition allows. **A team approach is essential, not optional.**
2. A properly resourced team has input from **medical and nursing staff, physiotherapists, occupational therapists, speech and language pathologists, clinical psychologists, dietitians and social workers**. Broadly, **doctors manage impairment, remedial therapists manage activity restriction, and social workers manage participation restriction**; **nurses hold a holistic brief that influences both activity and participation**.
3. **Doctor / geriatrician / physiatrist**: identifies and manages the presenting problem and coexisting impairments, minimises underlying risk factors and anticipates complications. In a patient with embolic stroke, for example, the doctor monitors anticoagulation, controls hypertension and manages coexisting angina and diabetes, while also preventing shoulder subluxation through correct early handling.
4. **Nurse**: delivers the therapy plan across 24 hours – skin integrity, continence, nutrition, medication, sleep, safety, education and encouragement – and is the member who converts an hour of therapy into a whole day of function.
5. **Physiotherapist**: provides therapies targeting specific problems and enhancing **cardiorespiratory, neuromuscular and locomotor function**; advises on and trains the use of **mobility aids**.
6. **Occupational therapist**: assesses and enhances competence with **ADLs and IADLs**; advises on aids and adaptations; performs the **pre-discharge home visit** so that modifications are appropriate and timed to facilitate discharge.
7. **Speech and language therapist**: manages **communication disorders** (dysphasia, dysarthria) and **swallowing disorders**, and advises on communication aids.
8. **Other members**: clinical psychologist (mood, motivation, adjustment to loss, cognition), dietitian, podiatrist, continence advisor, audiologist, pharmacist, and – in well-resourced centres – **prosthetists and orthotists**, who design, construct and fit prostheses (replacing body parts) and orthoses (supporting, improving or restricting movement).
9. **The patient and family are members of the team.** All members, **and particularly the patient**, must be involved in setting goals, with general agreement on their validity; a programme is seriously compromised if key people differ on what is being attempted. Set **short-term (intermediate) goals leading to long-term (final) goals**; patients with **ambitious goals make greater progress** than those with modest ones, so set targets that are ambitious but achievable, with flexible timeframes reviewed at least weekly.
10. **Communication is what makes a group of professionals a team.** Co-location allows regular informal exchange; in addition, teams hold **formal meetings to discuss progress, revise goals, plan discharge and organise community follow-up**. The **interdisciplinary team conference**, held after individual assessments are complete, is critical – it generates new ideas, sets priorities, disseminates findings and avoids duplication. Teams mature through the **forming, storming, norming and performing** phases, which takes commitment, skill and time.

Latest Updates (2023–present) — three key points

1. **WHO Rehabilitation 2030** and the **World Rehabilitation Alliance**, backed by the World Health Assembly resolution on strengthening rehabilitation in health systems, establish rehabilitation as an **essential health service to be integrated into universal health coverage** rather than an optional add-on. The WHO **Package of Interventions for Rehabilitation (PIR)** gives condition-specific team compositions and interventions that health systems are expected to fund.
2. **WHO ICOPE, 2nd edition (2025)** requires a single **integrated, person-centred care plan** built around the six domains of intrinsic capacity, delivered by a multidisciplinary team working at primary-care level – effectively exporting the rehabilitation team model out of the hospital and into the community.
3. India: the **National Commission for Allied and Healthcare Professions Act, 2021** created statutory registration, standardised curricula and defined scope of practice for physiotherapists, occupational therapists, speech-language pathologists and other allied professionals – a structural precondition for functioning rehabilitation teams. Tele-rehabilitation and hybrid team review are now accepted delivery modes.

Current Practice Update

Domain	Textbook position	Current practice
Status of rehabilitation	A specialist service for selected patients	**An essential health service within UHC** (WHO Rehabilitation 2030; WHA resolution)
Goal setting	Realistic, ambitious, patient-involved, reviewed weekly	Same principles, formalised as **SMART goals with shared decision-making** and documented patient-stated priorities
Team meeting	Regular formal case conference	Daily board rounds and digital huddles alongside the weekly conference; family joins remotely

Setting	Ward, unit, nursing home or home	Adds **tele-rehabilitation** and hospital-at-home models for post-discharge continuity
Workforce (India)	Unregulated allied health professions	**NCAHP Act 2021** – statutory councils, registration and defined scope of practice

Indian Context

Complete rehabilitation teams exist mainly in medical college PMR departments and large private hospitals. Under **NPHCE**, regional geriatric centres and district geriatric units are mandated to provide physiotherapy and rehabilitation services. In most district settings the "team" is realistically the **geriatrician or physician, one physiotherapist, a nurse, and the family caregiver** – so a good Indian answer states the ideal composition and then describes how the core functions are delivered with fewer people. Community delivery works through **ASHA and ANM home visits**, the **Kerala ward-level palliative home-care team** (nurse plus trained volunteers), and **Vayomithram**. Devices come through **ADIP–ALIMCO** and **Rashtriya Vayoshri Yojana**; the **Rehabilitation Council of India** governs training in disability rehabilitation.

Exam One-Liners

1. Rehabilitation reduces impairment, activity restriction and participation restriction.
2. Doctors address impairment, therapists address activity restriction, social workers address participation restriction.
3. Nurses hold a holistic brief influencing both activity and participation restriction.
4. Occupational therapists lead the pre-discharge home visit.
5. Orthoses support or restrict movement; prostheses replace a body part.
6. Patients with ambitious goals make greater progress than those with modest goals.
7. Short-term intermediate goals in succession deliver the long-term final goal.
8. The interdisciplinary team conference after individual assessment is the critical step in geriatric assessment programmes.
9. Teams evolve through forming, storming, norming and performing.
10. WHO Rehabilitation 2030 positions rehabilitation as an essential service within universal health coverage.

Question 5. Role of physiotherapy in the elderly [7 MARKS]

High-Yield Points

1. **Objectives** of physiotherapy in the older patient (Kane's): **relieve pain**; **evaluate, maintain and improve joint range of motion**; **evaluate and improve strength, endurance, motor skills and coordination**; **evaluate and improve gait and stability**; and **assess the need for, and teach the use of, assistive devices for ambulation** – wheelchairs, walkers and canes. Pathy's frames the same role as enhancing **cardiorespiratory, neuromuscular and locomotor function**.
2. **Exercise modalities**: active exercise (isometric and isotonic), passive exercise for the immobile or paralysed limb, and structured **sitting exercise programmes** for those who cannot stand.
3. **Physical modalities**: heat – hot packs, paraffin wax, diathermy; **ultrasound**; **hydrotherapy**; and **transcutaneous electrical nerve stimulation (TENS)** for pain. Note that hydrotherapy improves self-confidence but has not been shown to produce measurable functional improvement in arthritic joints.
4. **Falls, gait and balance**: lower-extremity strength training, balance training including **tai chi**, gait retraining, properly fitted footwear, and **habituation exercises** for benign paroxysmal positional vertigo. Physiotherapy is one of the named treatments for gait and balance disorders, muscle weakness and deconditioning in the falls algorithm.
5. **Musculoskeletal disease**: **daily range-of-motion exercise** is particularly important for restoring function in arthritic joints, though compliance is poor at all ages – **group activity adds a social component and improves compliance**. Age-related stiffening of joints and soft tissues is **reversible**: exercise increases joint flexibility and improves the strength, size and resilience of cartilage, ligaments and muscle.
6. **Prevention of the complications of immobility**: chest physiotherapy and breathing exercises, upright positioning to prevent atelectasis and aspiration, positioning and proper handling to prevent contractures and **shoulder subluxation in flaccid hemiplegia**, and mobilisation to prevent DVT and pressure injuries. Preoperative training in cough and lung expansion techniques, with chest physiotherapy for those at pulmonary risk, is part of standard anaesthetic preparation of the elderly.
7. **Neurological rehabilitation**: even severely affected stroke patients achieve meaningful functional gains with early rehabilitation, and **immobility and its complications can almost always be prevented or minimised**. **Treadmill training has repeatedly shown significant benefit for gait and balance in stroke survivors**; robot-assisted motor training has shown some positive benefit. Ongoing exercise after the acute phase maintains function, preserves quality of life and helps prevent recurrent stroke.
8. **Pulmonary and cardiac rehabilitation**: in COPD, pulmonary rehabilitation **reduces dyspnoea and fatigue, increases exercise capacity, enhances patient control of the disease, improves quality of life and may prevent hospitalisation**. Benefits are similar in all adults **including the "old old"**, and are **greatest in the most impaired patients**. Patients with asthma and interstitial disease benefit too. Even those hypoxic at rest or desaturating on exertion can be trained safely with supplemental oxygen.
9. **Dementia and frailty**: physical activity should be at **moderate intensity for 30 minutes five times a week, or vigorous intensity for 25 minutes three times a week**. Walking combined with strength, balance and flexibility exercise slows functional decline, increases gait speed, improves mood and sleep and reduces agitation. Compliance – more than cognitive status – is the limiting factor, so programmes must be **enjoyable, individualised, accessible, and delivered with conversation or music**, with staff communicating with the resident during the session.
10. **Safety and setting**: current guidance **no longer recommends routine stress testing before starting physical activity**; low-intensity activity can be safely initiated in asymptomatic sedentary older people regardless of recent medical evaluation, because **sedentary behaviour creates more risk than moderate physical activity**. Physiotherapy may be delivered in acute hospital, rehabilitation unit, skilled nursing facility, outpatient clinic or at home, individually or in groups depending on preference, cognition and motivation.

Latest Updates (2023–present) — three key points

1. **WHO physical activity guidance for adults aged 65 and over** is now the reference prescription: **150–300 minutes of moderate aerobic activity per week**, **muscle-strengthening on at least 2 days**, and – specifically for older adults – **multicomponent activity emphasising balance and strength on at least 3 days per week to prevent falls and functional decline**. "Every move counts"; some activity is better than none, and sedentary time should be limited.
2. **In-hospital exercise reverses the functional decline of acute admission.** The Martínez-Velilla multicomponent exercise trial (*JAMA Internal Medicine* 2019) remains the anchor; 2024–25 evidence extends it – a **2025 European Geriatric Medicine meta-analysis** supports progressive mobilisation in **hospitalised people with dementia**, and service evaluations show **functional resistance training on medical wards** produces significant gains in grip strength, 30-second sit-to-stand and DEMMI scores.
3. **Tele-rehabilitation and technology-assisted programmes** are now evidence-supported for post-discharge deconditioning (smartphone-delivered resistance and balance programmes for patients on physiotherapy waiting lists) and for delivering **Otago-based fall-prevention programmes** in early geriatric rehabilitation using digital trainers with real-time correction.

Current Practice Update

Domain	Textbook position	Current practice
Exercise prescription	Moderate 30 min × 5/week or vigorous 25 min × 3/week	WHO 65+: **150–300 min/week moderate + strengthening ≥2 days + balance-focused multicomponent ≥3 days**
Pre-exercise screening	Routine stress testing no longer recommended	Unchanged and reinforced – sedentary behaviour is the greater risk
Acute hospital	Rehabilitation begins after the acute illness settles	**Exercise during the acute admission itself** reverses functional decline; delivered from day 1
Dementia	Compliance-limited, benefits uncertain	2025 meta-analysis supports progressive mobilisation and multicomponent programmes in hospitalised dementia
Delivery mode	Face-to-face, institution or home	Adds **tele-rehabilitation** and digital/sensor-assisted training with real-time feedback

Indian Context

Physiotherapy is now a **statutorily regulated profession under the NCAHP Act, 2021**. Under **NPHCE**, physiotherapy is a mandated component of district geriatric units and regional geriatric centres, though rarely available below district level; the **Kerala palliative home-care network** provides one of the few functioning home-physiotherapy models. Practical, low-cost and culturally acceptable prescriptions carry most of the benefit: **chair-based exercise, supervised walking groups in temple or community grounds, stair and squat avoidance advice for knee osteoarthritis, thera-band resistance work, and yoga adapted for balance** (with caution about floor-level postures in the frail). Assistive devices – sticks, tripods, walkers, wheelchairs – are supplied free through **Rashtriya Vayoshri Yojana** and **ADIP–ALIMCO**. Counsel the family explicitly that **rest is not treatment**, since the belief that an unwell elder must be kept in bed is the commonest barrier to physiotherapy in Indian homes.

Exam One-Liners

1. The five physiotherapy objectives: relieve pain, improve range of motion, improve strength and endurance, improve gait and stability, and prescribe and teach assistive devices.
2. TENS, ultrasound, paraffin wax, diathermy, hot packs and hydrotherapy are the classic physical modalities.
3. Hydrotherapy improves self-confidence but not measurable joint function.
4. Treadmill training repeatedly improves gait and balance after stroke.
5. Pulmonary rehabilitation benefits are greatest in the most impaired patients, including the old old.
6. Age-related joint stiffening is reversible with exercise.
7. Group exercise improves compliance by adding a social component.
8. Routine stress testing is not required before starting low-intensity activity in asymptomatic older adults.
9. In dementia, compliance limits exercise programmes more than cognitive status does.
10. WHO 65+ prescription: 150–300 min moderate activity weekly, strengthening twice weekly, balance work three times weekly.

Question 6. Role of the occupational therapist in the life of an elderly person with mobility issues and an ageing spouse [15 MARKS]

> **How to attack this question:** it has **two halves** – the elder with mobility restriction, and the ageing spouse who is simultaneously the carer and a frail older person in their own right. Answers that describe only grab bars and reachers lose half the marks. Pathy's asks explicitly, as part of the OT assessment: "*Does the carer also need OT intervention in order to carry out their support effectively?*" That sentence is the spine of this answer.

High-Yield Points

The occupational therapy frame of reference

1. Occupational therapy focuses on the elder's **ability to participate in the activities that form their life and are important to them**, not on the impairment itself. Its three aims are to **collaborate with the older adult to plan client-centred care**, **tailor approaches to that person's activity needs**, and **address continued participation in society in a way that is achievable and meaningful**.
2. Assessment uses the **Person–Environment–Occupation–Performance (PEOP)** framework: intrinsic **person** factors (physiological, cognitive, neurobehavioural, psychological, spiritual) interacting with the extrinsic **environment** (social systems and support, economic support, culture and values, built environment and technology, natural world), across **occupations** (basic ADLs, IADLs, leisure, rest, work or service, education) and **roles** (spouse, parent, grandparent, home manager, lifelong learner, organisation member, volunteer).

Assessment — of the elder and of the spouse

3. The **occupational profile** is built by interviewing the patient and the family and asking five questions: (i) **what roles, routines, habits and new activities does the person want to perform** – the elder's own priorities; (ii) **what can be done to facilitate the activities they do perform**; (iii) **what are they currently able to perform** – intrinsic ability; (iv) **if they rely on a support system, what supports are provided and to what extent**; and (v) **does the carer also need OT intervention in order to carry out that support effectively?**
4. The assessment takes into account age, gender, socioeconomic background, sexual orientation, racial, ethnic, cultural and religious background, developmental status, health history and current status, and educational and vocational history – then combines interview with standardised, evidence-based performance measures.
5. **Home evaluation**: OT personnel evaluate the home to establish **PEOP compatibility** – comparing the elder's activity needs and priorities against their functional abilities and the physical environment in order to **predict the likelihood of the activity actually being performed**. The deficiencies found become the intervention targets. **These needs are frequently overlooked or underestimated at the point of discharge, and that gap puts the older adult at increased risk of dependency, falls and injury.**

Intervention for the elder with mobility restriction

6. **Remediation of sensorimotor deficits**: sitting and standing balance, strengthening, endurance, range of motion and coordination – but always **related back in the intervention process to ADL and IADL participation** and to the tasks and roles that are meaningful to that individual, rather than trained as abstract exercise.
7. **Retraining in functional occupations**: basic ADLs (transfers, toileting, bathing, dressing, grooming, feeding) and IADLs (home management, cooking, shopping, laundry, medication and money management, use of public transport, driving skills, use of the telephone and smartphone).
8. Where oral-motor dysfunction, muscular rigidity, joint pain or bradykinesia impede direct intervention – as in Parkinson's disease, stroke or dementia – OT practitioners use **facilitatory techniques and positioning approaches** to enable participation in meaningful activity that simultaneously achieves the mobilisation goal.
9. **Health promotion and prevention teaching**: **body mechanics, joint protection, energy conservation, activity and exercise guidelines, sleep hygiene** for physical deterioration; and for psychosocial deterioration – adjusting lifestyle to accommodate age-related and role changes, the value of purposeful and balanced activity, overall time management, self-esteem and mastery strategies, interpersonal and socialisation skills, and emphasis on the positive aspects of living.
10. **Physical environment adaptation**: additional lighting, railings, ramps, grab bars, and assistive devices to promote accessibility and independent mobility. Concrete measures from Pathy's case examples include an **elevated toilet seat with attached rails, a tall shower stool, a handheld shower, grab bars in the shower**, and **extensions on the legs of a favourite chair** so the person can sit and rise unaided. Furniture height for sitting, eating and hobbies is assessed deliberately.
11. **Technological aids**: low-technology – long-handled reaching device, sock aid, long-handled shoehorn, tap turners, zipper pulls, sock pulls, stretch laces, Velcro fasteners, bath bench; and high-technology – low-vision aids, hearing assistive devices, voice-activation software, adapted computers and smartphones. **Devices are recommended only if they support improved participation in activities identified as crucial by the elder and their family.** An aid can foster dependence rather than independence if it is given without this reasoning.
12. **Cognitive and psychological compensation** where dementia or stroke coexists: simplifying and organising the

environment (mounting **pictures of clothing types on dresser drawers and photographs on kitchen cupboards** so items can be associated with locations), establishing a **predictable daily routine**, orientation and safety cues, and step-by-step strategies for relearning problematic sequences such as transfers and dressing.

Intervention directed at the ageing spouse

13. The ageing spouse is simultaneously the principal support system and **an older adult with their own arthritis, visual and hearing loss, cardiac limitation and reduced strength**. OT formally assesses whether the transfers and personal care being asked of them are **physically safe and sustainable** – and whether the spouse themselves needs intervention.
14. **Carer skills training**: safe transfer and handling technique, correct use of the bath bench, transfer board or hoist, back care and body mechanics, energy conservation, and how to **prompt and supervise rather than do** – because performing tasks for an elder who retains the underlying capability produces deconditioning and immobility. Pathy's lists **family, carer and staff skills and coping** explicitly among geriatric OT services.
15. **Reduce the carer's load through equipment and layout rather than effort** – raising bed and chair heights, positioning items within reach, organising clothes on lower shelves and by colour groups, and installing rails at the points of greatest strain. This is what protects an ageing spouse from musculoskeletal injury.
16. **Carer wellbeing as an explicit goal.** In Pathy's stroke case, the OT worked with the wife **to help her realise more success and improved coping with her husband's condition, in addition to having more time for the activities that were important to her** – that is, preserving the spouse's own occupations, roles and identity, not merely her caring capacity.
17. **Dyadic education and community linkage**: both partners are included in education and goal setting; the couple is connected to local resources – in Pathy's dementia case the family was informed of the support provided by the local Alzheimer's Association – and to day services, respite, senior centres and support groups.
18. **Anticipatory planning**: what happens when the spouse can no longer sustain the care. Graded introduction of paid help, day care or supported living is discussed early rather than in crisis, alongside advance care planning and end-of-life activities, which Pathy's lists within the scope of geriatric OT.

Review, outcome and evidence

19. The OT process is a loop: **patient identification → occupational profile → needs, problems and priorities → occupational performance assessment → collaborative goal setting → occupation-based intervention → ongoing assessment and refinement → final assessment → discharge**, with continuing input from the elder, carers and family at every review. Outcome assessment determines the extent to which targeted goals were met and guides future therapy or discontinuation.
20. **Evidence base**: the landmark **Well Elderly / Lifestyle Redesign trial (Clark *et al.*, JAMA 1997)** showed that preventive occupational therapy for independent-living older adults improved health, function and quality of life, with benefits sustained on long-term follow-up. The emphasis on participation in meaningful occupation promotes **cost-effective care, individual competence and optimal quality of life**.

Latest Updates (2023–present)

1. **CAPABLE (Community Aging in Place, Advancing Better Living for Elders)** is the flagship model: an **occupational therapist plus a nurse plus a small home-repair budget**, delivered over about 10 visits, targeting "what matters" to the older adult. It **delays disability, prevents hospitalisation and avoids institutionalisation**. A 2025 real-world implementation through an area agency on ageing (90 participants) reported **69% completion**, a mean of **4.5 self-identified goals** per person, home modification costs averaging about **US$943**, and the commonest goal areas as **bathing, functional mobility and pain** – directly relevant to the scenario in this question.
2. **Dyadic occupational therapy in dementia**: the Dutch **COTiD** programme (Graff, BMJ 2006) produced large gains in ADL performance and in **carer sense of competence**. The UK replication, **COTiD-UK / VALID (PLoS Medicine 2021)** – 10 hours of OT over 10 weeks in the person's home – did **not** reproduce the effect on the primary ADL outcome, partly because usual care had improved. The practical lesson is that dyadic OT should be offered as a **person- and carer-centred programme with realistic expectations**, not as a guaranteed ADL cure. Ongoing trials (2024–27) are testing COTiD for recurrent falls after discharge in older people with neurocognitive disorders.
3. **Home modification delivered by occupational therapists reduces falls in high-risk community-dwelling older adults by around 39%**, and a 2024 randomised trial confirmed benefit specifically in **older adults with dementia**. A 2025 scoping review broadens the outcome set beyond falls to participation, quality of life and **relatives' and carers' outcomes**.
4. **Reablement and Lifestyle Redesign** – short-term, goal-directed OT to restore functional independence, and occupation-based redesign of daily routines – are now mainstream international models. A **2025 AJOT scoping review** of home-based OT for community-dwelling older adults calls for standardised outcome measurement, integration of **remote and tele-OT approaches**, and **culturally tailored programmes** – the last point directly applicable to India.
5. Carer-focused assessment tools have matured: the **I-HOPE Assist** (In-Home Occupational Performance Evaluation for

Providing Assistance) is designed specifically to capture the **informal caregiver's** perspective on the tasks they assist with and the barriers they face – precisely the ageing-spouse dimension of this question.

Current Practice Update

Domain	Textbook position	Current practice (2023–present)
Unit of care	Elder-centred, carer involved where indicated	**The dyad is the unit of care**; carer-specific assessment tools (I-HOPE Assist) and dyadic programmes (COTiD)
Service model	Assessment, aids, adaptation, review	**CAPABLE** – OT + nurse + funded home repairs against self-identified goals; **Reablement** as a short-term goal-directed model
Home modification	Recommended on OT judgement	Evidence-graded: ~**39% fall reduction** in high-risk elders; RCT support extended to dementia
Dementia dyads	Community OT shown effective (COTiD)	**VALID/COTiD-UK did not replicate** the ADL benefit – offer with realistic expectations and carer-focused goals
Delivery	Home visits and clinic sessions	Adds **tele-OT**, remote coaching and smart-home/assistive technology
Equity	Culture noted as a background factor	Explicit call for **culturally tailored OT programmes** and standardised outcome measures (AJOT 2025)

Indian Context — and practical adaptations for this scenario

1. **Workforce and regulation**: occupational therapy is now statutorily regulated under the **NCAHP Act, 2021**; the **All India Occupational Therapists' Association** is the professional body. Services remain concentrated in medical colleges, PMR departments and metropolitan private hospitals, so in most districts the OT role is discharged in part by physiotherapists, nurses and trained volunteers – state this openly and describe the task-shifted model.
2. **Assistive devices** are supplied free or subsidised through **Rashtriya Vayoshri Yojana** and **ADIP–ALIMCO** – walking sticks, tripods, walkers, wheelchairs, commodes, spectacles, hearing aids and dentures. **AB-PMJAY / Ayushman Vay Vandana Card** covers hospitalisation for the 70+ group.
3. **Home modifications that matter in an Indian home**: converting or fitting a **raised commode seat over an Indian squat toilet** with a grab bar; anti-skid mats and a grab bar in the perpetually wet bathroom; a bathing stool and mug rather than a shower; raising a floor-level mattress onto a correct-height cot; ramping the two or three steps at the entrance; removing loose rugs and door thresholds; brighter lighting on stairs; keeping the kitchen at standing height for an elder who can no longer squat.
4. **The ageing spouse in the Indian setting** is often an older woman with knee osteoarthritis and osteoporosis, doing the cooking, bathing and transfers alone while adult children work elsewhere or have migrated. The realistic OT plan is **equipment plus task-sharing plus respite**, not exhortation. Link to **ASHA and ANM home visits**, the **Kerala ward-level palliative home-care team** of nurse plus trained volunteers, **Vayomithram** mobile clinics, **Kudumbashree** neighbourhood groups, day-care centres under NPHCE and the state Old Age Homes scheme for respite.
5. **Legal and social safety net**: the **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** (as amended) creates an enforceable duty of maintenance on children and relatives, and Maintenance Tribunals provide a remedy where an ageing couple is left without support – a legitimate and often-missed point in a question about an elderly couple caring for each other alone.
6. **Cultural calibration**: respect for elders in Indian families often expresses itself as doing everything for them, which accelerates deconditioning. The most important single piece of family education is **"prompt, supervise and stand by – do not take over"**.

Exam One-Liners

1. Occupational therapy targets participation in meaningful occupation, not the impairment itself.
2. PEOP: Person, Environment, Occupation, Performance – the framework for OT assessment.
3. The occupational profile asks what the elder wants to do, currently does, can do, what support is provided, and whether the carer also needs intervention.
4. OT evaluates the home to predict whether a desired activity can actually be performed there.
5. Environmental needs are commonly underestimated at discharge, raising the risk of dependency, falls and injury.
6. An aid can foster dependence rather than independence – prescribe it only if it improves valued participation.
7. Photographs mounted on drawers and cupboards help a person with dementia locate items independently.
8. Chair-leg extensions, a raised toilet seat with rails, a tall shower stool and a handheld shower are the standard home package after hip surgery.

9. Teach the carer to prompt and supervise rather than take over, because doing tasks for a capable elder causes deconditioning.
10. Carer wellbeing includes freeing time for the carer's own valued activities, not just improving their caring capacity.
11. Clark's Well Elderly trial (JAMA 1997) showed preventive OT improves health, function and quality of life in independent-living elders.
12. CAPABLE combines OT, nursing and a small home-repair budget to delay disability and prevent institutionalisation.
13. OT-delivered home modification reduces falls in high-risk community-dwelling older adults by around 39%.
14. COTiD-UK (VALID, 2021) failed to replicate the ADL benefit of the original Dutch dyadic OT trial.

Question 7. How would you deal with constant itching (pruritus) in an elderly patient? [15 MARKS]

High-Yield Points

Definition and why old skin itches

1. **Chronic pruritus** is itch lasting more than **six weeks**. It is one of the commonest and most under-treated complaints of old age, disturbing sleep, causing irritability, low mood, excoriation and secondary infection, and materially reducing quality of life.
2. **Mechanism in ageing skin**: **epidermal barrier dysfunction** – thinning of the epidermis, slower regeneration of keratinocytes and fibroblasts, and reduced function of sebaceous and sweat glands. The result is a reduced ability to maintain an emolliated barrier, so the skin cannot retain water. This produces **xerosis, the single commonest cause of itch in the elderly**, and is further aggravated by **thyroid dysfunction and polypharmacy**. Immunosenescence and neuronal ageing add further mechanisms.

Causes — approach the question by category

3. **Dermatological**: **asteatotic eczema (eczema craquelé)** – xerotic skin with thin overlying scale and superficial fissures crossing in a pattern resembling a **dried riverbed**, from reduced intercellular lipids; **seborrhoeic dermatitis** (pruritic, well-demarcated yellow-red patches with greasy scale on scalp, eyebrows, nasolabial folds, ears, chest and flexures, driven by *Malassezia furfur*, and more prominent in stroke, epilepsy and Parkinson's disease); **stasis dermatitis** from venous hypertension; contact and allergic dermatitis; psoriasis; lichen simplex chronicus.
4. **Infestation – always exclude scabies first.** Nocturnal itch, burrows in finger web spaces, wrists, axillae, waist and genitalia, and **multiple affected members in the household or institution**. **Crusted (Norwegian) scabies** in the frail, bedbound or immunosuppressed presents with heavy scaling and **surprisingly little itch**, and is highly contagious. Also consider candidiasis, dermatophytosis, pediculosis and the prodrome of herpes zoster.
5. **Bullous pemphigoid** – the commonest autoimmune blistering disorder over the age of 60, with antibodies to **BPAG1 (BP230)** and **BPAG2 / collagen XVII (BP180)**. Its presentation is **polymorphic**: it may appear for months as **intractable pruritus, an eczematous dermatitis or urticaria before any blister forms**. Classic form: symmetrical **tense bullae** on lower trunk and flexures with a **negative Nikolsky sign** (distinguishing it from pemphigus vulgaris); oral mucosa involved in up to one-third. Strongly associated with **Parkinson's disease, dementia, cerebrovascular disease and epilepsy** – a cardinal geriatric association.
6. **Systemic causes**: chronic kidney disease (uraemic pruritus), cholestasis and primary biliary cholangitis, **thyroid dysfunction**, diabetes mellitus, iron deficiency, **polycythaemia vera** (aquagenic itch after bathing), **lymphoma** – note that a **generalised or refractory asteatotic eczema has been associated with underlying systemic lymphoma** – other malignancy, and HIV.
7. **Drugs** – a major and reversible cause in the polypharmacy-laden older patient: opioids, statins, ACE inhibitors, amiodarone, hydrochlorothiazide, allopurinol, antibiotics, calcium-channel blockers, and **DPP-4 inhibitors (gliptins), which are specifically linked to drug-induced bullous pemphigoid**.
8. **Neuropathic / neurogenic pruritus** results from damage to a single nerve or group of nerves, causing itch in the skin they innervate. **Notalgia paraesthetica** – a hyperpigmented patch **between the medial scapular borders**, from damage to the **T2–T6** sensory nerves. **Brachioradial pruritus** – itch of the **dorsolateral forearms and elbows** from **C5–C9 compression due to cervical spine degeneration**. Also post-herpetic itch and small-fibre neuropathy.
9. **Psychogenic and perpetuating factors**: anxiety, depression, delusional infestation; and the self-sustaining **itch–scratch cycle**, which continues long after the original trigger has gone.
10. **Anogenital itch** deserves separate mention. In women, **lichen sclerosus** – pale ivory-white plaques with a crinkly atrophic surface, purpura and scarring, destroying normal vulval architecture, with a **3.5–5% risk of squamous cell carcinoma**; treat with **clobetasol propionate 0.05% ointment**, emollients, soap substitutes and irritant avoidance, and biopsy any suspicious, ulcerated or raised area. Also squamous cell hyperplasia and **vulvodynia**. The commonest general diseases causing vulval itch are **diabetes, uraemia and liver failure**; irritants include perfumed soap and washing powder.

Assessment

11. **History**: duration; **timing** (nocturnal itch suggests scabies or cholestasis); distribution – generalised versus localised, and the **"butterfly sign"**, where the unreachable interscapular area is spared, suggesting a systemic rather than skin cause; relation to bathing (polycythaemia); water temperature, soap and bathing frequency; occupational and contact exposures; **a complete drug and supplement chart**; household or institutional contacts; and red flags – weight loss, fever, night sweats, jaundice, lymphadenopathy.
12. **Examination**: inspect the **whole skin** including scalp, web spaces, genitalia and perianal area. Distinguish **primary lesions** (indicating a dermatosis) from the **secondary changes of chronic scratching** – **linear excoriations, excoriated papulonodules (prurigo nodules), well-demarcated lichenified plaques (lichen simplex chronicus), and post-inflammatory hyperpigmentation**. Examine lymph nodes, liver, spleen and thyroid; assess mood, sleep and cognition.

13. **Investigations** when no primary skin disease is evident, in Indian conventional units: haemoglobin (g/dL) and full blood count with differential (eosinophilia, polycythaemia), ESR, fasting and post-prandial glucose (mg/dL), serum creatinine (mg/dL) with eGFR, liver function tests with bilirubin (mg/dL) and alkaline phosphatase, TSH (μIU/mL), serum ferritin (ng/mL) and iron studies, serum calcium (mg/dL), LDH, chest radiograph, and HIV serology where indicated. Add **skin scraping and dermoscopy for scabies mite, KOH mount for fungus**; **skin biopsy with direct immunofluorescence and anti-BP180 ELISA** when bullous pemphigoid is suspected; and **cervical spine imaging** for brachioradial pruritus.

Management

14. **General skin care is the foundation and is frequently curative on its own.** Short, lukewarm – never hot – showers; **soap substitutes or syndet cleansers and moisturising soaps** in place of ordinary soap and detergent; no scrubbing; **emollient or ointment applied liberally within a few minutes of bathing and at least twice daily** to restore the natural barrier function; **urea-, lanolin- or ammonium-lactate-containing creams** for marked xerosis; room humidification and avoidance of excessive room heating; cotton clothing; nails cut short. Educate the older person *and* the carer, since applying emollient to one's own back is often impossible.
15. **Stop the culprit drug** and rationalise polypharmacy using **Beers criteria and STOPP-START**. Suspect gliptins if bullous pemphigoid is in the differential.
16. **Treat scabies presumptively if there is any doubt** – **permethrin 5% cream** applied neck-down overnight and repeated after one week, or **oral ivermectin** (repeat dose at day 7–14; two or more doses with topical keratolytics for crusted scabies). **Treat all household and institutional contacts simultaneously and launder linen and clothing in hot water.** Warn that post-scabetic itch persists for 2–4 weeks and does **not** indicate treatment failure – otherwise the patient is repeatedly and unnecessarily re-treated.
17. **Topical therapy**: **topical corticosteroid ointment** in short courses for inflammatory dermatoses – discuss proper use explicitly, since improper prolonged use perpetuates further thinning of already atrophic skin. **Topical calcineurin inhibitors** (tacrolimus, pimecrolimus) are steroid-sparing and useful on the face and flexures. Antipruritic counter-irritants: **menthol, camphor, pramoxine and topical lidocaine**. **Topical capsaicin** for localised neuropathic itch such as notalgia paraesthetica and brachioradial pruritus.
18. **Systemic therapy**: **antihistamines are far less useful than commonly assumed** outside urticaria, and **sedating antihistamines should be avoided in older people** (Beers criteria – delirium, falls, urinary retention, anticholinergic burden). Preferred agents: **gabapentin or pregabalin** for neuropathic and uraemic itch, dose-reduced for renal function and started low to avoid sedation and falls; **SSRIs such as sertraline or paroxetine, or mirtazapine** for cholestatic, paraneoplastic and nocturnal itch; **naltrexone** (μ-opioid antagonist) for opioid-induced and cholestatic itch; and **narrow-band UVB phototherapy**, which is safe and effective in the elderly, including in renal and idiopathic pruritus.
19. **Cause-specific treatment**: **cholestasis** – cholestyramine, rifampicin, naltrexone, and treat the obstruction. **Chronic kidney disease** – optimise dialysis adequacy, correct hyperphosphataemia and hyperparathyroidism, gabapentin, and **difelikefalin**. **Stasis dermatitis** – leg elevation above heart level for 30 minutes three to four times daily and **compression stockings** after excluding arterial disease, with topical steroid only during acute flares. **Seborrhoeic dermatitis** – topical azole antifungal (ketoconazole daily during a flare, then twice weekly for maintenance), ciclopirox, zinc pyrithione, selenium sulfide or tar shampoo.
20. **Bullous pemphigoid**: potent topical clobetasol for localised disease; oral corticosteroids with or without doxycycline for extensive disease. **Osteoporosis and gastrointestinal ulcer prophylaxis must be given to every older patient started on oral steroids**, and methotrexate must be dosed cautiously because of the **natural 30% decline in glomerular filtration rate with ageing** in addition to other renal insults.
21. **Break the itch–scratch cycle and treat the person**: cool compresses, wet wraps, distraction and habit-reversal training, treatment of coexisting depression and anxiety, and attention to sleep. Refer to **orthopaedics or neurology** in selected neurogenic cases, and to **dermatology** for refractory itch or when pemphigoid or malignancy is suspected.
22. Finally, apply the geriatric wrap-around. **Social support, functional status, comorbidities, mobility and cognition** all determine whether a treatment plan can actually be carried out. Pathy's makes the point squarely: **even a simple intervention to treat a symptomatic lesion or dermatitis can provide relief and positively affect quality of life in the elderly patient.**

Latest Updates (2023–present)

1. **Chronic prurigo / prurigo nodularis has become a treatable disease.** The **IFSI stepwise algorithm** runs: **step 1** – topical corticosteroid, topical calcineurin inhibitor and H1 antihistamine; **step 2** – topical capsaicin, intralesional corticosteroid, UV therapy; **step 3** – gabapentin, pregabalin or antidepressants where neuropathic features predominate, versus ciclosporin or methotrexate where inflammation predominates; **step 4** – NK1-receptor antagonist, μ-opioid receptor antagonists, **dupilumab, nemolizumab**, and thalidomide as a last resort.
2. **Dupilumab** (anti-IL-4Rα, blocking IL-4 and IL-13) was the **first systemic therapy approved for prurigo nodularis**, on the phase 3 **LIBERTY-PN PRIME and PRIME2** trials. Pooled week-24 data: **58.8% versus 19.0%** achieved a clinically meaningful (≥4-point) improvement in itch, **46.4% versus 17.1%** achieved clear or almost-clear skin, and **35.3% versus 8.9%** achieved both. Benefit was independent of baseline demographics and of atopic status.

3. **Nemolizumab**, a first-in-class antibody against the **interleukin-31 receptor α** – IL-31 being the "itch cytokine" of neuroimmune crosstalk – was approved for prurigo nodularis in **2024** on the phase 3 **OLYMPIA 2** trial, with reduction in itch and sleep disturbance as early as **week 4**. A 68-week Japanese phase II/III study showed benefit maintained or increased through 68 weeks with **no rebound after cessation**.
4. **British Association of Dermatologists living guideline for nodular prurigo (2025)**: **offer a licensed biologic (dupilumab or nemolizumab)** to adults with moderate-to-severe disease who are candidates for systemic therapy (strong recommendation); consider **thalidomide only for disease resistant to all other treatment**, with counselling and informed consent; follow up at least once in the following 12 months using DLQI, HADS, GAD-7 and PHQ scores.
5. **Chronic pruritus of unknown origin (CPUO)** is now a named entity – itch beyond six weeks with cutaneous, systemic, neuropathic and psychogenic causes excluded. It is **most prevalent in older adults** (quoted prevalence in older populations ranges widely, up to around 30–45%), and is hypothesised to arise from **age-related polarisation towards a type 2 immune response as a consequence of immunosenescence**. The phase 3 **LIBERTY-CPUO-CHIC Study A (2024) missed its primary itch endpoint at week 24**, but showed nominally significant improvement on essentially every other itch measure (≥4-point WI-NRS response **44.4% versus 23.5%** at week 12) and on itch-related quality of life. A proof-of-concept **nemolizumab trial in CPUO** began in 2025. **The examinable message: there is still no drug licensed for CPUO.**
6. **Abrocitinib**, an oral JAK1 inhibitor, 200 mg daily for 12 weeks in an open-label phase 2 study (*JAMA Dermatology* 2024) reduced peak pruritus NRS by **78.3% in prurigo nodularis and 53.7% in CPUO** – promising, but JAK inhibitors carry **cardiovascular, thrombotic, infective and malignancy warnings** that are particularly weighty in an elderly, comorbid population.
7. **Difelikefalin**, a peripherally acting **kappa-opioid receptor agonist**, is approved for **pruritus associated with chronic kidney disease in adults on haemodialysis**, reflecting the role of opioid-pathway imbalance and kappa-receptor downregulation in uraemic itch. Case reports describe nemolizumab succeeding where difelikefalin has failed, supporting a shared IL-31 mechanism.
8. A **Cochrane review of interventions for CPUO** found only one eligible randomised trial in the entire literature; pragmatically, **serlopitant, pregabalin or dupilumab** are the options considered after first-line therapy fails.

Current Practice Update

Domain	Textbook position	Current practice (2023–present)
Underlying model	Histamine-centric; antihistamines listed as standard oral therapy	**Neuroimmune model** – IL-4/IL-13, **IL-31**, substance P/NK1 receptor, kappa-opioid imbalance. Antihistamines have little role outside urticaria; sedating agents avoided under Beers criteria
Prurigo nodularis	Topical steroid, capsaicin, anaesthetics, antihistamines, gabapentin, antidepressants, phototherapy	**Biologic era**: dupilumab (approved) and nemolizumab (approved 2024) as first-line systemics; **BAD 2025 living guideline** recommends offering a licensed biologic
Idiopathic itch of the elderly	Not separately named	Defined as **CPUO** with an immunosenescence / type 2 polarisation hypothesis; **no licensed drug**; dupilumab phase 3 missed its primary endpoint
Uraemic pruritus	Symptomatic care, gabapentin	**Difelikefalin** licensed for haemodialysis-associated pruritus
Emerging oral agents	Not covered	**JAK1 inhibitors** (abrocitinib) show large itch reductions in PN and CPUO but carry cardiovascular, thrombotic and malignancy warnings in the elderly
Thalidomide	Historically used for refractory prurigo	Restricted – **only for disease resistant to everything else**, with formal counselling (BAD 2025)
Outcome measurement	Descriptive	Standardised: **WI-NRS / PP-NRS**, IGA PN-S, DLQI, HADS – a ≥4-point NRS fall is the accepted clinically meaningful response

Indian Context

1. **Scabies is the single most important "do not miss" diagnosis in the itching Indian elder** – particularly in old-age homes, hospitals, long-term care facilities and crowded joint families, where institutional outbreaks are common. Treat the index case and **every contact simultaneously**; permethrin 5% and oral ivermectin are both cheap and widely available.
2. **Xerosis is aggravated by locally specific habits**: very hot bucket baths, hard water, vigorous use of harsh detergent bar soaps and scrubbing with a loofah, and winter room heating. The culturally acceptable, cheap and effective intervention is **pre-bath and post-bath application of coconut or sesame oil**, or a paraffin-based

emollient, with a syndet or soap substitute – often more successful than prescribing an expensive branded moisturiser.

3. **High background prevalence of the systemic causes**: diabetes mellitus, chronic kidney disease with a large and growing dialysis population, hepatobiliary disease, iron deficiency anaemia (very common in older Indian women), and thyroid disorders. A basic panel – haemoglobin g/dL, glucose mg/dL, creatinine mg/dL, LFT with bilirubin mg/dL, TSH µIU/mL, ferritin ng/mL – will identify most.
4. **Cost realism, which examiners appreciate**: dupilumab and nemolizumab are largely **out-of-pocket and unaffordable** for most Indian elderly, and **AB-PMJAY / Ayushman Vay Vandana Card** covers hospitalisation rather than chronic outpatient biologics. The practical Indian ladder therefore remains **emollients and soap substitutes → treat the cause → topical steroid or calcineurin inhibitor → gabapentin or an SSRI → narrow-band UVB phototherapy**, which is widely available in dermatology departments and is safe in the elderly.
5. **Polypharmacy** is prevalent and poorly documented; ask specifically about over-the-counter analgesics, ayurvedic and traditional preparations, and self-medicated steroid-antifungal combination creams, which are freely sold in India and produce steroid-modified tinea (*tinea incognito*) – a common and easily missed cause of persistent itch.

Rapid Recall Box

Mnemonic for the causes – "SCRATCHED":
Scabies and infestation · **C**holestasis · **R**enal failure (uraemic itch) · **A**naemia (iron deficiency) and polycythaemia · **T**hyroid disease · **C**ancer – lymphoma and paraneoplastic · **H**IV · **E**czema and xerosis (asteatotic) · **D**rugs. Add the three geriatric specials: **bullous pemphigoid, neuropathic itch (notalgia paraesthetica, brachioradial pruritus), and CPUO**.

Numerical anchors: chronic pruritus >6 weeks · notalgia paraesthetica T2–T6 · brachioradial pruritus C5–C9 · lichen sclerosus 3.5–5% risk of squamous cell carcinoma · bullous pemphigoid over age 60, oral involvement up to one-third · 30% age-related fall in GFR (methotrexate caution) · dupilumab PRIME/PRIME2 58.8% vs 19.0% itch response at week 24 · nemolizumab benefit from week 4, sustained to 68 weeks · ≥4-point NRS fall = clinically meaningful response · post-scabetic itch persists 2–4 weeks.

Examiner traps: (i) Reaching for a sedating antihistamine – explicitly inappropriate in the elderly. (ii) Missing **scabies**, especially crusted scabies with minimal itch in the bedbound. (iii) Missing the **pre-bullous phase of bullous pemphigoid** presenting as months of "eczema" or intractable itch. (iv) Forgetting **drug causes**, particularly gliptins. (v) Prescribing long-term topical steroid on already-atrophic skin. (vi) Failing to give **osteoporosis and ulcer prophylaxis** with oral steroids. (vii) Treating the itch without asking whether the elder can physically reach their own back to apply the emollient. (viii) Claiming a licensed drug exists for CPUO.

15-second answer skeleton: Chronic itch >6 weeks → ageing barrier dysfunction makes xerosis the commonest cause → but systematically exclude **scabies, bullous pemphigoid, drugs and systemic disease (SCRATCHED)** → history including timing, distribution, butterfly sign, drug chart, contacts → examine whole skin, separate primary lesions from scratch-induced secondary lesions → targeted bloods in Indian units, scraping, biopsy with DIF, cervical spine imaging → management: emollients and soap substitutes as the backbone, stop the drug, treat scabies presumptively, topical steroid/TCI/capsaicin, then gabapentinoid, SSRI, naltrexone, NB-UVB → cause-specific: difelikefalin for CKD, biologics for prurigo nodularis → break the itch–scratch cycle and treat mood and sleep → 2023–25 updates: IL-31 and nemolizumab, dupilumab, BAD 2025, CPUO with no licensed drug → Indian context: scabies, oil-based emollients, cost, NB-UVB.

Exam One-Liners

1. Chronic pruritus is itch lasting more than six weeks.
2. Epidermal barrier dysfunction of ageing skin makes xerosis the commonest cause of itch in the elderly.
3. Asteatotic eczema resembles a dried riverbed; a generalised or refractory form may signal underlying lymphoma.
4. Bullous pemphigoid may present as intractable pruritus or eczema for months before any blister appears.
5. Bullous pemphigoid has a negative Nikolsky sign and is associated with Parkinson's disease, dementia, stroke and epilepsy.
6. Notalgia paraesthetica: interscapular hyperpigmented patch from T2–T6 sensory nerve damage.
7. Brachioradial pruritus: dorsolateral forearm itch from C5–C9 cervical spine degeneration.
8. Crusted (Norwegian) scabies presents with heavy scaling and minimal itch in the frail or immunosuppressed.
9. Post-scabetic itch lasts 2–4 weeks and does not indicate treatment failure.
10. Sedating antihistamines are inappropriate in older adults under the Beers criteria.
11. Gabapentin and pregabalin are the drugs of choice for neuropathic and uraemic itch.
12. Difelikefalin is a peripherally acting kappa-opioid receptor agonist licensed for haemodialysis-associated pruritus.
13. IL-31 is the "itch cytokine"; nemolizumab blocks its receptor and was approved for prurigo nodularis in 2024.
14. Dupilumab was the first approved systemic therapy for prurigo nodularis (PRIME/PRIME2).
15. CPUO is commonest in older adults and still has no licensed treatment; dupilumab missed its primary endpoint in phase 3.

16. Lichen sclerosus carries a 3.5–5% risk of squamous cell carcinoma and is treated with clobetasol propionate 0.05%.
17. Every older patient on oral steroids for pemphigoid needs osteoporosis and gastrointestinal ulcer prophylaxis.

EXAMINATION ANSWER SERIES

MD GERIATRIC MEDICINE

Ethics & End-of-Life Care · Transitional Care · Sleep Medicine

1. Elder abuse / elder mistreatment ★ **recurring**
2. Advance care planning
3. End-of-life care issues
4. Transitional care home — admission, discharge & staffing
5. Sleep hygiene / pathophysiology of insomnia & management ★ **recurring**
6. Sleep apnoea / polysomnography

Prepared for **Dr. Sudarsan**

Primary texts: *Pathy's Principles and Practice of Geriatric Medicine*, 6th edition | *Kane's Essentials of Clinical Geriatrics*

Supplemented with international and Indian evidence to August 2026

Six 15-mark answers, each with a condensed 7-mark version

CONTENTS

1.	Elder abuse / elder mistreatment ★	15 + 7
2.	Advance care planning	15 + 7
3.	End-of-life care issues	15 + 7
4.	Transitional care home: prerequisites for admission and discharge, and staffing roles	15 + 7
5.	Sleep hygiene / pathophysiology of insomnia and its management ★	15 + 7
6.	Sleep apnoea / polysomnography	15 + 7

★ *Recurring high-yield topic — carries an additional recall box with mnemonic, numerical anchors, examiner traps and a 15-second answer skeleton.*

How each answer is built: numbered high-yield points under labelled subheadings → **Latest Updates (2023-present)** → **Current Practice Update** comparison table → **Exam One-Liners** → condensed 7-mark version.

1. ELDER ABUSE / ELDER MISTREATMENT — 15 MARKS ★ RECURRING

DEFINITION AND CONCEPT

1. **Elder abuse** is any **act or omission** that endangers a person's life, threatens their physical or psychological integrity, impairs their freedom, or compromises their personal development and/or **financial security** (Council of Europe, 1987). WHO adds that it occurs within a **relationship of expectation of trust**.
2. Vulnerable people of any age are the usual targets — especially those with **loss of autonomy and cognitive disorders**. Old age itself is not the risk; **dependency** is.
3. Two forms are distinguished: **individual mistreatment** (an act or omission by a third party against a person) and **institutional abuse** (occurring within an institution as a result of **inadequate governance**).
4. **Neglect must be separated from abuse.** Neglect results from forgetfulness, ignorance and inattention to professional duty — there is **no intent to harm**. Abuse implies intent. Both are harmful and both are reportable.

CLASSIFICATION (COUNCIL OF EUROPE)

5. **Physical violence** — beating, wounding, restraint, mishandling, sexual violence, disregard for pain.
   Psychological violence — familiarity, infantilisation, verbal violence, deprivation of visits.
   Material and financial violence — embezzlement, misappropriation of money or inheritance, abusive power of attorney.
   Medical violence — lack of basic and appropriate care, lack of information about treatment.
   Drug abuse — misuse of sedative and neuroleptic treatment (chemical restraint).
   Violation of rights — identity, freedom of movement, civil rights, religious practice, misuse of legal protection.
6. **Resident-to-resident aggression (RRA)** is a distinct and under-recognised form in long-term care: negative, aggressive and intrusive physical, sexual, verbal or material interactions between residents that would be unwelcome in a community setting. Coroners' data identified **28 RRA-related deaths in Australia (2000–2014)** and **101 fatal incidents in the USA (2003–2016)**.
7. **Psychological control ("right of way")** — a manipulative process using cognitive, affective and behavioural approaches to remove a person's capacity for discernment; it leads to **abuse of weakness**, usually by a relative, neighbour or family member.

EPIDEMIOLOGY

8. **Global** — approximately **1 in 6 (15.7%)** community-dwelling adults over 60 experience abuse each year (Yon et al. meta-analysis). Commonest subtypes: **psychological 11.6%**, **material/financial 6.8%**, neglect ~4%, physical ~2.6%, sexual ~0.9%. In institutions, roughly **2 in 3 staff** admit to committing some form of abuse in the past year.
9. **India — LASI Wave-1**: **5.2%** of those aged 60 and above reported ill-treatment. Highest in **Bihar (~12%)**, Karnataka (10%), West Bengal (8%). Among those ill-treated: **verbal/emotional 77.3%**, **neglect 52.6%**, **economic exploitation 26.5%**, **physical 23.7%**.
10. **HelpAge India 2024** (5,169 elders across 20 Tier-I and Tier-II cities): **7%** reported abuse; the **son was the commonest perpetrator (42%)**, followed by the daughter/daughter-in-law (28%); **73%** of those abused had an annual income below ₹1 lakh.
11. Community and hospital-based Indian studies report far higher figures (**14–45%**), confirming gross **under-reporting** in national surveys. Reasons: family honour, economic dependence, fear of abandonment, cultural expectation of filial care, and unawareness of the law.

RISK FACTORS

12. **Victim factors** — poor health, physical and cognitive impairment, functional dependency, female sex, widowhood, social isolation, low income, and lack of an independent pension.
13. **Perpetrator and environment** — **shared living arrangement with a relative or friend suspected of alcohol or substance abuse, mental illness, or a history of violence**; caregiver burden and burnout; **financial dependence of the abuser on the elder**; property disputes.
14. **Institutional** — low staff-to-resident ratios, untrained staff, high turnover, use of physical and chemical restraint, weak governance, absent complaint mechanisms and poor regulation.

CLINICAL CLUES AND DETECTION

15. **Frequent emergency department visits** for injury or for exacerbations of chronic illness should raise suspicion. Other red flags: delayed presentation, history inconsistent with the injury, injuries of different ages, bruising in atypical sites (inner arm, neck, ear, trunk), malnutrition, dehydration, pressure injury, poor hygiene, missed appointments, medication non-collection, unexplained withdrawals or sudden changes to a will, and a caregiver who answers all questions or refuses to leave the room.
16. **Always interview the older person alone and separately from the caregiver.** Document verbatim, use a body map, photograph injuries with consent, and record who accompanied the patient.
17. **Screening is part of the comprehensive geriatric consultation** in frail, dependent patients. Tools: **EASI** (Elder Abuse Suspicion Index, 6 items), **H-S/EAST**, **VASS**, and the **ED Senior AID** tool for emergency departments.
18. Assessment must be multidisciplinary: **capacity assessment**, cognitive screen (exclude delirium and dementia),

functional assessment, medication review for chemical restraint, financial capacity, social work assessment and a home visit.

MANAGEMENT

19. **Safety first** — treat injuries, assess immediate risk, and decide whether the person can safely return home. Admit, or arrange shelter, respite or emergency placement if not.
20. **If the person has capacity, their autonomy prevails** even if they choose to remain in an abusive setting. Offer a safety plan, written information, contact numbers and definite follow-up, and document the refusal. Do not abandon — the duty of care continues undiminished.
21. **If the person lacks capacity**, act in their **best interests**; involve the guardianship or adult-safeguarding authority, and consider legal protection.
22. **Address caregiver factors** — respite, day care, home nursing, caregiver education and skills training, treatment of caregiver depression and substance misuse, and financial support. Much neglect is the product of exhaustion and ignorance rather than malice.
23. **Legal frameworks** — UK **Care Act 2014** (adult safeguarding); **California** is one of the few jurisdictions where elder abuse is a criminal offence; the Australian Law Reform Commission recommended statutory adult-safeguarding agencies; the US Government Accountability Office (2019) required CMS to track nursing-home abuse by **perpetrator type**.

INDIAN LEGAL AND PROGRAMME FRAMEWORK

24. **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** — maintenance of up to **₹10,000 per month** awarded by **Maintenance Tribunals** at every sub-division, with disposal targeted within **90 days**; abandonment punishable by up to **3 months' imprisonment** and/or fine; **Section 23** allows a property transfer to be declared void if made on condition of maintenance that was subsequently not provided; also mandates old-age homes and medical provision.
25. **Elderline 14567** — the national toll-free helpline (2021) for counselling, rescue and abuse intervention. Supporting programmes: **NPHCE**, Integrated Programme for Senior Citizens, Rashtriya Vayoshri Yojana, SACRED re-employment portal, and the **Ayushman Vay Vandana Card** (₹5 lakh cover for all aged 70+).
26. **Prevention is a public-health and human-rights duty** — combat **ageism**, run public awareness campaigns, train institutional staff, reduce restraint use, mandate incident reporting, teach financial and digital literacy, and above all secure **economic independence of the older person**, which is the single strongest protective factor in Indian data.

LATEST UPDATES (2023–PRESENT)

- **USPSTF final recommendation, 24 June 2025** — screening for intimate partner violence in women of reproductive age is a **B recommendation**, but for **caregiver abuse and neglect of older or vulnerable adults the evidence remains insufficient (I statement)**. Tool performance was inconsistent: **H-S/EAST sensitivity 46%, specificity 73%**; **ED Senior AID sensitivity 94%, specificity 84%**. **Case-finding on clinical suspicion, not universal screening, remains the standard.** Accompanying JAMA commentary described the field as "stagnation at a critical juncture".
- **HelpAge India 2024** national report "*Ageing in India: Exploring Preparedness and Response to Care Challenges*" — identifies the **80-plus, those living alone and older women** as the highest-vulnerability segments requiring a special response.
- **Maintenance and Welfare of Parents and Senior Citizens (Amendment) Bill** proposals: widen the definition of "children" and "relatives" to include sons-in-law, daughters-in-law, adopted and step-children; **remove the ₹10,000 maintenance ceiling** (making it income-linked); mandate **registration and minimum standards for all senior-care homes**; provide for a dedicated senior-citizen police unit in each state.
- **Digital and cyber-financial abuse** of older adults (UPI fraud, "digital arrest" scams, KYC fraud) is now a recognised and rapidly growing category in Indian policing and NCRB-linked data — a new domain of financial abuse absent from older classifications.
- WHO's **Decade of Healthy Ageing (2021–2030)** retains elder abuse as one of its four priority action areas; the Global Report on Ageism (2021) frames ageism as the upstream driver.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
Screening	Screening for risk factors and elder abuse is important in frail dependent patients	USPSTF 2025 gives an **I statement** for universal screening; **targeted case-finding** on red flags plus a low threshold for enquiry is what is actually recommended
Classification	Six Council of Europe categories	Retained, plus **resident-to-resident aggression** and **digital/cyber-financial abuse** as emerging categories
Institutional abuse	Restraint use, staff-to-resident abuse and neglect	Systematic incident-reporting schemes and abuse tracking **by perpetrator type**; restraint reduction now a formal quality indicator
Indian law	MWPSC Act 2007 with ₹10,000 ceiling and tribunal	Amendment Bill proposes **removal of the ceiling**,

	route	wider definition of children, and **statutory registration of care homes**; Elderline 14567 operational nationally
Intervention	Ensure safety; involve social work and law	Emphasis on **caregiver-directed intervention** (respite, training, treatment of caregiver mental illness) and on **economic security** of the elder as primary prevention

EXAM ONE-LINERS

- Elder abuse = act or omission causing harm, within a relationship of **expectation of trust**.
- Global prevalence **1 in 6 (15.7%)**; commonest type is **psychological (11.6%)**.
- India LASI: **5.2%** ill-treated; of these **77.3% verbal, 52.6% neglect**; Bihar highest.
- HelpAge India 2024: abuse 7%; **son commonest perpetrator (42%)**.
- Neglect = no intent to harm; abuse = intent. Both must be acted on.
- Strongest risk marker: **shared living with a substance-misusing or mentally ill relative**.
- Always interview the elder **alone**.
- A capacitous elder may refuse intervention — respect it, plan for safety, keep following up.
- MWPSC Act 2007: **₹10,000, 90 days, 3 months' imprisonment, Section 23 property revocation**.
- National elder helpline: **14567**.
- USPSTF 2025: **I statement** for routine elder-abuse screening.

★ EXTRA RECALL — RECURRING TOPIC

Mnemonic for the six Council of Europe types — "6 P's":
Physical · **P**sychological · **P**roperty (material/financial) · **P**rescription (drug abuse / chemical restraint) · **P**ractice (medical violence — deficient care) · **P**rivileges (violation of rights)

Numerical anchors: 15.7% global · 11.6% psychological · 6.8% financial · LASI 5.2% · verbal 77.3% · neglect 52.6% · HelpAge 2024 = 7%, son 42% · ₹10,000 · 90 days · 3 months · Elderline 14567.

Examiner traps:

- Writing only about **physical** abuse — marks are for **financial, medical/neglect, chemical restraint and rights violations**.
- Omitting **institutional abuse and resident-to-resident aggression**.
- Saying "screen all older adults" — USPSTF gives an **I statement**; the correct word is **case-finding**.
- Overriding a capacitous person's refusal to leave an abusive home.
- Forgetting **Section 23** (property revocation) and the **14567** helpline in the Indian section.
- Framing all abuse as malicious — caregiver burden and ignorance are major mechanisms.

> **15-second answer skeleton:** Define (act/omission + trust) → individual vs institutional; abuse vs neglect → **6 P's** classification + RRA → epidemiology (global 1 in 6; LASI 5.2%; HelpAge 7%) → risk factors (dependency, cognitive impairment, shared living with substance-misusing relative) → red flags and interview alone → screening tools → safety, capacity, best interests → caregiver-directed intervention → MWPSC Act 2007 + Elderline 14567 → prevention and anti-ageism.

CONDENSED 7-MARK VERSION — "Short note on elder abuse"

1. **Definition:** any act or omission endangering life, integrity, freedom or financial security of a vulnerable older person, within a relationship of trust (Council of Europe / WHO).
2. **Types (6 P's):** Physical, Psychological, Property (financial), Prescription (chemical restraint), Practice (medical neglect), Privileges (rights violation). Add **resident-to-resident aggression** in institutions.
3. **Neglect vs abuse:** neglect is unintentional (ignorance/inattention); abuse implies intent.
4. **Epidemiology:** global 1 in 6 (15.7%); India LASI 5.2% (verbal 77.3%, neglect 52.6%); HelpAge India 2024 — 7%, son commonest perpetrator (42%).
5. **Risk factors:** dependency, cognitive impairment, female sex, social isolation, economic dependence; shared living with a relative who misuses substances or has mental illness; caregiver burden; poor institutional governance.
6. **Detection:** repeated ED visits, injuries of differing ages, malnutrition, pressure sores, unexplained financial change; **interview alone**; tools EASI, ED Senior AID.
7. **Management:** ensure safety → assess capacity → respect a capacitous refusal, act in best interests if incapacitous → MDT and caregiver support → report under safeguarding law.
8. **India:** MWPSC Act 2007 (₹10,000 maintenance, tribunals, 90 days, Section 23 property revocation, 3 months' imprisonment), Elderline 14567, NPHCE.

3-point current update: (i) **USPSTF June 2025** — I statement for routine screening of caregiver abuse in older adults; case-finding preferred. (ii) **HelpAge India 2024** report identifies 80-plus, those living alone and older women as highest-risk. (iii) **MWPSC (Amendment) Bill** proposes removing the ₹10,000 ceiling, widening "children", and

mandatory registration of senior-care homes; **cyber-financial abuse** is a new and rapidly growing category.

2. ADVANCE CARE PLANNING — 15 MARKS

DEFINITION AND TERMINOLOGY

1. **Advance care planning (ACP)** is a **process** of discussing and recording a person's **values, goals and wishes** for future care and treatment, and documenting them in an **Advance Care Directive (ACD)**.
2. Distinguish clearly: the **process** (ACP) — the **product** (ACD / advance directive / "living will") — and the **proxy appointment** (enduring guardian, durable power of attorney for health care).
3. An ACD has two components: **instructional** (which treatments are refused or accepted, and in which circumstances) and **proxy** (who decides when the person cannot).
4. An **advance decision to refuse treatment** is **legally binding** where valid and applicable; a **statement of wishes and preferences** is advisory only. A **request** for a particular treatment is never binding — no one can demand non-beneficial treatment.

VALIDITY, CAPACITY AND TIMING

5. **Requirements for a valid advance decision:** it must **apply to the specific situation** being considered; it must have been drawn up when the person had **mental capacity**; the decision must have been **voluntary and adequately informed**; the person must not have acted subsequently in a way that renders it invalid; and it must be appropriately **witnessed**.
6. **An advance decision comes into effect only once the person has lost capacity.** While capacity is retained, the clinician must confirm with the patient that the ACD still reflects their current wishes.
7. **Values rarely change over a lifetime, but care preferences do.** Therefore review the ACD **at least yearly**, whenever health deteriorates, and **before admission to an aged-care home**. What a person wants at 85 may differ at 97.
8. **Factors relevant to judging validity:** the person's age when the ACD was written; time elapsed since last review; the condition now being treated; and the type and burden of the proposed treatment and the consequences of giving or withholding it.
9. If the clinician **doubts the validity** of a documented ACD and the patient lacks capacity, the reason for doubt must be **clearly documented** and decision-making reverts to the **best-interests principle**.
10. **Capacity is decision-specific and time-specific.** Every effort must be made to **maximise** capacity before concluding a person cannot decide — correct sensory impairment, use plain language and adequate typeface, colour contrast and white space, choose the best time of day, exclude reversible contributors (delirium, depression, fear, pain, drug effects). Residents with varying degrees of dementia may still participate in many decisions.
11. **Autonomy does not mean "I want, therefore I get".** In a person with capacity it means "you may not do things to me without my permission". Even an apparently unwise refusal stands, and the clinician's duty of care does not diminish — all other care continues without prejudice.

SURROGATE DECISION-MAKING

12. **Hierarchy of treatment decision-makers** where there is no valid ACD (go to the first person who is 18 or over, has full legal capacity, and is reasonably available and willing): (1) **enduring guardian with authority** (2) guardian with authority (3) adult son or daughter (4) parent (5) sibling (6) primary unpaid carer (7) other person with a close personal relationship and frequent contact.
13. The proxy should be chosen on the basis of **knowledge of the person's preferences**, not merely kinship — a close friend or clergyman may know the patient's wishes better than a rarely-seen relative. Where several contenders exist, the court may decide; where no one is suitable, a **public guardian** may be appointed.
14. **Surrogates are fallible.** Their decisions frequently diverge from what the patient would have chosen, and they may be torn between the patient's expressed wishes and their own view of the patient's best interests. Where the proxy is uncertain, the principle of **beneficence** (weighing benefit against burden) guides the decision.
15. **Do not give relatives the incorrect impression that the decision is theirs** when it is not. Consultation with family provides valuable information about best interests; framing it as their decision imposes a heavy emotional burden and long-term guilt. Where families are unwilling to decide, **"informed assent"** — explicitly offering them the option to defer to the clinician's judgement — is the humane approach.

CONTENT, TIMING AND DELIVERY

16. **What to discuss:** cardiopulmonary resuscitation, mechanical ventilation, ICU admission, artificial nutrition and hydration, blood transfusion, antibiotics, dialysis, transfer to an acute hospital versus comfort care; also preferred place of care and death, organ or tissue donation, and funeral, burial or cremation preferences.
17. **Who and when:** new diagnosis of a life-limiting illness; **dementia (now recognised as a terminal illness)**; advancing frailty and multimorbidity; before elective high-risk surgery; and ideally **before entry to a care home**, so that uncertainty and emotional distress during a crisis are reduced.
18. **The worst time to ask is at the moment of admission.** Federal-style laws requiring that everyone entering a hospital or nursing home be offered the opportunity to make a directive produce anxiety and poorly considered decisions if done as a tick-box exercise. Ideally the discussion has already happened; admission merely revisits it.
19. **Barriers** — difficulty imagining hypothetical future health states; reluctance of patients, families and clinicians to

discuss death; poor prognostic literacy; time pressure; and the mistaken assumption that people in their 90s and 100s are "ready to die" — many are not, and want careful evaluation and treatment options discussed.

20. **Benefits** — care consistent with values, less non-beneficial intervention, fewer inappropriate hospital transfers, better decisions out of hours by unfamiliar clinicians, higher likelihood of dying in the preferred place, and reduced surrogate anxiety, depression and guilt.
21. **Care planning tools are no substitute for simple communication with the patient and clear documentation in the clinical record.** The clinician must ensure the person understands the nature and consequences of the proposed treatment, obtain their decision, and communicate it to all relevant care providers.

INDIAN LEGAL FRAMEWORK

22. **Common Cause v. Union of India (2018)** — the Supreme Court recognised the **right to die with dignity** as a facet of **Article 21**, legalised **passive euthanasia**, and gave legal recognition to **Advance Medical Directives (AMDs)**. The 2018 procedure proved unworkable and was used by virtually no one.
23. **Modification of 24 January 2023** (on the application of the Indian Society of Critical Care Medicine): the requirement for **countersignature by a Judicial Magistrate First Class was removed**; the AMD may now be attested before a **Notary or Gazetted Officer in the presence of two witnesses**; the executor may name **more than one** guardian or nominee; the Secondary Medical Board is nominated by the **Chief District Medical Officer** rather than the Collector; and the judicial role is limited to **High Court adjudication of disputes**. The AMD is revocable at any time before implementation.
24. **Requirements for a valid Indian AMD:** executed by an adult of sound mind, voluntarily and with full information; expressed in clear, unambiguous language; in writing; signed before **two independent witnesses**; attested by a **Notary or Gazetted Officer**; naming at least **two surrogate decision-makers**; and a copy given to the nominees, the family physician and the treating hospital.
25. **MoHFW draft Guidelines for Withdrawal of Life Support in Terminally Ill Patients (September 2024)** operationalise the Court's orders through a **Primary Medical Board** (treating doctor plus two subject experts) and a **Secondary Medical Board** including a nominee of the district Chief Medical Officer. Karnataka was the first state to issue implementing orders; Kerala has a state palliative-care and end-of-life care policy.

LATEST UPDATES (2023–PRESENT)

- **Supreme Court modification, 24 January 2023** — simplified execution of AMDs (notary/gazetted officer instead of JMFC), simplified two-tier medical board process, and timelines. Described as making the procedure "workable, though still cumbersome".
- **MoHFW draft guidelines, September 2024** — the first national clinical protocol for withholding and withdrawing life-sustaining treatment.
- **Harish Rana v. Union of India, Supreme Court, 11 March 2026** — the **first judicial implementation of India's passive-euthanasia framework in an individual case**. The Court held that **clinically assisted nutrition and hydration (CANH) delivered by PEG tube is medical treatment, not basic care**, and may therefore be lawfully withdrawn where continued treatment is not in the patient's best interests; withdrawal was ordered under a **tailored palliative care plan at AIIMS**; the Court expanded the **best-interests** test (futility, irreversibility, dignity, family and board opinion), stressed this was **not active euthanasia**, and urged **Parliament to enact a comprehensive statute**. Where both medical boards agree unanimously, the process may proceed **without court involvement**.
- **Efficacy debate:** Morrison, Meier and Arnold (JAMA 2021, "What's wrong with advance care planning?") showed that ACP reliably improves **documentation** but that evidence for **goal-concordant care**, healthcare utilisation and patient outcomes is inconsistent. A 2025 meta-review of reviews, however, found improvement in preference-concordant end-of-life care in **15 of 17** reviews. The debate is unresolved.
- **Shift of emphasis from documents to conversations** — from advance-directive completion toward **serious illness communication** and in-the-moment goals-of-care discussions, using the **Serious Illness Conversation Guide**, the **"What matters to you"** framework, and **ReSPECT** (Recommended Summary Plan for Emergency Care and Treatment). NHS England published **Universal Principles for Advance Care Planning (2022)**.
- **Reframed outcomes** — the clearest benefit of ACP is to the **surrogate**: greater clarity and confidence, a physical reminder of prior discussions, help with in-the-moment decisions, and less decisional regret and guilt. Surrogate-focused outcome measures are now recommended.
- **Technology** — EHR-embedded ACP templates, **video decision aids** (ACP PEACE trial: video plus clinician communication training raised documented ACP in oncology clinics), natural-language processing to identify ACP documentation, and digital/tele-ACP platforms.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
Primary goal of ACP	Document values and treatment preferences in an ACD	Emphasis shifted to **iterative serious-illness conversation** and preparing patient and surrogate for in-the-moment decisions; documentation is a means, not the endpoint
Evidence of benefit	Improves quality of end-of-life care and spares unnecessary suffering	Robust for documentation and **surrogate outcomes**; inconsistent for goal-concordant care —

		an active and unresolved debate
India — making an AMD	Not covered in the textbook	**2023 Supreme Court order**: notary or gazetted officer plus two witnesses; JMFC countersignature abolished; more than one nominee permitted
Artificial nutrition/hydration	Requires careful consideration of benefit, burden and risk	**Harish Rana (SC 2026)**: CANH via PEG is **medical treatment** and can be lawfully withdrawn in the patient's best interests, with palliative care mandated
Who decides in India	Statutory hierarchy of decision-makers (UK/Australia)	India has **no statutory hierarchy**; the AMD names nominees, otherwise a **two-board medical process** with family consultation applies
Format of the record	Paper ACD reviewed periodically	Digital, shareable plans (ReSPECT, NHS Universal Care Plan), EHR-integrated, accessible out of hours

EXAM ONE-LINERS

- ACP is the **process**; the ACD or advance directive is the **product**.
- An advance **refusal** is binding; an advance **request** is not.
- An advance decision takes effect **only after capacity is lost**.
- Values are stable; **preferences change** — review the ACD yearly, on deterioration, and before care-home entry.
- Hierarchy: enduring guardian → guardian → adult child → parent → sibling → primary unpaid carer → close contact.
- Choose the proxy who best knows the patient's wishes, not simply the next of kin.
- Never imply to the family that the decision is theirs when it is not; offer **informed assent**.
- Dementia is a **terminal illness** — ACP should begin at diagnosis.
- India: **Common Cause 2018** (Article 21) → **2023 modification** (notary, two witnesses, no JMFC) → **MoHFW 2024 guidelines** → **Harish Rana 2026** (CANH is medical treatment).
- Morrison 2021: ACP improves documentation, not necessarily goal-concordant care — hence the shift to serious-illness communication.

CONDENSED 7-MARK VERSION — "Short note on advance care planning"

1. **Definition:** a process of discussing and recording a person's values, goals and wishes for future care, documented in an advance care directive; distinct from the proxy appointment.
2. **Components:** instructional (what treatment is refused/accepted) and proxy (who decides). Advance **refusals** are binding; requests are not.
3. **Validity:** made with capacity, voluntary, informed, applicable to the situation, witnessed, not subsequently contradicted.
4. **Timing:** effective only after loss of capacity; review yearly, on deterioration, and before care-home admission.
5. **Surrogate hierarchy:** enduring guardian → guardian → adult child → parent → sibling → primary unpaid carer → other close contact; choose by knowledge of the patient's wishes.
6. **Content:** CPR, ventilation, ICU, artificial nutrition/hydration, antibiotics, dialysis, hospital transfer, preferred place of care and death, organ donation.
7. **Barriers:** hypothetical future states, reluctance to discuss death, poor prognostic literacy, tick-box completion at admission.
8. **India:** Common Cause 2018 (Article 21); 2023 modification — notary/gazetted officer plus two witnesses, two nominees, two-tier medical board; MoHFW draft guidelines 2024.

3-point current update: (i) **Supreme Court 2023** simplified execution of Advance Medical Directives, removing JMFC countersignature. (ii) **Harish Rana v. Union of India (March 2026)** — first individual passive-euthanasia order; CANH via PEG held to be medical treatment that may be withdrawn in the patient's best interests, with palliative care mandated. (iii) The field has shifted from **document completion to serious-illness communication** (Serious Illness Conversation Guide, ReSPECT), with **surrogate outcomes** now the recommended measure of benefit.

3. END-OF-LIFE CARE ISSUES — 15 MARKS

DEFINITIONS AND SCOPE

1. **End of life** refers to the **last 12 months of life**; **terminal care** refers to the **last few days or hours**. For many people with a life-limiting illness there is a period of hours to days when it is clear they are dying and require care appropriate to the terminal phase — but not all patients have a recognisable terminal phase, and some die suddenly (massive pulmonary embolus, terminal haemorrhage).
2. **Palliative care is not confined to cancer.** It is appropriate for chronic organ failure, **frailty and dementia**, and the **best outcomes occur when it is commenced early**, alongside disease-directed treatment.

RECOGNISING THE PATIENT APPROACHING THE END OF LIFE

3. **Gold Standards Framework (2016) — three triggers** for a palliative approach:
   (i) the **Surprise Question** — "Would you be surprised if this patient were to die in the next 6–12 months?"
   (ii) **Choice or need** — the patient with advanced disease chooses comfort care only, or has a special need for supportive/palliative care;
   (iii) **Clinical indicators** of advanced disease for specific conditions. **Note that diabetes is not included**, despite being a leading cause of death and suffering that could be managed with a palliative approach.
4. **Failure to recognise dying is the central clinical failure.** Unless the possibility is actively considered when a patient deteriorates, dying patients continue to receive resuscitation and are moved out of their homes and admitted to hospital for their last hours and days.
5. **When to involve specialist palliative care teams** — refractory or complex symptoms, complex psychosocial, spiritual or family distress, requests for hastened death, and difficult ethical decisions. Not everyone benefits from referral; many can be cared for well by their usual doctors and nurses at home or as inpatients.

PLANNING AHEAD AND THE CARE-HOME SETTING

6. Decisions that certain interventions **ought not to be considered** for a particular resident can and should be documented in advance — for example, any investigation or treatment requiring hospital admission, CPR, ventilation, or artificial nutrition in advanced dementia — while others, such as **antibiotics for a urinary tract infection**, may remain appropriate for almost all residents.
7. Ideally an individual entering a care home has an **ACD before admission**, to reduce uncertainty and emotional distress for everyone during a crisis.
8. **Out-of-hours risk:** where usual care services operate only during the working week (in the UK, only about **24% of the whole week**), a deteriorating patient will very likely be reviewed by a clinician unfamiliar with them. Without a clearly documented future-care plan, care may be inappropriately escalated or restricted. A crisis is not the time for an unfamiliar nurse or doctor to open a complex discussion.

WITHHOLDING AND WITHDRAWING TREATMENT

9. **Withholding and withdrawing are ethically and legally equivalent.** There is no obligation to provide treatment that is **non-beneficial**; decisions rest on the balance of **benefits, burdens and risks** for that individual.
10. **CPR** — survival after in-hospital arrest in the terminally ill is very poor, and television portrayal grossly misleads the public about outcomes. Members of the public who perform CPR are hailed as heroes, but no one asks whether the person had an advance directive; those resuscitated in public may not die free from suffering or with dignity. A **DNACPR decision restricts nothing else**; it must be documented, communicated and reviewed.
11. **Artificial hydration** — nutrition and hydration must be considered **separately**. People can live for a time with almost no nutrition, but hydration is essential because renal failure and dehydration develop rapidly. Where a patient cannot swallow, maintaining some hydration is an important **comfort measure**. **Subcutaneous fluid (hypodermoclysis)** can be set up in almost any environment through an abdominal-wall needle, carries very low complication risk, and is **as effective as intravenous hydration for long-term maintenance** — yet is rarely used. Avoid fluid overload, especially with cardiac decompensation. Hydration is an adjunct to, not a substitute for, **meticulous mouth care**.
12. **Nutrition is an emotionally charged area.** Families feel an overwhelming desire to provide food. Dying patients have no appetite, distorted taste and disease-related cachexia. Anorexia may be the first sign of subclinical nausea — therefore **exclude hypercalcaemia, hyperglycaemia, renal failure and infection (particularly urinary)**.
13. **Corticosteroids** stimulate appetite only briefly and cause hyperglycaemia, muscle wasting, gastrointestinal erosion and bleeding, emotional lability and impaired sleep; frank steroid psychosis is rare but mood disturbance is common. **Megestrol acetate has no advantage** over glucocorticoids.
14. **Nasogastric feeding** is very uncomfortable, irritating and disfiguring, and carries a significant risk of aspiration pneumonia; **PEG feeding in advanced dementia does not improve survival, nutrition, pressure-ulcer healing or quality of life**. Any form of artificial nutrition needs very careful consideration because in most such patients it is unlikely to benefit survival or quality of life.

CARE IN THE LAST DAYS OF LIFE

15. **Integrated care pathways** — the **Liverpool Care Pathway for the Dying Patient (LCP)** was the UK standard and was adopted or adapted in many countries including Australia. It was withdrawn in the UK following the Neuberger review and replaced by the **Five Priorities for Care of the Dying Person** (Leadership Alliance, 2014): **Recognise —**

Communicate — Involve — Support — Plan and do.

16. If the patient **improves or recovers**, the pathway must be discontinued, the situation reviewed, and the need to recommence interventions considered. **One important reason patients improve is that unnecessary medicines were stopped** — in retrospect it may be clear that the drugs, not the disease, caused the deterioration.
17. **Anticipatory ("just in case") prescribing** with subcutaneous PRN medication and a syringe driver: an **opioid** (morphine; oxycodone or fentanyl if renal impairment) for pain and breathlessness; **midazolam** for restlessness, anxiety and seizures; **haloperidol or levomepromazine** for nausea and delirium; an **antimuscarinic** (hyoscine butylbromide or glycopyrronium) for respiratory secretions. Stop non-essential drugs and convert essential ones to the subcutaneous route.
18. **Excessive secretions and cough** — rather than subject the patient to repeated suctioning, treat pharmacologically with an anticholinergic; reposition; explain the "death rattle" to the family, who are usually more distressed by it than the patient. Cough: treat the cause (diuretics in heart failure, antibiotics if infection), then central suppression with dextromethorphan or codeine linctus.
19. **Terminal restlessness** — always exclude reversible causes first: pain, **urinary retention**, faecal impaction, hypoxia, hypercalcaemia, hypoglycaemia, opioid toxicity, and withdrawal from nicotine, alcohol or benzodiazepines.
20. **Psychiatric symptoms at the end of life** — anxiety, depression, hallucinations and delirium are common and distress families more than patients. If the patient is not troubled by the symptom (for example, pleasant hallucinations), **no treatment is required**; support the family instead. Treatment of one symptom may create another — opioids for pain may cause delirium, in which case switch opioid or route.

PALLIATIVE SEDATION

21. **Sedation at the end of life should rarely be necessary.** It may be required where a patient is exhausted by complex pain or profoundly distressed following a neurological insult. Because it is a therapeutic intervention it requires **consent**; if the patient lacks capacity a short period of sedation (for example, to control difficult delirium) may be in their best interests, decided with the person holding power of attorney or, failing that, the preferred proxy and other interested parties.
22. **Titrate short-acting agents such as midazolam in increments** to the desired effect, review regularly, and lower the dose again at the agreed time. In the last days and hours patients may become restless and appear anxious; **small anxiolytic doses suffice — it is not necessary to render the patient deeply unconscious**. Review the benefits, burdens and risks of continued parenteral hydration and enteral nutrition in sedated patients.
23. **Palliative sedation is distinguished from euthanasia by three features: intention** (to relieve intractable symptoms, not to end life), **proportionality** (careful titration according to effect on symptoms), and **causation** (death results from the underlying disease). The Dutch "terminal sedation" protocol — high-dose continuous infusion with nutrition and hydration withheld — has been criticised as euthanasia without the required administrative framework.

PERSONHOOD, PLACE OF DEATH, BEREAVEMENT

24. **Personhood persists** even when the patient is actively dying and has lost many functions. While still alive they are no less a person, though they may be a different person from before the illness. Goals of care include being kept clean, having a designated decision-maker, dignity, optimal control of pain, breathlessness and anxiety, financial affairs in order, the opportunity to say goodbye, appropriate physical touch, life review, and reassurance that the family is prepared.
25. **Nursing homes** — a median of about **18%** of adults aged 65 and over die in a nursing home (range 3% in Korea to 38% in New Zealand and Iceland). At least **60%** of nursing-home decedents have dementia and most have two or more comorbidities. **Palliative care consultation in the nursing home is associated with significantly lower rates of end-of-life hospitalisation**, and there is expert consensus that hospice and palliative care should be a **standard service in nursing homes**.
26. **Bereavement** — anticipatory grief support, honest information, involvement in care, follow-up contact after the death, and identification of **complicated/prolonged grief disorder**. Carer distress before the death predicts poor bereavement outcome. Once the person dies they are a body, and responsibility passes to the named next of kin.
27. **Assisted dying** remains a controversial and separate issue from palliative care (Victoria, Australia legalised Voluntary Assisted Dying in 2017). **In India, active euthanasia and physician-assisted suicide remain illegal**; only **passive euthanasia** — withholding or withdrawing life-sustaining treatment — is lawful.

INDIAN ISSUES IN END-OF-LIFE CARE

28. **Opioid access** transformed by the **NDPS (Amendment) Act 2014**, which created the category of **Essential Narcotic Drugs** with a single state-level licence, replacing multiple licences under conflicting state rules. Coverage nevertheless remains poor outside a few states.
29. **Kerala's Neighbourhood Network in Palliative Care** and the **2008 Kerala Palliative Care Policy** (the first in India) remain the national and international model of a community-owned, volunteer-driven, home-based service integrated with local self-government. The **National Programme for Palliative Care (NPPC)** is now delivered through the NHM.
30. **Persistent problems** — over-medicalised death in ICUs, out-of-pocket catastrophic expenditure, family-centred (rather than patient-centred) decision-making, non-disclosure of prognosis to the patient, absence of dedicated legislation, and very limited palliative-care workforce and training.

LATEST UPDATES (2023–PRESENT)

- **Harish Rana v. Union of India, Supreme Court of India, 11 March 2026** — India's **first court-sanctioned individual case of passive euthanasia**. Key holdings: **CANH delivered by PEG tube is medical treatment, not basic care**; withdrawal is an **authorised omission** allowing the underlying condition to take its natural course, not an act causing death; a detailed **best-interests framework** (futility, irreversibility, dignity, family and medical-board opinion); withdrawal **must be accompanied by active palliative care**; the two-board process may proceed **without court involvement** where both boards agree; and Parliament was urged to enact a comprehensive end-of-life statute. The patient was transferred to the AIIMS palliative care unit and died on 24 March 2026.
- **MoHFW draft Guidelines for Withdrawal of Life Support in Terminally Ill Patients (September 2024)** — Primary and Secondary Medical Boards, four situations in which life-sustaining treatment may be foregone, and documentation requirements.
- **ISCCM position statement on end-of-life care in the ICU** and successive ICMR/national ethics documents have operationalised the 2023 Supreme Court order into ward-level protocols; Karnataka issued the first state implementation order.
- **Lancet Commission on the Value of Death (2022, continuing influence)** — calls for "rebalancing death and dying", criticises over-medicalisation and the professional monopoly over dying, and holds up **Kerala's compassionate-communities model** as the exemplar.
- **WHO ICOPE, 2nd edition (2025)** and the Decade of Healthy Ageing embed palliative care within integrated care for older people, with intrinsic-capacity-based rather than disease-based triggers.
- **Early integrated palliative care** now has trial-level support in non-malignant disease — advanced heart failure, COPD, end-stage renal disease, Parkinson's disease and dementia — strengthening the case for a needs-based rather than diagnosis-based referral trigger.
- **Prolonged Grief Disorder** is now a formal diagnosis in **ICD-11** and **DSM-5-TR (2022)** — persistent, pervasive grief beyond 6 months (ICD-11) or 12 months (DSM-5-TR) causing functional impairment; targeted psychotherapy is effective.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
Care of the dying pathway	Liverpool Care Pathway described as the standard for the terminal phase	LCP **withdrawn in the UK**; replaced by the **Five Priorities for Care** — individualised care, not a tick-box pathway
Artificial nutrition & hydration	Consider benefits, burdens and risks; subcutaneous fluid underused	Same clinical position, now reinforced legally in India: **CANH is medical treatment (Harish Rana 2026)** and may be withdrawn in best interests
Trigger for palliative care	Gold Standards Framework surprise question and clinical indicators	Needs-based triggers; **early integrated palliative care** in non-malignant disease; ICOPE intrinsic-capacity framing
Passive euthanasia in India	Not addressed	**Common Cause 2018 → 2023 modification → MoHFW 2024 guidelines → Harish Rana 2026**; two-board process without court where boards agree
Grief	Bereavement support for relatives	**Prolonged Grief Disorder** formally recognised in ICD-11 and DSM-5-TR with specific psychotherapy
Place of care	Palliative care consultation reduces hospitalisation in nursing homes	Hospice/palliative care recommended as a **standard service** in long-term care; growth of hospital-at-home for end-of-life care

EXAM ONE-LINERS

- End of life = last **12 months**; terminal = last **days to hours**.
- **Surprise question:** "Would I be surprised if this patient died within 6–12 months?"
- Withholding and withdrawing treatment are **ethically and legally equivalent**.
- **Subcutaneous fluid is as effective as IV** for maintenance hydration and far simpler.
- PEG feeding in advanced dementia does not improve survival or quality of life.
- Exclude **hypercalcaemia, hyperglycaemia, renal failure and infection** before accepting anorexia as terminal.
- Terminal restlessness: always exclude **urinary retention and faecal impaction** first.
- Palliative sedation vs euthanasia = **intention, proportionality, causation**.
- Anticipatory drugs: **opioid, midazolam, haloperidol, antimuscarinic** — all subcutaneous.
- If a dying patient improves, **stop the pathway and review** — deprescribing may have been the cause.
- India: only **passive** euthanasia is legal; **Harish Rana (2026)** held CANH to be medical treatment.
- Kerala's Neighbourhood Network in Palliative Care is the model community programme; NDPS Amendment 2014 opened opioid access.

CONDENSED 7-MARK VERSION — "Short note on end-of-life care issues"

1. **Definitions:** end of life = last 12 months; terminal phase = last days to hours; palliative care applies to frailty, dementia and organ failure, not only cancer, and works best when started early.
2. **Recognising dying:** Gold Standards Framework triggers — surprise question, patient choice/need, clinical indicators. Failure to recognise dying leads to futile resuscitation and inappropriate hospital transfer.
3. **Advance planning:** document in advance which interventions are not to be considered; ideally an ACD before care-home admission; essential for safe out-of-hours decisions.
4. **Withholding vs withdrawing:** ethically and legally equivalent; no obligation to give non-beneficial treatment; DNACPR restricts nothing else.
5. **Nutrition and hydration:** consider separately; subcutaneous fluid as effective as IV; exclude hypercalcaemia, hyperglycaemia, renal failure and infection as causes of anorexia; PEG does not help advanced dementia; steroids and megestrol have limited value.
6. **Symptom control in the last days:** subcutaneous opioid, midazolam, haloperidol and an antimuscarinic; stop non-essential drugs; exclude retention and impaction in terminal restlessness.
7. **Palliative sedation:** rarely needed; titrated; distinguished from euthanasia by intention, proportionality and causation.
8. **Psychosocial and bereavement:** dignity, personhood, saying goodbye, family support, follow-up for prolonged grief.

3-point current update: (i) The **Liverpool Care Pathway has been withdrawn** and replaced by the **Five Priorities for Care of the Dying Person** — individualised care rather than a pathway. (ii) **Harish Rana v. Union of India (SC, March 2026)** — CANH via PEG is medical treatment that may be withdrawn in the patient's best interests, with mandatory palliative care; MoHFW 2024 guidelines operationalise the two-board process. (iii) **Prolonged Grief Disorder** is now a formal ICD-11 / DSM-5-TR diagnosis, and **early integrated palliative care** is evidence-based in non-malignant disease.

4. TRANSITIONAL CARE HOME: PREREQUISITES FOR ADMISSION AND DISCHARGE, AND STAFFING ROLES — 15 MARKS

DEFINITION AND PURPOSE

1. **Transitional care** (also called **intermediate care**, **post-acute care**, **step-down care** or **reablement**) is **time-limited, goal-directed, multidisciplinary care** provided after the acute phase of illness. It was conceived in response to rising demand for acute hospital beds and aims to **promote faster recovery from illness, prevent unnecessary acute admissions, support timely discharge, and maximise independent living**.
2. It sits between the acute hospital and the patient's home or long-term care. Post-acute programmes admit selected older patients who have completed initial acute treatment but have an **ongoing need for post-acute and rehabilitative care**; they contain a **rehabilitation component with an interdisciplinary team assigning patients to specific therapies based on an individual geriatric assessment**.
3. Guiding principle: care is **functional-based rather than disease-based**. Many older people have multiple chronic conditions that will not be cured; goals focus on **maximising function**, and **functional status and quality of life** become the markers of successful recovery rather than measures of disease severity.
4. The philosophy is **biopsychosocial rather than biomedical** — the relationship between the patient and the social structures needed for effective treatment is central, and barriers to recovery are identified early.

PREREQUISITES FOR ADMISSION

5. **Medical stability** — the acute illness is diagnosed and stabilised; no requirement for continuous cardiac monitoring, ventilatory support, vasopressors or other intensive-care-level intervention; the essential diagnostic work-up is complete.
6. **A defined, achievable goal with an expected time frame** — either **rehabilitation potential** (mobility, ADL, gait, swallow, speech) or a specific care goal such as wound healing, completion of a parenteral antibiotic course, insulin titration, tracheostomy weaning or caregiver training. Transitional care is not a holding bay for social admissions.
7. **A completed comprehensive geriatric assessment (CGA)** documenting medical, functional (ADL/IADL, Barthel or FIM), cognitive, mood, nutritional, continence, mobility and falls, sensory, medication and social domains, with a written problem list and baseline scores against which progress will be measured.
8. **Three obligations of the referring clinician**: (i) the patient **truly needs care in such a setting and cannot reasonably get such care elsewhere**; (ii) the **institution is capable of providing the needed care**; (iii) the **patient is prepared for the transfer**.
9. **Informed consent** from the patient (or valid surrogate), with the family given a genuine role and sufficient time. The specific information to be presented includes **cost and cost-based alternatives, privacy, safety, social issues and access to appropriate health care**. Decisions about transitions between levels of care deserve the same seriousness as decisions about treatment.
10. **Documented goals of care, resuscitation status and, ideally, an advance care directive**; capacity for medical decision-making assessed within days of admission and a surrogate identified if the patient lacks capacity.
11. **Complete structured transfer documentation** — diagnoses and procedures, pending investigations, **reconciled medication list with reasons for every change**, allergies, functional and cognitive baseline, pressure-injury and falls risk, infection/multidrug-resistant organism status, lines, catheters and wounds, follow-up appointments and the named responsible physician. **Poor transmission of information to the receiving staff or to the patient is a principal cause of readmission.**
12. **Exclusions** — unstable acute illness or undiagnosed deterioration; active delirium still requiring acute work-up; need for surgical or intensive intervention; severe behavioural disturbance or suicidal risk beyond the facility's capability; infection requiring isolation the facility cannot provide; and patients whose only need is long-term custodial care, who belong in a nursing home rather than transitional care.
13. **Avoid the "first train leaving the station" phenomenon.** Discharge planners under pressure to move patients quickly leave little time for careful consideration of options or of what the patient and family want to achieve; availability of a placement then trumps suitability. Nursing-home discharges are easier to arrange and are therefore over-used. **Discharge planning must begin early in the admission, not at the end.**

PREREQUISITES FOR DISCHARGE

14. **Goal attainment or documented plateau** — the agreed functional goals have been met, or the interdisciplinary team has determined that **maximum progress toward the goals has been reached** and further gain is unlikely. Not every resident has areas in which improvement can reasonably be expected; for these, **strategies to maintain function** are developed instead.
15. **Clinical stability** — afebrile with stable vital signs, adequate oral intake and hydration, pain controlled, wounds healing, bowel and bladder plan working, and no ongoing need for parenteral therapy that cannot be delivered in the destination setting.
16. **Safe destination and environment** — home assessment and modification completed (grab rails, ramp or lift access, raised toilet seat, bathroom adaptation, lighting, removal of loose rugs), assistive devices supplied and the patient trained in their use. **Assessment of and recommendation for modifying the environment can be critically important for improving function and for discharge planning.**
17. **A competent, willing and trained caregiver**, or a funded package of home care; caregiver skills demonstrated by

teach-back (transfers, feeding, wound care, catheter care, insulin, inhalers).

18. **Medication reconciliation and deprescribing at discharge** — simplified written regimen, reasons for changes explained, high-risk drugs (anticoagulants, insulin, opioids) specifically reviewed, and the patient or carer able to demonstrate correct administration.
19. **Follow-up secured** — a named responsible clinician, a booked appointment, arranged home nursing and therapy, a written escalation plan ("what to do if…", who to call), and, in most cases, a strategy for **long-term follow-up and formal case management to ensure that needs and services remain appropriately matched**.
20. **Structured discharge summary sent to the community team and given to the patient** in accessible, ageing-friendly language, with teach-back to confirm understanding. Templated discharge communication and facilitated follow-up appointments are core components of geriatric-friendly services.
21. **Good discharge decision-making separates two distinct questions:** (i) **what type of care** is most likely to achieve the primary goals for this patient, and (ii) having chosen the modality, **which provider** can best deliver those services. These require quite different sets of information and are often wrongly conflated.

STAFFING AND ROLES

22. **Core interdisciplinary team** — in the geriatric assessment setting the key disciplines are, at a minimum, **physicians, nurses, social workers and physical and occupational therapists**, optimally extended to dieticians, pharmacists, ethicists and home-care specialists. **Special geriatric expertise among team members is crucial.**
    - **Medical director / geriatrician** — clinical governance, admission and discharge criteria, protocols, staff education, complex ethical and prognostic decisions.
    - **Attending physician / nurse practitioner / physician assistant** — daily medical review, comorbidity and medication management, review and signing of the care plan, and **strong advocacy for the autonomy and quality of life of residents**.
    - **Nursing staff** (with a **higher nurse and aide ratio** than acute wards) — 24-hour care, early detection of change in condition, delirium and falls prevention, continence and skin care, medication administration, family communication.
    - **Physiotherapist** — mobility, transfers, balance, gait, strength, endurance, falls rehabilitation.
    - **Occupational therapist** — ADL and IADL retraining, adaptive equipment, cognitive-functional strategies, and **home assessment and modification**.
    - **Speech and language therapist** — dysphagia assessment, diet texture and fluid consistency, communication rehabilitation after stroke.
    - **Clinical pharmacist** — medication reconciliation, deprescribing, Beers and STOPP/START review, drug–drug and drug–disease interaction screening, carer education.
    - **Dietician** — nutritional assessment within days of admission and periodically thereafter, dietary preferences, and an appropriate diet. **Restrictive diets are often not medically necessary and are unappetising**; weight loss must be identified and reported.
    - **Medical social worker / case manager** — psychosocial assessment within 1–2 weeks, family relationships and social resources, financial and entitlement issues, placement options, community linkage, and coordination of discharge. Social workers and nurse case managers are often best placed to delineate the choices and implications of a move.
    - **Clinical psychologist** — mood, adjustment, behavioural management, cognitive assessment.
    - **Podiatrist, dentist, optometrist and audiologist** — foot care and sensory correction, both of which strongly influence function.
    - **Chaplain / pastoral care and palliative care liaison**; **trained nursing aides and attendants**; **volunteers** for social engagement.
23. **The interdisciplinary team conference is the critical ingredient.** It takes place after individual assessments are complete; **most successful trials of geriatric assessment included such a conference**. It brings all perspectives together, generates new ideas, sets priorities, disseminates the full assessment to everyone treating the patient, and avoids duplication and incongruity. Effective teams evolve through **forming, storming, norming and performing**; the **patient and carer must be involved at some stage** to maintain the principle of choice.
24. **Documentation cycle** — an **interdisciplinary care plan within 1–2 weeks of admission and every 3 months thereafter**, listing problems, goals, approaches, target dates and assignment of responsibility across disciplines. The physician should review and sign it; care plans are a powerful driver of nursing behaviour and expectations.
25. **Structural and environmental prerequisites** — barrier-free access, non-slip flooring, grab rails, adequate and glare-free lighting, **enhanced signage, calendars and clocks for reorientation**, communication aids, low beds and call bells, a **restraint-reduction protocol**, assistive devices, a rehabilitation gymnasium, an ADL training kitchen and bathroom, and a formal transfer agreement with a nearby acute hospital.
26. **Quality indicators** — length of stay, functional gain (change in Barthel/FIM), proportion discharged home, 30-day readmission and emergency transfer rates, falls, pressure injuries, restraint use, healthcare-associated infection, medication errors, delirium incidence, and resident and family satisfaction.
27. **INTERACT** (Interventions to Reduce Acute Care Transfers) reduces unnecessary hospital transfers through three strategies: (i) **proactive identification** of conditions before they become severe enough to need hospital care (dehydration, delirium); (ii) **on-site management** of some conditions (pneumonia, congestive heart failure) when safe and feasible; and (iii) **improved advance care planning**, so that palliative or comfort care is considered when the risks of hospitalisation outweigh the benefits.

INDIAN CONTEXT

28. **NPHCE** provides **30-bedded departments of geriatric medicine at Regional Geriatric Centres**, 10-bedded geriatric wards at district hospitals, rehabilitation units at CHC level and home-based care through ASHAs — but **dedicated step-down/transitional facilities are not part of the public system**.
29. **No statutory regulation** currently governs transitional-care or step-down homes in India. Applicable frameworks are the **Clinical Establishments (Registration and Regulation) Act 2010**, the model minimum standards for senior-care homes developed for the Ministry of Social Justice and Empowerment, and state-level rules. **AB-PMJAY / Ayushman Vay Vandana does not reimburse rehabilitation or step-down bed-days**, which is the major financing barrier.

LATEST UPDATES (2023–PRESENT)

- **Hospital-at-home and "virtual wards"** have expanded rapidly as an alternative to facility-based transitional care — NHS England virtual wards and the CMS Acute Hospital Care at Home waiver, with meta-analyses showing comparable or lower mortality, less delirium, higher satisfaction and lower cost than inpatient care in selected older patients.
- The best-evidenced models remain **Naylor's Transitional Care Model** (advanced practice nurse-led, with home visits) and **Coleman's Care Transitions Intervention** (transition coach, personal health record, medication self-management, red flags, follow-up). 2023–25 syntheses confirm that **single-component interventions do not reduce readmission** — only bundled, person-delivered models do.
- **Pharmacist-led transitions of care** and structured medication reconciliation at both ends of the transfer have the strongest single-component evidence for reducing medication-related harm.
- Growing recognition of **"post-hospital syndrome"** — a transient acquired period of generalised vulnerability after hospitalisation driven by sleep deprivation, immobility, malnutrition and pain, which transitional care is specifically designed to buffer.
- **India:** the NITI Aayog position paper **"Senior Care Reforms in India: Reimagining the Senior Care Paradigm" (February 2024)** recommends a formal continuum of care spanning acute, transitional, long-term and home-based services, regulation of care homes, and integration of elder care into insurance; the proposed **Maintenance and Welfare (Amendment) Bill** would mandate registration and minimum standards for all senior-care homes.
- **Geriatric Emergency Department accreditation** and **Age-Friendly Health Systems (4Ms — What Matters, Medication, Mentation, Mobility)** have become the dominant organising frameworks for care transitions in older adults.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
Site of post-acute care	Facility-based post-acute and intermediate care units	Rapid shift toward **hospital-at-home and virtual wards**; facility care reserved for those needing 24-hour nursing or intensive rehabilitation
Reducing readmission	Good discharge planning and information transfer	Only **bundled, person-delivered models** (Transitional Care Model, Care Transitions Intervention) work; single-component fixes do not
Preventing acute transfer	Careful discharge decision-making	**INTERACT** as a formal quality-improvement programme; proactive identification, on-site management, and ACP-based decisions
Organising framework	ACE unit components; interdisciplinary team conference	**Age-Friendly Health Systems 4Ms** and Geriatric ED accreditation now structure care transitions internationally
India	Not addressed	No statutory regulation of step-down facilities; **NITI Aayog 2024** recommends a formal continuum; PMJAY does not fund rehabilitation bed-days

EXAM ONE-LINERS

- Transitional care = **time-limited, goal-directed, multidisciplinary** care between acute hospital and home.
- Aims: faster recovery, avoid unnecessary admission, support timely discharge, maximise independent living.
- Approach is **functional-based, not disease-based**; outcomes are function and quality of life.
- Three admission obligations: the patient needs this setting; the facility can provide it; the patient is prepared for transfer.
- Admission requires **medical stability + a defined achievable goal + a completed CGA**.
- Discharge requires **goal attainment or plateau + clinical stability + a safe environment + a trained caregiver + secured follow-up**.
- Poor information transfer at transition is the principal cause of readmission.
- The **interdisciplinary team conference** is the critical ingredient of every successful CGA trial.
- Care plan within **1–2 weeks** of admission and every **3 months** thereafter.
- Beware the **"first train leaving the station"** — availability trumping suitability.

- **INTERACT**: proactive identification, on-site management, advance care planning.
- India: NPHCE geriatric wards exist, but there is **no regulated transitional-care tier** and no PMJAY funding for rehabilitation bed-days.

CONDENSED 7-MARK VERSION — "Short note on transitional care"

1. **Definition:** time-limited, goal-directed, multidisciplinary post-acute care bridging hospital and home; aims to speed recovery, prevent admission, support timely discharge and maximise independence.
2. **Admission prerequisites:** medical stability; a defined achievable rehabilitative or care goal with a time frame; completed comprehensive geriatric assessment with baseline function; consent and preparation of patient and family; documented goals of care and resuscitation status; complete reconciled transfer documentation.
3. **Exclusions:** unstable illness, need for intensive or surgical care, severe behavioural disturbance, or a purely custodial long-term need.
4. **Discharge prerequisites:** goal attainment or documented plateau; clinical stability; safe modified home environment with assistive devices; a trained willing caregiver or funded home package; medication reconciliation with teach-back; named follow-up clinician, booked appointment and written escalation plan; discharge summary to the community team.
5. **Staffing:** geriatrician/medical director, attending physician or nurse practitioner, nurses at a higher ratio, physiotherapist, occupational therapist, speech therapist, pharmacist, dietician, medical social worker/case manager, psychologist, chaplain, trained aides and volunteers.
6. **Process:** interdisciplinary team conference after individual assessments; care plan within 1–2 weeks and reviewed 3-monthly with goals, target dates and assigned responsibility; patient and carer involved.
7. **Environment:** barrier-free access, grab rails, good lighting, orientation aids, restraint-reduction policy, rehabilitation gym and ADL training area, acute-hospital transfer agreement.
8. **Quality indicators:** functional gain, discharge-home rate, 30-day readmission, falls, pressure injuries, restraint use, infection, satisfaction.

3-point current update: (i) **Hospital-at-home / virtual wards** are displacing facility-based transitional care for selected patients, with comparable outcomes and less delirium. (ii) Only **bundled models** (Naylor's Transitional Care Model, Coleman's Care Transitions Intervention) and **pharmacist-led medication reconciliation** reduce readmission; single-component interventions do not. (iii) **India**: no statutory regulation of step-down facilities; **NITI Aayog (2024)** recommends a formal continuum of senior care, and the Maintenance and Welfare Amendment Bill proposes mandatory registration of care homes.

5. SLEEP HYGIENE / PATHOPHYSIOLOGY OF INSOMNIA AND ITS MANAGEMENT — 15 MARKS ★ RECURRING

NORMAL SLEEP AND CHANGES WITH AGE

1. **Sleep** is a reversible state of reduced responsiveness to the environment, comprising **non-rapid eye movement (NREM) sleep — stages N1, N2 and N3 (slow-wave sleep)** — and **rapid eye movement (REM) sleep**. NREM and REM alternate in cycles of about **90–110 minutes**, with **4–6 cycles** a night; slow-wave sleep dominates the first third of the night and REM periods lengthen toward morning.
2. **Changes in old age:** increased **sleep-onset latency**; reduced **total sleep time and sleep efficiency**; marked reduction in the absolute and relative amount of the **deeper stages (N3)** with a smaller reduction in REM; increase in light N1/N2 sleep; increased number and duration of **awakenings (increased wake after sleep onset)**; **circadian phase advance** (earlier bedtime, earlier morning awakening); and increased daytime napping.
3. **These changes are physiological, not pathological.** The older person's **ability** to sleep declines while the **need** for sleep is largely unchanged. Therefore, insomnia in later life is usually explained by **comorbidity, drugs, primary sleep disorders or circadian disruption**, and must never be dismissed as "just ageing".

DEFINITION

4. **Insomnia disorder** (ICSD-3 / DSM-5): dissatisfaction with sleep quantity or quality, with **difficulty initiating sleep, difficulty maintaining sleep, or early-morning awakening with inability to return to sleep**, occurring **despite adequate opportunity and circumstances for sleep**, and accompanied by **daytime impairment** (fatigue, mood disturbance, impaired attention or memory, social or occupational dysfunction). **Chronic insomnia disorder = symptoms at least 3 nights a week for at least 3 months.**
5. Characterise the pattern precisely, because it points to the cause: **delayed sleep onset** (anxiety, RLS, delayed phase, caffeine), **frequent awakenings** (pain, nocturia, sleep apnoea, PLMD, reflux), **early-morning awakening** (depression, phase advance, alcohol).

PATHOPHYSIOLOGY

6. **Hyperarousal is the core mechanism** — chronic insomnia is a disorder of 24-hour hyperarousal, not merely of night-time sleep loss. Evidence: raised whole-body metabolic rate, elevated cortisol and ACTH, sympathetic overactivity with reduced heart-rate variability, increased high-frequency **beta and gamma EEG activity** at sleep onset and during NREM, and increased regional brain glucose metabolism during NREM sleep.
7. **Neurochemistry of the sleep–wake switch:** wakefulness is driven by the ascending arousal system — **orexin/hypocretin** (lateral hypothalamus), histamine (tuberomammillary nucleus), noradrenaline (locus coeruleus), serotonin (raphe), acetylcholine and dopamine. Sleep is driven by the **ventrolateral preoptic nucleus (VLPO)** through **GABA and galanin**, with **adenosine** as the principal endogenous somnogen. The mutually inhibitory VLPO–arousal "flip-flop switch" is **stabilised by orexin**; loss of stabilisation produces state instability and fragmented sleep.
8. **Two-process model: Process S** — homeostatic sleep pressure accumulating with wakefulness (adenosine-mediated); **Process C** — the circadian drive generated by the **suprachiasmatic nucleus**, entrained by light through the retinohypothalamic tract and expressed via pineal **melatonin**. Ageing reduces the amplitude of both processes.
9. **Age-related circadian dysfunction: SCN neuronal loss and reduced SCN output**, decreased and phase-advanced melatonin secretion, reduced daytime light exposure (cataract, reduced pupil size, indoor living, institutionalisation), and reduced physical and social activity (weak *zeitgebers*) → **phase advance and reduced rhythm amplitude**, expressed clinically as early-evening sleepiness, early-morning awakening, daytime napping and, in dementia, **sundowning and irregular sleep–wake rhythm**.
10. **Spielman's 3-P behavioural model** explains the transition from acute to chronic insomnia:
    Predisposing — age, female sex, family history, trait hyperarousal, anxious or ruminative personality.
    Precipitating — acute illness, hospitalisation, pain, bereavement, retirement, relocation, a new drug.
    Perpetuating — maladaptive behaviours (excessive time in bed, prolonged daytime napping, clock-watching, early bedtime) and dysfunctional beliefs ("I must sleep 8 unbroken hours or I will be ill"). **Perpetuating factors are what CBT-I targets, and they are what keep insomnia going long after the trigger has resolved.**
11. **Conditioned (psychophysiological) insomnia** — through repeated pairing, the bed and bedtime routine become learned cues for wakefulness and anxiety rather than for sleep. This is the rationale for **stimulus-control therapy**.

CAUSES AND EVALUATION

12. **Physical symptoms underlying insomnia** (elicit from the patient **and the bed partner**): pain from musculoskeletal disorders; **orthopnoea, paroxysmal nocturnal dyspnoea or cough**; **nocturia**; gastro-oesophageal reflux — all worsened by recumbency. Also breathlessness, anxiety and restlessness.
13. **Symptoms of primary sleep disorders** — **periodic limb movements/restless legs** (uncomfortable leg sensations with an urge to move; RLS prevalence rises to about **20% in those aged 80 and over**); **sleep apnoea** (loud or irregular snoring, waking sweating, anxious and tachycardic, excessive movement, morning drowsiness); and **REM sleep behaviour disorder** (dream enactment, a prodrome of synucleinopathy).
14. **Behavioural factors** — daytime naps **longer than 30 minutes**, earlier bedtime, and increased time spent in bed not sleeping.

15. **Drugs** — **hypnotic withdrawal**, caffeine, **alcohol (causes sleep fragmentation and rebound awakening in the second half of the night)**, certain antidepressants (SSRIs, SNRIs, bupropion), diuretics (nocturia) and corticosteroids; also theophylline, beta-blockers, levodopa, donepezil, decongestants and thyroxine excess.
16. **Psychiatric** — insomnia is a cardinal symptom of depression and anxiety and may be the presenting complaint. But it is also a good example of a symptom that must be evaluated for a treatable underlying cause: **do not attribute insomnia to age or to depression before a comprehensive medical work-up is complete**. Older adults may also hold unrealistic sleep expectations.
17. **Assessment tools** — a **sleep diary for 1–2 weeks** (the single most useful instrument), collateral history from the bed partner or carer, actigraphy where available, and validated scales: **Insomnia Severity Index**, Pittsburgh Sleep Quality Index, Epworth Sleepiness Scale.
18. **Polysomnography is NOT routinely indicated for insomnia.** Reserve it for suspected sleep apnoea, periodic limb movement disorder, REM sleep behaviour disorder or other parasomnia with injury, suspected nocturnal seizures, or insomnia refractory to adequate treatment.

SLEEP HYGIENE

19. **Components of sleep hygiene:** a **fixed wake-up time seven days a week**; get out of bed when unable to sleep; **no clock-watching**; the bedroom dark, quiet and cool and used only for sleep and sex; avoid caffeine after midday; avoid alcohol and nicotine in the evening; avoid heavy meals and large fluid volumes before bed; **limit naps to under 30 minutes and before 3 pm**; regular daytime exercise but not within 2–3 hours of bedtime; **bright light exposure in the morning**; a consistent wind-down routine; and no screens in bed.
20. **In hospitals and care homes** — reduce night-time noise and light, cluster nursing care and avoid routine nocturnal observations and medication rounds, keep the room cooler at night, increase daytime activity and daylight exposure, and treat nocturia. Sleep hygiene is listed among the environmental modifications of the **Acute Care for Elders (ACE) unit**.
21. **Sleep hygiene alone is inadequate as monotherapy for chronic insomnia.** It is one component of CBT-I, not a treatment in its own right — a frequent and heavily penalised error in examinations.

MANAGEMENT

22. **Treat the underlying cause first** — analgesia and joint care; optimise heart failure and COPD; treat nocturia, prostatism and overactive bladder; treat reflux; treat depression and anxiety; correct **iron deficiency in RLS (target ferritin above 75 ng/mL)**; CPAP for sleep apnoea; move diuretics and corticosteroids to the morning; and review every drug on the list.
23. **Cognitive behavioural therapy for insomnia (CBT-I) is first-line for chronic insomnia in all ages**, including older adults and those with comorbidity, delivered face-to-face, in groups, or digitally. Five components:
    • **Stimulus control** — bed only for sleep; go to bed only when sleepy; leave the bed after about 20 minutes of wakefulness; fixed rising time; no daytime naps.
    • **Sleep restriction** — restrict time in bed to actual sleep time (minimum 5–5.5 hours), then titrate upward as efficiency exceeds 85–90%. **Use with caution in fall-prone patients, epilepsy, bipolar disorder and untreated OSA** because of transient daytime sleepiness.
    • **Relaxation training** — progressive muscular relaxation, diaphragmatic breathing, mindfulness.
    • **Cognitive restructuring** — correcting catastrophic beliefs about sleep loss and unrealistic expectations.
    • **Sleep hygiene education.**
    CBT-I benefits are **sustained after treatment ends**, unlike hypnotics.
24. **Circadian rhythm disorders and sundowning — there is currently no evidence for drug treatment**. Non-pharmacological measures, principally **good sleep hygiene practice and especially bright light therapy**, are first-line, supported by structured daytime activity, exercise and social engagement.
25. **Principles of drug therapy** — hypnotics are an adjunct, for the shortest possible period (generally **up to 4 weeks**); **start low and go slow**; monitor target symptoms and side effects closely and adjust; **never use long-acting benzodiazepines in geriatric patients**; and anticipate **rebound insomnia** on stopping benzodiazepines and melatonin used regularly.
26. **Agents** — benzodiazepines: lorazepam 0.5–2.5 mg and temazepam 7.5–30 mg (intermediate acting, half-life 8–20 hours). Benzodiazepine receptor agonists: **zolpidem 5–10 mg** (short acting), **zaleplon 5–20 mg** (ultra-short), **eszopiclone 1–3 mg** (intermediate). Melatonin receptor agonist: **ramelteon 8 mg**. The **effectiveness of short-term hypnotic use in older people has been questioned**, and the long-term effects of chronic hypnotic use in this population are unknown.
27. **AGS Beers Criteria** — benzodiazepines, "Z-drugs" and first-generation antihistamines (diphenhydramine, hydroxyzine, promethazine) are **potentially inappropriate in adults aged 65 and over** because of cognitive impairment, delirium, falls, fractures and motor-vehicle crashes. **Antipsychotics must not be used for insomnia**; all second-generation antipsychotics carry increased mortality in dementia.
28. **Insomnia in dementia** — benzodiazepines are the most frequently used drugs but cause significant adverse effects. **Low-dose trazodone** is indicated in sleeping disorders, especially with night-time agitation, and long-term use may benefit both sleep parameters and cognitive decline in Alzheimer's disease. **Mirtazapine 15 mg showed no improvement in nocturnal sleep duration or efficiency and increased daytime sleepiness. Suvorexant**, an orexin receptor antagonist, improves total sleep time and cognitive performance in probable Alzheimer's dementia with insomnia. Trials of **lemborexant** in Alzheimer's disease and **nelotanserin** for REM sleep behaviour disorder in dementia with Lewy bodies are under way.
29. **Deprescribing hypnotics** — gradual dose tapering (about 25% every 1–2 weeks) **combined with CBT-I** is the most

effective approach; direct-to-patient educational deprescribing (EMPOWER-type interventions) works and should be offered to every long-term hypnotic user.

LATEST UPDATES (2023–PRESENT)

- **European Insomnia Guideline update (European Sleep Research Society, Riemann et al., November 2023)** — **CBT-I, face-to-face or digital, is unequivocally first-line** for adults. Where CBT-I is unavailable or ineffective: benzodiazepines, benzodiazepine receptor agonists and low-dose sedating antidepressants for **short-term use only (up to 4 weeks)**; **daridorexant** may be used for longer, generally up to **3 months** and in individual cases up to **1 year**; **prolonged-release melatonin 2 mg** may be used for up to 3 months in those **older than 55 years**. **Antihistamines, antipsychotics and phytotherapeutic agents are not recommended**, and melatonin generally is not recommended except where circadian factors are involved.
- **Dual orexin receptor antagonists (DORAs)** are the most significant recent advance — **suvorexant, lemborexant and daridorexant**. They block orexin-1 and orexin-2 receptors, reducing the wake drive rather than sedating through GABA. **Daridorexant has the shortest half-life (~8 hours, versus 12 for suvorexant and 17–19 for lemborexant)**, which in theory reduces next-day impairment.
- **Efficacy in older adults** — a secondary analysis of the phase 3 daridorexant trial (n = 364 aged 65 and over) showed **similar reductions in wake after sleep onset and latency to persistent sleep, similar increases in self-reported total sleep time, and similar improvement in daytime functioning (IDSIQ), with a comparable safety profile, in those aged 65 and over and under 65**. A 2026 systematic review and meta-analysis of DORAs in older adults confirmed reduced WASO and latency and increased total sleep time at 1 and 3 months, with a **favourable safety profile for daridorexant**; lemborexant and suvorexant had higher rates of treatment-emergent adverse events without an increase in serious events.
- **Cautions with DORAs** — contraindicated in narcolepsy; avoid with potent CYP3A4 inhibitors or inducers; caution in severe hepatic impairment and (for somnolence) severe renal impairment; adverse effects include somnolence, headache, nightmares, sleep paralysis and hypnagogic hallucinations. Post-marketing data suggest low abuse and overdose potential and no evidence of physical dependence.
- A **2025 European expert consensus on switching and deprescribing hypnotics** notes that **daridorexant and prolonged-release melatonin 2 mg require no special deprescribing protocol**, unlike benzodiazepines and Z-drugs.
- **Sleep and dementia risk** — suvorexant reduced cerebrospinal fluid p-tau181/tau181 ratio by 10–15% and Aβ42 by 10–20% in cognitively unimpaired adults, supporting the **glymphatic clearance hypothesis** that improving sleep may modify amyloid and tau burden. This remains proof-of-concept, not clinical indication.
- **ICSD-3-TR (2023)** retains the merged category of **chronic insomnia disorder**, abolishing the old primary/secondary distinction — **insomnia is treated in its own right even when comorbid**, because treating the comorbidity alone rarely resolves it.
- **Vornorexant** and other next-generation orexin antagonists are in late-stage development; digital CBT-I applications (including validated free tools such as CBT-I Coach) are recommended to widen access.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
First-line treatment	Non-pharmacological measures tried before drugs; several drug alternatives listed	**CBT-I is definitively first-line** (ESRS 2023), face-to-face or **digital**; sleep hygiene alone is insufficient as monotherapy
Drug of choice	Benzodiazepines and BzRAs (zolpidem, zaleplon, eszopiclone), ramelteon	**Dual orexin receptor antagonists** preferred where a drug is needed; **daridorexant** has the shortest half-life and best-studied efficacy and safety in those aged 65 and over
Duration of therapy	Short-term use; long-term effects unknown; rebound insomnia expected	BZD/BzRA still **≤4 weeks**; **daridorexant up to 3 months**, extendable to 1 year in individual cases; PR melatonin 2 mg up to 3 months if aged over 55
Classification	Insomnia framed as a symptom of an underlying cause	**ICSD-3-TR** merged category — **chronic insomnia disorder is treated in its own right** even when comorbid
Insomnia in dementia	Benzodiazepines commonly used; low-dose trazodone for night-time agitation	**Suvorexant** improves total sleep time and cognition in probable AD; **mirtazapine 15 mg is ineffective and increases daytime sleepiness**; benzodiazepines to be avoided
Circadian disorders	No evidence for drug treatment	Unchanged — **bright light therapy plus sleep hygiene remain first-line**; structured daytime activity added

EXAM ONE-LINERS

- Ageing reduces the **ability** to sleep, not the **need** for sleep.
- Chronic insomnia = **3 nights a week for 3 months**, despite adequate opportunity, with daytime impairment.
- Core mechanism is **24-hour hyperarousal**, not simple sleep loss.
- **Orexin stabilises the VLPO–arousal flip-flop switch** — hence orexin antagonists as hypnotics.
- **3-P model**: predisposing, precipitating, perpetuating — CBT-I targets the perpetuating factors.
- Alcohol fragments sleep; it is a sedative, not a hypnotic.
- Naps over **30 minutes** and time spent in bed awake are the two commonest perpetuating behaviours.
- **CBT-I is first-line**; sleep hygiene alone is not a treatment.
- Sleep restriction: caution in fallers, epilepsy, bipolar disorder and untreated OSA.
- Beers: **avoid benzodiazepines, Z-drugs and first-generation antihistamines** in those aged 65 and over.
- **Daridorexant** — shortest half-life DORA (~8 h); efficacy and safety equal in those over and under 65.
- Bright light therapy is first-line for circadian rhythm disorder and sundowning; no drug is established.
- PSG is not indicated for uncomplicated insomnia.

★ EXTRA RECALL — RECURRING TOPIC

Sleep hygiene mnemonic — "BEDROOM":
Bedtime and rising time fixed · **E**xercise daily but not late · **D**ark, quiet and cool room · **R**estrict naps to under 30 minutes · **O**nly sleep and sex in bed · **O**ut of bed if awake beyond 20 minutes · **M**eals, caffeine, alcohol and nicotine avoided in the evening

CBT-I five pillars — "S-S-R-C-S": Stimulus control · **S**leep restriction · **R**elaxation · **C**ognitive restructuring · **S**leep hygiene education

Numerical anchors: sleep cycle 90–110 min · chronic insomnia = 3 nights/week × 3 months · naps <30 min, before 3 pm · out of bed after 20 min · sleep efficiency target 85–90% · hypnotics ≤4 weeks · PR melatonin 2 mg, age >55, up to 3 months · daridorexant half-life ~8 h (suvorexant 12 h, lemborexant 17–19 h) · RLS ferritin target >75 ng/mL · RLS prevalence ~20% at age 80+.

Examiner traps:

- Writing **sleep hygiene as the treatment** — it is one of five CBT-I components; CBT-I is first-line.
- Prescribing a benzodiazepine without mentioning **Beers**, falls and fracture risk.
- Attributing insomnia to normal ageing and stopping the work-up there.
- Failing to screen for **OSA, RLS/PLMD, RBD, nocturia, pain and depression** before treating.
- Ordering **polysomnography for uncomplicated insomnia**.
- Omitting the caution about sleep restriction in fall-prone patients.
- Not mentioning **deprescribing** for the patient already on long-term hypnotics — this is often the real question.
- Forgetting **bright light therapy** for sundowning and circadian disorder.

> **15-second answer skeleton:** Normal sleep architecture and cycles → age changes (latency up, N3 down, WASO up, phase advance) — ability not need → ICSD-3 definition (3×3 rule) → pathophysiology: **hyperarousal + orexin flip-flop instability + two-process/SCN decline + Spielman 3-P + conditioning** → causes: physical, primary sleep disorders, behavioural, drugs, psychiatric → evaluation: sleep diary, bed-partner history, ISI, PSG only if indicated → treat the cause → **CBT-I first-line (5 pillars)** + BEDROOM sleep hygiene + bright light for circadian → drugs: short-term, Beers cautions, DORAs preferred, trazodone in dementia → deprescribing.

CONDENSED 7-MARK VERSION — "Short note on insomnia in the elderly / sleep hygiene"

1. **Age changes in sleep:** increased sleep latency and awakenings, reduced total sleep time, sleep efficiency and slow-wave sleep, circadian phase advance, more naps. Ability to sleep declines; need does not.
2. **Definition:** difficulty initiating or maintaining sleep, or early awakening, despite adequate opportunity, with daytime impairment; chronic if 3 nights a week for 3 months.
3. **Pathophysiology:** 24-hour hyperarousal (raised cortisol, sympathetic tone, beta EEG); orexin-stabilised VLPO–arousal flip-flop instability; declining Process S and Process C with SCN degeneration and reduced melatonin and light exposure; Spielman's predisposing–precipitating–perpetuating model; conditioned insomnia.
4. **Causes:** pain, orthopnoea/PND, nocturia, reflux; RLS/PLMD, sleep apnoea, RBD; naps over 30 minutes and excess time in bed; caffeine, alcohol, diuretics, steroids, SSRIs, hypnotic withdrawal; depression and anxiety.
5. **Evaluation:** sleep diary 1–2 weeks, bed-partner history, Insomnia Severity Index, Epworth; polysomnography only for suspected apnoea, PLMD, parasomnia or refractory insomnia.
6. **Sleep hygiene (BEDROOM):** fixed rising time, daytime exercise not late, dark/quiet/cool room, naps under 30 minutes, bed only for sleep and sex, out of bed if awake beyond 20 minutes, no evening caffeine, alcohol or heavy meals; morning bright light.
7. **Management:** treat the underlying cause; **CBT-I first-line** (stimulus control, sleep restriction, relaxation, cognitive restructuring, sleep hygiene); bright light therapy for circadian disorder and sundowning; drugs short-term only, avoiding long-acting benzodiazepines, Z-drugs and antihistamines per Beers; low-dose trazodone in dementia; taper and deprescribe long-term hypnotics alongside CBT-I.

3-point current update: (i) **European Sleep Research Society guideline 2023** — CBT-I (including digital) first-line; BZD/BzRA and sedating antidepressants only up to 4 weeks; antihistamines, antipsychotics and phytotherapy not recommended; PR melatonin 2 mg up to 3 months if aged over 55. (ii) **Dual orexin receptor antagonists** (daridorexant, lemborexant, suvorexant) are the major advance; **daridorexant** has the shortest half-life (~8 h) with equal efficacy and safety in those aged 65 and over, and needs no special deprescribing protocol. (iii) **ICSD-3-TR** treats chronic insomnia as a disorder in its own right even when comorbid, and suvorexant's reduction in CSF tau and amyloid links sleep treatment to dementia-risk modification.

6. SLEEP APNOEA / POLYSOMNOGRAPHY — 15 MARKS

DEFINITIONS

1. **Sleep apnoea–hypopnoea syndrome (SAHS)** — repetitive episodes of complete or partial upper-airway obstruction during sleep producing intermittent hypoxaemia, hypercapnia, sympathetic surges and cortical arousals, with consequent daytime symptoms.
2. **AASM event definitions: Apnoea** = fall in airflow of 90% or more for **10 seconds or longer**. **Hypopnoea** = fall in airflow of 30% or more for 10 seconds or longer with either a **3% or greater desaturation** or an arousal. **RERA** = respiratory-effort-related arousal not meeting apnoea or hypopnoea criteria.
3. **Indices: AHI** = (apnoeas + hypopnoeas) per hour of sleep; **RDI** = AHI plus RERAs per hour; **ODI** = oxygen desaturations per hour; **T90** = percentage of sleep time with saturation below 90%; **hypoxic burden** = area under the desaturation curve.
4. **Types** — **obstructive** (respiratory effort present, airflow absent), **central** (both effort and airflow absent — includes Cheyne–Stokes respiration in heart failure and stroke), **mixed**, and **treatment-emergent central apnoea** appearing on PAP therapy.
5. **Severity:** mild AHI 5–15, moderate 15–30, **severe above 30** per hour. Diagnosis of OSA requires **AHI 15 or more**, or **AHI 5 or more with symptoms or associated comorbidity**.

EPIDEMIOLOGY

6. OSA is **the most common sleep-related problem in older adults**. Development is **age-dependent and male-dominant**, and incidence is higher in the obese and in those with **increased neck circumference**. Prevalence of AHI 15 or more approaches **20–30% in those over 65**, and the male-to-female ratio narrows sharply after the menopause. Sleep-disordered breathing is very common in heart failure.
7. **India** — urban adult prevalence is approximately **9–13% in men and 5–7% in women**. Indians develop OSA at a **lower BMI** than Caucasians because of craniofacial morphology (shorter mandible, narrower airway) and central adiposity; therefore use **Asian-Indian cut-offs — overweight BMI 23 kg/m², obesity 25 kg/m², waist circumference 90 cm in men and 80 cm in women**.

PATHOPHYSIOLOGY

8. Four contributing traits ("**PALM**"): **P**crit — anatomical collapsibility of the pharynx; **A**rousal threshold — a low threshold causes premature arousal and ventilatory instability; **L**oop gain — an unstable, over-responsive ventilatory control system; **M**uscle responsiveness — poor reflex recruitment of genioglossus and other dilators.
9. **Age-related contributions** — reduced upper-airway dilator tone and reflex responsiveness, increased pharyngeal fat deposition and airway length, loss of lung-volume tethering of the airway, increased loop gain, blunted arousal and chemoreflex responses, and reduced protective effect of oestrogen in women after the menopause.
10. **Consequences of untreated OSA** — nocturnal hypoxia with associated risk of **cardiac arrhythmias and myocardial and cerebral infarction**; resistant **hypertension** (a recognised secondary cause); heart failure, atrial fibrillation, pulmonary hypertension, type 2 diabetes and metabolic syndrome; **excessive daytime sleepiness with driving and occupational risk**; cognitive impairment and increased dementia risk; depression; and reduced **olfactory identification and discrimination** in proportion to severity (higher AHI and lower mean arterial oxygen saturation), thought to reflect central cholinergic dysfunction.

CLINICAL FEATURES AND SCREENING

11. **Nocturnal** — loud, irregular snoring; witnessed apnoeas; choking or gasping arousals; **waking sweating, anxious and tachycardic**; excessive movement during sleep; nocturia; dry mouth.
    Daytime — morning headache, morning drowsiness, excessive daytime sleepiness, poor concentration, irritability, depressed mood, reduced libido.
12. **Atypical presentation in older adults** — sleepiness may be absent or attributed to age. Instead consider OSA in **nocturia, nocturnal confusion or sundowning, falls, new or worsening cognitive impairment, refractory hypertension, recurrent atrial fibrillation and unexplained pulmonary hypertension**. Obesity is less prominent than in younger patients. **The bed-partner history is essential and is frequently unavailable in widowed or institutionalised elders** — ask nursing staff instead.
13. **Screening instruments — STOP-BANG** (Snoring, Tiredness, Observed apnoea, blood Pressure, BMI over 35, Age over 50, Neck over 40 cm, Gender male; 3–4 intermediate risk, 5 or more high risk). **Note that the age and gender items make almost every older man score positive, so specificity in geriatric practice is poor.** Also the **Epworth Sleepiness Scale** (above 10 abnormal), the Berlin Questionnaire and NoSAS.

POLYSOMNOGRAPHY

14. **Attended, in-laboratory polysomnography is the gold standard.** AASM levels of testing:
    Level 1 — attended, in-laboratory, full-channel PSG.
    Level 2 — unattended full-channel portable study.
    Level 3 — **home sleep apnoea test (HSAT)**, limited channels: airflow, respiratory effort, oximetry, with or without ECG, heart rate and body position.
    Level 4 — one or two channels, usually oximetry alone.

15. **Level-1 PSG channels:**
    • **Sleep staging** — EEG (frontal, central and occipital derivations referenced to the contralateral mastoid: F4-M1, C4-M1, O2-M1), **electro-oculogram** (two channels) and **submental EMG**.
    • **Airflow** — nasal pressure transducer (for hypopnoea) and oronasal thermistor (for apnoea).
    • **Respiratory effort** — thoracic and abdominal respiratory inductance plethysmography belts.
    • **Gas exchange** — pulse oximetry, with transcutaneous or end-tidal carbon dioxide where hypoventilation is suspected.
    • **Others** — ECG, **bilateral anterior tibialis EMG** (limb movements), body-position sensor, snore microphone, and **synchronised audio-video** (essential for parasomnias and REM sleep behaviour disorder).
16. **Scoring and report** — scored in **30-second epochs** as stages **W, N1, N2, N3 and R**. The report should include total sleep time, sleep efficiency, sleep-onset and REM latency, wake after sleep onset, percentage of each stage, **arousal index**, **AHI overall and in supine and REM sleep separately**, RDI, ODI, minimum and mean oxygen saturation, T90, periodic limb movement index, and cardiac rhythm.
17. **Indications for PSG** — suspected sleep apnoea; suspected **periodic limb movement disorder**; suspected **REM sleep behaviour disorder** or injurious parasomnia; suspected nocturnal seizures; narcolepsy (followed next day by the multiple sleep latency test); **PAP titration**; assessment of treatment failure or persistent symptoms despite therapy; and insomnia refractory to adequate treatment. **PSG is not indicated for uncomplicated insomnia, uncomplicated circadian rhythm disorders, or restless legs syndrome, which is a clinical diagnosis.**
18. **Home sleep apnoea testing** is acceptable in **uncomplicated adults with a high pre-test probability of moderate-to-severe OSA**. It is **not appropriate** where there is significant cardiorespiratory disease, suspected hypoventilation, neuromuscular disease, chronic opioid use, or suspicion of a non-OSA sleep disorder — all of which are common in geriatric practice. HSAT **underestimates the AHI** because total **recording** time rather than total **sleep** time is the denominator; therefore a negative or technically inadequate HSAT in a symptomatic patient **must be followed by in-laboratory PSG**.
19. **Practical problems in older adults** — the first-night effect, difficulty tolerating electrodes, mobility and transfer problems, nocturia interrupting the study, risk of delirium in an unfamiliar environment, and intrinsically fragmented sleep, all of which reduce the reliability of a single night's study.

MANAGEMENT

20. **General and behavioural** — weight reduction; **avoid evening alcohol, benzodiazepines and opioids**, which worsen upper-airway collapse and blunt arousal; smoking cessation; treat nasal obstruction and hypothyroidism; **positional therapy** for supine-predominant disease; optimise heart failure; and give explicit **driving advice** — untreated OSA with sleepiness is a driving hazard and, in many jurisdictions, a reportable one.
21. **Continuous positive airway pressure (CPAP) is first-line** and the standard of care for moderate-to-severe OSA. Auto-titrating PAP is acceptable in uncomplicated disease; **bilevel PAP** for hypoventilation or pressure intolerance. CPAP improves sleepiness, quality of life, blood pressure and mood; **adherence is the limiting factor** (conventional target: at least 4 hours a night on at least 70% of nights). Older patients adhere at least as well as younger ones when adequately supported.
22. **Oral appliances** — **mandibular advancement devices** for mild-to-moderate OSA, CPAP intolerance or supine-predominant disease. They require **adequate dentition**, a major limitation in older adults, and are contraindicated in significant temporomandibular joint disease.
23. **Surgery** — uvulopalatopharyngoplasty, nasal surgery, tonsillectomy and maxillomandibular advancement; results are poorer and risks higher in the elderly, so surgery is reserved for carefully selected patients with a correctable obstruction. **Hypoglossal nerve stimulation** is an option for CPAP-intolerant patients within defined AHI and BMI limits and in the absence of complete concentric palatal collapse.
24. **Central sleep apnoea and Cheyne–Stokes respiration** — optimise heart-failure therapy first; consider nocturnal oxygen; **adaptive servo-ventilation is contraindicated in symptomatic heart failure with an ejection fraction of 45% or less** (SERVE-HF trial showed increased mortality); phrenic nerve stimulation is an option in selected patients.

LATEST UPDATES (2023–PRESENT)

- **SURMOUNT-OSA (NEJM 2024)** — two 52-week phase 3 trials of **tirzepatide** (a dual GIP/GLP-1 receptor agonist, 10 or 15 mg weekly) in adults with moderate-to-severe OSA and obesity (mean baseline AHI about 50). **Trial 1 (not on PAP): AHI fell 25.3 per hour versus 5.3 with placebo. Trial 2 (on PAP): AHI fell 29.3 per hour versus 5.5.** Mean reduction in AHI up to **62.8%**; **43.0% and 51.5% respectively met criteria for disease resolution**. Tirzepatide also reduced body weight (about 18–20%), **hypoxic burden, hs-CRP and systolic blood pressure**, and improved sleep-related patient-reported outcomes. Adverse events were predominantly gastrointestinal.
- **FDA approval, 20 December 2024** — tirzepatide (Zepbound) became the **first ever prescription medicine approved for moderate-to-severe obstructive sleep apnoea in adults with obesity**, used with a reduced-calorie diet and increased physical activity. **CPAP remains first-line**; tirzepatide is an option for patients unable or unwilling to use PAP, or as an adjunct in those with obesity who remain symptomatic on PAP.
- **Other pharmacological agents remain investigational** — **AD109** (aroxybutynin plus atomoxetine, targeting upper-airway muscle tone; phase 3 SynAIRgy and LunAIRo, 2025) and **sulthiame** (carbonic anhydrase inhibitor, targeting loop gain). Neither is approved.
- **AASM Scoring Manual version 3 (2023)** — updated hypopnoea, arousal and paediatric rules, and formal recognition of alternative metrics.
- **Beyond the AHI** — the AHI correlates poorly with symptoms and cardiovascular risk. **Hypoxic burden and sleep-**

apnoea-specific hypoxic burden (SASHB), arousal burden and heart-rate response are prognostically superior, and the field is moving to **phenotype- and endotype-driven therapy based on the PALM traits** rather than AHI-only decision-making.

- **CPAP and cardiovascular outcomes** — SAVE and RICCADSA did not show reduction in major cardiovascular events in intention-to-treat analyses, but on-treatment analyses show benefit in adherent users; the pragmatic message is that CPAP is prescribed for **symptoms, quality of life and blood pressure**, with cardiovascular benefit dependent on adherence.
- **Consumer technology** — FDA-cleared **sleep apnoea notification features on smartwatches and rings** (2024 onwards) are increasing case detection; a positive alert requires confirmatory HSAT or PSG and must not be treated as a diagnosis.

CURRENT PRACTICE UPDATE

Issue	Textbook position	Current evidence / practice
Treatment options	CPAP, dental appliances and uvulopalatopharyngoplasty	CPAP still first-line; add **tirzepatide (FDA-approved December 2024)**, **hypoglossal nerve stimulation**, positional therapy and maxillomandibular advancement
Diagnostic testing	Refer to a sleep centre for further work-up	Tiered testing — **HSAT** for uncomplicated high-probability cases; **attended PSG** mandatory where comorbidity, hypoventilation, opioid use or another sleep disorder is suspected
Severity metric	Apnoea–hypopnoea index	AHI retained for diagnosis, but **hypoxic burden and arousal burden** better predict cardiovascular outcome; **endotype-driven therapy** emerging
Pharmacotherapy	No effective drug therapy	**Tirzepatide** reduces AHI by 25–29 events per hour with disease resolution in 43–51%; AD109 and sulthiame investigational
Central apnoea in heart failure	Not specifically addressed	**Adaptive servo-ventilation contraindicated when LVEF is 45% or less** (SERVE-HF mortality signal)
Case detection	Bed-partner report of loud snoring prompts referral	Bed-partner history often unavailable in older adults; use atypical presentations, and confirm **wearable-generated alerts** with formal testing

EXAM ONE-LINERS

- Apnoea = 90% airflow reduction for 10 seconds; hypopnoea = 30% reduction for 10 seconds with 3% desaturation or arousal.
- Severity: mild 5–15, moderate 15–30, **severe above 30**.
- OSA is **age-dependent and male-dominant**; prevalence approaches 20–30% over 65.
- Indians develop OSA at a **lower BMI** — use Asian cut-offs (BMI 23/25, waist 90/80 cm).
- PALM traits: **P**crit, **A**rousal threshold, **L**oop gain, **M**uscle responsiveness.
- In older adults, suspect OSA from **nocturia, nocturnal confusion, falls, refractory hypertension and cognitive decline**, not necessarily sleepiness.
- STOP-BANG loses specificity in the elderly because age and male sex already score.
- Level 1 PSG needs **EEG + EOG + submental EMG** to stage sleep — that is what an HSAT lacks.
- HSAT **underestimates AHI** (recording time, not sleep time, is the denominator).
- PSG is not indicated for uncomplicated insomnia or for restless legs syndrome.
- CPAP adherence target: **4 hours a night on 70% of nights**.
- Mandibular advancement devices need **teeth** — a real limitation in old age.
- **ASV is contraindicated in heart failure with LVEF 45% or less**.
- **Tirzepatide** (SURMOUNT-OSA; FDA approved December 2024) is the first drug approved for OSA — AHI down 25–29 per hour, resolution in 43–51%.

CONDENSED 7-MARK VERSION — "Short note on obstructive sleep apnoea / polysomnography"

1. **Definition:** repetitive complete (apnoea) or partial (hypopnoea) upper-airway obstruction in sleep causing intermittent hypoxaemia and arousals. Apnoea = 90% airflow fall for 10 s; hypopnoea = 30% fall for 10 s with 3% desaturation or arousal.
2. **Severity:** AHI mild 5–15, moderate 15–30, severe above 30. Diagnosis: AHI 15 or more, or 5 or more with symptoms.
3. **Pathophysiology:** PALM traits — airway collapsibility, low arousal threshold, high loop gain, poor dilator muscle responsiveness; ageing adds reduced muscle tone, pharyngeal fat, reduced lung-volume tethering and blunted chemoreflexes.

4. **Features:** loud irregular snoring, witnessed apnoeas, waking sweating and tachycardic, morning headache and drowsiness, daytime sleepiness. In older adults, presentation may instead be nocturia, nocturnal confusion, falls, refractory hypertension or cognitive decline.
5. **Complications:** arrhythmia, myocardial and cerebral infarction, resistant hypertension, heart failure, atrial fibrillation, pulmonary hypertension, diabetes, cognitive impairment, road-traffic risk.
6. **Polysomnography:** gold standard, Level 1 attended in-laboratory. Channels — EEG, EOG and submental EMG for staging; nasal pressure and thermistor for airflow; thoracoabdominal belts for effort; oximetry; ECG; tibialis EMG; position, snore and video. Scored in 30-second epochs; report AHI (total, supine, REM), RDI, ODI, arousal index, minimum and mean saturation, T90, PLM index. Level 3 home testing for uncomplicated high-probability cases only; it underestimates AHI.
7. **Management:** weight loss, avoid evening alcohol and sedatives, positional therapy, treat nasal obstruction, driving advice. **CPAP first-line** (adherence 4 h/night on 70% of nights); mandibular advancement device if mild-moderate or CPAP-intolerant and dentition adequate; selected surgery or hypoglossal nerve stimulation. ASV contraindicated if LVEF 45% or less.

3-point current update: (i) **SURMOUNT-OSA (NEJM 2024)** — tirzepatide reduced AHI by 25–29 events per hour with disease resolution in 43–51%, and on **20 December 2024 the FDA approved it as the first drug for moderate-to-severe OSA with obesity**; CPAP remains first-line. (ii) The field is moving **beyond the AHI** to hypoxic burden and endotype-driven (PALM) therapy, with AASM Scoring Manual v3 (2023) updating event rules. (iii) **FDA-cleared wearable sleep-apnoea notifications** are increasing detection but require confirmatory HSAT or PSG; in India, use **Asian BMI and waist cut-offs** because OSA occurs at lower BMI.

End of module — Elder abuse · Advance care planning · End-of-life care · Transitional care · Insomnia · Sleep apnoea
Next in series: cardiovascular, respiratory and neurology (Parkinson's disease)

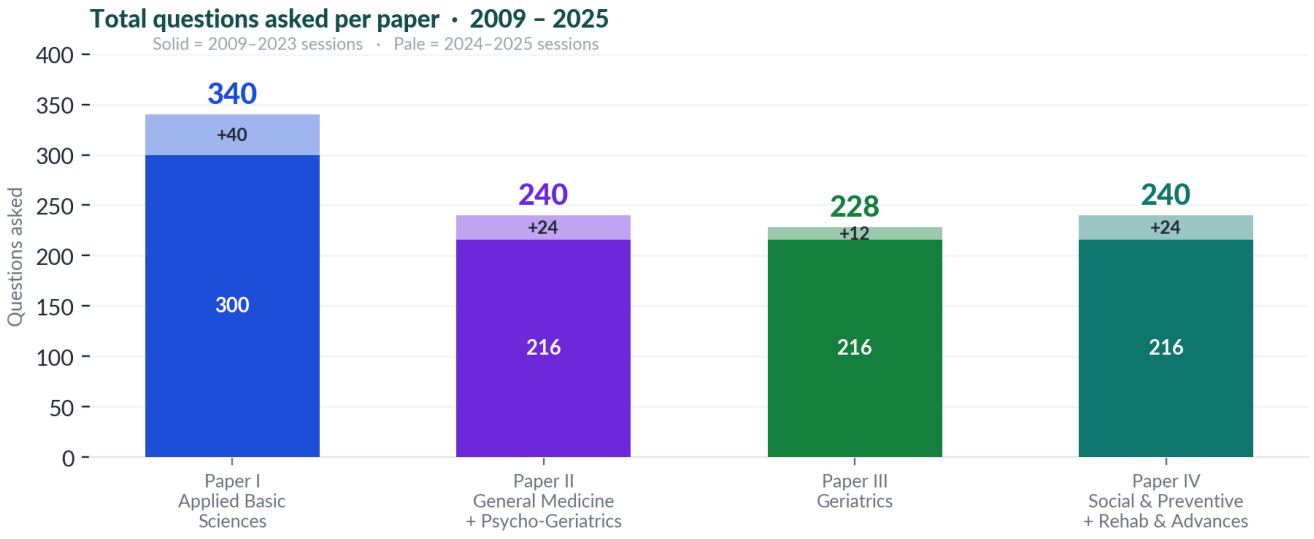
Part A · How this paper is examined

HOW TO READ THIS DOCUMENT



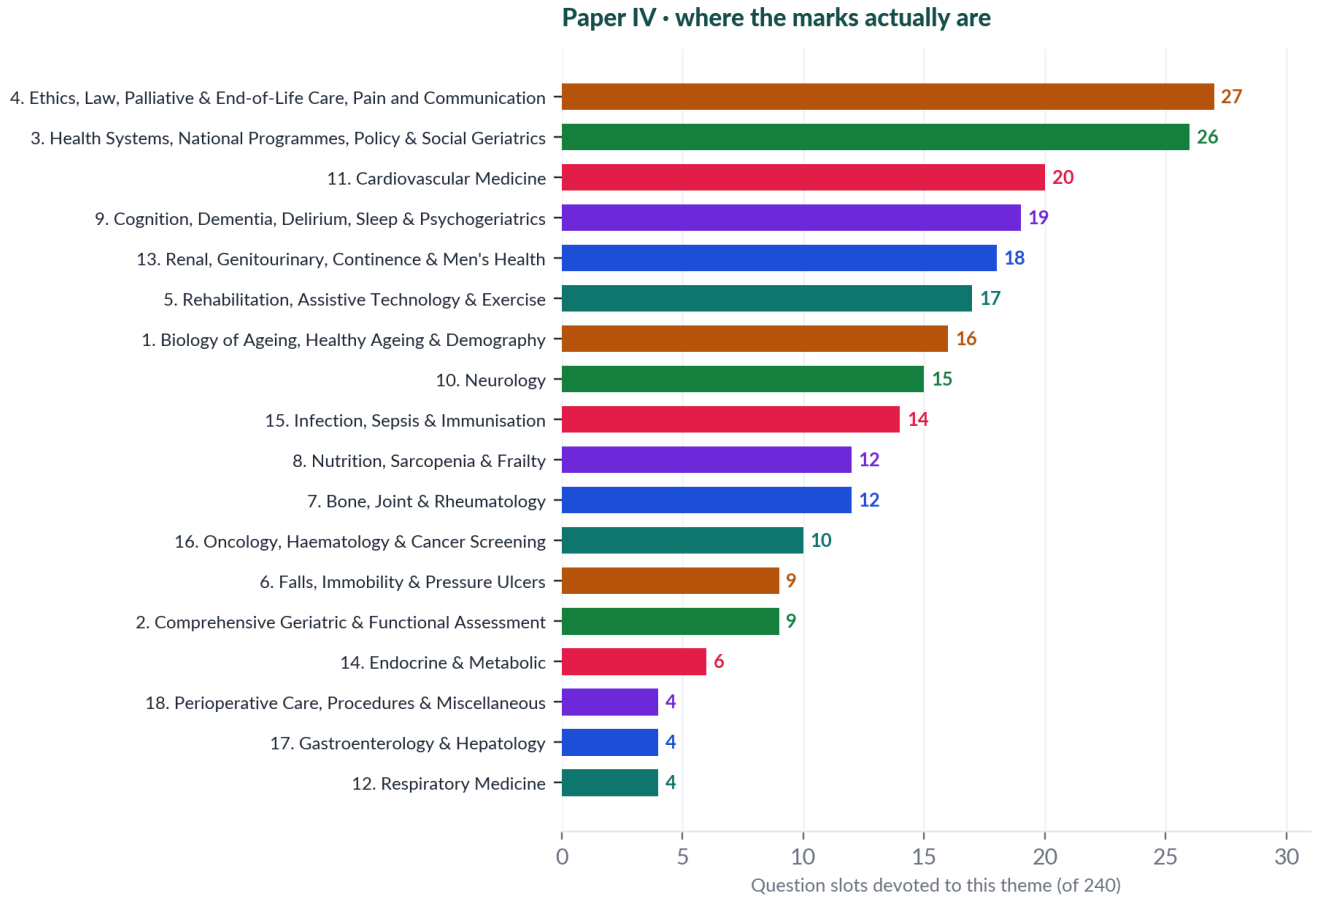
Every question ever set in Paper IV between March 2009 and October 2025 has been extracted, merged with the Ebenezer question bank, stripped of year tags and repeats, and re-grouped by system and theme. Nothing has been dropped: the 240 original question slots have each been traced into one of the 174 unique entries in Part B, and the mapping was verified programmatically before this document was generated.

Question counts across all four papers

The four papers do not carry equal question loads. Paper I uses a six-subject short-note format with twenty questions per session, while Papers II, III and IV each use two long essays plus ten short notes — twelve questions per session. Counts below are taken from the question papers available in the source archive.

Paper	Sub. Code	Sessions available	Questions per session	Total questions
Paper I — Applied Basic Sciences	2059 / 4041	17	20 (4+4+3+3+3+3)	**340**
Paper II — General Medicine incl. Psycho-Geriatrics	2056 / 4042	20	12 (2 essays + 10 notes)	**240**
Paper III — Geriatrics	2057 / 4043	19	12 (2 essays + 10 notes)	**228**
Paper IV — Social & Preventive Geriatrics	2060 / 4044	20	12 (2 essays + 10 notes)	**240**
All four papers combined	—	76	—	**1,048**

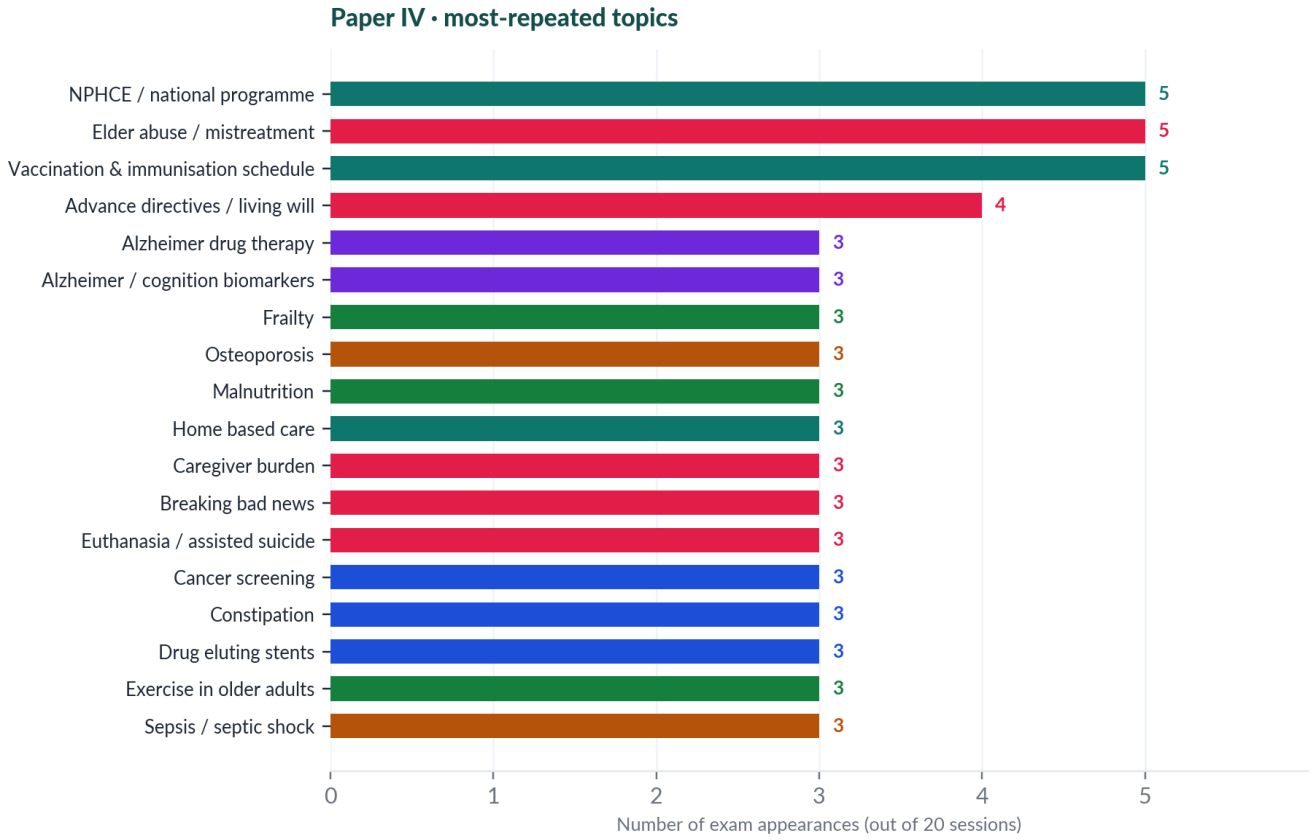
Paper I is missing the October 2013, 2014, 2015 and December 2024 Paper III sessions from the archive; the October 2024 Paper III paper is also absent. Counts reflect what is actually in the source files rather than every session the university has ever conducted.



The Paper IV mark scheme

Two formats have been used. Sessions up to March 2010 set two 20-mark essays and ten 6-mark notes. From May 2011 onward the paper has settled into two 15-mark essays and ten 7-mark notes, and this is the format you should calibrate every answer to. Each question in Part B carries its mark-format descriptor so you can size your answers correctly.

Period	Section I	Section II	Answer calibration
2009 – 2010	2 × 20 marks	10 × 6 marks	Historic format — treat 20-mark stems as 15-mark essays
2011 – 2025	2 × 15 marks	10 × 7 marks	Essay: ~11 pages / 35 min. Note: ~4 pages / 10 min



Where the marks actually are

Grouping all 240 question slots by theme shows how lopsided this paper is. Roughly a third of the paper is drawn from just four themes — health systems and national programmes, ethics and end-of-life care, rehabilitation, and cardiovascular medicine. The clinical-medicine sections exist because "Recent Advances" in the paper title is interpreted very broadly by examiners.

The most-repeated topics

Three topics have each appeared five times in twenty sessions: the National Programme for Health Care of the Elderly, elder abuse, and adult immunisation. If you prepare nothing else thoroughly, prepare these. The chart counts distinct exam appearances, not question slots.

What has changed in the examiner's style

SHIFT 1 · FROM TOPIC LABELS TO CLINICAL VIGNETTES

Up to about 2019 most short notes were bare topic labels — "Euthanasia", "Telomere", "Home based care". From 2022 onward a majority of notes are scenarios with a named patient and a specific decision to make: Mr. Atul with a saturation of 60%, Mr. Shivanand who is pale and in failure, the 65-year-old man with three urinary infections in six months. Prepare to write staged answers — differentials, then investigations, then ward management, then discharge planning.

SHIFT 2 · THE EXAMINER NOW ASKS YOU TO BUILD SOMETHING

Recent papers ask candidates to draw up a protocol, prepare a checklist, advise a director on a new service, or head a team. These are not knowledge questions; they are structure questions. Answer them with headings, numbered steps and an explicit evidence base.

SHIFT 3 · "RECENT ADVANCES" MEANS NEWER DRUG CLASSES

A steady stream of questions asks about the newest member of a drug family: newer anticoagulants, newer oral antidiabetics, newer insulins, newer antidepressants, newer Alzheimer drugs, antisclerostin antibodies. Keep a running list of what is new in each class and its geriatric caveats.

SHIFT 4 · INDIAN CONTEXT IS EXPECTED, NOT OPTIONAL

Questions increasingly specify India explicitly — advance directives in India, the social security system in India, how palliative care has evolved in India. Weave in NPHCE, NPOP, the Maintenance and Welfare of Parents and Senior Citizens Act 2007, the Mental Healthcare Act 2017, Elderline 14567, and ICMR and ARDSI data wherever they fit.

Part B · Master question list

All 240 questions ever asked in Paper IV, de-duplicated into 174 unique entries and grouped by system and theme rather than by year. Where a topic has been asked more than once, the wording of the fullest version has been kept and the repeat count is shown as a badge. Mark-format badges tell you what length of answer to prepare.

Badge key

ASKED ×3+ · ASKED ×2 · 15-mark essay · 7-mark note

No badge on repeat count means the question has been asked once. High-yield items — asked three or more times — carry a coral badge.

1 Biology of Ageing, Healthy Ageing & Demography

Theories, biomarkers, anti-ageing science, active ageing, demography

1. Enumerate and explain in detail the theories of ageing.
   ASKED ×2 · 15-mark essay + 7-mark note
2. Biomarkers of ageing.
   7-mark note
3. Anti-ageing interventions.
   7-mark note
4. Calorie restriction — role of caloric restriction in ageing.
   ASKED ×2 · 7-mark note
5. Telomere.
   7-mark note
6. Sirtuins in ageing and disease.
   7-mark note
7. Interleukin-6.
   7-mark note
8. Immunosenescence / immune senescence and its relevance to vaccination in the elderly.
   ASKED ×2 · 7-mark note
9. Interventions for healthy ageing.
   7-mark note
10. Describe active ageing and how will you achieve it?
    ASKED ×2 · 15-mark essay + 7-mark note
11. Geriatric demography and its implications.
    7-mark note
12. Geriatric syndromes.
    7-mark note

2 Comprehensive Geriatric & Functional Assessment

CGA, functional scales, disability assessment, decisional capacity

13. Write in detail on Comprehensive Geriatric Assessment and its usefulness in geriatric practice.
ASKED ×2 15-mark essay

14. Discuss the functional assessment in an 85-year-old lady.
15-mark essay

15. Barthel's Index of Activities of Daily Living.
7-mark note

16. Physical Self-Maintenance Scale.
6-mark note

17. Integrated care of older people (ICOPE).
15-mark essay

18. Discuss the causes of chronic disability in the elderly. Describe the methods of its prevention and management.
15-mark essay

19. What is decisional capacity? What are the factors affecting it and how would one assess decisional capacity in an older person?
ASKED ×2 7-mark note

3 Health Systems, National Programmes, Policy & Social Geriatrics

NPHCE, NPOP, long-term care, home care, day care, social work, service models

20. National Programme for Health Care of the Elderly (NPHCE) — background on which the programme was based, vision, objectives and expected outcomes; packages of services at different levels of care and the activities that centres must perform. As doctor in charge of a District Hospital, which components would you implement and how would you put theory into practice?
ASKED ×5 15-mark essay + 7-mark note

21. National Policy on Older Persons (NPOP) and the various existing beneficiary schemes for the elderly.
ASKED ×2 7-mark note

22. Role of Government in providing health care and economic security for older people.
6-mark note

23. Describe the social security system for older people in India.
ASKED ×2 15-mark essay + 7-mark note

24. Long term care.
ASKED ×2 7-mark note + 6-mark note

25. Community based long term care services.
7-mark note

26. Home based care.
ASKED ×3 7-mark note

27. House call programme.
6-mark note

28. Need for day hospitals in geriatric practice.
7-mark note

29. The director of your hospital is keen on starting a day care centre for older adults and seeks your opinion. Discuss the role, benefits and logistics of running a day care centre facility for older adults.
7-mark note

30. Hospice and respite care.
ASKED ×2 7-mark note

31. Ethno-geriatrics.
7-mark note

32. Role of geriatric social workers.
7-mark note

33. Geriatric Nurse Practitioner — discuss their role in the health care team.
7-mark note

34. Enumerate and briefly explain the components of the Hospital Elder Life Program (HELP).
7-mark note

35. Write a short note on the history of the "Stroke Clinics". Why were they set up and what issues do they address?
7-mark note

4 Ethics, Law, Palliative & End-of-Life Care, Pain and Communication

Elder abuse, advance directives, euthanasia, breaking bad news, palliative care, caregiver burden

36. Elder abuse / mistreatment of the elderly — epidemiology, types and different forms, risk factors, identification, diagnosis and management. Discuss the role of the social worker in identifying elder mistreatment.
ASKED ×5 15-mark essay + 7-mark note

37. Advance directives — current status in India.
ASKED ×4 7-mark note

38. What is a living will? What is the procedure to write a living will in India and how is it executed?
7-mark note

39. Euthanasia and physician-assisted suicide.
ASKED ×3 7-mark note

40. Informed consent.
7-mark note

41. How will you communicate bad news? / Breaking bad news.
ASKED ×3 7-mark note

42. Recognition and management of the terminally ill patient — e.g. a patient diagnosed with end-stage lung cancer with brain and liver metastases. What are all the issues that need to be addressed in the care of the terminally ill?
ASKED ×2 15-mark essay

43. What is palliative care? What are its principles? Name interventions in palliative care which would decrease the suffering of a person with painful bone metastasis, nausea, vomiting, constipation and breathlessness. How has this aspect of medical science evolved in India?
15-mark essay

44. Classify the types of pain. Discuss the pathophysiology, clinical evaluation and management of chronic or persistent pain in the elderly, and the role of palliative care in geriatric practice.
ASKED ×2 15-mark essay

45. End of life care issues.
7-mark note

46. Bereavement.
7-mark note

47. Caregiver burden / caregiver stress / apathy — what is it and how will you manage it?
ASKED ×3 7-mark note

5 Rehabilitation, Assistive Technology & Exercise

Rehab principles, the interdisciplinary team, aids and appliances, exercise, swallow

48. Definition, evaluation and components of rehabilitation in the elderly.
15-mark essay

49. Assessment of disability in older people and rehabilitation.
15-mark essay

50. Community based rehabilitation.
7-mark note

51. You are chosen to head the interdisciplinary team on a rehabilitation ward with neurology rehabilitation patients, post-orthopaedic procedure patients and patients deconditioned by comorbidities. Whom would you choose to be part of your team? Enumerate their job responsibilities. How would you address conflict management and care planning?
15-mark essay

52. Inputs from the occupational therapist on the team caring for the older person are not clearly understood. Highlight the role of the occupational therapist and how his or her presence can affect the care of the patient on the ward and at discharge.
7-mark note

53. Stroke rehabilitation.
7-mark note

54. Prior to initiating long term rehabilitation in a patient with stroke, what are the factors you would take into consideration before admitting such a patient into this facility?
7-mark note

55. Rehabilitation of a patient with osteoarthritis of the knee joints.
7-mark note

56. How will you rehabilitate an older adult with low vision?
7-mark note

57. Mobility aids / assistive devices for the elderly.
ASKED ×2 7-mark note

58. Artificial limb.
6-mark note

59. Gadgets which will improve the quality of life in the older person.
7-mark note

60. Exercise in the elderly — exercises in older adults: beneficial or harmful?
ASKED ×3 7-mark note + 6-mark note

61. Assessment of swallow — when, how, by whom and with what.
7-mark note

6 Falls, Immobility & Pressure Ulcers

Fall risk, prevention, sensor technology, immobility, pressure sores

62. Discuss the etiopathogenesis, risk factors, assessment, adverse consequences, prevention and management of falls in older adults.
15-mark essay

63. Assessment of fall risk and prevention of falls in the elderly.
15-mark essay

64. Fall risk assessment — tools for falls risk assessment.
ASKED ×2 7-mark note

65. How will you prevent falls in the elderly?
7-mark note

66. Role of sensor devices in the prevention of falls.
7-mark note

67. What are the causes of immobility in an elderly person? Write about the management and complications.
15-mark essay

68. Pressure sores — enumerate the prevention of pressure sores in an elderly bedbound patient. What are the stages of a pressure sore and the common sites involved? How is it preventable and what is the appropriate treatment for each stage?
ASKED ×2 7-mark note

7 Bone, Joint & Rheumatology

Osteoporosis, fracture prevention, Paget's, arthritis, vasculitis, myositis

69. Osteoporosis — definition, predisposing and risk factors, pathogenesis, diagnosis, prevention and management including newer interventions. Also elaborate on male osteoporosis and premenopausal osteoporosis.
ASKED ×3 15-mark essay + 7-mark note

70. Antisclerostin antibodies in the treatment of osteoporosis.
7-mark note

71. Prevention of fractures.
7-mark note

72. DEXA scan.
7-mark note

73. Paget's disease.
7-mark note

74. Osteoarthritis — pathogenesis, diagnosis and treatment.
7-mark note

75. Temporal arteritis — diagnosis, clinical features, treatment and prognosis.
7-mark note

76. Diffuse idiopathic skeletal hyperostosis (DISH) — presentation, investigations and treatment options.
7-mark note

77. Dermatomyositis in the elderly — presentation, associated comorbidities, laboratory investigations, treatment options and prognosis.
7-mark note

78. Role of bisphosphonates in osseous metastases.
7-mark note

8 Nutrition, Sarcopenia & Frailty

Malnutrition, nutritional assessment, anorexia, obesity, sarcopenia, frailty

79. Discuss the various nutritional disorders / malnutrition in older adults — causes, approach to diagnosis, assessment and management.
ASKED ×3 20-mark essay + 15-mark essay + 7-mark note

80. Nutritional assessment in older persons.
ASKED ×2 7-mark note

81. Anorexia of ageing.
7-mark note

82. Discuss obesity in the elderly and its management.
20-mark essay

83. Discuss sarcopenia in ageing. Briefly write about the diagnostic criteria, investigations and management.
15-mark essay

84. Frailty is a common syndrome in older adults — discuss the etiopathogenesis, assessment, management and prevention of frailty.
ASKED ×3 15-mark essay + 7-mark note

85. Compare and contrast the tests used to identify / screen for frailty.
7-mark note

9 Cognition, Dementia, Delirium, Sleep & Psychogeriatrics

Alzheimer's, biomarkers, delirium, depression, sleep, addiction, behaviour

86. Alzheimer's dementia — pathogenesis, latest advances in pathogenesis at the molecular level, drugs used in dementia (mechanism of action, efficacy, indications for use and side effects) and newer treatment modalities being tried.
15-mark essay

87. Advances in the diagnosis of early stages of Alzheimer's dementia and mild cognitive impairment.
15-mark essay

88. Biomarkers for Alzheimer's dementia / emerging biomarkers in cognition.
ASKED ×3 7-mark note

89. Current drug therapy, newer therapy and newer drugs for Alzheimer's disease.
ASKED ×3 7-mark note

90. Discuss confusional states in the elderly. How will you do the investigations and plan the management?
20-mark essay

91. Interventions to prevent delirium in post-operative older patients.
7-mark note

92. Discuss any three cognitive screening tests useful in the outpatient department.
7-mark note

93. Geriatric depression scales.
7-mark note

94. What are the newer antidepressants? What is the safety profile of these drugs in the older person?
7-mark note

95. Sleep protocol.
7-mark note

96. What are the causes, risk factors, clinical features, complications and treatment of REM (rapid eye movement) sleep behaviour disorder?
7-mark note

97. Impulse control disorders.
7-mark note

98. Nicotine dependence.
7-mark note

99. What are the effects and ill effects of alcohol in the geriatric population? How would you address the issue of alcoholism in an elderly patient? Write a note on alcohol de-addiction.
ASKED ×2 7-mark note

10 Neurology

Motor neuron disease, coma, stroke, parkinsonism, tremor, neuropathy

100. What is motor neuron disease? Discuss the etiopathogenesis, clinical presentation, symptoms, course, prognosis and the treatment modalities available.

ASKED ×2 | 15-mark essay + 6-mark note

101. Discuss the causes of coma in elderly people. (Asked together with: how will you investigate and manage diabetic ketoacidosis?)

20-mark essay

102. Dizziness in the elderly.

6-mark note

103. Thrombolysis in stroke.

7-mark note

104. Discuss the recent advances in the management of parkinsonism.

7-mark note

105. Surgical management of parkinsonism.

7-mark note

106. Management of motor fluctuations in Parkinson's disease.

7-mark note

107. Parkinsonism-plus syndrome.

6-mark note

108. Pathognomonic MRI findings in progressive supranuclear palsy and multiple system atrophy.

7-mark note

109. Differential diagnosis of tremor in the older person. Discuss the treatment modalities for each of these conditions.

7-mark note

110. What are the risk factors and criteria to diagnose Restless Leg Syndrome? How will you manage a case of restless leg syndrome?

7-mark note

111. Causes, evaluation and management of a person presenting with features of peripheral neuropathy.

7-mark note

112. Myasthenia gravis — presentations, laboratory evaluation and treatment.

7-mark note

113. Ring-enhancing shadow on CT brain.

6-mark note

11 Cardiovascular Medicine

ACS, stents, heart failure, arrhythmia, anticoagulation, risk reduction, lipids

114. What are the types of acute coronary syndromes? How are they diagnosed, investigated and treated based on the latest recommendations published in literature — both acutely and on outpatient follow-up?

15-mark essay

115. Discuss the management of ST elevation myocardial infarction. What are the recent advances in the approach to this entity?

15-mark essay

116. Newer cardiac biomarkers in myocardial injury and their interpretation.

7-mark note

117. Drug eluting stents — pros and cons; advantages and disadvantages over bare metal stents.

ASKED ×3 7-mark note

118. Etiopathogenesis and management of in-stent stenosis.

7-mark note

119. Heart failure is commonly encountered on the geriatric wards. Describe the etiopathology, clinical presentation, stages and management of heart failure.

7-mark note

120. Management of systolic heart failure in an elderly patient with chronic kidney disease with a GFR of 40 ml/min.

7-mark note

121. Complete heart block.

6-mark note

122. AHA guidelines for stroke prevention in atrial fibrillation.

7-mark note

123. CHADS2-VASc score — what is it used in and what is its clinical significance?

7-mark note

124. Role of newer anticoagulants.

7-mark note

125. Low molecular weight heparins — types, indications for use, benefits and side effect profile.

7-mark note

126. The orthopaedic team wants you to draw up an evidence based protocol on venous thromboembolic prophylaxis following elective total hip and knee replacements. Draw up this protocol based on evidence in literature.

7-mark note

127. Enumerate the causes for secondary hypertension — how would you evaluate and treat this entity?

7-mark note

128. Lifestyle modification to reduce cardiovascular risk.

7-mark note

129. Primary prevention of cardiovascular disease.

7-mark note

130. Statins in the elderly.
7-mark note

131. Ezetimibe — indications, mode of action, metabolism, excretion, side effects and dosage.
7-mark note

12 Respiratory Medicine
COPD, oxygen therapy, CPAP, airway pathology

132. Chronic obstructive pulmonary disease — management based on recent recommendations.
7-mark note

133. A known COPD patient on inhalers presents to the Emergency Department with severe breathlessness and an oxygen saturation of 60% after three days of cough with purulent sputum. How would you tailor oxygen requirements and oxygen delivery systems throughout his hospital stay and at discharge?
7-mark note

134. Role of CPAP in diseases of the elderly.
7-mark note

135. Describe the changes seen in the airways in emphysema and asthma.
7-mark note

13 Renal, Genitourinary, Continence & Men's Health
RRT, electrolytes, UTI, incontinence, catheters, LUTS, prostate, testosterone

136. Role of renal replacement therapy in the elderly.
7-mark note

137. Peritoneal dialysis.
6-mark note

138. Hyponatremia.
6-mark note

139. Hyperkalemia — how should you investigate hyperkalemia (including in a diabetic) and what is the line of management?
ASKED ×2 7-mark note + 6-mark note

140. Urinary tract infection in the elderly.
6-mark note

141. Management of recurrent urinary tract infection in the elderly. A 65-year-old man has had three confirmed urinary tract infections, all needing hospitalisation and intravenous therapy in the last six months, and solicits your advice for this recurrent problem. What advice and therapies will you give him?
ASKED ×2 7-mark note

142. Asymptomatic bacteriuria — definition, treatment and prognosis.
7-mark note

143. Behavioural intervention in urinary incontinence.
7-mark note

144. Stress urinary incontinence in women. Add a note on Kegel's exercises.
7-mark note

145. Long term catheterization / continuous bladder drainage.
ASKED ×2 7-mark note

146. What is the preliminary assessment done in an older male with lower urinary tract symptoms? When would you refer to a urologist?
7-mark note

147. Testosterone replacement therapy in the elderly male / testosterone therapy in older men.
ASKED ×2 7-mark note

148. Prostate specific antigen — to screen or not to screen: what does the recent evidence show and why?
7-mark note

149. Alpha receptor antagonists.
6-mark note

14 Endocrine & Metabolic

Diabetes emergencies, oral agents, insulins, diabetic foot, thyroid

150. How will you investigate and manage diabetic ketoacidosis? (Asked paired with: causes of coma in elderly people.)
20-mark essay

151. Newer oral antidiabetic agents.
7-mark note

152. Newer insulin analogues — onset and duration of action, and their advantage over the older insulins.
ASKED ×2 7-mark note

153. Diabetic foot syndrome.
7-mark note

154. What are the clinical features of hyperthyroidism in the older person? What are the investigations to be sent and what should be the line of management?
7-mark note

15 Infection, Sepsis & Immunisation

Adult immunisation, sepsis and shock, tuberculosis, hepatitis, malaria

155. Draw up an immunisation schedule for a fit elderly patient and give reasons for your choice of immunisation protocol based on evidence found in literature. Discuss the current guidelines for vaccination of older persons and the status of vaccination in the elderly with recent evidence.
ASKED ×5 7-mark note

156. Pneumococcal vaccination.
7-mark note

157. Travel recommendations for vaccinations in the elderly — CDC guidelines.
7-mark note

158. Define sepsis, septic shock, systemic inflammatory response syndrome and multiorgan dysfunction syndrome. Describe the epidemiology, etiopathogenesis, clinical presentation, diagnosis, investigations, management and prognosis of an older person with sepsis, and the recent advances in the management of sepsis.
ASKED ×3 15-mark essay + 7-mark note

159. How would you diagnose and manage multidrug-resistant tuberculosis based on the DOTS-Plus regime?
7-mark note

160. Malaria — treatment drugs: classes, uses, contraindications, side effect profile and efficacy. Also mention the drugs used in prophylaxis for malaria.
7-mark note

161. Recent trends in the treatment of Hepatitis C infection.
7-mark note

162. Treatment — older and newer modalities — of chronic Hepatitis B infection.
7-mark note

16 Oncology, Haematology & Cancer Screening

Screening strategy, tumour markers, MDS, plasma cell disorders, anaemia

163. Cancer screening in the elderly.
ASKED ×3 7-mark note

164. Screening for colon cancer.
7-mark note

165. Tumour markers — role in detection and management of cancer.
7-mark note

166. Myelodysplastic syndrome — WHO classification and distinguishing features of each class; diagnostic criteria and the differentials one has to consider.
ASKED ×2 7-mark note

167. POEMS syndrome — clinical features, laboratory investigations and treatment.
7-mark note

168. Bone marrow transplant.
7-mark note

169. A 68-year-old man presents to the outpatient department with shortness of breath. On examination he was found to be pale and in failure. Elaborate on how one should investigate and manage him.
7-mark note

17 Gastroenterology & Hepatology

Constipation, transplantation

170. How do you prevent and manage chronic constipation in the elderly? Discuss the complications and management of constipation.
ASKED ×3 7-mark note + 6-mark note

171. Liver transplantation.

6-mark note

18 Perioperative Care, Procedures & Miscellaneous

Pre-operative assessment, periprocedural planning, organ donation

172. Peri-operative care of the elderly / pre-operative assessment.

ASKED ×2 7-mark note + 6-mark note

173. You are tasked with preparing a checklist for older adults undergoing diagnostic and therapeutic procedures in the ward. Discuss the common medical issues that need planning prior to these procedures and how they need to be addressed in the periprocedural period to avoid adverse patient outcomes — e.g. management of antiplatelet agents in the periprocedural period.

7-mark note

174. Eye donation.

6-mark note

Part C · Ebenezer's bank — Paper IV topics not yet asked

Every Paper IV-relevant heading in Ebenezer's Geriatric Question Bank was cross-checked against the 174 questions in Part B. The topics below appear in the bank but have **never** been set in a Paper IV university paper. They are the highest-value gap list you have: a compiler thought them worth including, and the examiner has not yet used them.

Rehabilitation & Service Models

1. Transitional home care — admission and discharge criteria, and the role of management.
2. Advance care planning (as distinct from the advance directive document).
3. Role of physiotherapy in the elderly.
4. Role of the occupational therapist in an older person with mobility issues.
5. Phases of human walking — describe in detail with a diagram.
6. Deconditioning and its prevention.

Falls & Mobility

7. Post-fall syndrome.
8. Fear of falling — evaluation and prevention.
9. Drop attacks.
10. Gait and balance assessment.
11. The long lie — consequences and management.
12. Vestibular rehabilitation.

Continence & Genitourinary

13. Faecal incontinence — evaluation and management.
14. Overactive bladder.
15. Bladder retraining protocol.
16. Uroflowmetry.
17. Erectile dysfunction and the treatments available.
18. Hormone replacement therapy in older women.
19. Gynaecomastia in the older male.
20. Hirsutism and baldness in the elderly woman.

Psychogeriatrics

21. Non-pharmacological management of agitation in the elderly.
22. Suicide in elders and suicide risk assessment.
23. Anxiety and its management in the elderly.
24. Psychotic disorders in late life; late-onset schizophrenia.

25. Atypical antipsychotics — side effects and safety profile in the elderly.
26. Mood disorders in late life.
27. Age-associated personality changes.
28. Diogenes syndrome.
29. Age-associated changes in sexual activity.
30. Sleep hygiene; approach to insomnia and its treatment.
31. Obstructive sleep apnoea — clinical features, associated comorbidities, laboratory tests, management and prognosis.

Nutrition

32. Mini Nutritional Assessment (MNA) — components, interpretation and interventions to improve it.
33. Vitamin deficiencies in the elderly — recognition and correction.
34. Parenteral nutrition in the older adult.
35. Recommended micronutrients in the elderly, their sources and deficiency states.

Prevention, Pharmacotherapy & Safety

36. Polypharmacy and the polypill — prevention and deprescribing.
37. Anticholinergic burden.
38. The prescribing cascade.
39. Drug interactions in the elderly.
40. Pharmacokinetic and pharmacodynamic changes in the elderly and how they affect drug choice.
41. Evaluation of newer drug therapies.
42. Herd immunity.
43. COVID-19 — prevention, management and vaccination in older adults.
44. Infection control practice in hospitals; device-associated infections — prevention and management.
45. Atypical presentation of infections in the elderly.

Chronic Disease & Recent Advances

46. SGLT2 inhibitors in diabetes and heart failure.
47. SIADH — causes, evaluation and management.
48. Solitary thyroid nodule.
49. Subclinical hypothyroidism.
50. FRAX score and the fracture fragility index.
51. Macular degeneration — clinical presentation, aetiology, diagnosis, treatment and prevention.
52. Visual impairment — approach and age-related causes.
53. Tinnitus.
54. Chronic fatigue syndrome — diagnostic criteria, clinical manifestations, predisposing factors, course, prognosis and treatment.
55. Inanition.

56. Constant itching in the elderly.

57. Polymyalgia rheumatica.

58. Sjogren syndrome.

WHY THIS LIST MATTERS

58 topics sit in the Ebenezer bank without ever having been examined in Paper IV. Several of them — polypharmacy and deprescribing, the Mini Nutritional Assessment, fear of falling, faecal incontinence, obstructive sleep apnoea, and SGLT2 inhibitors — are so central to modern geriatric practice that their continued absence is itself a prediction signal.

Part D · Predicted questions

Predictions are built from three signals: how often a topic has been asked, how long it has been since it last appeared, and whether the recent literature has given the examiner a fresh angle. Probability labels are relative, not absolute — treat "very high" as a topic you cannot afford to walk in without, and "moderate" as one worth a prepared skeleton answer.

Paper IV · most likely 15-mark essays

Predicted essay	Odds	Reasoning
Comprehensive Geriatric Assessment — components, domains, tools, evidence base and application in Indian practice.	Very high	Twice as an essay, but not since 2019. The single most reliable Paper IV essay stem and overdue by six sessions.
NPHCE — objectives, service package at each level of care, and implementation; plus NPOP and current welfare schemes.	Very high	The most-asked Paper IV topic overall (5 appearances). Last set as a 7-mark note in 2024, so an essay slot is due.
Elder abuse — forms, epidemiology in India, risk factors, screening tools, legal framework (Maintenance and Welfare of Parents and Senior Citizens Act 2007, Elderline 14567) and management.	High	Five appearances, three of them essays; absent from both 2024 and 2025 papers.
Rehabilitation in the elderly — definition, evaluation, components, the interdisciplinary team and outcome measurement.	High	Rehabilitation is the single densest theme in Paper IV. Essay versions appeared in 2015, 2020 and 2021 but not since.
Frailty and sarcopenia — overlapping constructs: etiopathogenesis, Fried phenotype vs frailty index, EWGSOP2/AWGS criteria, assessment and management.	High	Frailty has four appearances and sarcopenia one; the examiner has begun pairing constructs in a single essay.
Palliative and end-of-life care — principles, symptom control in advanced malignancy, communication, advance directives and the Indian legal position after Common Cause (2018).	High	Essay in 2014, 2017, 2022 and 2024 — on a roughly three-year cycle.
Malnutrition in older adults — screening, MNA, diagnosis by GLIM criteria, and management including oral nutritional supplementation.	Moderate	Essay in 2009 and 2023; nutritional assessment recurs as a note.
Falls in older adults — multifactorial risk assessment, evidence-based intervention bundles and post-fall management.	Moderate	Essay in 2019 and 2024, so slightly less likely immediately, but never absent for more than three sessions.

Paper IV · most likely 7-mark notes

Predicted note	Odds	Reasoning
Vaccination and immunisation schedule in older adults, with the evidence base (pneumococcal, influenza, herpes zoster, COVID-19, Td).	Very high	Five appearances — the most frequent short-note topic in Paper IV.
Advance directives and the living will — current status and procedure in India.	Very high	Four appearances; a near-fixture of the note section.
Newer drugs for Alzheimer's disease — anti-amyloid monoclonal antibodies, indications, evidence and limitations.	Very high	Alzheimer's therapy has three note appearances; the anti-amyloid era makes a fresh 'recent advances' framing very likely.
Caregiver burden and caregiver stress — assessment tools and management.	High	Three appearances; last asked in 2019.
Home based care and community based long term care services.	High	Home based care has three appearances; the service-model family of questions is asked almost every year.
Cancer screening in older adults — principles, life expectancy thresholds and deprescribing screening.	High	Three appearances plus a colon-cancer-specific note in 2023.
Constipation in the elderly — prevention, pharmacological management and complications.	High	Three appearances across 2009, 2013 and 2019.
Breaking bad news — a structured protocol (SPIKES) applied to a geriatric scenario.	High	Three appearances; last asked in 2021.
Polypharmacy, deprescribing and the prescribing cascade — Beers, STOPP/START and anticholinergic burden.	High	Prominent in the Ebenezer bank but never yet asked in Paper IV. A classic overdue 'preventive geriatrics' note.
Sarcopenia — AWGS 2019 criteria, measurement of muscle mass and resistance exercise prescription.	Moderate	Asked once as an essay in 2012 and never since, despite dominating the recent literature.
SGLT2 inhibitors in the older adult — heart failure, CKD and diabetes indications with geriatric cautions.	Moderate	Newer agents recur in Paper IV ('newer insulins', 'newer anticoagulants', 'newer antidiabetics'); SGLT2 is the obvious next member of that family.
Restless legs syndrome and REM sleep behaviour disorder — diagnosis and management.	Moderate	RLS last appeared in 2013; RBD appeared for the first time in 2025, signalling examiner interest in sleep.
Fear of falling, post-fall syndrome and the long lie.	Moderate	Never asked directly, but falls appear in almost every paper and this is the untouched facet.
Faecal incontinence and overactive bladder — evaluation and management.	Moderate	Urinary incontinence recurs; the faecal and OAB facets remain unexamined.
Wearable and sensor technology in fall prevention and remote monitoring of older adults.	Moderate	Asked once in 2012, when the technology barely existed; 'gadgets to improve quality of life' in 2025 shows renewed interest.

A model predicted Paper IV

If you want a single paper to mock-write against, this is the twelve-question set the frequency and recency analysis produces.

	Question	Marks
I.1	Comprehensive Geriatric Assessment — domains, tools, evidence for benefit, and how you would run it in an Indian district hospital.	15
I.2	Elder abuse — forms, epidemiology, risk factors, screening, the Indian legal framework, and management.	15
II.1	Immunisation schedule for an older adult, with the evidence for each vaccine.	7
II.2	Advance directives and the living will — status and procedure in India.	7
II.3	Newer drugs for Alzheimer's disease, including anti-amyloid antibodies.	7
II.4	Polypharmacy and deprescribing — Beers, STOPP/START, anticholinergic burden.	7
II.5	Caregiver burden — assessment and management.	7
II.6	Sarcopenia — criteria, assessment and management.	7
II.7	Cancer screening in older adults — when to start and when to stop.	7
II.8	Breaking bad news using a structured protocol.	7
II.9	SGLT2 inhibitors in the older adult.	7
II.10	Fear of falling and post-fall syndrome.	7

Cross-paper watchlist — Papers I, II and III

Paper IV does not sit in isolation: the same themes recirculate across papers with a different emphasis. These are the highest-probability areas for the other three papers based on the same frequency and recency analysis.

Paper I — Applied Basic Sciences

1. Anatomy: blood supply and conducting system of the heart; bronchopulmonary segments; dermatomes; innervation of the urinary bladder; portocaval anastomosis.
2. Physiology: ageing changes in the heart; homeostasis and homeostenosis; Frank-Starling law; oxygen–haemoglobin dissociation curve; nephron and sites of electrolyte exchange.
3. Biochemistry: vitamin D; NT-proBNP; purine metabolism and gout; lipid metabolism; bone turnover markers.
4. Pharmacology: pharmacokinetic and pharmacodynamic changes with ageing; oral anticoagulants; drugs in benign prostatic enlargement; MAO-B inhibitors; anticholinergic burden.
5. Pathology: Lewy bodies and neurofibrillary tangles; iron deficiency anaemia smear; fatty liver types; inflammaging.
6. Microbiology: immunosenescence and inflammatory markers in ageing; pneumococcal vaccines; blood cultures in infective endocarditis; ELISA; antibiotic choice in lower UTI.

Paper II — General Medicine including Psycho-Geriatrics

1. Behavioural and psychological symptoms of dementia — types and stepped management.
2. Delirium — assessment tools, prevention bundles and management.
3. Depression in older adults and antidepressant choice; suicide risk assessment in late life.
4. Heart failure with preserved ejection fraction; GDMT and the four-pillar approach.
5. COPD by current GOLD criteria; asthma by GINA; late-onset asthma–COPD overlap.
6. Hyponatraemia and SIADH; hypercalcaemia work-up.
7. Late-onset rheumatoid arthritis versus early-onset disease.
8. Approach to vertigo, syncope and falls presenting to the Emergency Department.

Paper III — Geriatrics

1. The 5 Ms of geriatrics as an organising framework.
2. Pre-operative assessment and perioperative management of hip fracture in a comorbid older adult.
3. Reversible dementias — causes and investigation; Lewy body dementia.
4. Bone mineral density interpretation and the FRAX tool.
5. Screening tools for malnutrition; BMI cut-offs for Asians.
6. Acute kidney injury — differentials and investigation in the older adult.
7. Carotid stenosis — angioplasty versus endarterectomy.
8. Urinary incontinence — types, evaluation and management.

FINAL NOTE ON USING PREDICTIONS

Prediction is a way of ordering revision, not of restricting it. The three topics that have been asked five times each are near-certainties over any two-session horizon, but the paper always carries three or four genuinely novel questions — REM sleep behaviour disorder and Geriatric Nurse Practitioners were both new in the last two sessions. Prepare the high-frequency core to essay depth, keep a one-page skeleton for everything in Part C, and you will have something structured to write for any question on the paper.

MD GERIATRIC MEDICINE

High-Yield Examination Answers

Volume: Biology of Ageing, Health Promotion & Bioethics

Twelve compiled questions | 15-mark answer format

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition
Essentials of Clinical Geriatrics, 7th edition
Evidence updates: 2023 – 2026
Indian context: Supreme Court, MoHFW, ICMR, ICOPE
Compiled: August 2026

Textbook content and current evidence are presented separately throughout.

Contents

#	Question	Format
SECTION A — BIOLOGY OF AGEING		
1	Theories of ageing	15 marks
2	Biomarkers of ageing	15 marks
3	Telomeres and ageing	15 marks
4	Sirtuins in ageing and disease	15 marks
5	Interleukin-6 in ageing and disease	15 marks
6	Immunosenescence and its relevance to vaccination	15 marks

Q1. Theories of Ageing

> *Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th ed. — Ch. 1 "A Biological Perspective of Ageing" and Ch. 2 "Physiology of Ageing".*

High-Yield Points (Textbook Content)

Definition & Concept

1. **Ageing is a failure to maintain homeostasis under physiological stress.** It is a progressive process associated with dysfunction.
2. **No single theory explains ageing.** Each older person is unique, and the elderly population is **heterogeneous** — a 65-year-old may be immobile while a 90-year-old is fully independent.
3. Evolutionary theories explain **WHY** we age; biological/molecular theories explain **HOW** we age. Only the latter is directly relevant to clinical geriatrics.

Population Perspective

4. The **Gompertz curve** shows the incidence of death rises **exponentially** from reproductive maturity to maximum lifespan. Ageing is therefore the **primary intrinsic factor of death**.
5. The **naked mole-rat is "non-Gompertzian"** — its death rate does not rise with age, proving the curve reflects intrinsic ageing rather than external hazards alone.
6. After age 80 the death rate rises more slowly — the **"late-life mortality plateau."** Medical intervention produces **rectangularization (compression) of mortality** (Fries).

A. Error / Stochastic Theories (damage accumulates → cells harmed → organ function lost)

7. **Wear and tear theory** — the body simply wears out with repeated use.
8. **Free oxygen radical theory (Harman, 1956)** — **reactive oxygen species (ROS)** damage macromolecules. Pathy's notes this theory has been **reshaped**, because increased ROS may *prolong* lifespan in model organisms, and mitochondrial dysfunction can accelerate ageing *without* ROS.
9. **Mitochondrial DNA theory** — mtDNA is damaged with age; reduced biogenesis and poor autophagic quality control.
0. **Somatic DNA damage theory** — genomic instability from imbalance between DNA damage and repair. **Werner syndrome** (DNA helicase mutation) is the classical **progeroid** example.
1. **Cross-linking theory** and **caloric restriction theory** are also grouped under error theories.

B. Programmed Theories (ageing is genetically driven)

2. **Neuroendocrine theory** — the **hypothalamic-pituitary-adrenal (HPA) axis** is the most important regulator of ageing.
3. **Immunological theory** — **thymic atrophy** reduces mature T-lymphocyte production; humoral immunity falls, antibody production drops, and **infection risk rises**.
4. **Cellular senescence / Hayflick limit** — human fibroblasts stop dividing after **~50 divisions**. **Telomeres shorten** with each division until division stops. This protects against uncontrolled growth **at the expense of ageing**.
5. **Cell death theory** — **apoptosis** (programmed cell death) is responsible for tissue remodelling and homeostasis.

C. Evolutionary Theories

6. **Medawar's mutation accumulation theory** — natural selection cannot remove deleterious genes acting only in late life (the **"selection shadow"**), so harmful effects accumulate towards the end of life.
7. **Williams' antagonistic pleiotropy theory** — a gene with a **small early benefit but a large late harm** is still selected for, because early fitness matters more.
8. **Kirkwood's disposable soma theory** — limited energy must be divided between **reproduction/function** and **repair/maintenance**. The soma is maintained only until the germline is passed on.

D. Hallmarks of Ageing (Lopez-Otin 2013, as quoted in Pathy's)

9. **Nine hallmarks in three groups:**
   - **Primary (causes of damage):** genomic instability, telomere attrition, epigenetic alterations, loss of proteostasis
   - **Antagonistic (responses to damage):** deregulated nutrient sensing, mitochondrial dysfunction, cellular senescence
   - **Integrative (culprits of the phenotype):** stem cell exhaustion, altered intercellular communication
0. Pathy's Table 1.1 lists **eight components of biological ageing**: genomic instability, epigenetic changes, mitochondrial dysfunction, loss of proteostasis, metabolic dysfunction, cell senescence, stem cell exhaustion, and **immunosenescence**.

Clinical Application

1. Key mechanisms: **SASP** (senescence-associated secretory phenotype), **inflammageing**, **insulin/IGF-1 and mTOR downregulation**, and **epigenetic (DNA methylation) clocks** which predict age with error <5 years.
2. **Telomere length is NOT currently accepted as a biological age marker** despite its association with mortality — longitudinal changes are erratic.
3. **Geroscience hypothesis** — multimorbidity and functional loss in old age are driven by **common biological mechanisms**. **Frailty** and **intrinsic capacity** serve as clinical metrics of biological ageing.
4. **Therapeutic opportunities** listed in Pathy's: **senolytics, inflammasome inhibitors, mesenchymal stem cells, calorie-restriction mimetics (rapamycin, metformin), autophagy inducers**, plus **exercise and diet**.

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Hallmarks of ageing	**9 hallmarks** (Lopez-Otin 2013)	**12 hallmarks** (Lopez-Otin 2023) — three added
New hallmarks	Not mentioned	**Disabled macroautophagy, chronic inflammation, dysbiosis**
Explanatory paradigm	Damage/maintenance model dominant	**Hyperfunction and programmatic theories** now serious rivals
Biological age markers	Epigenetic (methylation) clocks only	**Organ-specific proteomic and MRI-based clocks**
Pace-of-ageing measures	Not covered	**DunedinPACE, DunedinPACNI** (third-generation clocks)
Senolytic drugs	Listed as "promising research"	**Phase 1 human trials completed; Phase 2 underway**
Metformin as geroprotector	Listed as potential anti-ageing drug	**21-year DPP follow-up shows no multimorbidity benefit**

Latest Updates (2023–Present)

1. Twelve Hallmarks of Ageing. Lopez-Otin and colleagues expanded the framework to twelve hallmarks: the original nine plus **disabled macroautophagy, chronic inflammation and dysbiosis**. These are interconnected and link to the proposed "hallmarks of health" (spatial compartmentalisation, maintenance of homeostasis, adequate stress responses). A process qualifies as a hallmark only if it **appears with age, accelerates ageing when accentuated, and slows ageing when therapeutically targeted**. *(Cell 2023)*

2. Challenge to the damage paradigm — hyperfunction theory. Blagosklonny's hyperfunction theory reframes ageing as the late-life continuation of growth-promoting pathways that become pathological once selective pressure declines. De Magalhaes' developmental theory describes ageing as a mismatch between developmental programmes optimised for early life and their persistence into later life. Continued mTOR signalling after growth is complete is itself considered hyperfunctional. These are **"quasi-programs"** — run-on of developmental programmes. *(Ageing Res Rev 2022; Aging 2022)*

3. Organ-specific and multi-omic ageing clocks. Plasma proteomic signatures of organ ageing track health and disease; brain and immune system ageing predict healthspan and longevity; organ-specific signatures predict 20-year risk of age-related disease in Whitehall II. Brain-imaging measures such as DunedinPACNI estimate pace of ageing from a single MRI. **First-generation clocks (Horvath, Hannum) predict chronological age; second-generation (PhenoAge, GrimAge) predict mortality; third-generation (DunedinPACE) measure rate of ageing.** *(Nature 2023; Lancet Digit Health 2025; Nat Aging 2025)*

4. Senolytics move into human trials. Two open-label Phase 1 trials — SToMP-AD and STAMINA — tested 12 weeks of intermittent oral **dasatinib plus quercetin** in older adults with or at risk of Alzheimer's disease. In STAMINA, reductions in plasma TNF-alpha correlated with improvement in MoCA ($r = -0.65$, $p = 0.02$). Safety, feasibility, CNS penetrance and biological activity were confirmed; a **Phase 2 RCT is now underway**. *(eBioMedicine 2025)*

5. Metformin as a geroprotector — a setback. In a 21-year follow-up of the Diabetes Prevention Program, metformin did not significantly reduce multimorbidity risk; 85% of participants developed two or more chronic conditions (82% lifestyle, 85% metformin, 87% placebo). Intensive lifestyle intervention was associated with lower long-term multimorbidity burden. **Lifestyle currently outperforms any pharmacological geroprotector.** TAME remains the pending definitive trial. *(JAMA 2026)*

Examiner's Tip — Minimum Skeleton

Definition → Gompertz curve → Error (stochastic) vs Programmed classification → Evolutionary theories (Medawar / Williams / Kirkwood) → Hallmarks of ageing (9 in Pathy's, 12 in 2023) → Geroscience hypothesis and therapeutic implications.

Q2. Biomarkers of Ageing

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 2, Ch. 7 "Physical Fitness and Exercise".

High-Yield Points (Textbook Content)

Concept & Rationale

1. A **biomarker of ageing** is a measurable parameter reflecting **biological age** rather than **chronological age**, which predicts adverse outcomes in late life.
2. The rationale is the **geroscience hypothesis** — accumulation of diseases and loss of function is driven by **common biological mechanisms**. Measuring these allows prediction of outcomes and testing of interventions that extend **healthspan**.
3. **Chronological age is only a surrogate marker** — it stands in for the specific impairments that actually increase vulnerability.
4. **The core problem: there is no agreed definition of what a biomarker of ageing should measure or predict.** This is the biggest obstacle in the field.
5. **Death alone is an insufficient outcome**, because death is often preceded by years of multimorbidity and disability.
6. Three outcomes currently anchor biomarkers: **age-related multimorbidity**, **frailty**, and **intrinsic capacity**.

A. Molecular & Cellular Biomarkers (Pathy's Table 1.1)

7. **Epigenetic clocks (DNA methylation age)** — methylation status of **CpG islets** predicts donor age with average error **<5 years** (Hannum, Horvath).
8. The gap between **methylation age and chronological age** is associated with **cognitive and physical function, frailty and age-related diseases**, and is an **independent predictor of all-cause mortality**. These are the **best-validated molecular markers**.
9. **Telomere length is NOT currently accepted as a biological age marker.** A meta-analysis of 25 studies showed telomere attrition predicts all-cause mortality, but longitudinal changes are **erratic**, probably due to **measurement error**.
0. **Genomic instability** — somatic mutations, translocations, aneuploidy. Robust evidence linking mutation burden to human ageing phenotypes is still lacking.
1. **Cellular senescence — p16INK4a** is the key marker. It correlates with age in human skin, and **p16INK4a-positive cell burden in thigh adipose tissue correlates with muscle strength and walking performance**.
2. In a meta-analysis of **372 GWAS**, the **ink4/ark locus was linked to the greatest number of age-associated diseases** — Alzheimer's, cardiovascular disease, cancer and type 2 diabetes.
3. **SASP** — matrix metalloproteases and pro-inflammatory cytokines released by senescent cells; a measurable output of senescence.
4. **Mitochondrial function** can now be measured **in vivo** and is associated with **muscle strength and mobility**. Powerful but **needs standardisation**.
5. **Proteostasis and autophagy** — autophagy is better maintained in offspring of exceptionally long-lived individuals.
6. **Metabolic markers** — insulin resistance, **increased visceral fat with reduced skeletal muscle mass**, and decline in **sex steroids, GH and IGF-1**. Reduced insulin/IGF-1/mTOR signalling is associated with longevity.
7. **Inflammageing and immunosenescence** — **raised IL-6, raised CRP, reduced IL-2 and IL-2 responsiveness, thymic atrophy, fewer naive T cells with inflation of memory T cells**, and shrinkage of the antigenic repertoire (Table 2.3). Plasma IL-6 rises with normal ageing and **correlates inversely with functional ability**.
8. **Stem cell exhaustion** is conceptually important but **difficult to measure before its clinical consequences appear**.

B. Clinical & Functional Biomarkers

9. **Physical function is the proposed clinical biomarker of healthy ageing** — aerobic capacity, **gait speed, balance, mobility, muscle strength**. It predicts adverse events, disability and mortality.
0. **Gait speed predicts mortality in older adults better than chronic diseases such as hypertension**, and takes no longer to measure than a routine vital sign.
1. **Grip strength** — EWGSOP2 cut-offs for low strength are **<27 kg in men and <16 kg in women**; low appendicular muscle mass is **<20 kg (men) and <15 kg (women)**.
2. **Short Physical Performance Battery (SPPB)** — 4-metre walk + repeated chair stands + balance; predicts **future disability, hospitalisation and mortality**.
3. **Frailty is the clinical metric of biological ageing.** Frail patients show higher **factor VIII, D-dimer, CRP,**

leukocytes, fibrinogen and glucose, with **low vitamin D and low haemoglobin**.

4. **Intrinsic capacity (WHO)** — the composite of all physical and mental capacities (cognition, psychological, sensory, locomotion, vitality) — is the key determinant of functional ability.

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Validation standards	No agreed framework; the main obstacle	**Biomarkers of Aging Consortium validation framework**
Type of clock	DNA methylation clocks only	**Proteomic, metabolomic, imaging and organ-specific clocks**
Scope of measurement	Single whole-body "biological age"	**Organ-by-organ ageing** — brain, heart, kidney, immune
What is measured	Age *gap* (biological minus chronological)	**Pace of ageing** — DunedinPACE, DunedinPACNI
Blood biomarker for frailty	IL-6, CRP, D-dimer, fibrinogen	**GDF-15** emerging as the strongest single candidate
Regulatory role	Research tools only	**Surrogate endpoints for gerotherapeutic trials**

Latest Updates (2023–Present)

1. A formal validation framework now exists. The Biomarkers of Aging Consortium published recommendations on how biomarkers of ageing must be validated before clinical translation, noting that systematic validation is what will accelerate their use in gerotherapeutic trials. The stated problem was that although omics-based biomarkers could serve as surrogate endpoints, no consensus existed on validation. A joint NIA–Consortium symposium in 2024 emphasised understanding the longitudinal, complex and heterogeneous nature of ageing. *(Nature Medicine 2024)*

2. Organ-specific ageing clocks. Ageing is no longer one number for the whole body. Plasma proteomic signatures of organ ageing track health and disease; brain and immune ageing predict healthspan and longevity; organ-specific signatures predict 20-year risk of age-related diseases. **Clinical meaning: a patient may have a "young heart" but an "old brain", allowing organ-targeted prevention.** *(Nature 2023; Nat Med 2025; Lancet Digit Health 2025)*

3. Third-generation clocks measure pace, not level. DunedinPACE measures the pace of ageing and is sensitive to short-term change and intervention; DunedinPACNI estimates pace from a single brain MRI. In the Framingham Offspring cohort, faster DunedinPACE was associated with worse global cognition and steeper cognitive decline after adjusting for education. *(Trends Mol Med 2025; Nat Aging 2025)*

4. GDF-15 — the most promising single blood biomarker in geriatrics. In the longitudinal FRASNET study, higher baseline GDF-15 prospectively identified individuals at high risk of developing **frailty (AUC 0.85–0.96), malnutrition (AUC 0.94) and falls (AUC 0.98)** over six years. In LIFE, GDF-15 showed one of the strongest associations with slower walking speed. BIOFRAIL evaluated plasma GDF-15 in 429 mobility-limited older adults (mean age 79.6) against CFS ≥5 and EWGSOP2 sarcopenia. **Mechanism: GDF-15 reflects mitochondrial dysfunction and inflammageing via AMPK signalling.** *(GeroScience 2025; Ageing Res Rev 2026)*

5. Organ-specific consensus frameworks. The Aging Biomarker Consortium now defines biomarker panels organ by organ — **cardiac ageing, vascular ageing, visual system ageing and adipose tissue ageing** — each providing a multi-dimensional framework covering functional, morphological and molecular biomarkers. *(Life Medicine 2023–2025)*

Examiner's Tip

Define biological vs chronological age → geroscience hypothesis → the validation problem → classify into **MOLECULAR** (epigenetic clocks, p16INK4a, SASP, mitochondrial, IL-6/inflammageing) and **CLINICAL/FUNCTIONAL** (gait speed, grip strength, SPPB, frailty, intrinsic capacity) → state that gait speed and epigenetic clocks are best validated → finish with organ-specific clocks and GDF-15.

Ideal biomarker criteria: must **change with age, predict outcomes better than chronological age, be measurable repeatedly without harm, and respond to intervention.**

Q3. Telomeres and Ageing

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 2, Ch. 42 (respiratory ageing); supplemented by Essentials of Clinical Geriatrics.

High-Yield Points (Textbook Content)

Structure & Basic Biology

1. **Telomeres are repetitive DNA sequences capping the ends of chromosomes**, protecting coding DNA from degradation and end-to-end fusion.
2. With **each cell division the terminal end of the chromosome is not fully replicated**, so the telomere progressively **shortens** (the end-replication problem).
3. Telomere shortening is a **specific type of genomic damage**, and **telomere attrition is one of the primary hallmarks of ageing**.
4. **Telomerase** adds DNA bases back onto telomeres. Transfecting its catalytic component into senescent cells **lengthens telomeres, extends replicative lifespan, and restores a "young" pattern of gene expression**.

Hayflick Limit & Replicative Senescence

5. **Hayflick limit** — human fibroblasts in culture stop dividing after about **50 doublings**. The classic example of **programmed ageing**.
6. When telomeres are exhausted the cell can no longer proliferate — this is **replicative senescence**.
7. **Replicative lifespan in vitro correlates inversely with donor age**.
8. **Key exam concept:** telomere shortening **protects the cell against uncontrolled division and abnormal growth — at the expense of ageing.** It is fundamentally an **anti-cancer (tumour-suppressor) mechanism**.

Which Tissues Are Affected

9. Cells fall into three groups by replicative capacity:
    - **Continuously replicating** — epidermal, gastrointestinal, haematopoietic (telomere biology matters most here)
    - **Replicating on challenge** — liver
    - **Non-replicating** — neurons, cardiac and skeletal muscle
0. In non-replicating tissues, **telomere shortening is not the mechanism** — cell loss causes a permanent deficit instead (e.g. dopaminergic neuron loss affecting gait and balance).
1. **Lung ageing:** decreased **telomerase activity** plus replicative senescence plus rising pro-inflammatory cytokines produce **low-grade chronic pulmonary inflammation — "lung inflammageing"** (Table 42.1).

Downstream Consequences

2. Telomere-triggered senescence produces the **SASP** — matrix metalloproteases and pro-inflammatory cytokines that spread senescence and drive **inflammageing**.
3. Senescence is **not only telomeric** — it is also triggered by **non-telomeric DNA damage** and **excessive mitogenic signalling** via **p16INK4a**.
4. **Stem cell exhaustion** is an integrative consequence of telomere shortening together with DNA damage, epigenetic alterations, senescence and mitochondrial dysfunction.

Evidence in Humans

5. **Telomere shortening occurs during normal ageing in mice and humans**, and experimentally altering telomere loss changes lifespan in mice.
6. A **meta-analysis of 25 studies showed telomere attrition predicts all-cause mortality**.
7. **Critical exam point — telomere length is NOT currently accepted as a biomarker of biological age.** Longitudinal studies show **erratic changes over time**, probably due to **measurement error**.
8. In the **oldest old, no relationship was found between telomere length and mortality**. However, **healthy centenarians had significantly longer telomeres than unhealthy centenarians** — telomere length reflects **health and function rather than exceptional longevity**.

Clinical & Therapeutic Relevance

9. **Telomerase inhibitors are potent potential anticancer agents**, because most cancers reactivate telomerase to achieve immortality.
0. **Werner syndrome** (DNA helicase mutation) is the classical **progeroid** illustration of genomic instability; the **telomere syndromes** are a separate recognised group of premature-ageing disorders.
1. **How far telomere shortening explains in-vivo human ageing remains unknown** — it explains finite cell life in

culture better than whole-organism ageing.

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Telomere length as biological age marker	Rejected — erratic longitudinal change	Position unchanged; **epigenetic clocks have replaced it**
Direction of cancer risk	Short telomeres → genomic instability → cancer	**Mendelian randomisation shows LONGER telomeres causally increase cancer risk**
Clinical entity	Telomere syndromes in passing	**Telomere Biology Disorders (TBD)** now a defined adult diagnosis
Measurement	Not specified	**Flow-FISH and qPCR**; age-adjusted TL **≤1st percentile** is diagnostic
Treatment	None described	**Danazol 800 mg/day** — stabilises telomere attrition
Experimental therapy	Telomerase transfection (lab only)	**ZSCAN4-based ex vivo telomere elongation** of haematopoietic stem cells

Latest Updates (2023–Present)

1. Telomere attrition retained as a core hallmark. Telomere attrition remains one of the **twelve hallmarks of ageing** in the updated framework. *(Cell 2023)*

2. The telomere–cancer paradox confirmed by Mendelian randomisation. In a two-sample MR study using East Asian cohorts, longer telomere length per 1-SD increase due to germline variants was associated with higher risk of site-specific cancer, strongest for **thyroid cancer (OR 2.49)**. Separate MR analysis found significant associations with **primary lymphoid malignancy (OR 1.52), Hodgkin lymphoma (OR 1.64), non-Hodgkin lymphoma (OR 1.70) and B-cell lymphoma (OR 1.57)**. MR in breast disease found longer telomeres increase risk of breast cancer, benign neoplasms and breast inflammation, with no reverse causation. **Take-home: short telomeres cause degenerative disease; long telomeres permit malignancy. Telomere length is a double-edged sword.** *(Cancer Epidemiol Biomarkers Prev 2025; Aging 2024)*

3. Telomere Biology Disorders — a real adult diagnosis. TBDs are inherited bone marrow failure syndromes caused by pathogenic germline variants in telomere-related genes, with a heterogeneous phenotype including **bone marrow failure, pulmonary and liver disease, and predisposition to haematologic and solid malignancies**. **Genes to remember: TERT, TERC, DKC1, RTEL1.** Trial inclusion requires age-adjusted telomere length ≤1st percentile and/or identified mutations plus one cytopenia and/or pulmonary fibrosis.

4. Danazol — first drug shown to preserve telomeres in humans. Long-term results of a prospective phase 1/2 study showed danazol **improved haematologic parameters and stabilised telomere attrition** in TBD. Patients received **danazol 800 mg daily for two years**, with telomere attrition as the primary biologic endpoint and flow-FISH for serial measurement. Androgens are thought to work by **enhancing telomerase activity and reducing the rate of telomere attrition**. *(Blood Advances 2026)*

5. Ex vivo telomere elongation of stem cells. Clinical use of **ZSCAN4** for telomere elongation in haematopoietic stem cells has been reported, forming the basis of the EXG34217 trial in TBD with bone marrow failure — the first attempt at directly lengthening human telomeres therapeutically. *(NEJM Evidence 2025)*

Examiner's Tip

Structure → end-replication problem → Hayflick limit → replicative senescence → SASP and inflammageing → anti-cancer role → telomerase and its inhibitors → why telomere length FAILS as a biomarker → telomere biology disorders and danazol.

Two lines that earn marks:
• "Telomere shortening protects against uncontrolled cell division **at the expense of ageing**."
• "Telomere length is **not currently accepted as a marker of biological age** because longitudinal change is erratic and measurement-error prone."

Q4. Sirtuins in Ageing and Disease

Primary source: Pathy's 6th ed. — Ch. 1; supplemented by Essentials of Clinical Geriatrics (Ch. 1, Theories of Aging).

High-Yield Points

Definition & Basic Biology

1. **Sirtuins are a family of NAD+ dependent enzymes** with **histone deacetylase** activity — the mammalian homologues of the yeast **Sir2 (Silent Information Regulator 2)** gene.
2. Because they **require NAD+**, sirtuins act as **cellular energy sensors** — activated when the NAD+/NADH ratio is high, i.e. in **caloric restriction, fasting and exercise**.
3. **Seven human isoforms (SIRT1–SIRT7)**: **SIRT1, SIRT6 and SIRT7 are mainly nuclear; SIRT2 is cytoplasmic; SIRT3, SIRT4 and SIRT5 are mitochondrial.**
4. **SIRT1 and SIRT6 are the two most relevant to ageing.** Sirtuins regulate genomic stability, lifespan, energy metabolism and tumorigenesis.

Mechanism — Why They Matter in Ageing

5. **NAD+ levels fall progressively with age**, reducing sirtuin activity — the central link between metabolism and ageing.
6. **Sirtuins are the molecular mediators of caloric restriction.** Dietary restriction extends lifespan by exerting **multiple effects on chromatin through sirtuins, TOR and other factors**.
7. This makes ageing partly an **epigenetic** phenomenon — sirtuins act by **deacetylating histones and non-histone proteins**, altering gene expression **without changing the DNA sequence**.
8. **SIRT1 targets** include **p53, FOXO transcription factors, NF-kappaB and PGC-1alpha** — linking sirtuins to apoptosis, stress resistance, inflammation and mitochondrial biogenesis.
9. **SIRT6 maintains chromatin structure at telomeres** by deacetylating **histone H3 lysine 9**, preventing telomeric DNA damage and cellular senescence. **SIRT6-deficient mice show genomic instability and premature ageing**, and SIRT6 is upregulated during caloric restriction.
0. **SIRT1 and SIRT6 act synergistically** — SIRT1 deacetylates SIRT6 at residue K33, and deacetylated SIRT6 then remodels chromatin.
1. **Anti-inflammatory action:** SIRT1, SIRT2 and SIRT6 **inhibit NF-kappaB signalling**, reducing the cytokine output that drives **inflammageing**.
2. **Mitochondrial sirtuins (SIRT3–5)** regulate oxidative metabolism and reduce ROS — relevant to **sarcopenia and frailty**.

Evidence — The Rise and Fall of the Sirtuin Hypothesis (key discrimination point)

3. **Initial excitement:** activation of a sirtuin was found to **extend lifespan in yeast**, generating intense interest in sirtuins as "longevity genes".
4. **Subsequent reversal:** the sirtuin story then **unravelled — those experiments were not replicated by other laboratories**. *(Science 2011)*
5. **Current textbook position:** in mice, **modulation of sirtuins does NOT extend lifespan, but it does expand healthspan** — less diabetes mellitus, healthier metabolic profiles and healthier livers.
6. **Resveratrol**, a molecule from red wine acting through a sirtuin, extended lifespan in **worms and flies**, but **these findings were also not confirmed elsewhere**. It may extend **healthspan rather than lifespan**.

Position Within the Wider Biology of Ageing

7. Sirtuins sit within **deregulated nutrient sensing**, one of the **antagonistic hallmarks of ageing**. The other arms are the **insulin/IGF-1 axis, mTOR and AMPK**.
8. **Reduced insulin/IGF-1 and mTOR signalling is associated with longevity**. Intense trophic and anabolic activity accelerates ageing; downregulation is a **defensive response**.
9. **Rapamycin (mTOR inhibitor)** extended lifespan in genetically heterogeneous mice **even when started in late life**; the practical barrier to human use is **immunosuppression**.
0. **Metformin** is a potential anti-ageing drug because of its effects on **deregulated nutrient sensing, mitochondrial dysfunction, DNA damage and inflammation**. It has since been shown to be a **direct SIRT1-activating compound**.
1. **Clinical bottom line:** caloric restriction is not practical in humans, so research has shifted to **caloric-restriction mimetics** — sirtuin activators, rapalogs, metformin and NAD+ precursors.
2. **Cautionary note:** resetting the epigenome carries a **risk of malignancy** in cells that have already accumulated mutations and then acquire increased proliferative potential.

Current Practice Update

Aspect	Textbook Position (2012–2022)	Current Evidence (2023–2026)
Isoform focus	"A sirtuin" (SIRT1 implied)	**SIRT1 and SIRT6** are the recognised ageing sirtuins
Lifespan vs healthspan	Lifespan claims discredited; healthspan retained	**Position unchanged and confirmed**
SIRT7	Not addressed	**SIRT7 knockout extends lifespan** — opposite direction
Resveratrol	Unconfirmed lifespan effect	Largely abandoned; **direct SIRT6 activators** developed
Pharmacology	Resveratrol only	**MDL-800 and pyrroloquinoxaline SIRT6 activators**
NAD+ boosters	Not covered	**NR and NMN reliably raise NAD+ but clinical outcomes remain negative**
Metformin	Anti-ageing candidate via nutrient sensing	Now shown to be a **direct SIRT1 activator**

Latest Updates (2023–Present)

1. SIRT1 and SIRT6 consolidated as the ageing sirtuins. Sirtuins are framed as NAD+ dependent enzymes regulating genomic stability, lifespan, energy metabolism and tumorigenesis, with SIRT1 and SIRT6 specifically regulating ageing-related signalling at molecular, cellular, tissue and whole-organism levels. **Name SIRT6 if asked for the single most important anti-ageing sirtuin** — it protects telomeric chromatin and its loss causes progeria in mice. *(Ageing Res Rev / Cellular Signalling 2023)*

2. The SIRT7 paradox — not all sirtuins are pro-longevity. While SIRT1 and SIRT6 are predominantly anti-inflammatory, SIRT7 can be **pro-inflammatory** in a tissue-specific manner under physiological stress; recent in vivo evidence shows **SIRT7 knockout mice have a longer lifespan and delayed onset of age-related conditions**. This overturns the simple "sirtuins = longevity genes" model. *(Narrative review 2026)*

3. Direct sirtuin activators have replaced resveratrol. Resveratrol's supposed SIRT1 activation was an assay artefact. Attention has moved to cellularly active SIRT6 allosteric activators: **MDL-800** improves genomic stability and pluripotency of aged murine iPS cells, and pyrrolo[1,2-a]quinoxaline derivatives have been developed as potent, selective SIRT6 activators. *(Exploration of Drug Science 2025)*

4. NAD+ precursors (NR and NMN) — biochemically effective, clinically disappointing. In a 12-week double-blind RCT of **nicotinamide riboside 500 mg twice daily** in 52 older adults with amnestic MCI, blood NAD+ approximately **doubled (23.4 to 48.5 micromol/L)** and left hippocampal perfusion increased significantly — but **cognitive function did not significantly improve**. A systematic review of NMN trials found a significant effect on raising NAD+ yet most clinically relevant metabolic outcomes did not differ from control. A further meta-analysis concluded evidence for NMN and NR effects on skeletal muscle mass and function in older adults **remains inconclusive**. *(Crit Rev Food Sci Nutr 2025; J Cachexia Sarcopenia Muscle 2025)*

5. Practical message. **No sirtuin-targeted agent is licensed for any ageing indication.** The interventions with proven benefit on the same nutrient-sensing pathways remain **exercise, dietary modification and weight management** — and metformin where indicated for diabetes.

Examiner's Tip

Define sirtuins as NAD+ dependent deacetylases (Sir2 homologues) → seven isoforms and compartments → NAD+ decline with age → mediators of caloric restriction → SIRT1 (p53/FOXO/NF-kappaB/PGC-1alpha) and SIRT6 (telomeric chromatin, H3K9) → the yeast lifespan claim and its failure to replicate → healthspan not lifespan → position within deregulated nutrient sensing alongside mTOR, IGF-1, AMPK → current drugs.

The line that earns the mark: "Sirtuin modulation does not extend lifespan in mammals — it expands healthspan."

Q5. Interleukin-6 in Ageing and Disease

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 2, Ch. 22 (anaemia), Ch. 28 & 36 (cardiovascular), Ch. 43 (respiratory infection).

High-Yield Points (Textbook Content)

Basic Biology

1. **IL-6 is a pro-inflammatory cytokine** produced by macrophages, T cells, endothelium, adipocytes and skeletal muscle — a central component of the innate immune cascade along with **IL-1, TNF-alpha, complement proteins and immunoglobulins**.
2. **Increased IL-6 is one of the defining age-related changes of the immune system** (Table 2.3), alongside **decreased IL-2 and IL-2 responsiveness, thymic atrophy, decreased cell-mediated immunity, accumulation of memory T cells, increased autoantibodies, impaired macrophage function**, and increased NK cell number with decreased cytotoxicity.
3. **Plasma IL-6 rises as a function of normal ageing** — not merely a marker of disease. **It is the best-characterised molecular marker of "inflammageing".**
4. **KEY EXAM POINT: plasma IL-6 correlates INVERSELY with functional ability in older people.** The higher the IL-6, the poorer the function.
5. **Higher circulating CRP and cytokine receptor levels are independently associated with physical dysfunction and disability.**

Why IL-6 Rises With Age

6. **Ageing behaves like a chronic stress state** — with **increased cortisol and catecholamines** and **decreased sex hormones and growth hormone**.
7. **Cortisol and catecholamines stimulate IL-6 and TNF-alpha release, whereas sex hormones inhibit IL-6.** The fall in oestrogen and testosterone with age therefore **disinhibits IL-6** — the core mechanism to quote.
8. Other drivers feeding into IL-6: **mitochondrial dysfunction, cellular senescence (SASP), loss of proteostasis, epigenetic alterations**, plus extrinsic factors such as **chronic infection (especially CMV) and altered microbiota**.
9. **Senescent cells secrete IL-6 as part of the SASP**, spreading senescence to neighbouring cells.

The Inflammageing Paradox

0. The ageing innate immune system shows **basal immune stimulation but immune paralysis when a specific response is required** — this paradox *is* inflammageing.
1. Clinically: **baseline alveolar IL-6 and TNF-alpha are higher in aged lungs**, yet **toll-like receptor activation is blunted**, so the acute response to a real pathogen is dampened. High baseline levels indicate a **dysregulated, not a better, immune response**.

Systemic Consequences — Where IL-6 Shows Up Clinically

2. **Anorexia of ageing** — **IL-1, IL-6 and TNF-alpha are satiating cytokines** that reduce food intake and body weight centrally and peripherally. **IL-1 and IL-6 are elevated in older people with cachexia.**
3. **Sarcopenia and frailty** — inflammation drives age-related loss of muscle mass and strength. Frail patients have higher **CRP, fibrinogen, factor VIII, D-dimer, leukocytes and glucose**, with **low vitamin D and low haemoglobin**.
4. The overlap of frailty and cardiovascular biomarkers suggests a **common biological pathway** linking frailty and CVD.
5. **Anaemia of chronic disease** — the classic IL-6 story. **IL-6 mediates the hypoferraemia of inflammation by inducing hepatic synthesis of hepcidin.**
6. **Hepcidin** blocks the **ferroportin** transporter, blocking duodenal iron absorption and iron release from macrophages, so iron is **locked in ferritin stores** — a **functional iron deficiency**.
7. **Laboratory picture of ACD: normocytic anaemia**; haemoglobin low; **serum iron low-to-normal, transferrin low-to-normal, transferrin saturation low, ferritin normal-to-high, soluble transferrin receptor NORMAL** (this last distinguishes it from iron deficiency, where sTfR is high).
8. Pro-inflammatory cytokines also **lower erythropoietin production**, damage EPO-producing renal cells, downregulate EPO receptors, and **directly damage erythroid precursors** by cytokine-mediated apoptosis.
9. **Atherosclerosis and endothelial dysfunction** — **TNF-alpha, IL-1beta and IL-6** released from ageing endothelium activate **NF-kappaB and AP-1**, inducing **COX-2 and iNOS**, generating superoxide and peroxynitrite (Figure 36.1).
0. **Depression in older adults** is associated with **raised IL-6**, along with vitamin D deficiency and white-matter hyperintensities.
1. **COVID-19** — the "cytokine storm" of dysregulated host immune response underlies complications, and **IL-6 is one such**

target. **Tocilizumab and sarilumab** were studied; a systematic review of observational data suggested tocilizumab reduced complication rate and illness duration.

2. **Proof of principle for anti-cytokine therapy: IL-1beta inhibition with canakinumab (CANTOS)** reduced the incidence of age-related diseases in humans.

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
IL-6 as target in CVD	Promising; canakinumab proof-of-concept	**ZEUS trial NEUTRAL — no MACE benefit despite target engagement**
IL-6 blockade in PMR	Not addressed	**Sarilumab FDA-approved (2023) — first biologic for PMR**
IL-6 blockade in GCA	Not addressed	**Tocilizumab approved; sarilumab GCA trial terminated early**
IL-6 in COVID-19	Observational data only	Established; in severe COVID guidelines
IL-6 as frailty biomarker	Correlates inversely with function	Used in **multi-marker panels with GDF-15, FGF-21, sRAGE, NfL**
Key conceptual lesson	Inflammation is a modifiable target	**Biomarker–outcome dissociation: lowering IL-6 does not equal better outcomes**

Latest Updates (2023–Present)

1. ZEUS trial — IL-6 inhibition fails in cardiovascular disease (July 2026). ZEUS was a multinational double-blind placebo-controlled trial of **6,376 participants with ASCVD, CKD and hsCRP ≥2 mg/L**, randomised to **ziltivekimab 15 mg subcutaneously monthly** or placebo. Mean age 69.5 years, 65.7% diabetes, 41.3% heart failure, mean eGFR 44.5 mL/min/1.73 m^2, median hsCRP 4.5 mg/L, median IL-6 4.9 pg/mL. Although ziltivekimab demonstrated **target engagement with expected reductions in free IL-6 and hsCRP**, this did **not translate into any MACE reduction (HR 0.99; 95% CI 0.88–1.11)**. Overall adverse event rates were similar, but a higher proportion of ziltivekimab-treated participants had a **serious infection**. HERMES (heart failure) and ARTEMIS (post-MI) continue. **Exam message: this demonstrates biomarker–outcome dissociation.** *(JAMA Cardiology 2026)*

2. Sarilumab — first biologic approved for polymyalgia rheumatica (2023). On **28 February 2023** the FDA approved **sarilumab**, an IL-6 receptor antagonist, for adults with PMR in whom glucocorticoids proved inadequate or who cannot tolerate a taper. Approval was based on the phase 3 **SAPHYR** trial in steroid-resistant active PMR: sarilumab 200 mg every two weeks with a 14-week steroid taper versus placebo with a 52-week taper, achieving **sustained remission in 28% versus 10% at 52 weeks (p = 0.0193)**. Tocilizumab, though beneficial in PMR studies, is **not FDA-approved for PMR**; it is approved for **giant cell arteritis**, which overlaps with PMR in about half of cases. **This is the first steroid-sparing biologic option for an almost exclusively geriatric disease.**

3. IL-6 blockade in giant cell arteritis. Tocilizumab showed beneficial effects in GCA leading to its approval; a phase 3 trial of sarilumab in GCA was conducted but recruitment difficulties exacerbated by the COVID-19 pandemic led to **premature discontinuation by the sponsor**. *(Arthritis Research & Therapy 2023)*

4. IL-6 in contemporary frailty biomarker panels. IL-6 is no longer used alone. Current work combines **IL-6 with GDF-15, FGF-21, sRAGE and neurofilament light** to identify frailty in community-dwelling older adults, with **GDF-15 emerging as the strongest single predictor** of incident frailty, malnutrition and falls.

Examiner's Tip

Define IL-6 → rises with normal ageing → mechanism (raised cortisol/catecholamines stimulate, falling sex hormones disinhibit, SASP contributes) → the inflammageing paradox → clinical consequences: anorexia, sarcopenia, frailty, anaemia of chronic disease via hepcidin, atherosclerosis, depression → therapeutics: tocilizumab, sarilumab, ziltivekimab → ZEUS negative result.

Two lines that earn marks:
• "Plasma IL-6 rises with normal ageing and correlates inversely with functional ability."
• "IL-6 induces hepcidin, which blocks ferroportin, producing the functional iron deficiency of anaemia of chronic disease."

Q6. Immunosenescence and its Relevance to Vaccination

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 2, Ch. 9 (preventive geriatrics), Ch. 39 (pneumonia), Ch. 43 (respiratory infection in the elderly).

High-Yield Points (Textbook Content)

Definition

1. **Immunosenescence covers all age-related changes that result in decreased immune function in the elderly** — not restricted to senescence of immune cells alone but **encompassing every immune system modification that characterises ageing**.
2. **Innate immunity is relatively little affected; adaptive (acquired) immunity is greatly affected.** This is the most important organising principle.
3. **Two components must be described together: immunosenescence (loss of specific responses) and inflammageing (excess non-specific inflammation).** The paradox is **basal immune stimulation with immune paralysis when a specific response is required**.

Changes in the Immune System With Age (Pathy's Table 2.3 — learn this list)

4. **Thymic atrophy with loss of thymic hormones**; decreased bone marrow production of B cells.
5. **Decreased cell-mediated immunity** and **decreased delayed-type hypersensitivity**.
6. Production of **lower-affinity antibodies**; **increased autoantibodies**.
7. **Increased IL-6**; **decreased IL-2 and IL-2 responsiveness**.
8. **Accumulation of memory T cells (CD45)**; decreased proliferative response to mitogens.
9. **Impaired macrophage function**; **NK cell number increases but cytotoxicity falls**.

Innate Immune Changes in Detail

0. **Toll-like receptor activation is diminished**, producing **dampened downstream cytokine responses** when a real pathogen arrives.
1. **Neutrophils** show impaired **phagocytosis, reduced ROS generation, reduced chemotaxis and decreased degranulation**.
2. **Dendritic cells** show impaired phagocytosis, cytokine release and **migratory capacity to lymph nodes**. **Impaired antigen-presenting cell activity is the hallmark of impaired innate AND acquired immunity in the elderly.**
3. **Efferocytosis** — clearance of apoptotic cells and debris from airways — is impaired.

Adaptive Immune Changes — The Basis of Vaccine Failure

4. **Thymic involution reduces thymic output**, so there are **few naive T cells relative to antigen-experienced memory T cells**. **This directly hampers vaccine efficacy** and the ability to respond to newly encountered pathogens.
5. **Cytokine production by CD4+ and CD8+ T cells is impaired**, and the **CD4:CD8 ratio is altered**.
6. **B cells: dearth of naive B cells**, and antigen-experienced cells lose function over time.
7. There is **shrinkage of the antigenic repertoire** of lymphocytes — "holes in the repertoire".
8. **Chronic CMV infection drives clonal expansion of CD8 T cells**; the resulting repertoire shrinkage **predicts mortality** in the very elderly (the **immune risk phenotype**).
9. **Haematopoietic stem cell exhaustion is thought to be a major driver of immunosenescence.**
0. Net result: **increased prevalence of infection, increased malignancy, and increased autoimmunity**, plus failure to clear **pre-malignant cells, senescent cells and misfolded proteins**.

> **The Key Vaccine Mechanism — Most Examinable Single Fact**
>
> **Studies showing reduced efficacy of pneumococcal vaccination in older versus younger adults found NO difference in IgG levels.** The explanation may be an **altered IgM response leading to reduced opsonisation and phagocytosis of bacteria**.
>
> **Antibody QUANTITY is preserved; antibody QUALITY and function are lost.**

Vaccination in Older Adults (Textbook Content)

Influenza

1. **Yearly influenza vaccination is indicated for ALL older patients** — robust, frail, demented and end-of-life alike. **More than 90% of deaths from pneumonia and influenza during epidemics occur in those aged 65 and over.**

2. Vaccination **reduces the risk of developing influenza by 50% and influenza mortality by 70%**.
3. **In nursing homes it is only 40% effective at preventing clinical illness, but is more effective at preventing pneumonia, hospitalisation and death. Vaccinating more than 80% of nursing home residents prevents outbreaks.**
4. **Adjuvanted influenza vaccine** contains a substance that **stimulates the immune response and enhances immunogenicity** — particularly valuable in **institutionalised elderly and those weakened by chronic disease**. **This is the direct clinical answer to immunosenescence.**
5. **Cocooning:** vaccinating healthcare personnel in long-term care reduces respiratory infection incidence and overall mortality among residents, **even when resident coverage is already high**. Extend the offer to regular visitors and family.

Pneumococcal

6. Pneumococcal vaccine is **less effective at producing protective antibody levels in older adults**, but still reduces **pneumococcal bacteraemia** in high-risk patients.
7. **CAPITA trial** — PCV13 reduced the incidence of pneumococcal pneumonia by **45%** in community-dwelling adults over 65. A large Japanese nursing home trial found **marked reduction in mortality and pneumonia** with PPSV23.

Herpes Zoster — The Best Illustration of Overcoming Immunosenescence

8. Zoster incidence rises with age, affecting **up to half of individuals aged 85 and over**; **post-herpetic neuralgia occurs in more than 40% of those over 60**.
9. **Zostavax (live attenuated) is only 30% protective. Shingrix (recombinant, adjuvanted) is 90% protective.** A **two-dose series is recommended from age 50**, and **those who previously received Zostavax should receive Shingrix**.

Tetanus, COVID-19 and Non-Vaccine Measures

0. **Over half of tetanus cases occur in people aged 60 and over.** Complete the primary series if history is uncertain, then **booster every 10 years**, with **at least one dose given as Tdap**.
1. **SARS-CoV-2 vaccination** is indicated for adults including those over 65, healthcare professionals, and family members in contact with older individuals.
2. **Physical activity may ameliorate immunosenescence** and thereby reduce age-related multimorbidity; **Mediterranean diet promotes epigenetic rejuvenation** (NU-AGE study).

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Pneumococcal age threshold	Routine from age 65	**Lowered to age 50 (ACIP, Oct 2024)**
Pneumococcal products	PCV13 then PPSV23 one year later	**PCV20 or PCV21 alone, or PCV15 then PPSV23**
New pneumococcal vaccine	Not available	**PCV21 (CAPVAXIVE) — 21 serotypes, adult-targeted**
RSV vaccination	Not available	**Three vaccines licensed; routine at 75+, risk-based 50–74**
High-dose influenza vaccine	Adjuvanted vaccine mentioned	**DANFLU-2 missed its primary endpoint**
Frailty as vaccine modifier	Associated with poor response	Now a formal **RSV eligibility criterion**

Latest Updates (2023–Present)

1. Pneumococcal vaccination — age threshold lowered to 50 years. As of **23 October 2024**, ACIP recommends that all PCV-naive adults aged **50 and over** receive a single dose of a pneumococcal conjugate vaccine — **PCV15 (Vaxneuvance), PCV20 (Prevnar 20) or PCV21 (Capvaxive)**. If PCV15 is used it must be followed by **PPSV23 at least one year later**, or after **8 weeks** in the immunocompromised or those with a cochlear implant or CSF leak. Before October 2024, PCV was recommended only for all adults 65 and over plus those aged 19–64 with risk conditions. PCV21 was FDA-approved in June 2024. *(MMWR 2025;74(1):1–8)*

2. RSV vaccination — an entirely new vaccine for older adults. Three vaccines are FDA-approved: **Abrysvo, Arexvy and mResvia**. ACIP routinely recommends a **single dose for all adults aged 75 and over**, and a single dose for adults **50–74 at increased risk** due to high-risk conditions, **frailty**, or **high-risk living arrangements such as residence in a long-term care facility**. RSV vaccination is currently a **single dose only**; revaccination is not recommended. **Frailty and institutionalisation are now formal eligibility criteria — a direct clinical application of immunosenescence.**

3. DANFLU-2 — high-dose influenza vaccine misses its primary endpoint. A pragmatic registry-based open-label randomised trial in Denmark across 2022/23 to 2024/25 enrolling **332,438 adults aged 65 and over**, randomised 1:1 to high-dose or standard-dose inactivated influenza vaccine. The high-dose vaccine **did not significantly lower hospitalisation for influenza or pneumonia**. However, hospitalisation for **any cardiorespiratory disease was lower** with high dose (relative vaccine effectiveness 5.7%; 95% CI 1.4–9.9%). A prespecified secondary analysis of 43,881 participants with diabetes found high-dose vaccine associated with reduced cardiorespiratory, cardiovascular, heart failure, influenza and laboratory-confirmed hospitalisations irrespective of diabetes status. **Exam message: enhanced-immunogenicity vaccines improve immune response and softer clinical endpoints, but a hard mortality benefit over standard dose has not been demonstrated.** *(NEJM 2025; JAMA Intern Med 2026)*

Examiner's Tip

Define immunosenescence → innate spared, adaptive affected → list Table 2.3 changes → thymic involution → fewer naive T cells, more memory T cells, shrunken repertoire, CMV-driven clonal expansion → inflammageing paradox → **consequence for vaccines: normal IgG titres but defective IgM/functional antibody** → strategies to overcome.

The four strategies to overcome immunosenescence — quote as a block:
(1) Adjuvants **(2)** Higher antigen dose **(3)** Recombinant/conjugate platforms **(4)** Herd protection by vaccinating carers

Q7. Caloric / Dietary Restriction in Ageing

> *Primary source: Pathy's 6th ed. — Ch. 1, Ch. 13 (anorexia of ageing), Ch. 14 (weight loss); supplemented by Essentials of Clinical Geriatrics (Ch. 1).*

High-Yield Points (Textbook Content)

Definition & Concept

1. **Caloric restriction (CR) means reducing caloric intake without depriving essential nutrients** — described in the textbook as **"nutritionally balanced semi-starvation."**
2. **Dietary restriction remains the single major intervention shown to enhance longevity** across species — the reference standard against which all anti-ageing interventions are compared.
3. CR sits within **deregulated nutrient sensing**, one of the **antagonistic hallmarks of ageing**, alongside the **insulin/IGF-1 axis, mTOR, AMPK and sirtuins**.

Evidence Across Species — Learn This Ladder

4. **Yeast, worms (C. elegans), flies (Drosophila) and rodents: CR reliably increases lifespan.** In rodents it **delays maturation** and can extend lifespan **by as much as 50%**.
5. **Primates: the data are conflicting.** The Wisconsin group (2009) reported CR **delayed disease onset and mortality in rhesus monkeys**; a later study did not confirm this.
6. **Humans: body weight below ideal is NOT associated with increased lifespan.** This is the crucial translational failure point.
7. **CR is therefore judged unlikely to be a successful intervention in humans** — hence the shift to **CR mimetics**.

Mechanisms

8. The mechanism is not fully understood but is thought to relate to **reduced IGF-1 levels**.
9. **Reduced GH signalling, and reduced insulin/IGF-1, are associated with increased longevity** in rodents, worms and flies.
0. **CR lowers oxidative stress and oxidative damage** and extends the maximum lifespan of rodents.
1. **CR acts epigenetically** — multiple effects on **chromatin through sirtuins, TOR and other factors**, making these molecules **targets for lifespan extension without actual food restriction**.
2. **mTOR senses cellular nutrient levels** and regulates rates of **protein synthesis and energy utilisation**.
3. **Protein restriction alone works too:** animals fed **isocaloric diets with reduced protein have increased lifespan**.
4. In animal models CR **decreases incidence and delays onset of disease** — including **chronic glomerulonephritis, muscular dystrophy and carcinogenesis**.

Caloric Restriction Mimetics

5. **Rapamycin (mTOR inhibitor)** extended lifespan in genetically heterogeneous mice **even when begun in late life**; the barrier to human use is **immunosuppression**.
6. **Metformin** is a candidate anti-ageing drug for its effects on **nutrient sensing, mitochondrial dysfunction, DNA damage and inflammation**.
7. **Sirtuin activation and resveratrol** produced initial excitement but were **not replicated**; they may **extend healthspan rather than lifespan**.

Caloric Restriction as a Clinical Intervention in Older Adults

8. In overweight older adults, **short-term caloric reduction improves blood pressure, cholesterol and metabolic rate — but these benefits require at least a 20% reduction in caloric intake.**
9. **Critical geriatric finding:** in long-term follow-up of weight-loss RCTs, the **caloric-restriction group lost more fat mass BUT ALSO more lean body mass** than the exercise group, and **in the long term there was no difference in physical performance** between the two.
0. **Look AHEAD:** intensive lifestyle intervention maintained weight loss, fitness and CV risk factor improvement, **but showed no reduction in cardiovascular events**, and there was **marginally greater cognitive decline in obese subjects over five years**.
1. **Improvement in comorbidities is largely independent of whether weight is actually lost** — blood pressure falls with dietary change without weight loss, CAD prevention is independent of weight loss, and **physical function improves without weight loss**.
2. A randomised trial found **no mortality difference** between those who lost a mean of **4.4 kg** and controls.

Why Caloric Restriction Is Dangerous in the Old — The Counter-Argument

23. **The anorexia of ageing means older people are already calorie-restricted involuntarily.** Energy intake falls by about **30% between ages 20 and 80** (NHANES III: **−1321 kcal/day in men, −629 kcal/day in women**).
24. **16–18% of community-dwelling older people already consume fewer than 1000 kcal daily.**
25. **Loss of homeostatic compensation (Roberts et al.):** when young and old men were underfed by about 750 kcal/day for 21 days, the **young men over-ate afterwards and rapidly regained weight; the old men did not compensate and never regained the lost weight. This is the single most important reason not to prescribe CR to older adults.**
26. **Weight loss after age 60 is disproportionately of lean tissue** — up to **3 kg of lean body mass lost per decade after age 50**, i.e. sarcopenia.
27. **Unintentional weight loss of 5% or more over 6–12 months signals adverse outcomes; 10% or more very likely means protein-energy malnutrition.**
28. **Ideal weight ranges are almost certainly higher in older than in younger adults.** A **BMI of 25–29.9 kg/m^2 carries no significant excess mortality** in older adults, and **BMI over 30 only about 10%** excess.
29. **Malnutrition prevalence** (Mini Nutritional Assessment): overall **22.8%** — rehabilitation units **50.5%**, hospitalised **38.7%**, community-dwelling **5.8%**.
30. **Protein-energy malnutrition is a strong independent predictor of mortality** in older people, in every care setting.

Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Human evidence for CR	None; considered impractical	**CALERIE RCT — first positive human trial**
Outcome measured	Lifespan / mortality	**Pace of biological ageing (DunedinPACE)**
Size of effect	Not quantified in humans	**2–3% slowing of pace of ageing**
Which clock responds	Not addressed	**DunedinPACE yes; PhenoAge and GrimAge no**
Alternative protocols	Continuous CR only	**Intermittent fasting and time-restricted eating**
Main geriatric risk	Lean mass loss	**Confirmed — TRE causes disproportionate lean mass loss**

Latest Updates (2023–Present)

1. CALERIE — first randomised human evidence that CR slows ageing. In a post hoc analysis of CALERIE, in which **220 adults without obesity were randomised to 25% caloric restriction or ad libitum diet for two years**, the intervention **slowed the pace of ageing measured by DunedinPACE**, but did not significantly change PhenoAge or GrimAge. The change corresponded to roughly a **3% slowing of the pace of ageing**; in independent studies a 3% slower DunedinPACE is associated with a **15% lower risk of death** — described as comparable to a smoking cessation intervention. **This is the first randomised evidence supporting the geroscience hypothesis in humans, and shows pace-of-ageing clocks are more sensitive to intervention than static biological-age clocks.** *(Nature Aging 2023)*

2. Intermittent fasting and time-restricted eating in adults 60 and over. A 2026 systematic review and network meta-analysis of seven RCTs found **moderate-certainty evidence** that **time-restricted eating (16:8)** and intermittent Sunnah fasting produce significant reductions in body weight (**ISF −2.36 kg; TRE 16:8 −1.92 kg**) and BMI versus usual diet, with improvements in HbA1c and blood pressure — while calling for longer trials with longitudinal muscle mass evaluation and sarcopenia biomarkers.

3. The lean mass warning — directly relevant to geriatrics. An RCT in adults with overweight or obesity found a 12-week hypocaloric time-restricted eating regimen caused **greater loss of lean mass** than a conventional hypocaloric diet, with lean mass accounting for approximately **65% of total weight loss** — far higher than the typical 20–30% with standard hypocaloric diets — leading to explicit calls for caution in those at risk of sarcopenia. A cross-sectional study of **3,680 community-dwelling Chinese adults aged 60 and over** found TRE significantly associated with **increased risk of severe sarcopenia**, possibly because compressing the eating window concentrates protein intake and fails to provide sustained substrate for muscle protein synthesis in a population with **anabolic resistance**. *(Frontiers in Nutrition 2025)*

4. The protein counter-prescription. Because exercise and protein intake are the primary anabolic stimuli preserving skeletal muscle with ageing, current recommendations are to distribute protein evenly across waking hours at approximately **0.4 g/kg per meal**, with a daily intake of about **1.2 g/kg/day**. **Any restriction protocol in an older adult must be paired with adequate protein and resistance exercise.**

Examiner's Tip

Define CR → evidence ladder (yeast/worm/fly/rodent positive → primates conflicting → humans no lifespan benefit) → mechanisms (reduced IGF-1, mTOR, sirtuins, reduced oxidative stress, epigenetic) → CR mimetics → CALERIE as first human RCT → **then pivot to the geriatric counter-argument** (anorexia of ageing, loss of homeostatic compensation, lean mass loss, higher ideal BMI in the old).

Two sentences that earn the highest marks:

• "Older adults do not compensate after underfeeding — unlike young adults, they do not regain the lost weight."

• "Caloric restriction is a longevity strategy for the young and middle-aged; in the frail older adult the priority is the opposite — preventing undernutrition and sarcopenia."

Q8. Anti-Ageing Interventions

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 2, Ch. 7, Ch. 9; supplemented by Essentials of Clinical Geriatrics.

High-Yield Points (Textbook Content)

Rationale & Framework

1. **Geroscience hypothesis:** the accumulation of diseases and loss of function with ageing is driven by **common biological mechanisms**. Targeting these should **delay multiple diseases simultaneously** and extend **healthspan**.
2. **Interventions that slow ageing are likely to delay the onset of cancer, diabetes, cardiovascular disease and neurodegenerative disease together** — the fundamental argument for anti-ageing medicine.
3. Pathy's lists the therapeutic opportunities as **senolytics, inflammasome inhibitors, mesenchymal stem cells, calorie-restriction mimetics and autophagy inducers** — plus **lifestyle interventions (physical activity, diet)**.

A. Exercise — The Best-Evidenced Intervention

4. **Habitual physical activity increases average life expectancy by about two years.**
5. **Many changes attributed to biological ageing can be prevented by chronic physical activity**, particularly the body-composition changes: **decreased muscle mass, decreased bone mass and strength, increased adipose tissue and central fat deposition**.
6. Exercise prevents and/or treats **obesity, cardiovascular disease, type 2 diabetes, hypertension, osteoarthritis, osteoporosis, stroke, peripheral vascular disease, renal failure, dementia and depression**.
7. **Strong evidence** that exercise improves **muscle strength, muscle mass, bone density, falls incidence and mobility** across the whole health and frailty spectrum.
8. **High-intensity resistance training is the optimal prescription for sarcopenia**, also improves balance, and **improves aerobic capacity as much as moderate-intensity aerobic training** — one prescription targeting both major deficits.
9. **Aerobic exercise does NOT improve strength or balance and is insufficient as an isolated prescription.** Falls-prevention programmes based on **walking are inferior** to strength-and-balance programmes and have been **associated with increased fracture rates** in those at risk.
0. **Explosive resistance training ("power training") is central**, because muscle **power** declines far more steeply than strength with age (fast-twitch fibre atrophy plus altered neural recruitment).
1. **Multicomponent exercise (resistance + balance + gait retraining) improves all the hallmarks of frailty.** The **VIVIFRAIL** programme provides individualised prescription "passports" based on **SPPB and gait speed**.
2. **Sequence in the very frail follows the physiology of mobility: strength/power to stand up → balance to stay upright → endurance to walk.**
3. **High-intensity strength training works even in nonagenarians** (Fiatarone, 1990) and in **acutely hospitalised and institutionalised** older adults.
4. **Physical activity may ameliorate immunosenescence** and thereby reduce age-related multimorbidity.

B. Nutritional Interventions

5. **Caloric restriction** increases lifespan by up to **50%** in mammals, acting through **reduced IGF-1, sirtuins and TOR** — but is **not practical in humans**, hence the search for **CR mimetics**.
6. **Mediterranean diet promotes epigenetic rejuvenation** (NU-AGE study).
7. **Antioxidant vitamins have failed:** there is **no significant loss of scavenging enzymes with ageing**, and **vitamins C and E do not increase longevity in experimental animals**. Broad-spectrum vitamin supplementation is nonetheless considered reasonable for most older people.
8. **Vitamin D 800–2000 IU daily** reduces fracture risk and prevents falls. **Salt restriction and weight loss (TONE trial)** effectively lower blood pressure in older people.

C. Hormonal Interventions — Mostly Negative

9. **Growth hormone:** GH falls with age causing muscle loss, **but GH replacement did NOT restore muscle strength despite increasing muscle mass, and was associated with increased cardiovascular mortality risk**, glucose intolerance and diabetes. Paradoxically, **reduced GH signalling correlates with increased longevity in rodents**.
0. **DHEA:** levels fall with age, but **replacement had no beneficial effect on memory or muscle strength** — only a slight effect on libido, mainly in women.
1. **Oestrogen:** KEEPS showed control of postmenopausal symptoms without a serious increase in cardiovascular mortality or VTE, but **HRT is not recommended after age 60**. WHI showed observational benefits were exaggerated and risks of

heart disease, stroke and cancer.

2. **Testosterone:** free testosterone falls with age (raised SHBG, raised fat mass) and correlates with **muscle mass, strength, frailty, sexual function and cognition**. Replacement improves symptoms and reverses **lower urinary tract symptoms**. Trials show benefit in **grip strength, Functional Independence Measure, and post-operative ability to stand**, with effects **confined to men aged 75 and over and the frail**. Evidence is **not conclusive but justifies further study**.
3. **Key exam line: growth hormone and testosterone cannot be recommended for older men with normal or low-normal hormone levels.**

D. Cellular & Pharmacological

4. **Senolytics** — selective elimination of senescent cells **attenuates age-related deterioration of several organs and extends lifespan in mice**. **Rapamycin** extends lifespan in mice even when begun late (barrier: immunosuppression). **Metformin** acts on nutrient sensing, mitochondrial dysfunction, DNA damage and inflammation. **Anti-IL-1beta (canakinumab) reduced the incidence of age-related diseases in humans.**
5. **Stem cells and epigenetic reprogramming:** transplanting **muscle-derived stem cells from young mice extended health- and lifespan in progeroid mice even where donor cells were undetectable**, suggesting benefit via **secreted factors**. However, **embryonic and pluripotent stem cells are NOT a reversal of ageing — they form tumours**. **Epigenetic reprogramming carries a malignancy risk**; the goal is to **reset the ageing clock while leaving the differentiated state untouched**.

Current Practice Update

Intervention	Textbook Position	Current Evidence (2023–2026)
Caloric restriction	Impractical in humans; no human data	**CALERIE: 2–3% slowing of DunedinPACE**
Senolytics	Mouse data only	**Phase 1 human trials complete; Phase 2 underway**
Metformin	Promising geroprotector	**21-year DPP follow-up: no multimorbidity benefit**
Epigenetic reprogramming	Conceptual, high malignancy risk	**OSK (c-Myc omitted) + cyclic dosing; first-in-human planned**
Framework	9 hallmarks	**12 hallmarks (Cell 2023)**
Measuring success	Lifespan/mortality	**Validated biomarkers of ageing (Nat Med 2024 framework)**

Latest Updates (2023–Present)

1. CALERIE — first randomised human evidence that an intervention slows ageing. 220 adults randomised to 25% caloric restriction versus ad libitum diet for two years showed slowing of the pace of ageing by DunedinPACE, without significant change in PhenoAge or GrimAge; roughly **3% slowing**, associated with **15% lower risk of death**. *(Nature Aging 2023)*

2. Senolytics reach human trials. STOMP-AD and STAMINA tested 12 weeks of intermittent oral **dasatinib plus quercetin** in older adults with or at risk of Alzheimer's disease; in STAMINA, reductions in plasma TNF-alpha correlated with MoCA improvement ($r = -0.65$, $p = 0.02$). Safety, feasibility, CNS penetrance and biological activity were established, and a **Phase 2 RCT is now underway**.

3. Metformin as a geroprotector — a major setback. In a 21-year DPP follow-up, metformin did not significantly reduce multimorbidity risk; **85% of participants developed two or more chronic conditions** (82% lifestyle, 85% metformin, 87% placebo). Intensive lifestyle intervention was associated with lower long-term multimorbidity burden. TAME remains the pending definitive test. *(JAMA 2026)*

4. Partial epigenetic reprogramming moves toward the clinic. In vivo reprogramming through transient Yamanaka factor expression shows promise for restoring regenerative competence across retina, skeletal muscle, heart, liver, brain and intestine, but carries critical safety concerns — **teratoma formation, organ failure and loss of cell identity** — mitigated by **cyclic induction and targeted delivery**. A protocol of **2 days on and 5 days off per week** has allowed safe long-term reprogramming; in neuron-restricted models cyclic induction improves hippocampal activity, restores youthful heterochromatin and enhances memory, whereas **continuous expression is ineffective or deleterious**. A platform using **Oct4, Sox2, Klf4 (OSK), omitting the c-Myc oncogene**, has its lead programme **ER-100** in development for optic neuropathies including glaucoma and NAION, with plans to enter the clinic in Q1 2026. *(Aging Cell 2025)*

5. The field now has validation standards. The Biomarkers of Aging Consortium published recommendations on validating biomarkers of ageing, noting systematic validation is required before use as surrogate endpoints in gerotherapeutic trials. *(Nature Medicine 2024)*

Examiner's Tip — Classify by Evidence Strength

PROVEN — exercise (high-intensity/power resistance + balance + multicomponent), smoking cessation, BP and lipid control, vaccination, vitamin D, Mediterranean diet.
PROMISING — caloric restriction and its mimetics (rapamycin, metformin), senolytics, anti-inflammatory agents.
DISPROVEN OR HARMFUL — growth hormone, DHEA, antioxidant megadoses, HRT after 60.
EXPERIMENTAL — stem cells, partial epigenetic reprogramming, telomerase activation.

The line that earns the mark: "Exercise remains the only intervention with proven benefit on physical function, cognition, falls, multimorbidity and mortality in older humans — every pharmacological geroprotector is still investigational."

Q9. Interventions for Healthy Ageing

Primary source: Pathy's 6th ed. — Ch. 1, Ch. 7, Ch. 9, Ch. 12–14 (nutrition); supplemented by Essentials of Clinical Geriatrics (Ch. 5, Prevention).

High-Yield Points (Textbook Content)

Concept & Definitions

1. **WHO defines healthy ageing as the process of developing and maintaining the functional ability that enables wellbeing in older age.**
2. **"Functional ability — retaining autonomy and independence as people age — is the cornerstone of healthy ageing."**
3. **Intrinsic capacity** is the **composite of all of an individual's physical and mental capacities** and is the **key determinant of functional ability**. Domains: **cognition, psychological state, sensory function (vision and hearing), vitality/nutrition and locomotion**.
4. **Healthspan = duration of life in good health.** Fries described **compression of morbidity** — medicine **rectangularises the survival curve**, delaying death closer to maximum lifespan without changing maximum lifespan itself.
5. **Key conceptual point:** "healthy ageing" and "successful ageing" are **biologically vague as descriptions**. Their proper function is **prescriptive** — a norm of intervention: **"keep as many people as possible as healthy as possible for as long as possible."**
6. **Frailty is the clinical counterpart** — loss of in-built capacity across multiple systems with reduced physiological reserve and resilience. **The focus in older patients should be on functionality rather than disease diagnosis.**

Measuring Healthy Ageing

7. **Physical function is proposed as the biomarker of healthy ageing** — aerobic capacity, **gait speed, balance, mobility and muscle strength** — predicting adverse events, disability and mortality.
8. **Gait speed predicts mortality in older adults better than chronic diseases such as hypertension.**
9. Older adults with **handgrip strength above the weakness thresholds** had lower odds of adverse events across most intrinsic capacity domains and lower hospitalisation rates.
0. **Multimorbidity is NOT the most important factor modulating intrinsic capacity domains** — function matters more than disease count.

Pillar 1 — Exercise (Strongest Evidence)

1. **Habitual physical activity increases average life expectancy by about two years** and prevents most of the body-composition changes of ageing.
2. Exercise prevents/treats **obesity, cardiovascular disease, type 2 diabetes, hypertension, osteoarthritis, osteoporosis, stroke, peripheral vascular disease, renal failure, dementia and depression**.
3. **Multicomponent exercise (resistance + balance + gait retraining) improves all the hallmarks of frailty. VIVIFRAIL** gives individualised "prescription passports" based on **SPPB and gait speed**.
4. **High-intensity and explosive (power) resistance training** is the optimal prescription for **sarcopenia**, and also improves **balance and cognition** (particularly in MCI).
5. **Sequence in the frail follows the physiology of mobility: strength/power to stand → balance to stay upright → endurance to walk.**
6. **Aerobic exercise alone does not improve strength or balance. Walking-based falls programmes are inferior** to strength-and-balance programmes and have been associated with **increased fracture rates** in those at risk.

Pillar 2 — Nutrition

7. **Screen for the anorexia of ageing and malnutrition** using **SNAQ or MNA** whenever weight falls **more than 5 lb (2.3 kg) per year**; diagnose using **GLIM criteria** (phenotypic + aetiologic).
8. **Oral nutritional supplements produce 1–3 kg weight gain over 1–3 months**, but have **not shown mortality or functional benefit in the general elderly population** — benefit is confined to those who are **frail, malnourished or recently ill**.
9. **Mediterranean diet promotes epigenetic rejuvenation** (NU-AGE); adequate **protein** and **vitamin D 800–2000 IU/day** support muscle and bone.

Pillar 3 — Preventive Geriatrics (Stratify by Prognosis)

0. **The Health Maintenance Clinical Glidepath stratifies every intervention into four categories:**
    - **Robust** — life expectancy over 5 years, functionally independent

- **Frail** — life expectancy under 5 years or significant functional impairment
- **Moderately demented** — life expectancy 2–10 years
- **End of life** — life expectancy under 2 years, functionally dependent

1. **At EVERY visit, for all categories:** blood pressure **including orthostatics**, weight, **pain assessment**, **medication review including OTC and herbal**, **awareness of elder abuse**, and **Rapid Geriatric Assessment**. Lifestyle education at each visit for the robust and frail.
2. **Yearly:** ADLs and IADLs, urinary incontinence, ADAM screen for hypogonadism in men; **consider** annual visual acuity and auditory testing.
3. **Immunisation:** influenza yearly in **all four categories**; pneumococcal; tetanus booster every 10 years with at least one dose as Tdap; **zoster — Shingrix 90% protective versus Zostavax 30%**.
4. **Screening tied to life expectancy:** osteoporosis by **DXA plus FRAX**; **one-time AAA ultrasound** in male ever-smokers aged 65–75; sleep apnoea (Epworth); targeted lipid and TSH screening; **cancer screening only if life expectancy is 10 years or more**; **smoking cessation must be prioritised at every encounter**.

Pillar 4 — Psychosocial & Environment

5. **Plasticity is retained into old age** — cognitive training, physical training and even neurogenesis are demonstrable. Longitudinal cohorts show that **good vision, volunteer or paid work, physical activity and IADL independence independently predict continued functional independence over 7 years**. Address the transitions of ageing — **retirement, bereavement, loss of driving, sensory loss** — and support **social connectedness and home environment modification**.

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023-2026)
Operational framework	Intrinsic capacity as a concept	**WHO ICOPE Handbook 2nd edition (2024) + App**
Who delivers it	Geriatrician-led	**GPs, nurses and community health workers — no specialist needed**
Real-world data	None	**INSPIRE ICOPE-CARE: over 3000 followed, delayed functional loss**
Dementia prevention	Risk factors listed generally	**Lancet Commission 2024: 14 factors, ~45% preventable**
New dementia risk factors	Not included	**High LDL cholesterol and untreated vision loss**
Multidomain trials	FINGER only	**7 of 10 trials in the 2020s show cognitive benefit**
Biological validation	Not possible	**CALERIE: lifestyle intervention slows DunedinPACE 2–3%**

Latest Updates (2023–Present)

1. WHO ICOPE Handbook, 2nd edition (2024) — the operational tool for healthy ageing. It supports health and care workers to put evidence-based recommendations into practice in primary care and community settings, describing pathways to **detect declines in intrinsic capacity, identify social care and support needs, and develop a personalised care plan**; an interactive App generates a printable summary. The pathway is designed for **general practitioners and trained non-experts such as community health workers or nurses, without requiring specialised geriatric expertise** — usable from urban clinics to rural outreach. Pilot programmes in **India, Mexico and Vietnam** demonstrated feasibility in resource-constrained environments with improved functional outcomes and reduced healthcare utilisation. In France, the **INSPIRE ICOPE-CARE** programme had over **3000 individuals actively followed** by October 2024, with high adherence and evidence of delayed functional loss. *(European Geriatric Medicine 2026)*

2. ICOPE Step 1 screening — what it actually finds. In a Singapore feasibility study of **367 community-dwelling older adults (mean age 71.8)**, ICOPE Step 1 screening found **284 (77.4%) with signs of intrinsic capacity decline** — commonest being **visual impairment (42.0%), hearing loss (33.5%) and cognitive deterioration (31.3%)**, followed by limited mobility (24.3%), malnutrition (16.1%) and depressive symptoms (16.1%). **Clinical message: sensory impairment is the commonest reversible threat to intrinsic capacity — screen vision and hearing first.**

3. Lancet Commission 2024 — dementia prevention as healthy ageing. The 2024 report adds **untreated vision loss and high LDL cholesterol**; around **45% of dementia cases are potentially preventable** by addressing **14 modifiable risk factors** across the life course: low education in early life; hearing loss, hypertension, obesity, excessive alcohol, traumatic brain injury, high LDL cholesterol, depression, physical inactivity, diabetes and smoking in mid-life; and social isolation, air pollution and visual impairment in late life.

4. Multidomain interventions have come of age. Five multidomain trials published 2015–2019 including FINGER did not show consistent cognitive improvement — but in the 2020s, **seven of ten trials reported beneficial effects** of multidomain interventions on cognitive outcomes, with additional benefits on physical function, reduced multimorbidity and healthcare resource use. *(Geriatrics & Gerontology International 2025)*

5. Biological proof that lifestyle slows ageing. CALERIE showed a lifestyle intervention slowed the pace of ageing by DunedinPACE — roughly **3% slowing**, associated with **15% lower risk of death**. *(Nature Aging 2023)*

Examiner's Tip

Define healthy ageing (WHO) → intrinsic capacity vs functional ability → compression of morbidity → measure it (gait speed, grip strength, SPPB, frailty) → **FOUR PILLARS**: (1) exercise — multicomponent with power training, (2) nutrition — protein, vitamin D, Mediterranean pattern, malnutrition screening, (3) preventive geriatrics — stratified by life expectancy, vaccination, screening, deprescribing, (4) psychosocial and environmental → finish with WHO ICOPE and Lancet Commission 2024.

The line that earns the mark: "Healthy ageing is defined by function, not by the absence of disease — so the target of intervention is intrinsic capacity, and the best-evidenced intervention remains multicomponent exercise."

Q10. Active Ageing and How to Achieve It

> *Primary source: Pathy's 6th ed. — Ch. 4 (Social and Community Aspects of Ageing), Ch. 7, Ch. 9, Ch. 11; supplemented by Essentials of Clinical Geriatrics.*

High-Yield Points

Concept & Framework

1. **WHO defines active ageing as "the process of optimising opportunities for health, participation and security in order to enhance quality of life as people age."**
2. **CRITICAL DEFINITION POINT: "active" does NOT mean merely physically active or economically productive.** It means **continuing participation in social, economic, cultural, spiritual and civic affairs**.
3. **Three pillars of active ageing: HEALTH, PARTICIPATION and SECURITY.** The slogan is **"add life to years," not just years to life**.
4. **Determinants:** health and social services; behavioural factors; personal (biological and psychological) factors; physical environment; social environment; economic factors — with **culture and gender as cross-cutting determinants**.
5. **Relationship to other terms:** *Successful ageing* (Rowe & Kahn) = absence of disease + high function + engagement. *Healthy ageing* (WHO) = maintaining **functional ability**. *Active ageing* is the **broadest policy framework**, adding participation and security to health.

Pillar 1 — Health

6. **Exercise is the single most effective intervention.** Habitual physical activity adds about **2 years** to life expectancy. **Multicomponent exercise improves all the hallmarks of frailty**; **VIVIFRAIL** provides individualised prescription passports.
7. **Exercise as a mental health intervention:** high-intensity aerobic exercise is **equipotent with antidepressants** in older adults with major depression. High-intensity progressive resistance training achieved a **61% clinical response versus 29% with low-intensity training and 21% with GP care** — showing that **intensity matters**.
8. **Correct sensory impairment — the highest-yield "participation" intervention.** At least **one-third of older adults have visual impairment and up to two-thirds report hearing loss**. **Each line of reduction in presenting visual acuity increases the risk of institutionalisation by 7%.**
9. **Hearing loss is associated with social isolation, depression and cognitive impairment.** Many older adults do not volunteer it. **Personalised sound amplifiers are an inexpensive alternative** to hearing aids in mild-to-moderate loss; **low-vision rehabilitation** should be used alongside standard ophthalmic care.
0. **Preventive geriatrics stratified by prognosis:** influenza vaccine yearly in **all** categories; pneumococcal, zoster and tetanus vaccination; **medication review including OTC and herbal preparations at every visit**; nutrition screening (SNAQ/MNA) if weight loss exceeds 5 lb per year.

Pillar 2 — Participation

1. **Employment:** adults over 55 make up about **22% of the US workforce**, and **workers aged 70–75 are expected to show the largest relative growth**. Many industries are **eliminating mandatory retirement ages**.
2. **But discrimination persists** — an adult over 50 who loses a job takes **much longer to find new work** and is **more likely to accept a pay cut**.
3. **Retirement is a risk period: about one-quarter of adults report that their quality of life WORSENED after retirement** — due to **boredom, financial worries or health changes**.
4. **The retirement prescription:** counsel older adults to **participate in social activities, foster connections with friends and family, exercise regularly, and engage in mentally stimulating activities** — all correlating with **higher quality of life and lower risk of dementia and social isolation**.
5. **Distinguish clearly: social isolation = objective physical separation from others; loneliness = subjective distress at feeling separated or alone.** Correlated but **not synonymous**.
6. **Epidemiology:** about **one-quarter** of community-dwelling older adults are socially isolated; **20–45% report feeling lonely** some or all of the time.
7. **Health consequences of loneliness/isolation:** increased **anxiety, depression and suicidality**; increased risk of **cognitive impairment and delayed dementia diagnosis**; **chronic inflammation leading to cardiovascular disease**; and a **suppressed immune system**.
8. **Treatment of loneliness has no one-size-fits-all approach.** Options: **treat psychological comorbidity, optimise hearing and vision, arrange reliable transport, cognitive-behavioural therapy, peer groups based on shared language/culture/interests, volunteering, senior centres, companionship volunteer organisations, and engagement with a religious community**.

9. **Technology enables participation:** two-thirds of Americans over 65 use the internet, 4 in 10 own a smartphone, 30% use social media. Benefits include **online ordering, on-demand transport, online banking, telehealth and chronic disease self-management**. Barriers are **lack of confidence and physical difficulty with devices**; counsel on **scams and misinformation**.
0. **Measure participation:** the **Saint Louis University Social Activities Assessment** quantifies frequency of going out socially, gardening, worship attendance, telephone contact, eating out, walking, dancing, concerts/theatre, time with grandchildren, and **satisfaction with social activity**.

Pillar 3 — Security

1. **Financial security:** only about 30% of older adults receive pension income and about 21% still earn from employment. **Older women, particularly those who never married, are at the highest risk of poverty.** Globally, poverty rates in over-65s range from **3% (Netherlands, Czech Republic) to about 50% (Republic of Korea) to 80% (Zambia)**.
2. **Elder abuse affects an estimated 5–10% of older adults, and nearly half of those with dementia.** It is grossly under-recognised — one US emergency department study reported an incidence of **0.013%**, orders of magnitude below true prevalence. Refer to **Adult Protective Services** or the local equivalent; report to the **ombudsman** as well if abuse occurs in a nursing home.
3. **Scams and fraud:** older adults are preferentially targeted. Protective measures include **freezing credit, credit monitoring, and granting a trusted family member account access to monitor for suspicious activity**.
4. **Housing — "age in place" first.** Suboptimal reasons to move (structural problems, financial difficulty, mobility limitation, perceived isolation) should first be addressed with **grants and volunteer repair services, social work input, PT/OT assessment with ramps and assistive devices, and community engagement**. Ideal reasons to move include an **unsafe or unimprovable environment or inability to live alone safely**. Innovative models include **senior-friendly communities, co-housing and student-for-services schemes**.

Cross-Cutting — Combating Ageism

Ageism — "one of the last socially acceptable forms of prejudice" — is stereotyping (how we think), prejudice (how we feel) and discrimination (how we act) on the basis of age. In healthcare it causes **delirium and disability to be dismissed as "normal ageing"**, and older people with ischaemic heart disease to be **less thoroughly investigated and less often offered intervention even when clinically indicated**. The geriatrician's unique skill is **striking the balance between therapeutic nihilism and therapeutic heroism**.

Frameworks Institute strategies (Pathy's Table 4.1):

- **Eliminate the "othering"** — say "when we age", not "when they age"
- **Reframe ageing** — avoid "fighting" or "battling" ageing; emphasise wisdom and life satisfaction, but **avoid unrealistic idealism**
- **Increase awareness** — call out ageism when encountered
- **Emphasise that social policies (transport, housing, social security) influence ageing** — not just individual choices
- **Appeal to values of justice, inclusion and equity**

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Global policy vehicle	WHO active ageing framework	**UN Decade of Healthy Ageing (2021–2030)**
Action areas	Health/participation/security	**Ageism, age-friendly environments, integrated care, long-term care**
Implementation tool	None specified	**WHO ICOPE Handbook 2nd edition (2024) + App**
Monitoring	Not addressed	**TAG4MHA indicator framework (2025); mid-term evaluation 2026**
Elder abuse response	Refer to APS	**WHO database of 89 promising interventions (2024)**
Social isolation	Health consequences described	**Now a formal modifiable dementia risk factor (Lancet 2024)**

Latest Updates (2023–Present)

1. The UN Decade of Healthy Ageing (2021–2030). Led by WHO, it focuses on four action areas — **age-friendly environments, combating ageism, integrated care and long-term care** — with the vision to **"add life to years,"** supported by four enablers: meaningful engagement of older people, leadership and capacity building, connecting stakeholders, and strengthening data, research and innovation. **By 2030, 1.4 billion people will be aged over 60, with low- and middle-income countries hosting 80% of older populations.**

2. First progress report — where countries actually stand. Based on a survey of **136 countries** (November 2023), there was an **over-20% increase** in countries reporting legislation against ageism, legislation supporting access to assistive products, national policies on comprehensive assessment of health and social care needs, and national age-friendly cities programmes. However, **fewer than one-third of countries reported having adequate resources** to deliver on the four action areas.

3. Measurement framework and mid-term evaluation. WHO, with its Technical Advisory Group for the Measurement of Healthy Ageing, published a monitoring framework and core indicator set (May 2025), with mandatory reporting due in **2026 and 2029**. As of late 2025, **162 of 194 Member States (83%)** were participating in the mid-term evaluation survey.

4. Elder abuse — from recognition to intervention. For World Elder Abuse Awareness Day 2024, WHO released an interactive database of **89 interventions** that show promise to prevent and respond to abuse of older people — the first product of the Decade's **Intervention Accelerator** initiative.

5. Social isolation formally enters the dementia prevention agenda. The 2024 Lancet Commission includes **social isolation** among the 14 modifiable dementia risk factors, alongside hearing loss and visual impairment, with addressing all 14 potentially preventing or delaying around **45% of dementia cases** worldwide. **This gives the "participation" pillar a hard clinical endpoint.**

Examiner's Tip

Define active ageing (WHO) → stress that "active" is not merely physical activity → **THREE PILLARS: Health, Participation, Security** → determinants → then **how to achieve it** under each: Health (exercise, nutrition, vaccination, sensory correction, deprescribing), Participation (flexible employment, retirement counselling, treating loneliness, technology, volunteering), Security (financial protection, elder abuse detection, safe housing, age-in-place) → cross-cutting: combat ageism → finish with the UN Decade four action areas.

Two lines that earn marks:

• "'Active' refers to continuing participation in social, economic, cultural, spiritual and civic affairs — not merely the ability to be physically active or to work."

• "Correcting vision and hearing is the highest-yield single intervention for participation — each line of lost visual acuity raises institutionalisation risk by 7%."

Q11. Exercise in the Elderly — Beneficial or Harmful?

Primary source: Pathy's 6th ed. — Ch. 7 "Physical Fitness and Exercise" (Tables 7.5, 7.7, 7.9), Ch. 11 (Patient Safety).

THE VERDICT (state this first). Exercise in the elderly is overwhelmingly **BENEFICIAL**. Harm arises not from exercise itself but from the **wrong modality**, the **wrong intensity**, the **wrong sequence**, or inadequate supervision. Pathy's is explicit: **"Considering the current evidence of the benefits of exercise in frail older adults, it is not ethical to NOT prescribe physical exercise to these individuals, as this means doing harm by withholding evidence-based and effective treatment."**

Part A — The Case for Benefit

1. **"There is no age above which physical activity ceases to have benefits across a wide range of diseases and disabilities."** Exercise is feasible in **nursing home residents up to 101 years of age** and in **hip fracture patients within 12 weeks of surgery**.
2. **"Insufficient physical activity and excess sedentary behaviour are lethal conditions; physical activity is the antidote."** Sedentary behaviour is a potent risk factor for **all-cause and cardiovascular mortality, obesity, sarcopenia, hypertension, insulin resistance, diabetes, stroke, colon cancer, depression, dementia, osteoarthritis, osteoporosis, recurrent falls, frailty and disability**.
3. **Ageing and disuse produce nearly identical physiological changes** — much of what is attributed to chronological age is in fact deconditioning.
4. **Habitual physical activity increases average life expectancy by about two years.**
5. **Exercise reduces cardiovascular disease risk by about 50%**, even after controlling for smoking, obesity, hypertension and dyslipidaemia.
6. **It is never too late:** sedentary middle-aged adults with low fitness who became fit at follow-up had **markedly reduced cardiovascular mortality** — "preventive exercise prescriptions instituted in middle age or beyond may be as important as those initiated at younger ages."
7. **Body composition:** exercise prevents the decreases in **muscle mass and bone density** and the increase in **central adiposity**. A **5% fall in total body fat can produce a 25% or greater reduction in visceral fat**.
8. **Sarcopenia:** high-intensity resistance training is the **optimal prescription**, and — less well known — it **improves aerobic capacity as much as moderate-intensity aerobic training**, addressing both major deficits with one prescription.
9. **Frailty:** a **12-week multicomponent programme with explosive resistance training in institutionalised frail nonagenarians** improved **muscle cross-sectional area, muscle fat infiltration, maximal strength, power output, balance, gait and sit-to-stand ability, with a reduction in falls**. **Frailty is not a contraindication to robust exercise — it is one of the strongest indications for it.**
0. **Depression:** high-intensity aerobic exercise is **equipotent with antidepressants** in older adults with major depression. High-intensity progressive resistance training produced a **61% clinical response, versus 29% with low-intensity training and 21% with GP care** (equivalent to placebo).
1. **Cognition:** high-intensity resistance training is the most promising modality, particularly in **mild cognitive impairment**; four months of low-intensity **high-speed** resistance training improved both cognition and physical performance in MCI.
2. **Fracture prevention:** in the **EPIDOS** study of 6901 women over 75, **low physical activity more than doubled the risk of proximal humerus fracture (RR 2.2)** — a **greater** risk than **low bone density (RR 1.4), maternal history of hip fracture (RR 1.8) or impaired balance (RR 1.8)**.
3. **Hospital and institutional settings:** exercise reduces functional decline in **very elderly patients during acute hospitalisation** and improves cognition; **triceps strength is critical to transfer ability, and improving it reduces nursing home admission after hip fracture**. The VIVIFRAIL programme **protected institutionalised older adults from severe functional decline through 14 weeks of COVID confinement**.
4. **Randomised trial evidence exists** for exercise in the prevention of **secondary cardiovascular events, diabetes mellitus and osteoporotic fracture**.

Part B — The Case for Harm (where marks are actually won)

5. **WRONG MODALITY IS HARMFUL.** "Falls-prevention programmes **inclusive of walking are inferior** to those focusing on strength and balance exercises and have also been **associated with increases in osteoporotic fracture rates in those at risk.**" **Walking is not a falls-prevention intervention.**
6. **WRONG SEQUENCE IS HARMFUL.** "Prescribing progressive aerobic training in the absence of sufficient balance or

strength is likely to result in **knee pain, fear of falling, falls, fractures**, and limited ability to progress aerobically — and **is not recommended**."

7. **Musculoskeletal injury with power training:** risk of **injury to tendons and cartilage, particularly the rotator cuff and knee** where degenerative tears are commonplace, and **exacerbation of abdominal or inguinal hernias**. Avoid **heavy repetitive workloads** and **unfavourable positioning** such as overhead or military press in rotator cuff disease.
8. **BUT the measured risk is very small:** a systematic review of resistance training in frail older adults reported **only ONE case of shoulder pain across 20 studies and 2544 subjects**.
9. **HIIT is unproven in the frail:** high-intensity interval training (85–95% peak heart rate for 1–4 minutes) has been studied mainly in **healthy and cardiovascular cohorts**; its **feasibility in frail older adults with multiple comorbidities remains to be established**.
0. **Low-intensity exercise is not "safer" — it is ineffective, which is its own harm.** Low-intensity resistance training is **ineffective in peripheral vascular disease**; low-intensity aerobic training in depression is **no better than social contact**; and there is **no evidence of benefit for low-intensity, minimally progressive multimodal exercise for cognitive outcomes**.
1. **Uncertain benefit in care homes:** a Cochrane meta-analysis concluded the evidence is **uncertain regarding the effect of exercise, medication review or multifactorial interventions on fall rates in care homes**.
2. **Non-responders exist:** there is significant **inter-individual variability in response** to exercise, including **adverse metabolic responses** in a minority.
3. **Acute illness requires caution:** in hospitalised patients, **"it is crucial to pay special attention to clinical vital signs before performing the physical exercise intervention, to prevent adverse events."**

Part C — How to Prescribe Safely (Pathy's Table 7.9)

Modality	Frequency	Volume	Intensity
Resistance	2–3 days/week	1–3 sets × 8–12 reps, 8–10 major muscle groups	**Borg 15–18 (70–80% 1RM)**, 6 s per rep, 1 min rest between sets
Aerobic	3–7 days/week	20–60 min/session	**Borg 12–14 (40–60% HR reserve)**
Balance	1–7 days/week	1–2 sets × 4–10 static and dynamic postures	Progressive difficulty as tolerated

Safety Rules to Quote

- **Titration method:** measure **1 RM**, then use **50%, 60%, 70% and 80% of 1 RM over the first four days**; thereafter progress by perceived exertion.
- **Power training** at **20–80% 1 RM**, concentric phase as fast as possible; **80% gives optimal adaptation**. **Screen for rotator cuff and meniscal tears first.**
- **Start with ONE modality**, then add others — introducing everything at once compromises adherence and adaptation.
- **Correct strength and balance deficits BEFORE starting aerobic training.**
- **Sequence in the frail: strength/power (to stand) → balance (to stay upright) → endurance (to walk).**
- **Flexibility/stretching** has limited independent clinical benefit — best used as a **cool-down component**.
- **Screen for sedentary behaviour at every major healthcare encounter.**

Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current Evidence (2023–2026)
Falls risk framework	Exercise recommended generically	**World Falls Guidelines: low / intermediate / high risk stratification**
Who gets exercise	All older adults	**All — but tailored by fall-risk category**
Cognitive impairment	Exercise data emerging	**WFG recommends individualised exercise even in cognitive impairment**
Global consensus	ACSM 2009 position stand	**Izquierdo 2024 ICFSR global recommendations**
Framing	Exercise as intervention	**Exercise as precision medicine — individualised prescription**
Drug review alongside	Not linked	**STOPPFall before prescribing fall-risk-increasing drugs**

Latest Updates (2023–Present)

1. World Falls Guidelines — exercise stratified by risk. The 2022 WFG classify an older adult with no fall history, or a single non-severe fall without gait or balance problems, as **low risk** — needing primary prevention and annual reassessment. Those with a single non-severe fall **plus gait or balance problems** are **intermediate risk** and benefit from a **strength and balance exercise intervention**. **High risk** includes those with a fall plus any of: accompanying injury, two or more falls in 12 months, known frailty, inability to get up for at least an hour, or suspected transient loss of consciousness. Developed by **96 multidisciplinary experts from 39 countries**. *(Age and Ageing 2022)*

2. AGS endorsement and additions (2024). The AGS response to the WFG endorsed several additions to the earlier AGS/BGS guideline: assessment and intervention for **hearing impairment** and **concern about falling**, **assessment and individualised exercises for older adults with cognitive impairment**, and performing a standardised assessment such as **STOPPFall** before prescribing a medication that could increase fall risk. *(JAGS 2024)*

3. Global exercise recommendations for longevity (Izquierdo 2024). Comprehensive global recommendations developed through an international consensus process from the ICFSR. Because programmes should be individualised, they form part of the evolving discipline of **precision medicine**; recommendations include **structured exercise supplemented by incidental lifestyle activity**, and strongly support **multicomponent interventions extending beyond aerobic exercise**. *(J Nutr Health Aging 2025)*

4. Resistance training and mobility disability. A meta-analysis of 24 articles from 22 studies (**3,656 participants, mean age 63–87**) found resistance training produced greater improvements than control in **6-minute walk distance (+16.1 m), lower extremity strength, and usual gait speed (+0.05 m/s)** — results held whether resistance training was the sole intervention or part of a multicomponent programme.

5. Falls prevention in aged care — where evidence remains weakest. WHO guidelines recommend all older adults undertake physical activity for falls prevention and other benefits including reduced mortality and improved cardiovascular, mental and cognitive health — but trial endpoint meta-analyses in **long-term residential aged care** continue to show this is the setting where evidence is least certain, consistent with the textbook position. *(Age and Ageing 2023)*

Examiner's Tip

Open with the verdict → benefits by system (mortality, CVD, body composition, sarcopenia, frailty, falls/fracture, depression, cognition, hospitalisation) → **then the harms section** (wrong modality, wrong sequence, power-training injury, HIIT unproven in frail, low-intensity ineffective, non-responders, acute illness) → resolve with the safe prescription table and sequencing rule → close with the ethical statement.

Three lines that earn the highest marks:

• "Frailty is not a contraindication to robust exercise — it is one of the most important reasons to prescribe it."
• "Falls-prevention programmes based on walking are inferior to strength-and-balance programmes and have been associated with increased fracture rates in those at risk."
• "It is not ethical to withhold exercise from frail older adults — that is doing harm by withholding effective treatment."

Q12. Advance Directives — Current Status in India

> *Primary source: Essentials of Clinical Geriatrics, 7th ed. — Ch. 17 "Ethical Issues in the Care of Older Persons" (Table 17-2); Pathy's 6th ed. Indian legal position from Supreme Court judgments and MoHFW/ICMR documents.*

Part A — Concept and Types (Textbook)

1. An **advance directive (AD)** is a **legal document that allows a patient to convey decisions about the care they want if they later become unable to express their wishes**.
2. **Purpose:** it makes the person think about care preferences **before a crisis**, simplifies decision-making, and **lets the family feel confident they did what the patient wanted** regardless of their own beliefs.
3. **Two main types:**
   - **Living will** — specifies care preferences in a **terminal state or vegetative state**, usually covering CPR, intubation, artificial nutrition and hydration, dialysis and IV therapy.
   - **Durable power of attorney for health care (proxy/agent)** — appoints a person to make decisions on the patient's behalf.
4. **Limitation of the living will:** it addresses only a few defined clinical situations. It **cannot decide the nuanced questions**, such as when an antibiotic is life-supporting versus comfort care.
5. **Components of a durable power of attorney** (Table 17-2): statement of intention citing the enabling statute; **designation of the agent with contact details**; general statement of the authority granted; **statement of desires, special provisions and limitations**; dated signature; and **witnesses — who must NOT be the agent, healthcare providers, or employees of the facility giving care**.
6. **Decision standard for the proxy:** use **substituted judgment** (what the patient would have wanted); where uncertain, fall back on **beneficence** — weighing benefits against burdens.
7. **Who should be proxy?** Not automatically the next of kin, but **the person who best knows the patient's preferences** — which may be a close friend or clergyman rather than a rarely seen relative.
8. **Pitfalls:** agents may pursue **their own interests**; surrogate decisions may be **incongruent with the patient's actual wishes**; decisions once made are hard to revoke; and **there is no reliable test of capacity** to decide whether someone can change their mind.
9. **Key clinical caution:** making end-of-life judgments while in good health is difficult. **Do not assume the old-old are "ready to die."** What a patient wants at **85 may differ from what they want at 97** — so **discussions must be ongoing, not one-off**.
0. **POLST/MOLST** (Physician/Medical Orders for Life-Sustaining Treatment) convert an AD into an **actionable standing medical order**, particularly for those who want to avoid life-sustaining treatment, live in long-term care, or **may die within the next year**.
1. **Legislation alone does not work:** the US Patient Self-Determination Act (1991) mandated that all persons entering a hospital or nursing home be offered the opportunity to make an AD, yet it had **minimal impact on the number actually completing one**.
2. **A trial of therapy is permissible** — patients and families must be told that **a treatment once started need not be continued indefinitely**.

Part B — The Indian Legal Position

Evolution

3. **Aruna Shanbaug v. Union of India (2011)** — the Supreme Court **permitted passive euthanasia** for the first time in India.
4. **Common Cause (A Regd. Society) v. Union of India (2018) 5 SCC 1** — a **five-judge Constitution Bench** held that the **right to die with dignity is a fundamental right under Article 21**. It **legalised passive euthanasia** and gave **legal recognition to Advance Medical Directives (AMD)**.
5. The **2018 procedure proved unworkable** — it required **countersignature by a Judicial Magistrate First Class (JMFC)** plus **two layered medical boards**, causing delays that defeated the purpose.
6. **Common Cause (Modification Order), 24 January 2023** — following a Miscellaneous Application by the **Indian Society of Critical Care Medicine**, the Supreme Court **substantially simplified the procedure**. **This 2023 order is the operative law today.**

Requirements of a Valid AMD in India (Post-2023)

7. Must be executed by an **adult with decision-making capacity, voluntarily and without coercion**, and be **in writing**.

8. Must state in **unambiguous terms** the decision to withhold or withdraw treatment, and specify the **circumstances in which it applies**.
9. Must be signed in the presence of **two attesting witnesses** and **attested by a Notary or a Gazetted Officer** — **the JMFC requirement has been removed**.
0. Must **nominate at least two guardians or close relatives** empowered to give consent, and a copy must be given to the **nominated persons, the family physician and the local custodian**.
1. **Revocable at any time** before implementation. An AMD **does not apply if circumstances have arisen that the executor did not anticipate** and which would have altered the decision.
2. **Applies only to terminal illness with no hope of recovery, or persistent vegetative state.**

The Implementation Process

3. **Primary Medical Board** — constituted by the hospital, minimum **three treating doctors**. If it certifies the patient is terminal/irreversible, the case goes to the **Secondary Medical Board**, which must **decide within 48 hours**. The **Chief District Medical Officer nominates one member** of the Secondary Board.
4. **Where there is NO advance directive**, the same medical board procedure applies with the consent of the family/surrogate — **High Court permission is no longer routinely required**.

Critical Distinctions

25. **Passive euthanasia (withholding/withdrawing life-sustaining treatment) is LEGAL. Active euthanasia and physician-assisted suicide remain ILLEGAL** under the Bharatiya Nyaya Sanhita provisions on abetment of suicide and culpable homicide.
26. **A separate and independent framework exists under Section 5 of the Mental Healthcare Act, 2017**, which permits advance directives for **mental health treatment**. The two frameworks are **not interchangeable**.
27. **A patient refusing life-sustaining treatment remains fully entitled to palliative care** — withdrawal of LST is never withdrawal of care.

Current Practice Update

Aspect	Textbook (US model)	India (2023–2026)
Legal basis	State statute + PSDA 1991	**Article 21; Common Cause 2018 + Modification Order 2023**
Attestation	Witnesses, ideally notarised	**Two witnesses + Notary OR Gazetted Officer**
Judicial involvement	None routinely	**JMFC requirement removed in 2023**
Actionable order	POLST/MOLST	**Primary + Secondary Medical Board; 48-hour decision**
Registry	Electronic health record integration	**Local government "custodian"; no national registry yet**
Scope of euthanasia	Varies by state	**Passive only — active euthanasia remains a criminal offence**
Uptake	Low despite legislation	**Very low; awareness minimal outside a few states**

Latest Updates (2023–Present)

1. The 2023 Modification Order — what actually changed. The clarification order **removed the requirement of Magistrate attestation**, replaced the earlier two-board arrangement with a streamlined board of **three doctors**, allowed **hospital ethics committees** to participate, and introduced **digital registration and storage**. The current position is that a valid Indian AMD requires **written form, two witnesses, and attestation by a Notary or Gazetted Officer**, and should be accessible to the nominated person and to the treating physician. *(Common Cause v. Union of India, 2023 SCC OnLine SC 99, decided 24 January 2023)*

2. MoHFW draft guidelines for withdrawal of life support (September 2024). The Ministry issued draft guidelines translating into clinical reality the streamlined procedure set out by the Supreme Court. **Terminal illness is defined as an irreversible or incurable condition from which death is inevitable in the foreseeable future**, and **severe brain injury with no recovery after 72 hours** is included. Doctors are advised to base the decision on factors including **declaration of brainstem death, poor prognosis with no likely benefit from treatment, or documented informed refusal** by the patient or family. The end-of-life care pathway is adapted from the **ISCCM–IAPC Expert Consensus and Position Statements for End of Life and Palliative Care in the ICU**.

3. State-level operationalisation — the real bottleneck. **Karnataka** became the second state after **Kerala** to implement the order, with a Health Department circular of **30 January 2025** mandating primary and secondary medical boards in hospitals to review WLST requests based on living wills, together with a state AMD format; the Indian Association of Palliative Care noted this made Karnataka the **first state government in India to make the WLST process feasible statewide**, with the secondary medical board required to confirm or refuse within **48 hours**. **Goa** became the first state to fully operationalise the AMD facility, with a Bombay High Court judge executing the first living will before two witnesses and a gazetted officer.

4. Persistent implementation problems. The orders require an officer of the local government to be nominated as **"custodian"** of all advance medical directives, but have proved challenging: decisions about withholding or withdrawing life-sustaining treatment often need to be made **within hours**, assembling six different medical experts in that time is difficult **especially in non-urban settings**, and it is impractical to approach the district Chief Medical Officer to nominate a Secondary Medical Board member for every such decision.

5. Supporting ICMR documents. Two ICMR publications — on **definitions of terms used in limitation of treatment**, and on **Do-Not-Attempt-Resuscitation** — clarified terminology and helped standardise and remove ambiguity around terminal illness, withholding/withdrawal, and end-of-life care. *(Indian Journal of Medical Research 2020 and 2026)*

Examiner's Tip

Define AD → two types (living will vs durable power of attorney/proxy) → limitations of each → **INDIAN LAW**: Aruna Shanbaug 2011 → Common Cause 2018 (Article 21, five-judge bench) → why it failed → 2023 Modification Order (notary/gazetted officer, JMFC removed, 48-hour board) → requirements of a valid AMD → Primary and Secondary Medical Board process → passive legal / active illegal → Mental Healthcare Act 2017 Section 5 as a separate track → state implementation (Kerala, Karnataka, Goa) → MoHFW 2024 draft guidelines → barriers.

Three lines that earn marks:

• "The right to die with dignity is a fundamental right under Article 21 — *Common Cause v. Union of India*, 2018."
• "The 2023 Modification Order removed the Judicial Magistrate requirement; an AMD now needs only two witnesses and attestation by a Notary or Gazetted Officer."
• "Withdrawal of life-sustaining treatment is never withdrawal of care — palliative care continues in full."

Appendix — Rapid Revision Grid

> *Last-night revision sheet: the numbers, trials and one-liners most likely to earn marks.*

1. Numbers You Must Not Get Wrong

Item	Value
Hayflick limit	**~50 population doublings**
Hallmarks of ageing	**9 (2013, in Pathy's) → 12 (2023)**
Epigenetic clock accuracy	**Error <5 years**
Human sirtuin isoforms	**7 (SIRT1–7); SIRT1 & SIRT6 = ageing**
Grip strength — low (EWGSOP2)	**<27 kg men, <16 kg women**
Low appendicular muscle mass	**<20 kg men, <15 kg women**
Caloric restriction — rodent lifespan gain	**Up to 50%**
CALERIE caloric restriction dose	**25% for 2 years, n = 220**
CALERIE effect size	**~3% slower DunedinPACE = 15% lower death risk**
Fall in energy intake, age 20→80	**~30% (men −1321 kcal/d, women −629 kcal/d)**
Lean mass lost per decade after 50	**Up to 3 kg**
Significant unintentional weight loss	**≥5% in 6–12 months (≥10% = PEM)**
Malnutrition prevalence (MNA)	**Overall 22.8%; rehab 50.5%; hospital 38.7%; community 5.8%**
Exercise — life expectancy gain	**~2 years**
Exercise — CVD risk reduction	**~50%**
Resistance training dose	**2–3 d/wk, 1–3 sets × 8–12 reps, Borg 15–18 (70–80% 1RM)**
Aerobic training dose	**3–7 d/wk, 20–60 min, Borg 12–14 (40–60% HRR)**
Influenza vaccine efficacy	**50% illness reduction; 70% mortality reduction**
Influenza vaccine in nursing homes	**40% for illness; >80% coverage prevents outbreaks**
Zoster vaccine efficacy	**Zostavax 30% vs Shingrix 90%**
Post-herpetic neuralgia over age 60	**>40%**
Deaths from pneumonia/influenza aged 65+	**>90% during epidemics**
CAPITA trial (PCV13)	**45% reduction in pneumococcal pneumonia**
Pneumococcal vaccine age threshold	**Lowered from 65 to 50 (ACIP, Oct 2024)**
RSV vaccine	**Routine at 75+; risk-based 50–74; single dose**
Vitamin D dose	**800–2000 IU/day**
Protein target in the older adult	**1.2 g/kg/day; ~0.4 g/kg per meal**
Elder abuse prevalence	**5–10% overall; ~50% in dementia**
Loneliness / social isolation	**Lonely 20–45%; isolated ~25%**
Visual acuity and institutionalisation	**Each line lost = +7% risk**
Preventable dementia (Lancet 2024)	**~45% via 14 risk factors**
ICOPE Step 1 — commonest deficits	**Vision 42%, hearing 33.5%, cognition 31.3%**
Secondary Medical Board decision (India)	**Within 48 hours**

2. Named Trials and Studies

Trial	Field	Result to quote
CALERIE	Caloric restriction	25% CR × 2 yr slowed DunedinPACE ~3%; no change in PhenoAge/GrimAge
DPP / DPPOS	Metformin as geroprotector	21-yr follow-up: **no** multimorbidity benefit; lifestyle superior
TAME	Metformin	**Awaited** — definitive geroprotector trial
SToMP-AD / STAMINA	Senolytics	Dasatinib + quercetin Phase 1 safe; TNF-alpha fall correlated with MoCA gain
ZEUS	IL-6 inhibition	Ziltivekimab, n = 6376: **HR 0.99 — no MACE benefit** despite hsCRP fall
CANTOS	IL-1beta inhibition	Canakinumab reduced incidence of age-related diseases
SAPHYR	PMR	Sarilumab sustained remission **28% vs 10%** at 52 weeks
CAPITA	Pneumococcal	PCV13 reduced pneumococcal pneumonia by 45%
DANFLU-2	Influenza	n = 332,438: high-dose **missed primary endpoint**; cardiorespiratory rVE 5.7%
EPIDOS	Fracture	Inactivity RR 2.2 > low BMD RR 1.4 for humerus fracture
Look AHEAD	Weight loss	Risk factors improved but **no CV event reduction**
TONE	Hypertension	Salt restriction + weight loss lowers BP in older adults
FINGER	Multidomain	First multidomain dementia prevention trial; 7/10 trials positive in the 2020s
NU-AGE	Diet	Mediterranean diet promotes epigenetic rejuvenation
KEEPS / WHI	HRT	HRT **not recommended after age 60**
VIVIFRAIL	Exercise	Individualised passports by SPPB + gait speed; protected residents in COVID confinement
Fiatarone 1990	Exercise	High-intensity resistance training effective in nonagenarians
Roberts et al.	Caloric restriction	Old men **fail to compensate** after underfeeding; never regain weight

3. Classifications and Frameworks

Framework	Contents
Theories of ageing	Error/stochastic • Programmed • Evolutionary
Evolutionary theories	Medawar (mutation accumulation) • Williams (antagonistic pleiotropy) • Kirkwood (disposable soma)
9 hallmarks (2013)	**Primary:** genomic instability, telomere attrition, epigenetic alterations, loss of proteostasis. **Antagonistic:** deregulated nutrient sensing, mitochondrial dysfunction, cellular senescence. **Integrative:** stem cell exhaustion, altered intercellular communication
3 added in 2023	Disabled macroautophagy • chronic inflammation • dysbiosis
Epigenetic clock generations	1st Horvath/Hannum (chronological age) • 2nd PhenoAge/GrimAge (mortality) • 3rd DunedinPACE (pace)
Intrinsic capacity domains	Cognition • psychological • sensory (vision, hearing) • vitality/nutrition • locomotion
Active ageing pillars	Health • Participation • Security
UN Decade action areas	Ageism • age-friendly environments • integrated care • long-term care
Health Maintenance Glidepath	Robust • Frail • Moderately demented • End of life
World Falls Guidelines risk	Low • Intermediate (fall + gait/balance problem) • High (injury, ≥2 falls, frailty, long lie, TLoC)
Ageism (3 components)	Stereotyping (think) • prejudice (feel) • discrimination (act)
Indian AMD requirements	Written • adult with capacity • two witnesses • Notary OR Gazetted Officer • two nominees

4. Mnemonics and Memory Hooks

Hook	Use
"MWK"	**M**edawar – **W**illiams – **K**irkwood: the three evolutionary theories, in order
"Stand → Stay → Stride"	Exercise sequence in the frail: strength/power → balance → endurance
"Quantity kept, quality lost"	Vaccine failure in the elderly: IgG normal, IgM/opsonisation defective
4 ways to beat immunosenescence	Adjuvant • higher dose • recombinant/conjugate • vaccinate the carers (cocooning)
"IL-6 → hepcidin → ferroportin block"	The whole pathogenesis of anaemia of chronic disease in one line
"Double-edged telomere"	Short = degenerative disease; long = cancer permitted
"Healthspan, not lifespan"	The correct verdict on sirtuins, resveratrol and most geroprotectors
"Function, not diagnosis"	The organising principle of healthy ageing and of geriatric assessment
"2018 → 2023"	India: right recognised (Common Cause) → procedure made workable (Modification Order)

The Twelve One-Liners — If You Read Nothing Else

1. Ageing is a failure to maintain homeostasis under physiological stress.
2. Chronological age is only a surrogate; gait speed predicts mortality better than hypertension.
3. Telomere shortening protects against uncontrolled division — at the expense of ageing.
4. Sirtuin modulation does not extend lifespan in mammals; it expands healthspan.
5. Plasma IL-6 rises with normal ageing and correlates inversely with functional ability.
6. In vaccine failure, antibody quantity is preserved but antibody quality is lost.
7. Older adults do not compensate after underfeeding — they never regain the lost weight.
8. Exercise is the only proven anti-ageing intervention; every geroprotector remains investigational.
9. Healthy ageing is defined by function, not by the absence of disease.
10. "Active" means continued participation — not merely being physically active.
11. Frailty is not a contraindication to robust exercise; it is the strongest indication for it.
12. Withdrawal of life-sustaining treatment is never withdrawal of care.

MD GERIATRIC MEDICINE — POSTGRADUATE EXAMINATION PREPARATION

Metabolic Bone Disease & Geriatric Rheumatology

High-yield 15-mark answers with Latest Updates (2023–present), Current Practice Update tables and Exam One-Liners

1. Osteoporosis — definition, pathogenesis, diagnosis and management including newer interventions; male and premenopausal osteoporosis
2. Predisposing factors, prevention and management of osteoporosis
3. DEXA scan
4. Antisclerostin antibodies in the treatment of osteoporosis
5. Paget's disease of bone
6. Osteoarthritis — pathogenesis, diagnosis and treatment
7. Temporal arteritis — diagnosis, clinical features, treatment and prognosis
8. Dermatomyositis in the elderly — presentation, comorbidities, investigations, treatment and prognosis
9. Diffuse idiopathic skeletal hyperostosis — presentation, investigations and treatment

Q1. Osteoporosis — Definition, Pathogenesis, Diagnosis and Management including Newer Interventions; Male and Premenopausal Osteoporosis

A. Definition and Burden

1. Osteoporosis is a **systemic skeletal disease** in which bone mass is reduced and the **microarchitecture of bone tissue deteriorates**, so that bone becomes fragile and fractures easily.

2. The **WHO densitometric definition** uses the DXA T-score: **normal ≥ −1.0**, **osteopenia −1.0 to −2.5**, **osteoporosis ≤ −2.5**, and **severe (established) osteoporosis ≤ −2.5 with a fragility fracture**.

3. One in three women and one in five men over 50 will sustain an osteoporotic fracture. About **15% of women at age 80 have had a hip fracture**, and hip fracture incidence rises **exponentially with age**.

4. Typical osteoporotic fractures are **vertebral, hip, distal radius (Colles) and proximal humerus**. Hip fracture carries the greatest burden of mortality and disability-adjusted life years.

5. Indian context: LASI wave-1 data show a very high burden of low bone mass; osteoporosis presents roughly **a decade earlier** than in the West, vitamin D deficiency exceeds 70%, and average dietary calcium intake is often **under 400 mg/day** against an ICMR-NIN requirement of 1000 mg/day.

B. Pathogenesis

6. Bone is continuously remodelled in **bone multicellular units (BMUs)** — **osteoclasts** resorb, **osteoblasts** form, and **osteocytes** couple the two processes. Osteoporosis results when resorption exceeds formation in each BMU.

7. Oestrogen normally increases osteoclast apoptosis, suppresses **RANKL**, and increases **osteoprotegerin (OPG)**, the decoy receptor for RANKL. Menopausal **hypo-oestrogenism prolongs the resorption phase and shortens the formation phase**, giving rapid postmenopausal bone loss.

8. The **RANK–RANKL–OPG axis** is the final common pathway for osteoclast formation and survival — the target of **denosumab**.

9. The **Wnt/β-catenin pathway** drives osteoblastic bone formation. **Sclerostin**, secreted by osteocytes, blocks it at LRP5/6 — the target of **romosozumab**.

10. Age-related contributors: **secondary hyperparathyroidism** from vitamin D and calcium deficiency, decline of the **GH/IGF-1 axis**, **sarcopenia and immobility** (reduced mechanical loading), and **inflammaging** (IL-1, IL-6, TNF-α).

11. Trabecular bone (spine, femoral neck, distal radius) is lost earlier and faster; increasing **cortical porosity** dominates later hip fracture risk.

C. Risk Factors and Secondary Causes

12. Non-modifiable: age, female sex, **prior fragility fracture** (strongest single predictor), parental hip fracture, early or surgical menopause, low BMI, Asian or Caucasian ethnicity.

13. Modifiable: smoking, alcohol above 3 units/day, immobility, low calcium and vitamin D, low protein intake, falls.

14. Secondary osteoporosis: glucocorticoids (commonest drug cause), rheumatoid arthritis, hyperthyroidism, primary hyperparathyroidism, hypogonadism, type 1 and type 2 diabetes, coeliac disease and IBD, aromatase inhibitors, androgen deprivation therapy, anorexia nervosa, transplantation, COPD, HIV, CKD-MBD, myeloma, anticonvulsants and long-term PPIs.

D. Diagnosis

15. DXA of the lumbar spine and hip is the reference standard. Screen **women ≥65 and men ≥70**, and younger patients with risk factors. USPSTF 2024 reaffirmed screening of women ≥65 and younger postmenopausal women at increased risk.

16. FRAX integrates clinical risk factors with or without BMD to give the **10-year probability of a major osteoporotic fracture and of hip fracture**. It can be modulated by **TBS, glucocorticoid dose, falls history, type 2 diabetes and hip axis length**. An **India-specific FRAX** model is available.

17. Vertebral fracture assessment (VFA) or lateral spine X-ray is indicated for **height loss over 4 cm**, new kyphosis, or unexplained back pain — **two-thirds of vertebral fractures are clinically silent**.

18. Baseline laboratory screen to exclude secondary causes: serum **calcium (mg/dL)**, phosphate, **alkaline phosphatase**, **creatinine (mg/dL)**, **25(OH)D (ng/mL)**, PTH, TSH, complete blood count, serum protein electrophoresis, **testosterone (ng/dL) in men**, coeliac serology and 24-hour urinary calcium.

19. Bone turnover markers — **s-CTX** (resorption) and **P1NP** (formation) — are used at **3–6 months** to confirm adherence and response, not to make the diagnosis.

E. Management

20. Universal measures for everyone: calcium **800–1000 mg/day** (diet preferred), protein **≥1 g/kg/day**, vitamin D **800–1000 IU/day**, daily weight-bearing and resistance exercise, balance training, smoking and alcohol reduction, **falls prevention**, and medication review using **Beers/STOPP-START and STOPPFall**.

21. Risk-stratified pathway (Kanis/ESCEO): *low risk* → reassurance, lifestyle, consider MHT or a SERM; *high risk* → **oral or IV bisphosphonate, or denosumab**; *very high or imminent risk* → **anabolic agent first, followed by an antiresorptive**.

22. Bisphosphonates: alendronate 70 mg weekly, risedronate 35 mg weekly (gastro-resistant formulation improves adherence), **zoledronic acid 5 mg IV yearly**. Zoledronate is first-line after hip fracture, reducing both re-fracture and mortality.

23. Denosumab 60 mg SC 6-monthly — anti-RANKL, safe in renal impairment, but **must never be stopped abruptly**: discontinuation causes **rebound multiple vertebral fractures**, so always follow with a bisphosphonate for 1–2 years.

24. Anabolic agents: teriparatide 20 mcg SC daily (up to 24 months), **abaloparatide** 80 mcg SC daily (18 months), **romosozumab** 210 mg SC monthly (12 months). All are self-limited and **must be followed by an antiresorptive** or the gains are lost.

25. Other options: raloxifene (reduces vertebral fracture and breast cancer risk, increases VTE and hot flushes), menopausal hormone therapy in early postmenopause, and **local osteo-enhancement procedure (LOEP)** in selected patients at high hip fracture risk. Calcitonin is now largely obsolete.

26. Drug holiday: consider after **5 years of oral or 3 years of IV bisphosphonate** in low-risk patients, reviewing yearly; **continue treatment in high-risk patients** and after any incident fracture. **No holiday is permissible with denosumab.**

27. Fracture Liaison Services (FLS) and the IOF **"Capture the Fracture"** initiative systematically identify and treat every patient after a fragility fracture; orthogeriatric co-management improves hip fracture outcomes. The **treatment gap remains large worldwide, especially in the very old.**

F. Male Osteoporosis

28. Men account for about **one-third of hip fractures worldwide** and have **higher post-fracture mortality** (approaching 30% at one year) than women, yet are far less often investigated or treated.

29. Secondary causes are present in 40–60% of men — hypogonadism (including androgen deprivation therapy for prostate cancer), alcohol excess, glucocorticoids, smoking, hypercalciuria, myeloma, COPD, hyperthyroidism and malabsorption. A **secondary work-up is mandatory in every man**.

30. Use the **same T-score threshold of ≤ −2.5** for diagnosis; ISCD recommends a **male reference database** for men.

31. Testosterone replacement (target **300–400 ng/dL** in older men, lower than the young adult target) increases BMD in genuinely hypogonadal men but has **no fracture-reduction data** — it is not a substitute for a bisphosphonate. **Prostate carcinoma is an absolute contraindication**; monitor PSA and haematocrit.

32. Alendronate, risedronate, zoledronate, denosumab, teriparatide, abaloparatide and romosozumab are all **approved for men**.

G. Premenopausal Osteoporosis

33. In premenopausal women, use the **Z-score, not the T-score**. A **Z-score ≤ −2.0** is reported as "below the expected range for age". Diagnosis requires a **fragility fracture or an identified secondary cause** together with low bone mass.

34. Causes: anorexia nervosa and the female athlete triad, glucocorticoids, coeliac disease and IBD, hyperthyroidism, primary hyperparathyroidism, idiopathic hypercalciuria, **pregnancy- and lactation-associated osteoporosis**, and idiopathic disease.

35. Treat the underlying cause first — restore nutrition, weight and menses, correct calcium and vitamin D, and reduce glucocorticoid exposure. Reserve drugs for continuing fractures or ongoing bone loss.

36. Bisphosphonates cross the placenta and have a very long skeletal half-life — counsel about contraception. **Teriparatide is preferred** when a drug is needed in a woman who may become pregnant.

Latest Updates (2023–Present)

- **ASBMR/BHOF goal-directed treatment position statement (JBMR 2024)** introduced **treat-to-target** for osteoporosis: aim for a **T-score above −2.5**. For a baseline lumbar spine T-score of −3.0, the probability of reaching target was **55% with alendronate alone, 81% with romosozumab→alendronate, and 93% with romosozumab→denosumab**.
- **Sequence matters.** Anabolic-first followed by antiresorptive is superior to the reverse. Transitioning **from a bisphosphonate to teriparatide causes total hip BMD to fall for at least 12 months**, and **denosumab→teriparatide causes hip BMD to stay below baseline for 2 years**.
- **ACP Living Guideline on osteoporosis** (updated on a rolling basis): bisphosphonates for most patients; **short-course anabolic therapy followed by a bisphosphonate for those at very high risk** — older age, prior fracture, chronic steroid use.
- **NOGG 2024 UK guideline** and NICE TA464: **IV zoledronic acid should be first-line after hip fracture**, because it reduces re-fracture risk and mortality and has better adherence than oral bisphosphonates.
- **RACGP / Healthy Bones Australia 2024–2025 guideline**: formal endorsement of **osteoanabolic therapy as first-line in treatment-naive very-high-risk patients**; romosozumab for 12 months or abaloparatide for 18 months, each mandatorily followed by an antiresorptive.
- **ISCD 2023 Official Positions**: updated DXA reporting, follow-up BMD testing and TBS application; **TBS formally**

endorsed as a FRAX adjustment; **opportunistic CT** accepted for case-finding (**L1 attenuation <100 HU** suggests osteoporosis, **>150 HU** suggests normal bone).

- **VITAL trial** confirmed that vitamin D supplementation in vitamin D–replete populations does **not** reduce cancer or cardiovascular events; the skeletal indication (800–1000 IU/day with calcium in deficient older people) stands.
- **Indian developments:** ISBMR position statements on vitamin D and osteoporosis management, the **ICMR-NIN 2024 RDA raising adult calcium to 1000 mg/day**, and increasing availability of teriparatide biosimilars and denosumab biosimilars in the Indian market.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
First-line in very high risk	Antiresorptive commonly first; anabolic "may be considered"	**Anabolic-first, then antiresorptive** is preferred (ASBMR/BHOF 2024, ACP living guideline, RACGP 2024)
Treatment target	Fracture-risk category based	**Goal-directed: achieve T-score above −2.5** (ASBMR/BHOF 2024)
After hip fracture	FLS referral, oral bisphosphonate	**IV zoledronate first-line** — reduces re-fracture *and* mortality (NOGG 2024)
Bone quality assessment	BMD ± FRAX; TBS mentioned	**TBS formally endorsed (ISCD 2023)**; opportunistic CT for case-finding
Abaloparatide	Limited availability	Now approved across Europe and Australia; a mainstream anabolic
Vitamin D	800–1000 IU/day, broad benefits implied	Skeletal benefit only; **no cancer/CVD benefit (VITAL)**; avoid high intermittent bolus doses (increase falls)

Exam One-Liners

- **T-score for diagnosis; Z-score for premenopausal women, men under 50 and children.**
- **Prior fragility fracture is the single strongest predictor** — and risk is highest in the first 2 years ("imminent risk").
- **Never stop denosumab without bisphosphonate cover** — rebound vertebral fractures.
- **Anabolic first, antiresorptive after** — never the reverse in very-high-risk patients.
- **Zoledronate 5 mg IV yearly is first-line after hip fracture** (reduces mortality).
- **40–60% of men with osteoporosis have a secondary cause** — always investigate.
- **Testosterone raises BMD but has no fracture data** — it is not an osteoporosis drug.

Q2. Predisposing Factors, Prevention and Management of Osteoporosis

A. Predisposing Factors

1. Constitutional: advancing age, female sex, postmenopausal state, **prior fragility fracture** (doubles future risk), parental hip fracture, small frame, and Caucasian or Asian ethnicity.

2. Nutritional: low dietary calcium (Indian intake frequently under 400 mg/day against a requirement of 1000 mg/day), **vitamin D deficiency**, low protein intake, low BMI **below 20 kg/m²**, and undernutrition.

3. Lifestyle: physical inactivity and immobilisation, **smoking**, alcohol above 3 units/day, excess caffeine, and inadequate sun exposure.

4. Endocrine: early or surgical menopause, hypogonadism in men, **hyperthyroidism including over-replacement with levothyroxine**, primary hyperparathyroidism, Cushing's syndrome, type 1 and type 2 diabetes, and acromegaly.

5. Gastrointestinal and nutritional disease: coeliac disease, inflammatory bowel disease, bariatric surgery, chronic liver disease, pancreatic insufficiency and anorexia nervosa.

6. Drugs: glucocorticoids (the commonest secondary cause), aromatase inhibitors, androgen deprivation therapy, anticonvulsants (phenytoin, carbamazepine), long-term heparin, proton pump inhibitors, SSRIs, thiazolidinediones and loop diuretics.

7. Chronic disease: rheumatoid arthritis, CKD-MBD, multiple myeloma, COPD, HIV and antiretroviral therapy, post-transplant state, and immobility from stroke or Parkinson's disease.

8. Geriatric amplifiers: sarcopenia, frailty, falls, poor vision, orthostatic hypotension, cognitive impairment and polypharmacy — these convert low bone density into an actual fracture. **Osteoporosis breaks bones only when the patient falls.**

B. Prevention

9. Primordial prevention: peak bone mass is attained by about **age 30**; adequate childhood and adolescent calcium, protein, sunlight and impact exercise determine the "bone bank" available for later life.

10. Nutrition: calcium **1000–1200 mg/day** preferably from diet (milk, curd, paneer, ragi, sesame, green leafy vegetables, small fish with bones), protein **≥1 g/kg/day**, and vitamin D **800–1000 IU/day** with **15–30 minutes of sun exposure** without sunblock.

11. Exercise: progressive **resistance and weight-bearing impact exercise at least 3 days a week**, plus **balance training such as Tai Chi**. Swimming and cycling do not load bone. Long-term exercise training reduces falls, fractures, hospitalisation and mortality.

12. Lifestyle modification: stop smoking, restrict alcohol to ≤2 units/day, and maintain BMI above 20 kg/m².

13. Falls prevention: home hazard modification, adequate lighting, grab rails, correct footwear, vision and hearing correction, treatment of orthostatic hypotension, **deprescribing fall-risk-increasing drugs using STOPPFall**, vitamin D correction, and hip protectors in selected institutionalised patients.

14. Case-finding and screening: DXA in women ≥65 and men ≥70, earlier with risk factors; **FRAX-based intervention thresholds** to decide who to treat. The **SCOOP trial** showed that community FRAX-based screening of older women **reduced hip fractures**.

15. Secondary prevention: actively identify and treat secondary causes. In **glucocorticoid therapy**, start bone protection with any dose in patients ≥70 or with prior fracture, and at ≥7.5 mg prednisolone daily for ≥3 months in others.

16. Tertiary prevention: Fracture Liaison Service after every fragility fracture, orthogeriatric care of hip fracture, early mobilisation, and rehabilitation to prevent post-fracture disability and institutionalisation.

C. Management (Rapid Recall)

17. Foundation for all: calcium, vitamin D, protein, exercise, falls prevention and medication review — continued even after drug therapy starts.

18. High risk: oral bisphosphonate (alendronate/risedronate), **IV zoledronate 5 mg yearly**, or **denosumab 60 mg 6-monthly**.

19. Very high or imminent risk: romosozumab, teriparatide or abaloparatide first, then an antiresorptive to consolidate the gain.

20. Special situations: denosumab or teriparatide in CKD (avoid bisphosphonates if eGFR <30–35 mL/min); raloxifene or MHT in younger postmenopausal women; vertebral augmentation only for refractory painful acute vertebral fracture.

21. Monitoring: DXA at 1–2 years on the **same machine**, interpreting change only if it exceeds the **least significant change** (about 3% spine, 5% hip); **CTX or P1NP at 3–6 months** for adherence; **annual height measurement** as a simple marker of new vertebral fracture.

22. Adherence is poor — under 50% at one year. Use gastro-resistant or less frequent formulations, patient education, group education programmes and reminder systems.

23. Indian service delivery: osteoporosis care is delivered through **NPHCE** geriatric clinics and district hospitals; hip fracture surgery is covered under **AB-PMJAY**; assistive devices come through **ADIP and Rashtriya Vayoshri Yojana**; and calcium/vitamin D are widely available in the essential medicines list.

Latest Updates (2023–Present)

- **SCOOP trial** remains the key evidence that **community-based FRAX screening reduces hip fractures** without increasing anxiety or overall costs; it underpins the case-finding approach in current guidelines.
- **NOGG 2024** restated intervention thresholds by FRAX category and confirmed **IV zoledronate as first-line after hip fracture**.
- **USPSTF 2024** reaffirmed DXA screening for women ≥65 and postmenopausal women under 65 at increased risk; evidence remains insufficient for routine screening of men.
- **ICMR-NIN 2024** raised the Indian RDA for calcium in adults to **1000 mg/day** (1200 mg in the elderly) and reiterated vitamin D sufficiency targets.
- **Exercise evidence strengthened:** meta-analyses confirm that long-term exercise training reduces falls, fractures, hospitalisations and mortality; **combined resistance plus balance training** is the most effective prescription in older adults.
- **Deprescribing as fracture prevention:** STOPPFall and the 2023 Beers update emphasise reducing benzodiazepines, Z-drugs, antipsychotics, anticholinergics and orthostatic agents as a direct fracture-prevention strategy.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Who to treat	T-score ≤ −2.5 or fragility fracture	**FRAX probability–based intervention thresholds**, with T-score as only one input
Screening strategy	Opportunistic case-finding	**Systematic community FRAX screening reduces hip fractures** (SCOOP)
Calcium target	800–1000 mg/day	**1000–1200 mg/day**, diet-first (ICMR-NIN 2024 for India)
Falls prevention	General advice	**Structured multifactorial programmes with formal deprescribing (STOPPFall)** as core fracture prevention
Post-fracture care	FLS recommended	FLS **plus** orthogeriatric co-management and mandatory bone protection within 120 days (NHFD KPI-7)

Exam One-Liners

- **Prevention has four levels:** primordial (peak bone mass), primary (calcium/vitamin D/exercise), secondary (treat secondary causes and glucocorticoid prophylaxis), tertiary (FLS after fracture).
- **Glucocorticoids are the commonest drug cause** — bone protection from day one in the old or previously fractured.
- **Swimming and cycling do not build bone** — impact and resistance exercise do.
- **The SCOOP trial** = community FRAX screening reduces hip fractures.
- **Height loss over 4 cm** = look for a silent vertebral fracture.

Q3. DEXA Scan

*(Note: the internationally correct abbreviation is **DXA**, not DEXA — formalised in the ISCD 2023 Official Positions.)*

A. Principle

1. DXA (dual-energy X-ray absorptiometry) passes **two X-ray beams of different photon energies** through the region of interest. Bone and soft tissue attenuate the two energies differently, allowing the machine to subtract soft tissue and compute **bone mineral content (g)** and **areal bone mineral density (g/cm²)**.

2. It is a **two-dimensional areal measurement**, so it is influenced by bone size — **small bones read falsely low** and **large bones falsely high**. It does not measure true volumetric density.

3. Radiation dose is very low (roughly 1–10 microsievert per site), less than one day of natural background radiation and far less than a chest radiograph. Scanning takes 10–20 minutes.

B. Reporting

4. T-score = the number of standard deviations from the **mean peak bone mass of a young healthy adult of the same sex**. Used in **postmenopausal women and men aged ≥50**.

5. Z-score = standard deviations from the **mean for age, sex and ethnicity-matched controls**. Used in **premenopausal women, men under 50, and children**. A Z-score **≤ −2.0** is reported as "below the expected range for age".

6. WHO categories (T-score): normal **≥ −1.0**; **osteopenia/low bone mass −1.0 to −2.5**; **osteoporosis ≤ −2.5**; **severe or established osteoporosis ≤ −2.5 plus a fragility fracture**.

7. Standard sites: PA lumbar spine (L1–L4) and **proximal femur (femoral neck and total hip)**. The **lowest T-score of the valid sites** is used for diagnosis.

8. The **33% (one-third) radius** is the accepted third site — used when spine and hip are unmeasurable or invalid: weight above table limit, bilateral hip replacement, or **hyperparathyroidism** (cortical bone is preferentially lost).

9. Vertebral exclusion rules: exclude vertebrae that are fractured, have focal structural change, or differ by **more than 1.0 T-score** from adjacent vertebrae; **at least two evaluable vertebrae are required**, otherwise the spine is not reportable.

C. Indications

10. Women **≥65** and men **≥70**; younger postmenopausal women and men aged 50–69 with risk factors; **any adult with a fragility fracture**; glucocorticoid therapy or any disease or drug associated with bone loss; radiographic osteopenia or vertebral deformity; and monitoring of osteoporosis treatment.

D. What Else DXA Can Provide

11. Vertebral fracture assessment (VFA) — lateral spine imaging at the same sitting at very low dose, detecting **clinically silent vertebral fractures** that immediately upgrade the patient to treatment.

12. Trabecular bone score (TBS) — grey-level texture analysis of the lumbar spine DXA image reflecting **trabecular microarchitecture**. It predicts fracture **independently of BMD** and can adjust FRAX probability.

13. Whole-body DXA measures **appendicular lean mass**, used to confirm low muscle mass in the diagnosis of **sarcopenia** (EWGSOP2, AWGS 2019).

14. Hip structural analysis and hip axis length add geometric information to fracture prediction; DXA also gives **body composition** and can screen for **abdominal aortic calcification**.

E. Pitfalls, Especially in the Elderly

15. Degenerative change falsely raises lumbar spine BMD — osteophytes, facet joint sclerosis, vertebral compression fracture, scoliosis and **aortic calcification**. In older people the **hip is the more reliable site**.

16. Artefacts: recent oral or intravenous contrast, radionuclide studies, calcium tablets in the gut, surgical clips, spinal instrumentation, vertebroplasty cement, coins or metal in clothing, and previous fractures.

17. Technical/patient factors: poor positioning, severe kyphosis or inability to lie flat, tremor or movement, obesity beyond the table limit, and inconsistent analysis between operators.

18. DXA **cannot distinguish osteoporosis from osteomalacia** — both show low BMD. Interpretation must always be with biochemistry.

F. Monitoring

19. Repeat DXA on **the same machine, with the same software and technologist**, and compare the **absolute BMD in g/cm², not T-scores**.

20. Change is meaningful only if it exceeds the **least significant change (LSC)**, which each centre must calculate — typically about **3% at the lumbar spine and 5% at the hip**.

21. Usual interval is **1–2 years on treatment**, longer (2–5 years) if stable or untreated. ISCD 2023 emphasises that the **clinical context prompting the repeat** should drive the interval rather than a fixed rule.

Latest Updates (2023–Present)

- **ISCD 2023 Official Positions** (9th Position Development Conference, Northbrook): new positions on **DXA reporting, follow-up BMD testing, bilateral hip reporting and TBS application**, and the formal statement that the correct term is **"DXA — not DEXA"**.
- **TBS: 2023 ISCD Official Positions** — use **L1–L4 without exclusions** for TBS; TBS is most likely to change management in patients **aged ≥40 who sit close to the pharmacological intervention threshold**; TBS **version 4.0** now corrects directly for soft tissue thickness, improving accuracy in obesity.
- **Opportunistic CT screening:** an **L1 attenuation below 100 Hounsfield Units** suggests osteoporosis and **above 150 HU** suggests normal bone density — usable to trigger formal bone health assessment, provided machine-specific cut-offs and scanner stability are validated.
- **QCT equivalence:** femoral neck and total hip T-scores derived from **2D projections of QCT data are now accepted as equivalent to DXA T-scores** for WHO diagnosis; spinal trabecular QCT predicts vertebral fracture at least as well as AP spine DXA in postmenopausal women.
- **REMS (radiofrequency echographic multi-spectrometry)** — a radiation-free ultrasound-based method giving spine and hip BMD, of particular interest for **resource-limited and rural Indian settings** and for pregnancy, though not yet a WHO-endorsed diagnostic standard.
- **USPSTF 2024** reaffirmed DXA screening for women ≥65 and younger postmenopausal women at increased risk; evidence remains insufficient for men.
- **Artificial intelligence** is increasingly applied to automated DXA analysis and to **opportunistic detection of vertebral fractures on routine chest X-rays and CT scans**.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Terminology	"DEXA" used interchangeably	**DXA is the correct term** (ISCD 2023)
Diagnostic anchor	T-score ≤ −2.5 alone	**BMD combined with FRAX ± TBS, VFA and fracture history**; most fractures occur in people with a T-score better than −2.5
Microarchitecture	Not routinely assessed	**TBS formally endorsed** as a FRAX adjustment (ISCD 2023)
Alternative modalities	DXA only	**QCT-derived hip T-scores equivalent**; **opportunistic CT (L1 <100 HU)** and **REMS** now recognised
Repeat interval	Fixed 1–2 years	**Clinical context–driven**, interpreted against the centre's own LSC (ISCD 2023)

Exam One-Liners

- **DXA measures areal, not volumetric, density** — small bones read falsely low.
- **Lowest T-score of spine, femoral neck or total hip** makes the diagnosis.
- **Degenerative disease and aortic calcification falsely raise spine BMD** — trust the hip in the elderly.
- **Need at least two evaluable vertebrae**; exclude any differing by more than 1.0 T-score.
- **Compare g/cm², not T-scores**, when monitoring; change must exceed the LSC.
- **Z-score, not T-score, in premenopausal women and men under 50.**

Q4. Antisclerostin Antibodies in the Treatment of Osteoporosis

A. The Biology of Sclerostin

1. Sclerostin is a glycoprotein encoded by the **SOST gene** and secreted almost exclusively by **osteocytes** — the mechanosensing cells buried within bone.

2. It binds the **LRP5/6 co-receptors** and thereby **blocks canonical Wnt/β-catenin signalling**, the master pathway for osteoblast differentiation and bone formation. Sclerostin is therefore a **physiological brake on bone formation**.

3. Sclerostin also **increases RANKL and reduces osteoprotegerin**, so blocking it reduces bone resorption as well as increasing formation.

4. Human proof of concept: loss-of-function mutations in *SOST* cause **sclerosteosis** and **van Buchem disease** — conditions of very high bone mass with strong, fracture-resistant bone, which established sclerostin as a drug target.

5. Mechanical loading and PTH suppress sclerostin; **immobilisation, glucocorticoids and unloading increase it** — this explains disuse osteoporosis at a molecular level.

B. The Drug — Romosozumab

6. Romosozumab is a **humanised IgG2 monoclonal antibody against sclerostin** and is currently the only anti-sclerostin agent in clinical use for osteoporosis.

7. It has a **unique "dual effect": it increases bone formation and simultaneously decreases bone resorption**. This is different from teriparatide and abaloparatide, which increase both formation and resorption.

8. Dose: 210 mg subcutaneously once monthly (given as two 105 mg injections) for 12 months only. The anabolic window is **self-limited** — P1NP rises sharply then wanes by 9–12 months, while CTX stays suppressed.

9. It **must be followed by an antiresorptive** (a bisphosphonate or denosumab); otherwise the BMD gain is rapidly lost.

10. BMD gains are the **largest of any currently available agent** — roughly **13% at the lumbar spine and 6% at the total hip over 12 months**, exceeding alendronate and teriparatide.

C. Trial Evidence

11. FRAME (postmenopausal osteoporosis): romosozumab versus placebo for 12 months, then denosumab in both arms — **73% reduction in new vertebral fractures at 12 months**, with benefit maintained at 24 months.

12. ARCH (high fracture risk): romosozumab for 12 months then alendronate, versus alendronate throughout — **48% fewer new vertebral fractures, 27% fewer clinical fractures and 38% fewer hip fractures at 24 months**. This trial also generated the cardiovascular safety signal.

13. STRUCTURE: in women already treated with bisphosphonates, romosozumab produced **greater hip and spine BMD gains than teriparatide** — relevant because prior antiresorptive use blunts teriparatide's hip response.

14. BRIDGE: demonstrated efficacy in **men with osteoporosis**.

D. Safety

15. Boxed warning — cardiovascular risk. ARCH showed an **excess of major adverse cardiovascular events** (myocardial infarction, stroke, cardiovascular death) in the romosozumab arm. It is **contraindicated within 12 months of a myocardial infarction or stroke**, and cardiovascular risk must be assessed before starting.

16. Hypocalcaemia — correct calcium and vitamin D before starting and supplement throughout; use with caution in **CKD**, where the risk is higher.

17. Other adverse effects: injection-site reactions, arthralgia, headache, hypersensitivity and, rarely, **osteonecrosis of the jaw and atypical femoral fracture** (class effects of potent antiresorptive activity). A dental review before starting is prudent.

E. Place in Therapy

18. Indicated for **postmenopausal women (and men) at very high or imminent fracture risk** — a recent fracture, multiple vertebral fractures, a very low T-score, fractures occurring while on antiresorptive therapy, or high-dose glucocorticoid-induced osteoporosis.

19. Anabolic-first sequencing gives the best outcome. Starting with romosozumab and following with denosumab produces the **highest probability of reaching a target T-score above −2.5**; the reverse sequence (antiresorptive first) blunts the anabolic response, particularly at the hip.

20. In the Indian context, cost and availability remain the principal barriers. **Teriparatide (including biosimilars) is the more accessible anabolic agent**, with romosozumab reserved for selected very-high-risk patients in tertiary centres.

Latest Updates (2023–Present)

- **ASBMR/BHOF goal-directed treatment statement (JBMR 2024)**: for a baseline lumbar spine T-score of **−3.0**, the probability of achieving a T-score above −2.5 was **55% with alendronate alone, 81% with romosozumab→alendronate and 93% with romosozumab→denosumab**. For a starting T-score of **−3.5**, the corresponding figures were **11%, 46% and 67%** — a compelling case for anabolic-first therapy in severe disease.

- **First-line approval in treatment-naive patients:** the **Australian PBS (2025)** now funds romosozumab for 12 months (and abaloparatide for 18 months) in **high-risk patients with no prior antiresorptive or anabolic exposure** — a formal shift away from "use only after antiresorptive failure".
- **ACP Living Guideline and RACGP/Healthy Bones Australia 2024** both endorse **short-course anabolic therapy followed by a bisphosphonate** for very high fracture risk, explicitly naming romosozumab.
- **Transition data**: moving **from a bisphosphonate to romosozumab still improves total hip BMD and hip strength**, although less markedly than in treatment-naive patients — unlike teriparatide, where hip BMD actually falls after prior antiresorptive use. This makes romosozumab the **preferred anabolic after antiresorptive therapy**.
- **Cardiovascular safety**: accumulating real-world and post-marketing data have been broadly reassuring, but the **boxed warning stands** and pre-treatment cardiovascular risk assessment is now routine practice.
- **Setrusumab (BPS-804)**, a second anti-sclerostin antibody, is in **phase 3 development for osteogenesis imperfecta** (ORBIT/COSMIC trials), not for age-related osteoporosis — a useful point of distinction in vivas.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Position of romosozumab	Listed as an anabolic option for very high risk	**Preferred first-line anabolic** in treatment-naive very-high-risk patients (RACGP 2024, PBS 2025)
Mechanism framing	Grouped with anabolic agents	Emphasis on its **unique dual action** — increases formation *and* decreases resorption
Sequencing	"Anabolic followed by antiresorptive"	Quantified: **romosozumab→denosumab gives the highest probability of reaching a T-score target** (ASBMR/BHOF 2024)
Anabolic after prior bisphosphonate	Not differentiated	**Romosozumab preferred over teriparatide** — teriparatide causes transient hip BMD loss (STRUCTURE)
Cardiovascular safety	Not emphasised	**Boxed warning**; contraindicated within 12 months of MI or stroke

Exam One-Liners

- **Sclerostin is made by osteocytes, blocks Wnt at LRP5/6, and inhibits bone formation.**
- **Sclerosteosis and van Buchem disease** = natural human knockouts of *SOST*, with high bone mass.
- **Romosozumab is the only anti-sclerostin drug in clinical use** — 210 mg SC monthly for **12 months only**.
- **Dual effect:** bone formation up, bone resorption down.
- **FRAME** = 73% fewer vertebral fractures; **ARCH** = superior to alendronate but with the **cardiovascular signal**.
- **Always follow with an antiresorptive**, or the gain is lost.
- **Contraindicated within 12 months of MI or stroke.**

Q5. Paget's Disease of Bone

A. Definition and Epidemiology

1. Paget's disease of bone (**osteitis deformans**) is a **focal disorder of greatly accelerated and disorganised bone remodelling**, affecting one bone (**monostotic**) or several (**polyostotic**) — but never the entire skeleton, which distinguishes it from metabolic bone disease.

2. It is **rare before the age of 40** and its prevalence **rises steeply with age** (about 1–3% of people over 55 in the UK), with a **male predominance**.

3. Geographically it is common in the **United Kingdom, Western Europe, Australia and North America** and **distinctly rare in India, Asia, Scandinavia and Africa** — but it does occur in Indians and should not be dismissed.

4. Both **prevalence and severity have fallen worldwide** over recent decades, which strongly suggests a **waning environmental trigger**.

B. Aetiology and Pathogenesis

5. Genetic: mutations in **SQSTM1 (p62)**, particularly **P392L**, are found in **40–50% of familial** and **5–10% of sporadic** cases, inherited in an **autosomal dominant** pattern with incomplete penetrance. Other genes include *OPTN*, *TNFRSF11A* and *VCP*.

6. Environmental: paramyxovirus (measles, canine distemper, respiratory syncytial virus) nuclear inclusions have been described in pagetic osteoclasts but remain **unproven**. Other proposed factors are low dietary calcium in youth, repetitive mechanical loading, and environmental toxins.

7. The **primary abnormality is in the osteoclast** — pagetic osteoclasts are **large, multinucleated, hyperactive and hypersensitive to vitamin D and RANKL**, producing intense focal resorption.

8. This is followed by **frantic, disorganised osteoblastic repair**, laying down **structurally abnormal woven bone** with a **"mosaic" pattern of irregular cement lines**, marked **hypervascularity** and **marrow fibrosis**. The bone is bigger and denser but **mechanically weak**.

9. Three phases: (i) **osteolytic** — resorption predominates; (ii) **mixed osteolytic–osteoblastic**; (iii) **osteosclerotic or "burnt-out"** — dense sclerotic bone with low turnover.

C. Clinical Features

10. Up to 70–80% are asymptomatic, detected incidentally through an **unexplained isolated rise in alkaline phosphatase** or an X-ray performed for another reason.

11. Commonest sites in descending order: pelvis > lumbar spine > femur > thoracic spine > sacrum > skull > tibia > humerus.

12. Bone pain is the commonest symptom — deep, boring, **worse at rest and at night**, unlike mechanical pain; the overlying skin may be **warm** because of hypervascularity.

13. Deformity: anterolateral **bowing of the tibia ("sabre tibia")** and femur, kyphosis, **frontal bossing with increasing hat size**, and **secondary osteoarthritis** of the hip and knee from altered joint mechanics — often the actual cause of pain.

14. Skull involvement: deafness (both **conductive** from ossicular involvement and **sensorineural** from cochlear capsule and VIIIth nerve compression) — Paget's disease is a listed cause of hearing loss in the elderly and should be evaluated radiologically and with alkaline phosphatase. Also tinnitus, headache, **platybasia and basilar invagination** leading to hydrocephalus and brainstem compression.

15. Spinal involvement: back pain, **spinal stenosis**, radiculopathy, and rarely cord ischaemia from a vascular "steal" phenomenon.

16. Complications: pathological and fissure fractures, **high-output cardiac failure** (extensive disease, now rare), **hypercalcaemia of immobilisation**, hypercalciuria and renal stones, and **osteosarcoma in under 1%** — suspect this if there is **new severe pain, a soft-tissue mass, or a sudden further rise in ALP**; the prognosis is dismal.

D. Investigations

17. Serum total alkaline phosphatase is the key screening and monitoring test, raised roughly in proportion to disease activity and extent. **Calcium, phosphate and PTH are characteristically normal.**

18. Biochemical differentiation of metabolic bone disease:

Disease	Calcium	Phosphate	Alkaline phosphatase	PTH
Paget's disease	Normal / high	Normal / high	**High**	Normal
Osteoporosis	Normal	Normal	Normal	Normal / high
Osteomalacia	Low / normal	**Low**	High / normal	**High**
Primary hyperparathyroidism	**High**	Low / normal	High / normal	**High**
Hyperthyroidism	High	High	High / normal	Low

19. If ALP is normal or liver disease coexists, use **bone-specific ALP or P1NP**; **urinary NTX/CTX** reflect resorption. Any older person with a **borderline low calcium and a raised ALP** should also be assessed for **vitamin D deficiency**.

20. Plain radiography is diagnostic — cortical thickening, coarse trabeculae, bone expansion, and mixed lysis with sclerosis. Classic signs: **"osteoporosis circumscripta"** of the skull, **"cotton-wool" skull**, the **"blade of grass" or "flame-shaped" lytic front** advancing along a long bone, **"picture-frame" vertebra**, **"ivory" vertebra**, and **pseudofractures on the convex (tension) surface**.

21. Radionuclide bone scan (Tc-99m MDP) is the **best test to map the full extent of disease** — intense uniform uptake in affected bones. It is **more sensitive but less specific** than X-ray, so every hot spot needs radiographic confirmation.

22. CT and MRI are reserved for suspected complications — spinal stenosis, basilar invagination, or **sarcomatous transformation**.

E. Management

23. Asymptomatic patients with limited disease at low-risk sites may simply be observed with periodic alkaline phosphatase measurement.

24. Indications for bisphosphonate therapy: bone pain, **before elective surgery at a pagetic site** (to reduce hypervascularity and blood loss), **hypercalcaemia of immobilisation**, and **disease at high-risk sites** — skull, spine, weight-bearing long bones and bone adjacent to major joints.

25. Zoledronic acid 5 mg as a single intravenous infusion is the treatment of choice. It normalises ALP in most patients and produces **remission lasting several years**, and is more effective than pamidronate or risedronate at normalising ALP.

26. Alternatives: risedronate 30 mg daily for 2 months, alendronate 40 mg daily for 6 months, or IV pamidronate. Give **calcium and vitamin D before and after** to prevent hypocalcaemia, and warn about the **transient flu-like acute-phase reaction** (about 40% after the first infusion, much milder subsequently).

27. Calcitonin is now second-line, reserved for patients in whom bisphosphonates are contraindicated. **Denosumab** has been used off-label in selected refractory cases.

28. Adjunctive measures: analgesics and NSAIDs for pain, **walking aids and shoe raises** for deformity and leg-length discrepancy, **hearing aids and audiological rehabilitation**, physiotherapy, and falls prevention.

29. Surgery for fracture fixation, **joint replacement in secondary osteoarthritis**, osteotomy for deformity, and decompression for spinal stenosis or basilar invagination. **Pre-treat with a bisphosphonate to reduce operative bleeding.**

30. Monitoring: ALP at 3–6 months, then 6–12 monthly. Retreat if pain recurs or ALP rises, but **not within 12 months** of neridronate or zoledronate.

Latest Updates (2023–Present)

- **PRISM and PRISM-EZ (long-term randomised trials)**: **intensive bisphosphonate therapy aimed at normalising alkaline phosphatase gave no advantage** over symptom-driven treatment for fractures, orthopaedic procedures, quality of life or hearing loss. This is the single most important change in modern practice — the goal is **symptom control, not biochemical normalisation**, in established disease.
- **ZiPP randomised trial (Ann Rheum Dis 2024; NIHR 2024)**: prophylactic zoledronic acid in **asymptomatic SQSTM1 mutation carriers** reduced the development of new bone lesions on imaging but did **not** improve clinically significant outcomes. **Genetic testing with pre-emptive treatment is therefore not routine practice.**
- **SIOMMMS 2024 (Italian) guideline**: radiograph the symptomatic site first, then use a **radionuclide bone scan to define extent**; favour **intravenous bisphosphonates, especially zoledronic acid, for retreatment**; retreat only after at least 12 months; use analgesics, NSAIDs or neuropathic agents when antiresorptives fail to control pain; and **re-image any site with worsening pain** to exclude fracture, osteoarthritis or neoplastic degeneration.
- **Endocrine Society / JBMR clinical guideline** reaffirms a **single 5 mg zoledronate infusion as the standard of care** and recommends radionuclide bone scanning for extent assessment.
- **Epidemiological trend:** the continuing decline in incidence and severity of Paget's disease worldwide reinforces the environmental-trigger hypothesis and means the condition is now often seen in a milder, monostotic form.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Treatment goal	Suppress bone turnover, normalise ALP	**Symptom control**; biochemical normalisation does not improve outcomes (**PRISM-EZ**)
Drug of choice	Bisphosphonates generally; calcitonin listed as an option	**Single 5 mg IV zoledronate** is standard first-line; **calcitonin second-line only**
Assessing extent	Plain radiography	**Radionuclide bone scan for extent**, X-ray for confirmation of each hot spot
Genetic testing	Not discussed	**SQSTM1 testing available**, but prophylactic treatment of carriers is not justified (**ZiPP 2024**)
Retreatment	Not specified	Only if pain or ALP recurs, and **not within 12 months** of zoledronate/neridronate (SIOMMMS 2024)

Exam One-Liners

- **Focal, never generalised** — that separates Paget's from metabolic bone disease.
- **Biochemistry: high ALP with normal calcium, phosphate and PTH.**
- **The osteoclast is the primary abnormal cell**; SQSTM1/p62 is the key gene.
- **X-ray for diagnosis; bone scan for extent.**
- **"Blade of grass" lytic front, "cotton-wool" skull, "picture-frame" vertebra, sabre tibia.**
- **Single 5 mg IV zoledronate is the treatment of choice.**
- **New severe pain + soft-tissue mass + rising ALP = osteosarcoma until proved otherwise.**
- **PRISM-EZ: treat symptoms, not the alkaline phosphatase.**

Q6. Osteoarthritis — Pathogenesis, Diagnosis and Treatment

A. Definition and Epidemiology

1. Osteoarthritis is a **whole-joint disease** characterised by **focal hyaline cartilage destruction with joint space loss, subchondral sclerosis and osteophyte formation**, together with synovial hypertrophy, capsular and ligamentous change and peri-articular muscle weakness.

2. It is the **most common joint disease among older adults** and the **major cause of knee, hip and back pain**. Almost **60% of Americans aged 65 and over report arthritis or chronic joint symptoms**, and musculoskeletal disorders are the **commonest cause of disability in old age**.

3. In India, symptomatic knee osteoarthritis affects roughly **25–30% of adults over 60**, with a female preponderance; **deep squatting, floor-sitting, stair use in unlifted buildings and manual labour** are important local contributors.

4. OA is **not by definition inflammatory**, although **synovial hypertrophy and joint effusions are typical** — a key distinction from rheumatoid arthritis.

B. Risk Factors

5. Systemic: age, **female sex** (especially post-menopause), **obesity**, genetic predisposition, and **metabolic syndrome** (the "metabolic OA" phenotype).

6. Local and mechanical: previous joint injury or surgery (meniscectomy), **malalignment** (varus knee), joint dysplasia, occupational kneeling, squatting and lifting, **quadriceps weakness**, and **proprioceptive loss**.

C. Pathogenesis

7. OA is **not simply "wear and tear"**. Progression revolves around a **complex interplay of chondrocyte dysregulation of the extracellular matrix, genetic influences, local mechanical factors and inflammation**.

8. Abnormal mechanical loading activates chondrocytes to release **matrix metalloproteinases (especially MMP-13)** and **aggrecanases (ADAMTS-4 and -5)**, which degrade **type II collagen and aggrecan faster than they can be resynthesised**.

9. IL-1β, TNF-α, IL-6, nitric oxide and prostaglandin E2 from chondrocytes and synovium amplify catabolism; **adipokines such as leptin** link obesity to cartilage damage **beyond simple mechanical load**.

10. Subchondral bone shows increased turnover, **sclerosis, bone marrow lesions and cysts**; **osteophytes** form at the joint margin by endochondral ossification, representing an attempted repair response.

11. Pain in established OA is **mixed** — nociceptive from subchondral bone, synovium, capsule and entheses (cartilage itself is aneural), **plus peripheral and central sensitisation**. This explains the **poor correlation between radiographic severity and symptoms**.

12. A **vicious cycle operates in older people**: joint pain → activity avoidance → muscle weakness and joint instability → further injury and pain → loss of cardiorespiratory fitness → **an unfit, inactive, arthritic person with compromised independence**.

D. Clinical Features and Diagnosis

13. Diagnosis is clinical: activity-related joint pain, **morning stiffness lasting minutes rather than hours**, gelling after inactivity, crepitus, restricted range of movement, bony enlargement, and minimal warmth or erythema.

14. Distinguishing OA from inflammatory arthritis:

Clinical feature	Osteoarthritis	Inflammatory arthritis
Duration of stiffness	**Minutes**	**Hours**
Pain	Usually with activity	Occurs even at rest and at night
Fatigue	Unusual	Common
Swelling	Common, little synovial reaction	Very common, with synovial proliferation and thickening
Erythema and warmth	Unusual	Common

15. Typical joints: knees, hips, first carpometacarpal joint, **distal interphalangeal (Heberden's nodes)** and **proximal interphalangeal (Bouchard's nodes)**, first metatarsophalangeal joint (**hallux rigidus**), midfoot, and cervical and lumbar facet joints.

16. Foot OA affects one in six people over 50, with two phenotypes: **isolated first MTP joint OA (hallux rigidus)** — localised pain, stiffness and a dorsal exostosis — and a **polyarticular midfoot form** presenting as dorsal foot pain worse on prolonged standing and walking on uneven ground.

17. Plain radiography remains the main modality — **joint space narrowing, subchondral sclerosis, osteophytes and subchondral cysts** (Kellgren–Lawrence grades 0–4). **MRI and ultrasound are more accurate and comprehensive** measures of joint change but are rarely needed for diagnosis.

18. Blood tests are normal. ESR, CRP, rheumatoid factor and anti-CCP are used only to exclude alternatives. **Aspirate the joint** if there is an effusion with warmth, to exclude **sepsis or crystal arthropathy** — remember that gout and pseudogout commonly coexist with OA in the elderly.

E. Treatment

19. Non-pharmacological management should be the focus of intervention: patient education and self-management, **weight loss**, **land-based and aquatic exercise**, **quadriceps strengthening**, **daily range-of-motion exercise**, local ice and heat, and acupuncture. Group exercise improves poor compliance by adding a social component.

20. Assistive devices and biomechanics: a **cane held in the contralateral hand** reduces load on an arthritic hip; **cane length should equal the distance from the wrist crease to the floor**, and **stick rubbers must be checked and replaced** to avoid falls. For knee pain the patient should experiment with the cane in either hand. **Moulded splints** protect arthritic hand joints; **foot orthoses and shoe-stiffening inserts** are effective for first MTP and midfoot OA.

21. Time analgesia before activity — OA pain is exacerbated by exercise, so medication is best given beforehand rather than afterwards.

22. Pharmacological therapy is symptomatic: topical NSAIDs first for knee and hand OA in older adults (best benefit-to-risk ratio); paracetamol has modest effect; **oral NSAIDs at the lowest dose for the shortest duration**, with PPI cover and careful attention to renal, cardiac, GI and Beers-criteria risk.

23. Intra-articular corticosteroid gives short-term relief of a flare (weeks). **Viscosupplementation with hyaluronic acid and nutraceuticals (glucosamine, chondroitin) have not shown significant pain benefit** beyond placebo, and **vitamin D neither reduces pain nor repairs structural damage**.

24. Duloxetine is useful where central sensitisation dominates. **Avoid long-term opioids** in older adults. Refractory pain is best managed by a **multidisciplinary pain team** with anaesthetic, psychological and physiotherapy input.

25. Surgery: total knee or hip arthroplasty is reserved for severe symptomatic disease failing conservative treatment; patients should be **medically stable, encouraged to lose weight and strengthen relevant muscles before operation**. **Arthroscopic lavage and debridement have little evidence of efficacy** and are not recommended for degenerative knee disease.

26. Optimal management usually requires **several modalities combined**, and the best combination **varies from patient to patient** — a genuinely individualised, function-focused approach.

Latest Updates (2023–Present)

- **STEP 9 trial (NEJM 2024)** — 68 weeks, 407 participants with obesity and moderate knee OA: **semaglutide 2.4 mg weekly** produced a mean weight change of **−13.7% versus −3.2%** on placebo, a **WOMAC pain reduction of 41.7 versus 27.5 points**, and significantly better physical function and SF-36 scores. Both arms received diet and exercise counselling.
- A **2025 network meta-analysis** established a therapeutic threshold of about **7–10% weight loss** as necessary for meaningful symptom improvement in knee OA, and **weight loss of ≥7.5% is associated with roughly a 31% lower risk of knee replacement**.
- **GLP-1 receptor agonists are not yet on-label for osteoarthritis** and do not appear in the current OARSI or ACR guidelines; ACR Convergence 2025 sessions emphasised that current data show **symptom improvement, not proven structural joint repair**.
- **NICE NG226 (current UK guideline)**: diagnose knee OA **clinically without imaging** in people aged 45 or over with activity-related pain and either no morning stiffness or stiffness lasting under 30 minutes; offer **therapeutic exercise and weight management as core treatment**; **use topical NSAIDs before oral NSAIDs**; and **do not offer glucosamine or intra-articular hyaluronan**.
- **ACR/Arthritis Foundation and OARSI** continue to **strongly recommend both aquatic and land-based aerobic and resistance exercise** and weight loss as core therapy, and recommend against most passive modalities.
- **Repeated intra-articular corticosteroid injections** have been linked to **accelerated cartilage loss on MRI** — limit frequency (commonly no more than 3–4 per joint per year).
- **Disease-modifying OA drugs remain investigational**: **lorecivivint** (Wnt pathway inhibitor), **sprifermin** (FGF-18), and **anti-NGF antibodies such as tanezumab**, which reduced pain but caused **rapidly progressive osteoarthritis** and were not approved.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Concept of disease	Cartilage destruction with secondary changes	**Whole-joint disease** with low-grade inflammation, subchondral bone lesions and central sensitisation
First-line analgesia	Paracetamol and oral NSAIDs	**Topical NSAIDs first** in older adults; paracetamol relegated to modest adjunct (NICE NG226)
Weight management	Advised generally	**Quantified target: 7–10% weight loss**; **semaglutide** shown to reduce WOMAC pain (STEP 9)
Diagnosis	Radiography central	**Clinical diagnosis without imaging** in typical cases aged ≥45 (NICE NG226)
Glucosamine / hyaluronic acid	“Used, evidence limited”	**Explicitly not recommended** (NICE NG226)
Arthroscopy	Considered when inflammation present	**Not recommended** for degenerative knee disease

Exam One-Liners

- **OA is a whole-joint disease, not just wear and tear.**
- **Stiffness in minutes = OA; stiffness in hours = inflammatory arthritis.**
- **Heberden’s = DIP; Bouchard’s = PIP.**
- **Cartilage has no nerves** — pain comes from bone, synovium, capsule and central sensitisation.
- **Cane in the contralateral hand; length = wrist crease to floor.**
- **Exercise and weight loss are the only interventions with both symptom and structural benefit.**
- **STEP 9:** semaglutide reduced knee OA pain by 41.7 WOMAC points with 13.7% weight loss.
- **Glucosamine, chondroitin, hyaluronan and arthroscopic debridement: no proven benefit.**

Q7. Temporal Arteritis (Giant Cell Arteritis) — Diagnosis, Clinical Features, Treatment and Prognosis

A. Definition and Epidemiology

1. Giant cell arteritis is a **granulomatous large- and medium-vessel vasculitis** affecting the **aorta and its extracranial branches**, with a predilection for the **superficial temporal, ophthalmic, posterior ciliary and vertebral arteries**.

2. It is the **commonest primary systemic vasculitis of older people**. It **virtually never occurs before the age of 50** — age ≥50 is an entry criterion for classification — and incidence peaks between **70 and 80 years**. **Female to male ratio is about 2–3:1.** It is far commoner in Northern Europeans than in Indians.

3. GCA overlaps closely with **polymyalgia rheumatica**: about **40–50% of GCA patients have PMR features** and **15–20% of PMR patients develop GCA**.

B. Pathogenesis

4. Dendritic cell activation in the arterial **adventitia** recruits **CD4+ T cells**; **Th1 (interferon-γ)** and **Th17 (IL-17)** pathways drive granuloma formation with **multinucleated giant cells** and **fragmentation of the internal elastic lamina**.

5. IL-6 drives the systemic inflammatory response, explaining the very high ESR and CRP — and the effectiveness of **IL-6 receptor blockade**.

6. Intimal hyperplasia narrows the lumen and produces ischaemia. Involvement is **segmental with skip lesions**, which is why an adequate biopsy length is essential.

C. Clinical Features

7. Cranial symptoms: new-onset temporal or occipital headache (the commonest presenting feature), **scalp tenderness** (pain on combing the hair or resting on a pillow), and a **thickened, tender, nodular, pulseless temporal artery**.

8. Jaw claudication — masseter pain on chewing — is the **single most specific symptom**. Tongue claudication and, rarely, tongue or scalp necrosis may occur.

9. Visual features — the emergency: amaurosis fugax, diplopia, and **sudden painless permanent monocular visual loss**, usually from **anterior ischaemic optic neuropathy** with a **pale, swollen "chalky white" disc**; also central retinal artery occlusion. Untreated, **the second eye is at risk within days to weeks**.

10. Constitutional features: fever (GCA is a classic cause of **pyrexia of unknown origin in the elderly**), weight loss, anorexia, malaise and depression. GCA is an important **reversible cause of frailty and functional decline** in older people, and is often misdiagnosed.

11. PMR features: aching and morning stiffness of the **neck, shoulder and pelvic girdle** lasting more than 45 minutes, with difficulty rising and combing hair.

12. Large-vessel GCA: limb claudication, **asymmetric pulses or blood pressure**, bruits, and late **thoracic aortic aneurysm or dissection**. Rarely, **vertebrobasilar territory stroke** — giant cell arteritis should be considered in any elderly patient with posterior circulation ischaemia.

D. Diagnosis

13. GCA is a medical emergency and a clinical diagnosis. Treatment must never be delayed for investigations or biopsy.

14. Acute-phase response: ESR is characteristically very high — an ESR above 75 mm/h in a patient with headache, jaw claudication or visual change should prompt urgent action. **CRP is more sensitive and rises earlier**. Also expect **normocytic normochromic anaemia**, thrombocytosis, raised alkaline phosphatase and low albumin. About **4% have both a normal ESR and CRP**.

15. Temporal artery biopsy remains the diagnostic gold standard. Take a segment **at least 1–2 cm long** because of skip lesions, and perform it **within 1–2 weeks of starting steroids** — the yield falls with prolonged treatment, though positivity persists for some weeks. **A negative biopsy does not exclude GCA.**

16. Histology: transmural mononuclear infiltrate, **granulomas with multinucleated giant cells**, **disruption of the internal elastic lamina**, and intimal hyperplasia with luminal narrowing.

17. Colour Doppler ultrasound of temporal and axillary arteries shows the **non-compressible "halo sign"** (hypoechoic circumferential wall oedema) — now the **first-line investigation** in fast-track clinics, with the advantage of immediate availability.

18. Large-vessel imaging: CT or MR angiography and **FDG-PET/CT** identify aortitis and subclavian/axillary involvement; PET is especially valuable when GCA presents as a PUO. **Baseline and periodic aortic imaging** is advised for aneurysm surveillance.

19. 2022 ACR/EULAR classification criteria (for classification, not diagnosis) require **age ≥50 as an entry criterion**, then score: morning stiffness of shoulder/neck, sudden visual loss, jaw or tongue claudication, new temporal headache, scalp tenderness, abnormal temporal artery examination, raised ESR/CRP, positive biopsy or halo sign, bilateral axillary

involvement, and FDG-PET uptake in the aorta.

E. Treatment

20. Start high-dose glucocorticoids immediately on clinical suspicion. For **uncomplicated GCA**, prednisolone **40–60 mg/day** (about 1 mg/kg). For **visual symptoms or established visual loss**, **IV methylprednisolone 500–1000 mg daily for 3 days**, followed by oral prednisolone.

21. Symptoms usually improve **dramatically within 24–72 hours**; a poor response should prompt reconsideration of the diagnosis.

22. Taper slowly, guided by symptoms and inflammatory markers: maintain the initial dose for 2–4 weeks, reduce to about **15–20 mg by 3 months** and **5 mg by 12 months**. Most patients need **1–2 years** of treatment, some longer.

23. Steroid-sparing therapy: tocilizumab (IL-6 receptor blocker) **162 mg subcutaneously weekly or every other week**, or 6 mg/kg IV every 4 weeks — the **GiACTA trial** showed sustained steroid-free remission with a markedly lower cumulative glucocorticoid dose. **Methotrexate** is a cheaper alternative with modest benefit, relevant in Indian practice. **Infliximab is not beneficial and is not recommended.**

24. Adjunctive care in every patient: low-dose aspirin (reduces ischaemic events; weigh bleeding risk), a **proton pump inhibitor**, **calcium, vitamin D and a bisphosphonate** for glucocorticoid-induced osteoporosis, **blood glucose and blood pressure monitoring**, **Pneumocystis prophylaxis** if on high-dose steroid with additional immunosuppression, and vaccination.

25. Comprehensive geriatric assessment matters. Glucocorticoid toxicity in older people causes **hyperglycaemia, hypertension, cataract, proximal myopathy, skin fragility, insomnia, delirium, infection and fracture** — steroid harm often exceeds vasculitis harm after the acute phase.

F. Prognosis

26. Overall life expectancy is close to normal. Most morbidity comes from **glucocorticoid toxicity** and from **aortic aneurysm and dissection** (a roughly **17-fold increase in thoracic aortic aneurysm**), rather than from the vasculitis itself.

27. Established visual loss is usually permanent — recovery is rare even with intravenous steroids. **The entire aim of emergency treatment is to protect the second eye.** The risk of blindness falls from about **30% untreated to under 5%** with prompt therapy.

28. Relapse occurs in 40–60%, mostly during tapering in the first 18 months, and usually presents as **headache or PMR symptoms rather than visual loss**. Relapses require dose escalation and consideration of a steroid-sparing agent.

Latest Updates (2023–Present)

- **SELECT-GCA (NEJM 2025; Blockmans et al., 428 patients)** — **upadacitinib 15 mg once daily** with a 26-week glucocorticoid taper achieved **sustained remission in 46.4%** versus **29.0%** for placebo with a 52-week taper. The **7.5 mg dose was not effective**. **FDA and EMA approved upadacitinib for GCA in 2025** — the first **oral targeted therapy** for the disease, and particularly attractive for older patients who prefer tablets to injections.
- **2024 EULAR treat-to-target recommendations for GCA and PMR (Ann Rheum Dis)** define **remission as absence of clinical signs and symptoms plus normalised ESR and CRP**, and set explicit targets for tapering and sustained remission.
- The **ACR/Vasculitis Foundation guideline** conditionally recommends **adding tocilizumab to high-dose glucocorticoids in newly diagnosed GCA**, and prefers **tocilizumab over methotrexate** in relapsing disease with cranial ischaemia.
- **Tocilizumab dose optimisation** after 12 months of sustained remission — halving the IV dose (8 to 4 mg/kg) or extending subcutaneous dosing from weekly to every other week — maintained remission at similar rates with **significantly fewer severe infections (6.6% versus 12.9%)** and lower cost.
- **EULAR imaging recommendations** now place **ultrasound as the first-line investigation** in suspected cranial GCA, with biopsy or additional imaging when ultrasound is negative but clinical suspicion persists. **Fast-track pathways** combining same-day ultrasound with immediate steroids have **substantially reduced permanent visual loss**.
- **JAK inhibitors in relapsing GCA**: real-world series confirm effectiveness in refractory disease, though **cardiovascular, thrombotic and malignancy warnings apply to JAK inhibitors in the over-65 population** and must be weighed carefully.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
First diagnostic test	Temporal artery biopsy	**Colour Doppler ultrasound (halo sign) first-line**; biopsy if negative and suspicion persists (EULAR)
Steroid-sparing therapy	Methotrexate; infliximab not recommended	**Tocilizumab** (GiACTA) and now **oral upadacitinib** (SELECT-GCA 2025, FDA/EMA approved)
Treatment target	Symptom control and falling ESR	**Formal treat-to-target**: no clinical signs **plus** normalised ESR/CRP (EULAR 2024)
Long-term surveillance	Not emphasised	**Periodic aortic imaging** for aneurysm (17-fold increased risk)
Service model	Individual referral	**Fast-track GCA clinics** with same-day ultrasound reduce blindness

Exam One-Liners

- **Never occurs under age 50**; peak incidence 70–80 years.
- **Jaw claudication is the most specific symptom**; **visual loss is the feared complication**.
- **ESR often >75 mm/h**, but **4% have normal ESR and CRP** — treat on clinical suspicion.
- **Start steroids first, biopsy after** — biopsy stays positive for a couple of weeks.
- **Biopsy 1–2 cm long** because of skip lesions; a negative biopsy does not exclude GCA.
- **Visual loss + GCA = IV methylprednisolone 1 g for 3 days** to save the other eye.
- **Established blindness is irreversible** — the aim is protecting the second eye.
- **SELECT-GCA 2025:** upadacitinib 15 mg is the first oral targeted therapy approved for GCA.

Q8. Dermatomyositis in the Elderly — Presentation, Comorbidities, Investigations, Treatment and Prognosis

A. Definition and Basis

1. Dermatomyositis is an **idiopathic inflammatory myopathy** combining **characteristic cutaneous features** with **symmetrical proximal muscle weakness**.

2. The mechanism is **humoral and complement-mediated**: deposition of the **C5b-9 membrane attack complex** on **endomysial capillaries** causes capillary dropout and ischaemia of the periphery of the fascicle — hence the pathognomonic **perifascicular atrophy** on muscle biopsy. This contrasts with polymyositis and inclusion body myositis, which are CD8+ T-cell mediated.

3. The disease has a **bimodal age distribution**; the adult peak is in the **fifth to sixth decades**, and **elderly onset carries the highest malignancy risk of any myositis subtype**.

B. Presentation in the Elderly

4. Skin changes often precede muscle disease by weeks to months: the **heliotrope rash** (violaceous periorbital discoloration with oedema) and **Gottron's papules** over the MCP, PIP and DIP joints, with **Gottron's sign** over elbows and knees.

5. Photodistributed erythema: the **shawl sign** (upper back and shoulders), **V-sign** (anterior chest and neck), **holster sign** (lateral thighs, notably a non-sun-exposed site), and facial erythema.

6. Other cutaneous signs: periungual erythema with dilated, tortuous nailfold capillary loops and ragged cuticles, **mechanic's hands** (hyperkeratotic fissured lateral fingers, associated with the anti-synthetase syndrome), **poikiloderma**, **calcinosis cutis** (less common in adults than in juvenile disease), and **intense pruritus** — a prominent and frequently overlooked complaint.

7. Muscle involvement: insidious **symmetrical proximal weakness** — difficulty rising from a chair or toilet, climbing stairs, combing hair and hanging out clothes. **Pain is not prominent**, and **neck flexor weakness** is characteristic.

8. The critical geriatric pitfall: proximal weakness in an older person is easily misattributed to **normal ageing, sarcopenia, deconditioning, polymyalgia rheumatica, statin myopathy, hypothyroid myopathy or steroid myopathy** — leading to dangerous delay in diagnosis and malignancy search.

9. Dysphagia from pharyngeal and upper oesophageal striated muscle involvement occurs in up to a third; it predicts **aspiration pneumonia and death**, and may be accompanied by dysphonia and nasal regurgitation.

10. Clinically amyopathic dermatomyositis accounts for about **20% of cases** — the classical rash with **no clinically evident weakness**. It still carries the **full risk of malignancy and interstitial lung disease** and must be investigated identically.

C. Comorbidities and Associations

11. Malignancy is the dominant geriatric concern. Cancer-associated myositis is defined as a malignancy occurring **within 3 years before or after** the myositis diagnosis. Some myositis develops as a **paraneoplastic syndrome**, and treating the tumour often improves the myositis.

12. Anti-TIF1-γ (anti-p155) is the key marker — present in about **7–15% of dermatomyositis overall** but in **more than half of cancer-associated myositis**; roughly **40% of anti-TIF1-γ-positive patients have a malignancy**, with the association strongest in the elderly. **Anti-NXP2** is also malignancy-associated and causes calcinosis and dysphagia.

13. Commonest associated tumours: ovary, lung, breast, stomach, colorectum and pancreas in Western series; **nasopharyngeal carcinoma is over-represented in Asian populations** — highly relevant in the Indian context.

14. Interstitial lung disease occurs in **20–40%**. **Anti-MDA5** predicts **rapidly progressive ILD** with a characteristic **ulcerating cutaneous vasculopathy and palmar papules**, and carries the **worst prognosis** of all subtypes. **Anti-synthetase syndrome** (anti-Jo-1 and others) = myositis, ILD, arthritis, Raynaud's, fever and mechanic's hands.

15. Cardiac involvement: myocarditis, conduction defects, arrhythmias and heart failure — a **leading cause of death**; there is also accelerated atherosclerosis.

16. Other comorbidities: aspiration pneumonia, **venous thromboembolism**, **glucocorticoid-induced osteoporosis and fracture**, infection, severe deconditioning and sarcopenia, and **overlap syndromes** with systemic sclerosis, SLE and Sjögren's syndrome.

D. Investigations

17. Muscle enzymes: creatine kinase, aldolase, LDH, AST and ALT. Note two traps — CK may be **normal in amyopathic disease** and is often **relatively lower in the elderly** because of reduced muscle mass; and the raised transaminases produce a **false "hepatitis" pattern that is actually muscle in origin**.

18. Autoantibodies are now central. Check ANA, then an **extended myositis panel** for **myositis-specific antibodies (anti-TIF1-γ, NXP2, MDA5, Mi-2, SAE and the synthetases)** and **myositis-associated antibodies (PM-Scl, Ro52, U1-RNP)**. These **define phenotype, malignancy risk and prognosis better than any other single test**.

19. Electromyography: a **myopathic irritative pattern** — short-duration, small-amplitude polyphasic motor unit

potentials with **fibrillations, positive sharp waves and increased insertional activity**.

20. MRI of the thighs with T2/STIR sequences shows **patchy muscle oedema**, guides the biopsy site, and distinguishes **active inflammation from irreversible fatty replacement** — useful in the elderly for deciding whether persistent weakness warrants more immunosuppression.

21. Muscle biopsy: perifascicular atrophy, perimysial and perivascular infiltrate of CD4+ T cells, B cells and plasmacytoid dendritic cells, **capillary dropout with MAC deposition**, and **MHC class I upregulation**. Skin biopsy shows **interface dermatitis** indistinguishable from lupus.

22. Malignancy screening is mandatory in every patient over 40. Baseline: full history and examination including breast, pelvic, rectal and lymph node assessment; complete blood count, biochemistry, urinalysis and faecal occult blood; chest radiograph; **age- and sex-appropriate screening** (mammography, cervical cytology, PSA, colonoscopy); and **CA-125 with transvaginal ultrasound in women**. **High-risk patients need CT of chest, abdomen and pelvis, with FDG-PET/CT considered**, repeated **annually for 3 years**.

23. Organ-specific baseline work-up: HRCT chest and pulmonary function tests with DLCO for ILD; **ECG, troponin and echocardiography** for cardiac involvement; and **videofluoroscopic swallow assessment** if there is any dysphagia.

E. Treatment

24. Prednisolone 0.5–1 mg/kg/day is first-line, tapered over 6–12 months once strength improves. Use **IV methylprednisolone pulses** for severe disease, dysphagia, cardiac involvement or rapidly progressive ILD.

25. Start a steroid-sparing agent early in older people to limit steroid toxicity: **methotrexate or azathioprine** first-line; **mycophenolate mofetil**, particularly with ILD; **calcineurin inhibitors (tacrolimus, ciclosporin)** for anti-MDA5 ILD; and **cyclophosphamide or rituximab** for refractory or severe disease.

26. Intravenous immunoglobulin 2 g/kg is effective in refractory disease, in dysphagia, and where immunosuppression is hazardous (active infection or malignancy) — but watch for **thromboembolism, volume overload and renal impairment** in older patients.

27. Skin disease requires its own plan: rigorous **photoprotection**, topical corticosteroids and calcineurin inhibitors, **hydroxychloroquine**, and antipruritics — cutaneous disease often persists after myositis has responded.

28. Supportive and geriatric care matters as much as immunosuppression: early **physiotherapy and graded resistance exercise** (no longer contraindicated and now recommended), **speech and swallow therapy** with texture modification and aspiration precautions, **nutritional support**, **VTE prophylaxis**, **bone protection with calcium, vitamin D and a bisphosphonate**, **Pneumocystis prophylaxis**, glucose monitoring, vaccination and falls prevention.

29. Treat any underlying malignancy — the myositis frequently improves with successful tumour therapy, which justifies an aggressive and repeated cancer search.

F. Prognosis

30. Poor prognostic factors: older age, **malignancy**, **interstitial lung disease (especially anti-MDA5)**, **dysphagia**, **cardiac involvement**, delayed treatment, and severe weakness at presentation.

31. Malignancy-associated dermatomyositis has substantially higher mortality; overall survival in elderly-onset disease is markedly worse than in younger patients. The leading causes of death are **cancer, aspiration pneumonia, interstitial lung disease, cardiac disease and infection**.

32. Functional recovery is often incomplete — residual weakness, fatigue and deconditioning are common, so rehabilitation goals should be **functional and realistic**, focused on activities of daily living, transfers and safe swallowing rather than complete normalisation of strength.

Latest Updates (2023–Present)

- **IMACS International Guideline for IIM-Associated Cancer Screening (Nature Reviews Rheumatology, 2024)** — the major practice change. It stratifies patients into **standard, moderate and high risk**. High-risk features include **dermatomyositis subtype, anti-TIF1-γ or anti-NXP2 positivity, age over 40 at onset**, and refractory or severe disease. Worked example: a **70-year-old with anti-NXP2-positive dermatomyositis meets three high-risk criteria** and requires **enhanced screening with CT chest, abdomen and pelvis at diagnosis and annually for 3 years**.
- **ProDERM trial (NEJM 2022)** established **IVIG 2 g/kg every 4 weeks** as an evidence-based therapy for adult dermatomyositis, leading to **FDA approval of IVIG for this indication** — the first drug formally approved for dermatomyositis.
- **2017 EULAR/ACR classification criteria** have replaced Bohan and Peter in research and increasingly in practice; they use a **probability-based score** and permit classification **without a muscle biopsy** when the characteristic rash is present.
- **Anti-MDA5 dermatomyositis with rapidly progressive ILD** is now treated with **upfront triple therapy** — high-dose glucocorticoid plus a calcineurin inhibitor plus cyclophosphamide — with **JAK inhibitors (tofacitinib)** showing benefit in refractory cases based on the type I interferon signature.
- **Multiple simultaneous myositis-specific antibodies** are increasingly reported (about 15.7% of MSA-positive patients), complicating phenotype prediction and reinforcing the need to interpret panels alongside the clinical picture.
- **Exercise is now actively recommended** rather than avoided: supervised aerobic and resistance training improves strength and function without increasing muscle inflammation, and is especially important in older patients at risk of

steroid myopathy and sarcopenia.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Diagnostic framework	Bohan and Peter criteria, biopsy-centred	**2017 EULAR/ACR criteria**; **myositis antibody panel** now central and biopsy sometimes avoidable
Cancer screening	“Screen for malignancy in the elderly”	**Risk-stratified IMACS 2024 guideline** — antibody-driven, with CT chest/abdomen/pelvis annually for 3 years in high risk
Refractory disease	Steroids plus conventional immunosuppressants	**IVIG is now FDA-approved and evidence-based (ProDERM)**; rituximab for refractory disease
Exercise	Traditionally cautioned against in active disease	**Supervised aerobic and resistance exercise recommended**; safe and improves function
Anti-MDA5 phenotype	Not described	Recognised as a distinct, **often amyopathic, rapidly progressive ILD phenotype with the worst prognosis**; needs upfront triple therapy

Exam One-Liners

- **Perifascicular atrophy** = the histological hallmark; the mechanism is **complement-mediated capillary injury**.
- **Heliotrope rash + Gottron’s papules** = dermatomyositis until proved otherwise.
- **Anti-TIF1-γ = malignancy; anti-MDA5 = rapidly progressive ILD; anti-Jo-1 = anti-synthetase syndrome; anti-Mi-2 = classic rash with good prognosis.**
- **Amyopathic dermatomyositis carries the same malignancy and ILD risk** as classic disease.
- **Dysphagia predicts aspiration and death** — assess the swallow in every patient.
- **Every patient over 40 needs malignancy screening, repeated annually for 3 years.**
- **ProDERM:** IVIG 2 g/kg is FDA-approved for adult dermatomyositis.
- **Treating the tumour often treats the myositis.**

Q9. Diffuse Idiopathic Skeletal Hyperostosis (DISH) — Presentation, Investigations and Treatment

A. Definition and Epidemiology

1. DISH (**Forestier–Rotés-Querol disease**, originally "senile ankylosing hyperostosis") is a **systemic, non-inflammatory skeletal disorder** characterised by **ossification and calcification of spinal and extraspinal ligaments and entheses**, particularly the **anterior longitudinal ligament**.

2. It is a **disease of older adults** — prevalence rises steeply after 50 and reaches **up to 25–40% of men over 70**, with a **male to female ratio of about 2:1**. The **majority of cases are asymptomatic** and found incidentally.

3. DISH is a **"new bone formation" disorder** — it is **neither degenerative disc disease nor an inflammatory spondyloarthropathy**, though imaging overlap with both is common.

B. Aetiology and Associations

4. The cause is unknown. The core abnormality is **differentiation of enthesial fibroblasts into bone-forming cells**, driven by local growth factors — **insulin, IGF-1, growth hormone, TGF-β, bone morphogenetic proteins and endothelin-1**.

5. Strong metabolic associations: type 2 diabetes and hyperinsulinaemia, obesity, hypertension, dyslipidaemia and hyperuricaemia. DISH is increasingly regarded as **the skeletal manifestation of the metabolic syndrome**.

6. Other associations: male sex, advancing age, **long-term retinoid use** (isotretinoin, etretinate) and hypervitaminosis A, **hypoparathyroidism**, acromegaly, and probable genetic contributions (*COL6A1*).

7. Paradox worth remembering: patients with DISH have **higher bone mineral density than controls**, yet **fracture easily** — the long, rigid, ankylosed spine behaves mechanically like a long bone.

C. Clinical Presentation

8. Most patients are asymptomatic; DISH is commonly an incidental finding on a chest radiograph or CT performed for another reason.

9. Axial symptoms: dull **mid-thoracic and lumbar back pain** with progressive **stiffness**, typically mild, worse after inactivity and in cold weather, and **without the dramatic NSAID response seen in spondyloarthritis**.

10. Reduced spinal range of movement with preserved sacroiliac joints, progressive **thoracic kyphosis** and loss of lumbar lordosis, contributing to postural instability and falls.

11. Cervical DISH and dysphagia — the key geriatric presentation. Large **anterior osteophytes at C3–C5** mechanically compress and tether the oesophagus, producing **progressive dysphagia to solids and then liquids, with weight loss**. This is an **under-recognised and reversible cause of dysphagia** in older adults, sometimes termed **"DISHphagia"**.

12. Other cervical complications: hoarseness, globus sensation, **stridor and acute airway obstruction**, obstructive sleep apnoea, **aspiration pneumonia**, and **difficult intubation or failed nasogastric tube placement**.

13. Peripheral enthesopathy: calcaneal (heel) spurs, olecranon and patellar spurs, and **"whiskering" of the iliac crest, ischial tuberosity and greater trochanter** — these can cause local pain and be mistaken for tendinitis or bursitis.

14. Serious spinal complications: ossification of the posterior longitudinal ligament (OPLL) and ligamentum flavum causing **myelopathy or radiculopathy**; and — most important — **unstable three-column hyperextension fractures of the rigid spine after trivial falls**, which carry high rates of **delayed diagnosis, neurological injury and mortality**.

D. Investigations

15. Diagnosis is radiological, using the Resnick and Niwayama criteria on a **lateral thoracic spine radiograph**: (i) **flowing ossification along the anterolateral aspect of at least four contiguous vertebral bodies**; (ii) **preserved intervertebral disc height** in the involved segments without significant degenerative disc disease; and (iii) **absence of apophyseal (facet) joint ankylosis and of sacroiliac erosion, sclerosis or fusion**.

16. The classic radiographic appearance is **"flowing" or "dripping candle wax" ossification**, most often on the **right side of the thoracic spine** — the pulsating descending thoracic aorta is thought to protect the left side.

17. CT is best for defining osteophyte size, oesophageal and airway compression, and — critically — for **fracture detection in the rigid spine**. **Always obtain CT (and MRI if there is any neurology) rather than plain films when a DISH patient falls**, because fractures are easily missed.

18. Barium swallow / videofluoroscopy dynamically demonstrates the **level responsible for dysphagia** and confirms adequate oesophageal decompression after surgery. **Flexible endoscopy** excludes malignancy and **manometry** excludes a motility disorder.

19. Laboratory tests are normal — ESR and CRP normal or only mildly raised, **HLA-B27 negative**, calcium, phosphate and alkaline phosphatase normal. **Screen every patient for diabetes, lipids, uric acid and blood pressure**, since the metabolic comorbidity is the real health burden.

20. Key differential diagnoses:

Condition	Distinguishing features
Ankylosing spondylitis	Younger onset, **sacroiliitis**, thin vertical **syndesmophytes**, HLA-B27 positive, raised ESR/CRP, marked NSAID response, inflammatory back pain
Spondylosis deformans	Disc space **narrowing**, horizontal/beak-like osteophytes, no flowing ossification
OPLL	Posterior longitudinal ligament ossification, myelopathy; may coexist with DISH
Acromegaly	Enlarged extremities, prognathism, raised IGF-1
Fluorosis	**Important in endemic areas of India** — dental mottling, generalised osteosclerosis, ligamentous calcification, raised urinary fluoride
Hypoparathyroidism	Low calcium, high phosphate, ectopic calcification

E. Treatment

21. There is **no disease-modifying therapy**; management is **symptomatic and complication-focused**.

22. Conservative care: analgesics and **NSAIDs** for pain, **physiotherapy** for posture, range of motion and core strength, activity modification, local heat, and **weight reduction with tight control of diabetes, lipids and blood pressure** — metabolic control is the only intervention likely to influence the underlying process.

23. Management of dysphagia: diet and texture modification with speech-and-language therapy, anti-reflux measures and proton pump inhibitors, **upright positioning and small frequent meals**, and muscle relaxants where spasm contributes. **Enteral feeding or gastrostomy** for refractory dysphagia with weight loss.

24. Local corticosteroid injection helps symptomatic peripheral enthesopathy; **bisphosphonates** have been used for painful enthesopathy with limited evidence.

25. Surgery is reserved for failure of conservative treatment, **severe dysphagia with significant weight loss**, or **airway compromise**. The procedure is **anterior osteophytectomy** through a **Smith–Robinson or trans-pharyngeal approach**, sometimes combined with **cricopharyngeal myotomy**. Symptom relief is generally excellent, but counsel about **recurrence and complications** — recurrent laryngeal nerve palsy, haematoma, oesophageal perforation and dysphonia. **Tracheostomy** may be needed for acute airway obstruction.

26. Spinal decompression and stabilisation for myelopathy or fracture. **Any DISH patient who falls and has new spinal pain must be assumed to have an unstable fracture until CT proves otherwise** — a classic and dangerous geriatric trap.

27. Anaesthetic and nursing implications: anticipate **difficult intubation** (fibreoptic technique, cervical rigidity), difficult nasogastric tube insertion, careful positioning of the rigid kyphotic spine, and **meticulous pressure-area care**.

Latest Updates (2023–Present)

- **Resnick's criteria remain the gold standard**, but 2024–2025 real-life cohort imaging studies confirm **substantial overlap of inflammatory and degenerative features between DISH, degenerative disc disease and axial spondyloarthritis** on radiographs and MRI. DISH and axSpA can coexist — **the presence of DISH should not stop a spondyloarthritis work-up** in a symptomatic patient.
- **Systematic reviews and case series (2024–2025)** confirm that **anterior osteophytectomy for DISH-related dysphagia gives excellent and durable symptom relief**, with **barium swallow fluoroscopy emphasised** both for identifying the culpable level pre-operatively and for confirming oesophageal decompression post-operatively.
- **Growing recognition of DISH as a skeletal marker of metabolic syndrome**, with proposals that patients found to have incidental DISH on imaging should be **screened for diabetes and cardiovascular risk** — a practical, low-cost intervention for Indian practice.
- **Increasing reports of stridor and acute respiratory distress from cervical DISH**, including from Indian centres, highlighting the need to consider DISH in any older adult with unexplained stridor, and reporting a **prevalence of up to 42% in individuals over 65**.
- **Rare presentations** now documented include **upper cervical (C1–C3) DISH with ossification of the anterior longitudinal and alar ligaments**, with implications for airway management and cervical stability.
- **Emphasis on fracture risk** continues to grow: DISH patients have **higher BMD but sustain unstable hyperextension fractures after low-energy trauma**, so **CT and MRI are mandatory even after apparently minor falls**.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline
Nature of the disease	Age-related ossifying disorder	**Skeletal manifestation of metabolic syndrome** — screen for diabetes and cardiovascular risk
Relationship to axSpA	Considered mutually exclusive	**Substantial imaging overlap; DISH and axSpA can coexist** (2024 cohort studies)
Dysphagia work-up	Plain radiography	**CT plus dynamic barium swallow fluoroscopy** to identify the culpable level and confirm post-operative decompression
Bone strength	High BMD implies safety	**High BMD but high fracture risk** — rigid spine sustains unstable fractures after trivial trauma
Post-fall imaging	Plain films	**CT (± MRI) mandatory** after any fall with new spinal pain
Surgical outcome	Reserved, uncertain	**Excellent durable relief** from anterior osteophytectomy in appropriately selected patients

Exam One-Liners

- **Resnick's criteria:** flowing ossification of **≥4 contiguous vertebrae**, **preserved disc spaces**, **no facet or sacroiliac fusion**.
- **"Dripping candle wax" appearance, right side of the thoracic spine.**
- **HLA-B27 negative, ESR normal, sacroiliac joints normal** — this separates DISH from ankylosing spondylitis.
- **Cervical DISH is a reversible cause of dysphagia in the elderly** ("DISHphagia").
- **DISH = the skeletal face of metabolic syndrome** — always check the sugar.
- **High BMD but fractures easily** — a rigid spine breaks like a long bone.
- **Any DISH patient who falls needs a CT, not a plain film.**
- **Think DISH in unexplained difficult intubation or failed NG tube placement.**

Cross-Topic Rapid Revision Grid

Condition	One-line hallmark	Key investigation	First-line treatment
Osteoporosis	Low mass + poor microarchitecture, fragility fracture	DXA T-score ≤ −2.5, FRAX	Calcium/vitamin D + bisphosphonate; anabolic-first if very high risk
Paget's disease	Focal, disorganised remodelling; high ALP with normal calcium	X-ray + radionuclide bone scan	Single 5 mg IV zoledronate
Osteoarthritis	Activity pain, stiffness in minutes, osteophytes	Clinical ± X-ray	Exercise + weight loss + topical NSAID
Giant cell arteritis	Headache, jaw claudication, visual loss, ESR >75	Ultrasound halo sign / temporal artery biopsy	Immediate high-dose steroid ± tocilizumab or upadacitinib
Dermatomyositis	Heliotrope rash + Gottron's + proximal weakness	Myositis antibody panel, MRI, biopsy	Prednisolone + early steroid-sparing agent; IVIG if refractory
DISH	Flowing ossification, dysphagia, metabolic syndrome	Lateral thoracic X-ray (Resnick), CT	Symptomatic; metabolic control; surgery for dysphagia

MD GERIATRIC MEDICINE

Examination Preparation — Structured Answers

MODULE:
LONG-TERM CARE, COMMUNITY SERVICES AND CAREGIVER SUPPORT

Primary sources: Pathy's Principles and Practice of Geriatric Medicine (6th edition) and Kane's Essentials of Clinical Geriatrics
with Latest Updates (2023–2026) and Indian clinical & policy context

Compiled for Dr. Sudarsan | Seven questions with high-yield points, latest updates, current practice comparison tables and exam one-liners

Contents

1.	Long-term care — concept, continuum, nursing home care and regulation	15 marks
2.	Community-based long-term care services (HCBS)	15 marks
3.	Home-based care in the elderly	15 marks
4.	Day hospitals and day care centres for older adults	15 marks
5.	House call programme (home-based medical care)	15 marks
6.	Components of the Hospital Elder Life Program (HELP)	15 marks
7.	Role of the geriatric social worker	15 marks
8.	Caregiver burden, stress and burnout — assessment and management	15 marks

How each answer is structured:

- **High-yield numbered points** (15–20) under labelled subheadings, keywords in bold
- **Latest Updates (2023–Present)** — named trials, guidelines and Indian policy cited inline
- **Current Practice Update** — table contrasting textbook position with current evidence
- **Exam One-Liners** — rapid recall for the night before the examination

Q1. Long-Term Care

Concept, continuum of services, nursing home care, quality regulation and financing — 15 marks

A. Definition and Concept

1. **Long-term care** is a range of **health, personal care and social services** given to people who have lost some capacity for **self-care**. Services may be continuous or intermittent, but are delivered over a **sustained period**.
2. The single common thread is **dependence on another person for a substantial period**. Need is measured by an index of **functional incapacity (ADL/IADL loss)**, not by diagnosis or age.
3. LTC is **not primarily medical care**. It is delivered along a **continuum**: informal family care → home care → community and day services → assisted living → nursing home → hospice.

B. Epidemiology and Burden

1. Nursing home use rises **steeply with age** — about **1% at 65–74 years, 4% at 75–84 years and 14% at ≥85 years**. Institutional use has fallen over recent decades because of **alternative residential settings**.
2. A person turning 65 will need on average about **3 years of LTC**; among actual users this is about **4.3 years**, split almost equally between **community-based and facility-based care**.
3. For every person in a nursing home there are **one to three equally disabled persons living in the community** — placement is therefore not determined by disability alone.
4. Nursing home residents are typically **older, female, unmarried or widowed**, with **multiple chronic conditions** and greater disability than earlier cohorts.

C. Determinants of Institutionalisation

1. Key risk factors: **advanced age, widowhood, living alone, dementia with behavioural symptoms, incontinence, immobility, recurrent falls, poverty and carer breakdown**.
2. Risk of nursing home use rises sharply with **lifestyle-related disease** — **hypertension, diabetes mellitus and physical inactivity**.

D. Components of the LTC Continuum

1. **Informal (family) care is the backbone** — over **80% of community care is informal**, largely provided by women. Formal services should **supplement, not replace**, family care.
2. **Home care** has two arms: **home health services** (nursing, physiotherapy, occupational therapy, speech therapy) and **homemaker/chore services** (bathing, meals, medication supervision). Most older people need **homemaking more than home health**.
3. **Community services**: **adult day care, day hospitals, senior centres, home-delivered meals, transport, respite care and case management**. **Respite care** is critical to prevent carer burnout.
4. **Assisted living**: the resident is treated as a **tenant**, not a patient — a **lockable single unit**, own living and sleeping space, bathroom and minimal cooking facility, with services brought in. It maximises **autonomy and privacy**.
5. **Adult foster homes** (usually ≤5 residents) and **nursing homes** complete the spectrum. Nursing homes serve **two distinct streams**: **short-stay post-acute rehabilitation** (most discharged by 21–90 days) and **long-stay custodial care** (mainly dementia and chronic disability).

E. Clinical Care in the Nursing Home

1. Common problems: **dementia with behavioural disturbance, depression, stroke, parkinsonism, delirium, incontinence, falls, pressure ulcers, malnutrition and dehydration,**

chronic pain, UTI and pneumonia, polypharmacy, and **iatrogenic disability from restraints and catheters**.

2. **Initial medical assessment within 72 hours to 1 week**: verify diagnoses, perform **medication reconciliation**, document baseline function, cognition and skin, and **define the goal of admission** (rehabilitation, long-term care or palliative care).
3. **Interdisciplinary care planning** — nursing, social work, dietetics, activities and rehabilitation — meets **within 2 weeks of admission and quarterly thereafter**. The **Minimum Data Set (MDS 3.0)** of the **Resident Assessment Instrument** is completed within **14 days**, updated quarterly and on any significant change. **Physician–nurse practitioner teams reduce hospitalisation.**

F. Quality, Regulation and Safety

1. **OBRA 1987** transformed LTC — it mandated **systematic assessment and care planning**, **restraint reduction**, **rational psychotropic use** and better staff training, with the goal of the **"highest practicable level of functioning."** Frequently cited deficiencies remain **restraints, unnecessary psychotropics, weight loss, pressure ulcers and fall injuries**.
2. Quality is tracked through **quality indicators/measures** (falls with injury, pressure ulcers, antipsychotic use, catheter use, worsening function, weight loss, vaccination, rehospitalisation), publicly reported as the **Five-Star rating** on **Nursing Home Compare**, and improved through **QAPI**. Nursing homes have roughly **one-sixth the staff-per-bed ratio of hospitals**, mostly aides; **stable staffing predicts better quality**, while **marketisation and private-equity ownership** are linked to poor quality.

G. Ethics, Financing and Principles

1. Recurring ethical issues are **autonomy versus safety, capacity assessment, advance directives, tube feeding, hospital transfer and end-of-life decisions**. Financing is fragmented — insurance typically covers **skilled/post-acute care only**, with **custodial care paid out-of-pocket or by welfare after "spend-down." Culture-change models** (Eden Alternative, Wellspring, small living communities) humanise care. **The guiding principle: nursing home placement should be the last resort, not the first.**

Latest Updates (2023–Present)

Global burden and WHO position

- An estimated **142 million older people worldwide cannot meet their basic needs independently**, and **two out of three older people** are likely to need care and support at some point. WHO estimates about **65% will need help with activities of daily living**, and **unpaid informal care accounts for about 80% of all long-term care**.
- The **WHO Framework for an Integrated Continuum of Long-Term Care** defines six system elements — **governance, sustainable financing, information/monitoring and evaluation systems, workforce, service delivery, and innovation and research** — built on establishing foundations for LTC as part of **universal health coverage**, building a **sustainable trained workforce**, and **supporting unpaid caregivers**.
- **ICOPE handbook, 2nd edition (WHO, January 2025)** — *Integrated Care for Older People: Guidance for Person-Centred Assessment and Pathways in Primary Care* — emphasises personalised, comprehensive, coordinated care and a shift from a **disease-oriented to a holistic approach**, focused on optimising **intrinsic capacity and functional ability**, spanning promotion and prevention through treatment, palliative care and long-term care.
- **PAHO Policy on Long-Term Care (2025–2034)**, adopted by the 61st Directing Council, is the first dedicated regional LTC policy, guiding Member States to develop, strengthen and expand LTC capacity.

- **WHA78 (2025)**: the **Global Action Plan on the Public Health Response to Dementia was extended to 2031** — directly relevant, as dementia is the commonest driver of LTC need. The **UN Decade of Healthy Ageing (2021–2030)** reached its mid-point in 2025.

Indian data and policy

- **India Ageing Report 2023 (UNFPA–IIPS, based on LASI)**: the elderly population is growing at a **decadal rate of 41%**; by 2050 more than **20% of India's population will be elderly**, and the elderly will **outnumber children by 2046**. The **80+ population will grow by about 279% between 2022 and 2050**, with a predominance of widowed, highly dependent very old women. More than **40% of elderly Indians are in the poorest wealth quintile** and about **18.7% live without any income**.
- Its key LTC recommendations: bring **all old age homes under regulatory purview**, raise awareness of existing schemes, and facilitate **in-situ (at-home) ageing** by creating short-term care facilities such as **elder creches and day-care centres**.
- The **Global Observatory for Long-Term Care (2025)** records that India has **no national formal long-term care system** — extended care occurs at home, supported by relatives or privately hired caregivers.
- **AB PM-JAY expansion** (Cabinet approval September 2024; launched 29 October 2024): coverage of **₹5 lakh per family per year for all senior citizens aged 70 years and above irrespective of income**, covering about **6 crore seniors in 4.5 crore families**, with a distinct **Ayushman Vay Vandana Card**; those already covered receive an additional top-up of ₹5 lakh. Note it funds **hospitalisation, not custodial long-term care**.
- **AVYAY (Atal Vayo Abhyuday Yojana)** remains the umbrella welfare scheme — grants for old-age homes, physiotherapy centres and mobile medicare units, assistive devices under **RVY**, the **Elder Line (14567)**, the **SACRED** portal for elderly employment, and **SAGE** for elder-care start-ups — alongside **NPHCE** for health services.

Nursing home staffing regulation — a major reversal

- CMS finalised the **Minimum Staffing Standards for Long-Term Care Facilities** rule in April 2024, setting a total nurse staffing standard of **3.48 hours per resident day (HPRD)**, including at least **0.55 HPRD registered nurse** and **2.45 HPRD nurse aide** care, plus **24/7 onsite RN** cover.
- Federal courts in **Texas (April 2025)** and **Iowa (June 2025)** blocked the rule, and the 2025 reconciliation law imposed a **10-year moratorium on enforcement until 30 September 2034**. CMS then formally **repealed** the HPRD minimums and the 24/7 onsite RN requirement, **reinstating the earlier standard of an RN for at least 8 consecutive hours a day, 7 days a week, with a full-time RN Director of Nursing**; the interim final rule takes effect **2 February 2026**. The **enhanced facility assessment** requirement — staffing according to actual resident acuity — **remains in force**.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Conceptual basis of LTC	Service- and facility-centred; defined by dependence and functional incapacity	**Intrinsic capacity and functional ability** model; LTC as one segment of an **integrated continuum** (WHO ICOPE, 2nd ed. 2025)
Preferred site of care	Shift from nursing home to home- and community-based services already under way	Explicit global and Indian policy of **"ageing in place" / in-situ ageing**, with elder day-care and creche models
Standard assessment tool	MDS 3.0 / Resident Assessment Instrument	

		MDS 3.0 in USA, **interRAI** in several countries; **ICOPE screening + person-centred pathway** for community and primary care
Nursing home staffing	No firm numeric federal minimum; quality tied to stable staffing	2024 numeric HPRD standards introduced, then **vacated by courts and repealed by CMS effective 2 Feb 2026**; acuity-based **facility assessment** retained
Financing for older Indians	Not part of the classical LTC financing model	**AB PM-JAY universal cover for ≥70 years (₹5 lakh)**, but still **no funded custodial LTC benefit** in India
Regulation of old age homes in India	—	**India Ageing Report 2023** recommends bringing all old age homes under a **regulatory body**
Dementia in LTC	A leading cause of long-stay admission	**Global Dementia Action Plan extended to 2031 (WHA78, 2025)** with emphasis on carer support

Exam One-Liners

- **LTC = care for dependence, not for disease** — defined by **functional incapacity**, not diagnosis.
- **Informal care provides >80%** of all community long-term care.
- **Nursing home use: 1% (65–74), 4% (75–84), 14% (≥85).**
- **Average LTC need after age 65 ≈ 3 years**; among users ≈ **4.3 years**.
- **OBRA 1987** = landmark LTC reform → **RAI/MDS, restraint reduction, psychotropic reduction**.
- **MDS 3.0** completed within **14 days** of admission; care plan reviewed **quarterly**.
- **Assisted living = tenant model** (lockable single unit, privacy, autonomy).
- **Respite care prevents carer burnout** and delays institutionalisation.
- **ICOPE (WHO)** = intrinsic capacity-based integrated care pathway; **2nd edition January 2025**.
- **WHO LTC framework pillars**: governance, financing, information systems, workforce, service delivery, innovation.
- **India Ageing Report 2023**: elderly **>20% by 2050**; **80+ up 279%**; elderly outnumber children by **2046**.
- **AB PM-JAY** now universal for **≥70 years — Ayushman Vay Vandana Card, ₹5 lakh/family/year**.
- **India has no formal national LTC system** — family remains the default provider.
- **Nursing home placement is the last resort, not the first.**

Q2. Community-Based Long-Term Care Services

Home and community-based services (HCBS) — components, case management, integrated models — 15 marks

A. Definition and Rationale

1. **Community-based long-term care (Home and Community-Based Services, HCBS)** means the delivery of **health, personal care and social services to dependent older people in their own homes and neighbourhoods**, instead of in an institution.
2. The justification is numerical. **Over two-thirds of disabled older people live in the community**, and for every person in a nursing home there are **one to three equally disabled persons living at home**.
3. The aim is **"ageing in place"** — preserve **function, autonomy and quality of life**, support the family carer, and **delay or prevent institutionalisation**.
4. Community care is **preferable but not always cheaper**. Because dependency-based eligibility brings in many people who would never have entered a nursing home (the **"woodwork effect"**), entry must be controlled — which is why **case management** became central.

B. Home-Based Services

1. **Home care has two arms**: **home health services** (skilled nursing, physiotherapy, occupational therapy, speech therapy) and **homemaker/chore services** (bathing, dressing, meal preparation, housekeeping, medication supervision, minor repairs). **Most older people need homemaking more than home health.**
2. Access is often restricted by rules requiring the person to be **"homebound" and to need intermittent skilled care**. This excludes many **custodial** dependent elders, and **personal care aides are usually not funded**.
3. **Home-based medical care**: domiciliary visits by the general practitioner or geriatrician, with rapid specialist access during crisis. **Hospice care at home** is a key component, though home hospice **cannot provide continuous 24-hour personal care**.

C. Day and Community Services

1. **Adult day care** provides supervised **recreational and restorative activity**; some centres are **dementia-specific**. Its greatest value is **respite for the primary carer**. Most programmes serve a client **2–3 days a week**.
2. **Adult day health centre** = day care **plus nursing, physiotherapy and social work**. The **day hospital** is a more medical model offering nearly all hospital services on an **ambulatory basis**, with emphasis on **rehabilitation**.
3. **Transportation is the universal problem** of all day programmes — costly, time-consuming, and it restricts catchment area.
4. Other community programmes: **congregate and home-delivered meals (Meals-on-Wheels), senior centres** (the most used service, aimed at the *well* elderly), **telephone reassurance, emergency alarm systems, respite care, caregiver support groups, home modification and repair, transport, legal aid and ombudsman services**.

D. Residential and Transitional Alternatives

1. **Assisted living** — the resident is a **tenant** with a **lockable single unit**, own bathroom and minimal cooking facility; **autonomy and privacy preserved**, services brought in. **Adult foster homes** take usually **≤5 residents** in a family-like setting.

2. **Intermediate and transition care** — home-based intermediate care, community rehabilitation, falls-prevention services, memory clinics and **post-hospital transition programmes** that provide time-limited rehabilitation and **reduce the risk of entering an institution**.

E. Assessment, Case Management and Integration

1. Entry requires a **multidisciplinary comprehensive geriatric assessment** at home or in hospital, which determines **eligibility** and matches the person to services. Such teams also handle **suspected elder abuse and guardianship** issues.
2. **Case management** has five components: **assessment → care plan (prescription) → authorization → coordination → monitoring**. Its types are **eligibility management, care coordination, utilization management, disease management and chronic care coordination**.
3. **Eligibility management is the commonest type and does not directly improve care**; overall, the **effectiveness of case management is not well established**. The case manager is trapped between being a **patient advocate and a gatekeeper** — two incompatible roles — and often has **responsibility without purchasing authority**.
4. **Integrated models**: **PACE (Program of All-Inclusive Care for the Elderly)** pools **capitated funding** to deliver combined health and social care to people who are **nursing-home eligible but still living in the community** — effective, but **narrowly targeted and expensive**. **"Cash and counselling"** consumer-directed schemes let disabled elders **purchase their own services, including from relatives**, obtaining more care for less money without adverse effects.

F. Family Carers and the Physician's Role

1. **Informal care is the backbone — more than 80% of all community care is informal**, mostly given by women. Formal services should **supplement, not replace**, family care; **respite is the single most important support**. Sustainability is threatened as more women enter the workforce.
2. The physician should **detect functional dependency early, refer for assessment, advocate actively for community options**, make home visits where needed, and **help develop services that are needed but locally absent**.

G. Limitations

1. Persistent weaknesses: **fragmented multiple programmes with patchy coordination, waiting lists, chronic underfunding, poor gate-keeping and weak exit strategies, transport difficulties, and very uneven geographic development** — public money spent on home care remains a fraction of that spent on institutions.

Latest Updates (2023–Present)

Global burden and WHO direction

- About **142 million older people** worldwide cannot meet their basic needs independently; **two of three older people** will need care and support; about **65% will need help with ADLs**; **unpaid informal care is roughly 80% of all long-term care** — confirming that family care is the backbone.
- The **WHO framework for an integrated continuum of long-term care** makes **support to unpaid caregivers** an explicit system pillar, alongside UHC financing and a sustainable trained workforce.
- **ICOPE handbook, 2nd edition (January 2025)** — guidance for **person-centred assessment and care pathways in primary care**, centred on **intrinsic capacity and functional ability** — is now the reference tool for **community-level screening and care planning**.

- **PAHO Policy on Long-Term Care (2025–2034)** gives Member States technical guidance to develop and expand LTC capacity, with strong emphasis on community-based delivery.

India — community-based LTC architecture

- **Operational Guidelines for Elderly Care at Health and Wellness Centres (Ayushman Arogya Mandirs)** define India's community model: the **ASHA maps the elderly population into bed-bound, restricted-mobility and mobile categories**, and separately identifies **poor and single elderly**; the **PHC Medical Officer** performs in-depth assessment and issues a **personalised care plan**; the **ANM/MPW makes weekly visits to bed-bound elderly**, with monthly visits from the sub-health centre, plus **family counselling**.
- **NPHCE** explicitly includes community LTC: health promotion, preventive services, diagnosis and management of geriatric problems (OPD and IPD), **day care services, rehabilitative services and home-based care**. At district level it provides a **geriatric clinic twice weekly, a rehabilitation unit for physiotherapy and counselling, and domiciliary visits by the rehabilitation worker for bed-ridden elderly** with family counselling on home-based care.
- Current NPHCE structure: geriatric OPD, physiotherapy and IPD services at **AAM–HWCs, PHCs, CHCs and District Hospitals**, plus **2 National Centres for Ageing (AIIMS New Delhi and Madras Medical College, Chennai) and 17 Regional Geriatric Centres**.
- **India Ageing Report 2023**: elderly will exceed **20% of the population by 2050** and outnumber children by 2046. It recommends **in-situ (at-home) ageing** through **elder creches and day-care centres**, and bringing **all old age homes under regulatory purview**.
- The **Global Observatory for Long-Term Care (2025)** records that India has **no national formal LTC system**. Community supports run through **AVYAY** — old-age homes, **physiotherapy centres and mobile medicare units**, assistive devices under **RVY**, **Elder Line (14567)**, **SACRED** and **SAGE**.
- **Community-based dementia care in India (scoping review, 2025)**: existing models include **community memory clinics, dementia day-care centres, home-based caregiver support programmes, task-sharing through mobile technology and tele-mentoring of primary care physicians**; integrating dementia care into **primary health care** is proposed as the scalable and sustainable model.

Workforce and financing of HCBS

- **CMS "Ensuring Access to Medicaid Services" final rule (22 April 2024)** — the biggest HCBS reform in years — covers **direct care worker compensation, HCBS waiting lists, grievance processes, critical incident reporting and HCBS quality reporting**, with greater payment-rate transparency. Its central provision, the **"80/20 rule"**, requires HCBS providers to spend **at least 80% of Medicaid payments on direct care worker compensation**, with **six years to demonstrate compliance**. It applies to **homemaker, home health aide and personal care services**.

Hospital-level care moved into the home

- The **Acute Hospital Care at Home (AHCAH)** initiative has been extended for five years **through 30 September 2030** under the Consolidated Appropriations Act, 2026, with operational requirements unchanged — **24/7 RN coverage, two in-person visits daily and EMS coordination**. **366 programmes across 139 health systems in 37 states** are approved. This directly serves the geriatric goal of avoiding **hospital-associated functional decline and delirium**.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)

Default site of care	Balance already shifting from institution to HCBS	**Ageing in place / in-situ ageing is explicit global and Indian policy**; even **acute hospital care** is now delivered at home (AHCAH extended to 2030)
Assessment tool	Local multidisciplinary assessment for eligibility	**WHO ICOPE screening of intrinsic capacity + personalised care pathway**; in India, **ASHA-led mapping and PHC-MO care plan** at Ayushman Arogya Mandirs
Direct care workforce	Low-paid, high-turnover aides; a background problem	**Explicitly regulated** — CMS **80/20 rule** mandates ≥80% of payments to direct care worker compensation; WHO names workforce as a system pillar
Carer support	Respite described as a service	**Support to unpaid caregivers is a formal pillar** of the WHO LTC framework
Case management	Effectiveness unproven; eligibility management commonest	Shift toward **integrated, capitated, person-centred models** and **consumer-directed care**; HCBS **waitlist and quality reporting** now mandated
Day care	Recreational/restorative, respite value	Expanded to **dementia-specific day care** and, for India, proposed **elder creches / short-term care facilities**
India-specific delivery	Not part of the classical HCBS model	**NPHCE home-based care and domiciliary visits, HWC elderly-care guidelines, AVYAY, Elder Line 14567, AB PM-JAY for ≥70 years**

Exam One-Liners

- **HCBS = health + personal + social care delivered at home and in the neighbourhood.**
- **Two-thirds of disabled older people live in the community**; 1–3 equally disabled at home per nursing home resident.
- **>80% of community long-term care is informal**, mostly provided by women.
- **Homemaking is needed more often than home health.**
- **Adult day care's greatest value = respite for the carer.**
- **Day hospital = ambulatory hospital services with a rehabilitation emphasis.**
- **Transportation is the commonest limiting factor** for day programmes.
- **Case management = assessment → care plan → authorization → coordination → monitoring.**
- **Advocate versus gatekeeper** — the central conflict of the case manager's role.
- **PACE** = capitated integrated care for **nursing-home-eligible people living in the community**.
- **"Cash and counselling"** = consumer-directed purchase of services, including from relatives.
- **"Woodwork effect"** = dependency-based eligibility draws in people who would never have been institutionalised.
- **India's community LTC**: ASHA maps **bed-bound / restricted / mobile** elderly; ANM makes **weekly visits to bed-bound**; PHC-MO gives the **personalised care plan**.
- **NPHCE** includes **day care, rehabilitation and home-based care**, with **2 National Centres for Ageing and 17 Regional Geriatric Centres**.
- **CMS 80/20 rule** = ≥80% of HCBS payments must go to **direct care worker compensation**.
- **Acute Hospital Care at Home extended to 30 September 2030.**

Q3. Home-Based Care in the Elderly

Components, eligibility, home visit yield, technology, evidence and limitations — 15 marks

A. Definition and Historical Context

1. **Home-based care** is the delivery of **medical, nursing, rehabilitative, personal and social care in the patient's own residence**, so that a dependent older person can remain at home instead of moving to an institution.
2. Historically, medicine was practised at home — in the mid-1900s about **40% of all patient–physician encounters took place at home**, falling to **under 1% by 1980**. Home healthcare began growing again in the **1980s** as an organised, multidisciplinary service.
3. The present model is delivered mainly by **nurses, therapists and personal care providers**; **physician house calls remain grossly under-utilised** for frail older adults.

B. Components of Home-Based Care

1. **Home health services** — skilled **nursing, physiotherapy, occupational therapy and speech therapy**. Typical uses are **medication management, disease assessment, wound care, home safety evaluation and patient/family education**.
2. **Personal care and homemaker services** — bathing, dressing, toileting, laundry, housekeeping, meal preparation. These are what most older people actually need, yet they are **usually not funded**, so the cost falls on the family.
3. **Home-based palliative and hospice care** provides nursing, therapy, social work and family support at home; **home hospice cannot provide continuous 24-hour personal care**.
4. **Support services**: home-delivered meals, transport, legal aid, individual case management and social services — often on a **sliding-fee scale**, with availability varying widely by locality.
5. **Home-based intermediate care and community rehabilitation**: community matron services, falls-prevention services, memory clinics and **community geriatric teams delivering comprehensive geriatric assessment at home**.

C. Eligibility and Process of Care

1. Entry usually requires a **physician's order**, documentation that the person is **"homebound"**, and need for **intermittent skilled care by a nurse or therapist**. The definition of "homebound" is **vague**, and large numbers of dependent but "custodial" elders are therefore **excluded**.
2. The average enrollee receives about **30 visits**; payment has shifted from **fee-for-service to prospective payment** per certification period, which shortened episodes but increased the number of recipients.
3. Quality is tracked by a **structured outcome dataset (OASIS)** completed at defined stages, generating around **28 functionally based quality measures** (e.g. improvement in bathing or toileting) plus **emergency and hospital utilisation**, which are publicly reported.

D. Clinical Content of the Home Visit

1. The **yield of a home visit** is unique: verification of diagnoses, **direct inspection of all medicines**, nutrition, observation of **ADL/IADL performance in the real environment**, cognition and mood, **carer capability and strain**, detection of **elder abuse or neglect**, and the true social situation.
2. **Home safety and environmental assessment** — the occupational therapist evaluates the **person–environment fit** and recommends **home modification** (grab bars, railings, raised toilet seat, shower chair, lighting), **assistive devices** (long-handled reacher, sock aid, adapted utensils) and **task simplification**. Poor environmental fit increases risk of **dependency, falls and injury**.

3. A **restorative philosophy is essential**. If carers do everything for the person, the result is **deconditioning, dependency, contractures and the sequelae of immobility** — the older person must be encouraged to perform their own ADLs at home.

E. Evidence and Effectiveness

1. **House calls are effective for homebound, chronically ill patients**, with the clearest benefit in **chronic relapsing diseases such as congestive cardiac failure and COPD**; regular professional visits **improve disease control and reduce hospitalisation**, producing societal cost savings.
2. **Preventive home visitation** aims at **primary prevention** (immunisation, exercise), **secondary prevention** (detecting untreated problems) and **tertiary prevention** (improving medication use), to delay functional decline and institutionalisation. **Benefits have not been definitively confirmed, so routine preventive home visits cannot be recommended as standard practice** — though home visits remain valuable within outpatient and inpatient programmes.
3. Home care must include a strategy for **long-term follow-up and, often, formal case management**, so that needs and services are correctly matched and followed through.

F. Technology in Home Care

1. Technology has widened what is possible at home: **mobile radiology and laboratory services, intravenous access and infusion devices** (allowing IV therapy without hospital transfer), **portable ECG, point-of-care testing and telemonitoring**. Monitoring studies, mostly in **chronic cardiac disease**, show **reduced hospitalisation, mortality, healthcare utilisation and exacerbations**.
2. **Smart home technology**: ambient light and **bed-occupancy sensors** with **passive infrared sensors** guide the older person safely to the toilet at night, prompt medication, detect **wandering in dementia** and **detect falls** with automatic alerts. Caution — the smart home is like **an extra carer that never tires, but it can never supply human care** and must not be used as a cheap substitute.

G. Family Carers and Limitations

1. **Informal family care remains the backbone** — home services should **bolster, not replace**, family effort, with **respite, carer education and psychological support**. Main limitations: **restrictive eligibility, no funding for personal/custodial care, fragmentation between programmes, workforce shortage and turnover, transport difficulties and carer burnout**.

Latest Updates (2023–Present)

Hospital-level care at home

- The **Acute Hospital Care at Home (AHCAH)** initiative is now durable — extended for five years **through 30 September 2030** under the Consolidated Appropriations Act, 2026, with unchanged requirements of **24/7 registered nurse coverage, two in-person visits daily and EMS coordination**. **366 programmes across 139 health systems in 37 states** are approved.
- **Meta-analytic evidence in older adults**: a systematic review and meta-analysis of RCTs to April 2024 (**11 RCTs, 3,301 patients**) found hospital-at-home gave a **significantly shorter length of stay** than traditional hospital care. A separate synthesis of **15 trials** found **early-discharge hospital-at-home associated with lower mortality (low-certainty evidence) and shorter treatment duration**, with inconclusive effects on readmission and mental status. For **admission-avoidance** hospital-at-home, pooled data suggest **reduced readmission (RR 0.76, 95% CI 0.58–1.01)**, most marked in **respiratory disease (RR 0.53, 95% CI 0.39–0.73)**, with **no significant difference in mortality**.

WHO framework

- About **142 million older people worldwide cannot meet basic needs independently**; **two of three** will need care and support; roughly **65% will need help with ADLs**; and **unpaid informal care accounts for about 80% of long-term care** — the empirical basis for insisting that home care must support the family.
- The WHO long-term care framework makes **supporting unpaid caregivers** an explicit pillar. The **ICOPE handbook, 2nd edition (January 2025)** provides **person-centred assessment and care pathways for primary care and community settings**, covering the continuum through to long-term care and carer support.

India — home-based elderly care

- Under the **Elderly Care at Health and Wellness Centre (Ayushman Arogya Mandir) guidelines**, the **ASHA maps the elderly into bed-bound, restricted-mobility and mobile categories** and identifies **poor and single elderly**; the **PHC Medical Officer** provides in-depth assessment and a **personalised care plan**; the **ANM/MPW visits bed-bound elderly weekly**, with monthly visits from the sub-health centre and **family counselling**.
- **NPHCE** funds **day care services, rehabilitative services and home-based care**, and district hospitals provide **domiciliary visits by the rehabilitation worker for bed-ridden elderly** with counselling of family members. Structurally there are **2 National Centres for Ageing (AIIMS New Delhi, Madras Medical College Chennai) and 17 Regional Geriatric Centres**.
- **Burden of home-based palliative need (LASI analysis, BMC Palliative Care 2024)**: **one in eight Indians aged ≥60 years (12.2%)** has supportive or palliative care needs, with higher odds in those **aged ≥70 years (AOR 1.86), women (1.33), rural residents (1.72)**, and those with **cancer (2.84), respiratory disease (3.14) or stroke (2.58)**; needs were lower with higher education and health insurance.
- **Coverage is highly uneven**: parliamentary data of December 2025 show **Kerala recorded about 650,000 home visits in eight months to October 2025** and Maharashtra about 167,000, while **Uttar Pradesh reported about 42,500 visits** and **Bihar delivered services in only six districts**.
- **Workforce**: the **PM-SPECIAL (Training of Geriatric Care Givers)** scheme of the Ministry of Social Justice and Empowerment creates a professional cadre through four courses — **Geriatric Caregiver (Institutional and Home Care), Elderly Caretaker (Non-Clinical), Elderly Care Companion and Wellness Therapist for the Elderly** — with registration through the **Skill India Digital Hub**.
- The **Global Observatory for Long-Term Care (2025)** notes India has **no national formal long-term care system**; **AB PM-JAY (≥70 years) covers hospitalisation, not home care**, which remains largely out-of-pocket.

Home care workforce regulation elsewhere

- The CMS **"80/20 rule"** requires HCBS providers to spend **at least 80% of Medicaid payments on direct care worker compensation**, with six years to comply, applying to **homemaker, home health aide and personal care services** — intended to stabilise a workforce whose turnover is the greatest threat to home care access.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Scope deliverable at home	Skilled nursing, therapy, IV therapy, mobile imaging and laboratory	**Full inpatient-level acute care at home** (AHCAH secured to 2030) with defined operating standards

Evidence for hospital-at-home	Emerging; house calls beneficial in CCF and COPD	Meta-analyses in older adults: **shorter length of stay, lower mortality (low certainty) for early discharge, reduced readmission especially in respiratory disease**
Preventive home visits	Benefits unconfirmed → not recommended routinely	Still not universal, but replaced by **risk-stratified targeting** (ASHA bed-bound mapping) and **ICOPE-based screening**
Home care workforce	Aides largely untrained, high turnover	**80/20 compensation rule** (US); **PM-SPECIAL NSQF-certified geriatric caregiver courses** (India)
Technology	Telemonitoring and smart homes promising	**Routine remote monitoring, digital tools and tele-mentoring of primary care physicians** for home dementia care
Palliative care at home	Hospice model; home hospice cannot give 24-hour care	India: home-based palliative care is **explicit policy**, but **1 in 8 older Indians has palliative need** against sharply unequal state coverage
Carer support	Respite described as a service	**Support to unpaid caregivers is a formal pillar** of WHO's long-term care framework

Exam One-Liners

- **Home-based care = care delivered where the patient lives, not where the doctor works.**
- **40% of encounters at home in mid-1900s → <1% by 1980**; revival from the 1980s.
- **Physician house calls remain the most under-used element** of home care.
- **Eligibility triad**: physician order + **homebound status** + need for **intermittent skilled care**.
- **"Homebound" is a vague definition** that excludes many custodial-need elders.
- **OASIS** = the structured outcome dataset for home health quality measurement.
- The **medicine-bag review** and observation of **ADLs in the real environment** are the unique yield of a home visit.
- **OT home hazard assessment** = established falls-prevention intervention.
- **Doing everything for the patient causes deconditioning** — home care must be restorative.
- **House calls benefit CCF and COPD most**, reducing hospitalisation.
- **Routine preventive home visits are not recommended** — benefit unconfirmed.
- **Smart home = an extra carer that never tires, but never a substitute for human care.**
- **AHCAH extended to 30 September 2030**; requires **two visits daily and 24/7 RN cover**.
- **India**: ASHA maps bed-bound / restricted / mobile; **ANM visits bed-bound weekly**.
- **1 in 8 Indians aged ≥60 (12.2%) has supportive or palliative care needs.**
- **PM-SPECIAL** = MoSJE scheme creating a trained **geriatric caregiver cadre**.

Q4. Day Hospitals and Day Care Centres for Older Adults

Need for day hospitals in geriatric practice and the practical running of a day care centre — 15 marks

A. Definitions and Types

1. A **geriatric day hospital** is an **outpatient facility where older patients attend for a full or near-full day and receive multidisciplinary assessment, treatment and rehabilitation "under one roof"** — virtually all hospital services made available on an **ambulatory basis**, with emphasis on **physiotherapy and occupational therapy**.
2. Four levels must be distinguished: **senior centre** (recreational, for the *well* elderly; the most frequently used community service); **adult day care** (social model — supervised recreational and restorative activity for people with limited function; some dementia-specific); **adult day health centre** (day care plus nursing, physiotherapy and social work); and **geriatric day hospital** (medical model — full multidisciplinary CGA, treatment and rehabilitation).
3. The concept descends from **Marjorie Warren's principle** that every older person deserves **comprehensive assessment and a trial of rehabilitation before being consigned to long-term institutional care**. The British day hospital model was subsequently exported worldwide.

B. Need for Day Hospitals in Geriatric Practice

1. **Demographic pressure with shrinking inpatient capacity** — rising numbers of frail, disabled older people at a time when **acute beds are being reduced and lengths of stay shortened**, creating a gap between hospital and home that the day hospital fills.
2. **Avoids the hazards of admission** — hospitalisation causes **disorientation, delirium, deconditioning ("pyjama paralysis") and unnecessary institutionalisation**, particularly in dementia. The day hospital allows treatment **without occupying a bed**.
3. **Focal point for entry into the geriatric care system** — provides **multidimensional assessment coupled with an intervention** (rehabilitation, counselling or placement decision), which is what distinguishes assessment programmes that work from those that do not.
4. **Prevents admission, facilitates early discharge and reduces inpatient bed use** by continuing rehabilitation after the patient goes home.
5. Offers **intensity and rapidity of assessment** for the frail or acutely unwell — an advantage over office-based outpatient assessment — while **avoiding the cost of an inpatient stay**.
6. **Supports the carer.** Day attendance is the main organised form of **respite**; when carer strain is high, **day care or respite is preferable to admission**, which itself carries a higher risk of transition into permanent care.
7. Fills the **middle position in the rehabilitation spectrum**, between the inpatient rehabilitation unit and home-based rehabilitation — the latter suits only the **least disabled who have good live-in support**.

C. Services Provided

1. **Core services**: multidisciplinary CGA, medical review and **rationalisation of drugs**, physiotherapy, occupational therapy, speech and swallowing therapy, nursing procedures (dressings, injections, catheter care), investigations, dietetics, podiatry, social work and psychology.
2. **Specialist programmes**: **falls and balance clinic, post-stroke and post-fracture rehabilitation, continence clinic, memory clinic, Parkinson's and leg-ulcer clinics, anticoagulation review, dementia day respite and palliative day care**.

D. Running a Day Centre — Practical Organisation

1. **Team**: geriatrician-led **interdisciplinary team** — nurse, physiotherapist, occupational therapist, speech therapist, social worker, dietitian, pharmacist, psychologist, care assistants and a coordinator. The **interdisciplinary team conference is the critical step**: it pools perspectives, sets priorities, prevents duplication, and must involve the **patient and carer to preserve choice**.
2. **Physical design**: ground-floor or lift access, **barrier-free layout**, handrails, non-slip floors, accessible toilets, good lighting with **large clear signage and contrasting colours** (dementia-friendly), therapy gymnasium, **ADL kitchen and bathroom for training**, treatment room, dining area, a quiet **de-stimulation space**, rest area and an established link to the parent hospital.
3. **Transport is the single greatest operational determinant** — difficult to arrange, expensive and time-consuming. **Special vans are needed**, and to avoid exhausting travel times the **catchment area must be kept small**.
4. **Attendance pattern**: most clients attend **2–3 days a week rather than 5**, which increases efficiency and allows more patients to be served.
5. **Process**: explicit **referral criteria and sources** (GP, hospital discharge, emergency department, self/family), initial CGA with **goal setting**, an individualised care plan with defined therapy targets, **periodic review and clear discharge criteria** to prevent "silting up" of places, followed by structured hand-back to primary care with **long-term follow-up and case management**.
6. **Governance and outcome measurement**: collect data at **entry and at discharge** to prove effectiveness and permit comparison between programmes — **Barthel Index, FIM, Berg Balance Scale, Timed Up-and-Go, MMSE/MoCA, GDS and carer burden scales** — with audit and standardised documentation.

E. Evidence and Limitations

1. **Evidence**: day hospital attendance is clearly **better than no comprehensive care** — less death, institutionalisation and deterioration in ADLs — but shows **little advantage over other comprehensive geriatric services or home-based care, and may cost more**. In old-age psychiatry the supporting literature was sparse and **many day hospitals were decommissioned**, with voluntary, charitable and private day care plus **crisis resolution home treatment teams** taking their place.
2. **Limitations**: transport dependence, high staff intensity and cost per attendance, reliance on a carer to prepare and hand over the patient, blocked places from unclear discharge criteria, and **very poor coverage in low- and middle-income countries**, where the mismatch between rehabilitation need and available resource is greatest.

Latest Updates (2023–Present)

Evidence for the medical day hospital

- The definitive synthesis remains the **Cochrane review (Brown, Forster, Young, Crocker, Benham, Langhorne)**: **16 trials, 3,689 participants, 37 day hospitals**. There is **low-quality evidence that day hospitals are effective compared with no comprehensive care** for the combined outcome of **death or poor outcome and for deterioration in ADL**, with **no clear advantage over other forms of medical care provision**. Economic value relative to other services is unclear; the authors concluded the findings **do not support closure of day hospital services but do support exploring alternative systems** for delivering equivalent or superior comprehensive care.

Evidence for adult day services / day care centres

- An **updated systematic review covering 2015–2025** strengthens the case: regular adult day service use is associated with **reduced caregiver stress, improved mood and physiological**

stress reduction; on attendance days caregivers report **lower negative affect and higher positive affect**. Participation is linked to **delayed nursing home placement and consequent cost savings**. Utilisation remains suboptimal because of **financial constraints, limited awareness, caregiver reluctance and poor availability**; facilitators include **caregiver education, culturally tailored programming, financial assistance and high-quality staff engagement**.

- Day services can **delay or prevent nursing home placement by supporting informal caregiving** — caregivers experiencing stress and burden are more likely to institutionalise a relative with dementia.
- **Carer support should be built into the day centre**: the **ADS Plus multisite cluster-randomised trial (Gerontologist, 2024)** across **34 adult day services** tested a staff-delivered caregiver programme providing **dementia education, support and validation, referrals and linkages, and strategies for care challenges and self-care** over 12 months, built on five components — **care management, referral/linkage, dementia education, situational counselling and stress reduction, and skills to manage behavioural symptoms**.
- **Dementia now dominates the clientele**: in Taiwan, which is scaling up **a day care centre in every junior high school district**, about **70% of day-care clients are persons with dementia**.

WHO direction and India

- The **ICOPE handbook, 2nd edition (January 2025)** makes the day centre a natural site for **intrinsic capacity screening and pathway delivery**; **support to unpaid caregivers** is an explicit WHO pillar.
- **NPHCE** already mandates **day care services and rehabilitative services** alongside home-based care, with districts linked to Regional Geriatric Centres.
- The **India Ageing Report 2023 (UNFPA–IIPS)** recommends promoting **in-situ ageing** by creating **short-term care facilities such as elder creches and day-care centres**.
- Under **AVYAY**, the **Integrated Programme for Senior Citizens (IPSrC)** funds basic amenities, medical care and recreation for indigent elders; the **Senior Citizen Homes (SrCH)** scheme funds running and maintenance of homes; and **Regional Resource and Training Centres (RRTCs)** act as nodal technical agencies.
- **Kerala's models are nationally cited**: **Sayamprabha Homes** provide **day-care facilities in partnership with local self-government institutions** (initially about **70 centres**), offering counselling, yoga, meditation and peer companionship; **Vayomithram** provides mobile clinics, free medicines, palliative care and a help desk for those above 65 in municipal and corporation areas, each unit staffed by a **medical officer, staff nurse and junior public health nurse**, with dementia specifically covered.
- An **EAC-PM working paper** highlights Kerala's **Vayomithram and Kudumbashree** elder-care models for linking training with employment, while noting that **AVYAY has limited reach** and that **workforce development remains fragmented because there is no standardised certification system**.

Competing service models

- The **Acute Hospital Care at Home** initiative has been extended to **30 September 2030**; together with **virtual wards and same-day ambulatory frailty services**, these are increasingly the "alternative systems" the Cochrane authors called for.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)

Status of the day hospital	A core, established component of geriatric services	Many **decommissioned**; role reframed as a **hub for CGA and frailty management**, with hospital-at-home, virtual wards and ambulatory frailty units substituting
Evidence base	Benefit over no treatment; little advantage over other comprehensive services	**Confirmed by Cochrane (16 trials, 3,689 participants, low certainty)** — closure not supported, but **alternative delivery systems should be explored**
Adult day care benefit	Chiefly respite value for the carer	Recent evidence adds **reduced caregiver stress and stress biomarkers, delayed nursing home placement and cost savings**
Carer support	Incidental to the patient's attendance	Should be a **structured, staff-delivered embedded programme** (ADS Plus trial, 34 sites)
Case mix	Some programmes dementia-specific	**Dementia now dominates** day-centre attendance (~70% in Taiwan); dementia-friendly design is standard
India	Not part of the classical model	**NPHCE day care and rehabilitation; elder creches/day centres** recommended by India Ageing Report; **AVYAY–IPSrC** funding; **Kerala Sayamprabha and Vayomithram** as replicable models
Outcome measurement	Entry-versus-discharge comparison	Move toward **uniform outcome sets and Goal Attainment Scaling**; caregiver outcomes still under-collected

Exam One-Liners

- **Day hospital = multidisciplinary rehabilitation "under one roof" on an ambulatory basis.**
- **Senior centre = well elderly; day care = functionally limited; day health centre = intermediate; day hospital = medical model.**
- **Marjorie Warren's principle**: assessment and rehabilitation *before* institutionalisation.
- **Assessment must be coupled with an intervention** — that is what makes geriatric assessment effective.
- **Day hospital prevents admission, shortens stay and facilitates early discharge.**
- **Respite for the carer may be the single most important output** of day attendance.
- **Transportation is the commonest limiting factor** — special vans, small catchment area.
- **Most clients attend 2–3 days a week, not 5.**
- **The interdisciplinary team conference is the critical step** in the process of care.
- **Clear discharge criteria prevent "silting up"** of day hospital places.
- **Cochrane**: 16 trials, 3,689 participants — better than no comprehensive care, **no clear advantage over other comprehensive services**; **closure not supported**.
- **Adult day services delay nursing home placement** and reduce caregiver stress.
- **ADS Plus** = embedding structured caregiver support inside the day centre.
- **NPHCE includes day care and rehabilitative services** in its service package.
- **India Ageing Report 2023** recommends **elder creches and day-care centres**.
- **Kerala: Sayamprabha Homes and Vayomithram** are the model Indian programmes.

Q5. House Call Programme (Home-Based Medical Care)

Target population, structure, conduct of the visit, evidence and ethical issues — 15 marks

A. Definition and Rationale

1. A **house call programme** is the organised delivery of **physician-led (or physician–nurse-practitioner-led) medical care in the patient's own home**, for people who cannot readily reach a clinic. It is the medical component of home-based care, distinct from home health nursing.
2. In the **mid-1900s about 40% of all patient–physician encounters occurred at home**, falling to **under 1% of healthcare visits by 1980**. Home healthcare revived in the **1980s**, but **physician house calls remain under-utilised**.
3. Justification: the **homebound frail elderly** are the highest-cost, highest-need group; the home visit gives **diagnostic information obtainable nowhere else**, avoids the hardship of transport and the hazards of hospital (delirium, deconditioning, iatrogenesis), and strengthens **continuity and carer support**.

B. Target Population and Indications

1. Ideal candidates: **homebound with functional dependency; frailty and multimorbidity; advanced dementia; recurrent admissions; recent hospital discharge needing transition care; end-of-life patients; repeated clinic "no-shows"; suspected self-neglect, hoarding or elder abuse; and carer strain**.
2. **Targeting matters** — the sickest and most frail, at highest risk of hospitalisation, gain the most; applied indiscriminately, the yield falls sharply.
3. Four classic indications: **management of acute or chronic illness at home; coordination of post-hospitalisation transition of care; comprehensive health/functional assessment; and end-of-life care**.

C. Structure of the Programme

1. **Team**: physician or nurse practitioner leading an interdisciplinary team — **nurse, social worker, physiotherapist, occupational therapist, pharmacist and care coordinator** — with **24-hour telephone access, rapid response to urgent needs, embedded palliative care and explicit support to family caregivers**.
2. **Logistics**: a **defined, small geographic catchment** (travel time is the main cost driver), visits **clustered by locality**, a realistic panel size per clinician, staff safety protocols and structured **communication back to the primary physician**.
3. **Linkages**: formal tie-ups with a **home health agency, pharmacy, mobile laboratory and imaging services, hospice and social services**, so that the house call translates into delivered care.
4. **The house-call bag**: sphygmomanometer, stethoscope, pulse oximeter, glucometer, thermometer, torch, otoscope and ophthalmoscope, tuning fork, portable ECG, point-of-care and urine dipstick tests, dressings, catheters, syringes, gloves and sanitiser, sharps container, emergency drugs and **assessment forms/scales**.
5. **Technology support**: **mobile radiology and laboratory services, intravenous access and infusion devices** (allowing IV therapy without transfer), **portable ECG, point-of-care testing and telemonitoring**.

D. Conducting the Visit

1. Use a **structured framework** covering **Immobility, Nutrition, Home environment, Other people (carers), Medications, Examination, Safety, Spiritual health and Services** — the widely taught **INHOMESSS** checklist.
2. **High-yield elements unique to the home**: the **"brown-bag" review of every medicine actually in the house**, **observed ADL and IADL performance in the real environment**, inspection of the kitchen and food stores, **skin and pressure areas**, continence, cognition and mood, **falls hazards**, and detection of **elder abuse, neglect or self-neglect**.
3. **Home safety and environmental modification** with occupational therapy input — grab bars, railings, raised toilet seat, shower chair, lighting, decluttering and assistive devices — correcting the **person–environment mismatch** that drives falls and dependency.
4. **Close the visit properly**: agreed goals, **rationalisation of drugs**, advance care planning and documentation of preferences, a written care plan, follow-up schedule, escalation plan, and a **strategy for long-term follow-up with formal case management**.

E. Evidence and Outcomes

1. House calls are **effective for the aged and chronically ill homebound**, with clearest benefit in **chronic relapsing diseases such as congestive cardiac failure and COPD**; regular professional visits **improve disease control and reduce hospitalisation**, generating societal cost savings.
2. **Preventive home visitation** (primary — immunisation, exercise; secondary — detecting untreated problems; tertiary — improving medication use) aims to delay disability and institutionalisation, but **benefits are not definitively confirmed and it cannot be recommended as routine practice**. Home visits retain value **within outpatient and hospital-discharge programmes** — the hospital–home assessment model shortens stay and allows evaluation of the home itself.

F. Limitations and Ethical Issues

1. **Practical limitations**: travel time and inefficiency, limited on-site diagnostics, physician reluctance and workforce shortage, staff safety, weak reimbursement, and the persistently **vague "homebound" criterion**.
2. **Ethical issues**: the clinician is a **guest, not the host** — confidentiality within a shared household, professional boundaries and hospitality, **autonomy versus safety** when living conditions are unsafe, capacity and consent, and balancing the wishes of the patient against those of the family.
3. **In India**, house calls are largely **private and out-of-pocket** or delivered by NGOs and state programmes; the public backbone is **domiciliary visiting by rehabilitation workers, ANMs and ASHAs** rather than by physicians.

Latest Updates (2023–Present)

> **Independence at Home (IAH) — the reference house call programme**
>
> - IAH was authorised under **Section 3024 of the Affordable Care Act**, extended repeatedly, and **concluded on 31 December 2023**. It tested a payment-incentive and service-delivery model of **home-based primary care for Medicare fee-for-service beneficiaries with multiple chronic illnesses and functional limitations**, examining whether comprehensive, coordinated, continuous, accessible home care reduces preventable hospitalisations, readmissions and ED visits.
> - **Performance Year 10 results (published June 2025)**: only **one participant remained — Northwell Health House Calls**. Its beneficiaries' expenditures were **34.0% below the spending target (US$7.6 million), an average reduction of US$18,727 per beneficiary**

(per-beneficiary-per-month target US$6,436 versus actual US$4,249), earning an incentive payment of about **US$5.1 million**.

- The **six IAH quality measures** are the model set for any house-call programme: follow-up contact **within 48 hours of a hospital admission, discharge or ED visit**; **medication reconciliation in the home within 48 hours** of discharge or ED visit; **annual documentation of patient preferences**; **all-cause 30-day readmissions**; **hospital admissions for ambulatory-care-sensitive conditions**; and **ED visits for ambulatory-care-sensitive conditions**.

The evidence is genuinely mixed — know both sides

- **Positive**: earlier IAH reporting showed a **23% reduction in hospitalisations, a 27% decrease in 30-day readmissions and savings of US$111 per beneficiary per month (US$70 million over three years)**, while a large systematic review (**nine studies, N = 46,154**) of home-based primary care for homebound older adults found **fewer hospitalisations, fewer hospital bed-days, fewer ED visits and fewer long-term care admissions and bed-days**.
- **Cautionary**: a **CMS update of January 2023** concluded there is **"no compelling evidence"** that primary care delivered at home reduces Medicare spending or hospital use, though it may lead to better — or at least different — care. The independent evaluation found that **simply providing primary care in someone's home does not reduce total hospitalisations**, while patients and caregivers report **high satisfaction**.
- There is **moderate-strength evidence that the most complex patients — those at highest risk of hospitalisation or most frail — have the greatest potential to benefit**, which is why patient selection is central.
- Successful home-based primary care practices share five features: **interdisciplinary teams, integration of behavioural care and social supports, rapid response to urgent and acute needs, embedded palliative care, and active support of family caregivers**.

Interface with hospital-level home care, and India

- The **Acute Hospital Care at Home** initiative has been extended five years **to 30 September 2030**, with **24/7 nursing availability and two in-person visits daily**, and **366 programmes across 139 health systems in 37 states** approved — house-call teams increasingly act as the step-down service for these patients.
- India's public equivalent runs through primary care: under the **Ayushman Arogya Mandir elderly-care guidelines**, the **ASHA maps elderly people as bed-bound, restricted-mobility or mobile**; the **PHC Medical Officer** provides in-depth assessment and a **personalised care plan**; and the **ANM/MPW visits bed-bound elderly weekly**. **NPHCE** funds **domiciliary visits by the rehabilitation worker for bed-ridden elderly**.
- **Need is large and coverage uneven**: a LASI-based analysis found **one in eight Indians aged ≥60 years (12.2%) has supportive or palliative care needs**. Parliamentary data of December 2025 show **Kerala recorded about 650,000 home visits in eight months to October 2025** against **about 42,500 in Uttar Pradesh** and services in **only six districts of Bihar**.
- The **Global Observatory for Long-Term Care (2025)** records that India has **no national formal long-term care system**. The **PM-SPECIAL scheme** is building a trained cadre through courses including **Geriatric Caregiver (Institutional and Home Care)**.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Status of house calls		A defined discipline of **home-based primary care** with team standards; but the flagship **IAH**

	Effective but under-utilised; a small physician/NP home-care industry emerging	**demonstration ended December 2023** with only one practice remaining
Evidence	House calls reduce hospitalisation in CCF and COPD	**Mixed** — large observational and review data favourable, but CMS/independent evaluation found **no compelling reduction in spending or hospital use overall**; benefit concentrated in the **sickest and frailest**
Quality measurement	Not specified for house calls	Six explicit measures — **48-hour follow-up contact, 48-hour home medication reconciliation, annual documentation of preferences, 30-day readmissions, ACSC admissions and ACSC ED visits**
Preventive home visits	Not recommended routinely	Still not routine; replaced by **risk-stratified targeting** and **ICOPE-based screening**
Scope of care at home	Mobile imaging, IV therapy, point-of-care testing	Extends to **full inpatient-level acute care at home**, secured to 2030
India	Not addressed	**NPHCE domiciliary visits + weekly ANM visits to bed-bound elderly**; home-based palliative care is policy, but delivery is **grossly unequal between states**

Exam One-Liners

- **House call = organised physician-led medical care delivered in the patient's home.**
- **40% of encounters at home in the mid-1900s → <1% by 1980.**
- **Four indications**: acute/chronic illness, post-hospital transition, assessment, end-of-life care.
- **INHOMESSS** = Immobility, Nutrition, Home environment, Other people, Medications, Examination, Safety, Spiritual health, Services.
- The **"brown-bag" medication review** and **observed ADLs** are the unique yield of a home visit.
- **Benefit is greatest in CCF and COPD**, where visits reduce hospitalisation.
- **Routine preventive home visits are not recommended** — benefit unconfirmed.
- **Target the frailest** — moderate evidence that the sickest gain most.
- **IAH quality set**: 48-hour follow-up contact, 48-hour home medication reconciliation, documented preferences, 30-day readmission, ACSC admissions, ACSC ED visits.
- **IAH concluded 31 December 2023**; Year 10 showed expenditures **34% below target**.
- **CMS (2023): "no compelling evidence"** that home-based primary care alone reduces spending or hospital use.
- **Five features of successful programmes**: interdisciplinary team, behavioural/social supports, rapid urgent response, palliative care, caregiver support.
- **Travel time and catchment size are the main cost drivers.**
- The clinician on a house call is a **guest, not the host** — autonomy usually outweighs the clinician's view of safety.

Q6. Components of the Hospital Elder Life Program (HELP)

Target risk factors, core protocols, staffing, adapted models and evidence — 15 marks

A. Definition and Underlying Principle

1. **HELP is the original evidence-based, protocol-driven, multicomponent non-pharmacological programme** designed to **prevent delirium and cognitive and functional decline** in hospitalised older patients, developed by **Sharon Inouye** and first reported in 1999.
2. Its founding principle: **delirium is multifactorial**, so prevention requires a **multicomponent intervention targeting several modifiable risk factors simultaneously** — not a single drug. **Non-pharmacological measures are the mainstay of delirium prevention.**
3. Delivery model: **trained volunteers** working under an **interdisciplinary team**, with **daily protocol-driven visits** to patients identified as high risk on admission (usually aged ≥70 years).

B. The Six Target Risk Factors

1. HELP addresses six modifiable risk factors: **cognitive impairment, sleep deprivation, immobility, visual impairment, hearing impairment and dehydration** — with **medication review** as an essential accompanying element.

C. The Six Core Intervention Protocols (key examination content)

1. **Orientation protocol** — orientation board, repeated reorientation to time, place and person, and **therapeutic cognitively stimulating activities** (word games, reminiscence, discussion) three times daily for patients with cognitive impairment.
2. **Non-pharmacological sleep protocol** — warm drink, relaxation music, back massage, noise reduction, rescheduling of night-time medications and procedures; **avoids sedative-hypnotics**.
3. **Early mobilisation protocol** — **ambulation or active range-of-motion exercises three times a day**, and **minimising "tethers"** (urinary catheters, intravenous lines, restraints) that immobilise the patient.
4. **Vision protocol** — provision of **spectacles, magnifiers, large-print materials, adaptive illuminated equipment**, and reinforcement of their daily use.
5. **Hearing protocol** — **hearing aids and portable amplifiers, cerumen disimpaction** and special communication techniques.
6. **Dehydration/feeding protocol** — **early recognition of volume depletion, encouragement of oral fluids, volume repletion and feeding assistance** at mealtimes.

D. Structural and Staffing Components

1. **Core personnel**: a **geriatrician (or geriatric nurse specialist), an Elder Life Specialist, an Elder Life Nurse Specialist, a programme director and trained volunteers**, supported by therapy, pharmacy, nutrition and social work.
2. **Systematic case-finding**: screening of all admissions against **eligibility and risk criteria**, followed by enrolment and an individualised set of protocols matched to the patient's specific risk factors.
3. **Geriatric interdisciplinary rounds and nurse-specialist consultation**, provider education, and **linkage with community services at discharge**.
4. **Quality assurance**: continuous tracking of **protocol adherence**, delirium rates, falls and length of stay, with volunteer training, supervision and retention as a defined programme function — adherence is the main determinant of effectiveness.
5. **Family engagement** — families should remain at the bedside to **reassure and reorient, facilitate oral intake and encourage mobility**; risk of postoperative delirium should be discussed as part of **informed consent** for surgery.

E. Adapted Models

1. **mHELP (modified HELP)** — three **nurse-delivered daily protocols**: **orienting communication, oral hydration and nutritional assistance, and early mobilisation** — designed for older patients undergoing elective abdominal surgery.
2. **ABCDEF bundle** for the ICU — **A**ssess/prevent/manage pain; **B**oth spontaneous awakening and breathing trials; **C**hoice of analgesia and sedation; **D**elirium assess, prevent and manage; **E**arly mobility and exercise; **F**amily engagement and empowerment.

F. Evidence of Effectiveness

1. **Original controlled trial**: delirium occurred in **9.9% on the intervention unit versus 15.0% on usual-care units (matched OR 0.60, 95% CI 0.39–0.92)**.
2. **Systematic review and meta-analysis**: **14 studies showed a significant reduction in delirium incidence (OR 0.47, 95% CI 0.37–0.59)**; three studies showed a **42% reduction in falls**; nine studies on cost showed savings of **US$1,600–3,800 per patient in hospital costs** and **US$16,000 per person-year in long-term care costs** in the year following an episode of delirium. **mHELP cluster RCT**: relative risk of delirium **0.44 (95% CI 0.23–0.83)** with **length of stay two days shorter**.
3. HELP has been implemented in **over 200 hospitals worldwide** and is regarded as the **reference standard model** for delirium and fall prevention in hospitalised older adults. Where full implementation is not possible, clinicians should **implement individual components with their interprofessional team and advocate for system-level adoption**.

Latest Updates (2023–Present)

Contemporary meta-analytic evidence

- A **systematic review and meta-analysis restricted to randomised controlled trials (Geriatric Nursing, 2024)** searched four databases to January 2024 and included **9 RCTs with 2,583 patients**. HELP **significantly reduced the incidence of delirium and shortened length of hospital stay**, but showed **no statistically significant difference in delirium severity scores or fall rates** — a more conservative estimate than the earlier mixed-design meta-analysis.
- The larger earlier synthesis remains the basis for HELP's reputation, concluding it reduces delirium incidence and fall rate with a trend toward shorter stay and less institutionalisation, and that HELP has **"emerged as a reference standard model"** for improving hospital care of older people worldwide.

HELP-ME — the remote adaptation

- The **Modified and Extended Hospital Elder Life Program (HELP-ME)** was developed because HELP depends on **face-to-face protocols and volunteers**, which became impossible during the COVID-19 pandemic. HELP-ME adapts the established protocols for **remote and/or physically distanced delivery**, and was implemented at **four expert HELP sites**, with sites modifying one or two protocols per action cycle and refining them using patient data and feedback. It was developed at Beth Israel Deaconess/Hebrew SeniorLife by Fong and Inouye, with feasibility targets of enrolling 100 hospitalised patients and achieving at least **75% protocol adherence** — relevant wherever volunteer access is limited, including resource-constrained wards.
- Current descriptions of the programme list the targeted risk factors as **cognitive impairment, vision and hearing impairment, malnutrition and dehydration, immobility, sleep deprivation and medications** — with **medications now explicitly named** as a target.

Integration with Age-Friendly Health Systems (the 4Ms)

- A **JAGS 2023 special article** shows how traditional delirium prevention maps onto the **Age-Friendly Health Systems 4Ms — What Matters, Medication, Mentation, Mobility** — presenting an explicit **crosswalk between HELP core interventions and the 4Ms**. The **IHI guides for using the 4Ms in hospitals and ambulatory practice were updated in 2024**, adding tools for integrating **equity** into every step and clarifying the meaning of **mobility**.
- The 4Ms operational guidance echoes HELP directly: establish a **delirium prevention and management protocol including orientation and mobility**, ensure **personal adaptive equipment (glasses, hearing aids, dentures, walkers)** is available and noted on the whiteboard, make a **sleep kit orderable in the EHR**, offer **non-pharmacological options for sleep and pain**, and **ambulate three times a day**.
- **Delirium prevention is becoming a reportable quality metric**: the **CMS Age Friendly Hospital Measure**, based on the 4Ms together with Geriatric Surgery Verification and Geriatric Emergency Department Accreditation, gives hospitals a structured route to implement practices designed to reduce iatrogenic harm in older adults, including **delirium, falls and adverse drug events**.

Guideline position and newer delivery adaptations

- **NICE CG103** (delirium: prevention, diagnosis and management in hospital and long-term care) had its evidence reviewed in **January 2023**, with **new recommendations on assessing and diagnosing delirium**, while multicomponent non-pharmacological prevention remains the recommended approach.
- An **adapted HELP delivered by certified nursing assistants in long-term care** has been piloted, and trials are testing **family caregivers applying HELP principles after training by a geriatric nurse specialist** in older patients with fractured femur — a model directly transferable to Indian wards, where **family attendants substitute naturally for volunteers**.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Target risk factors	Six: cognition, sleep, immobility, vision, hearing, dehydration	**Medications explicitly added** as a seventh target; malnutrition grouped with dehydration
Delivery	Volunteer-based, face-to-face, in-hospital	**HELP-ME** enables **remote/physically distanced delivery**; adaptations by **nursing assistants in long-term care** and by **trained family caregivers**
Effect size	OR 0.47 for delirium; 42% fewer falls (mixed designs)	RCT-only meta-analysis (**9 RCTs, 2,583 patients**) confirms **reduced delirium and shorter stay**, but **no significant effect on fall rate or delirium severity**
Framework	Stand-alone delirium prevention programme	Embedded within the **Age-Friendly Health Systems 4Ms**, with a published **HELP–4Ms crosswalk**
Accountability	Local quality improvement	**CMS Age Friendly Hospital Measure** makes age-friendly, delirium-preventive practice a **hospital-level reportable attestation**
Guideline	Multicomponent non-pharmacological prevention	**NICE CG103 evidence reviewed January 2023** with new assessment and diagnosis recommendations; **antipsychotics still not recommended for prevention**

Exam One-Liners

- **HELP = Inouye's multicomponent, protocol-driven, volunteer-delivered delirium prevention programme (NEJM 1999).**
- **Six target risk factors**: cognitive impairment, sleep deprivation, immobility, visual impairment, hearing impairment, dehydration.
- **Six protocols**: orientation/therapeutic activities, sleep, early mobilisation, vision, hearing, hydration-feeding.
- **Mobilise three times a day and minimise "tethers"** (catheters, lines, restraints).
- **Original trial: delirium 9.9% vs 15.0%; matched OR 0.60.**
- **Meta-analysis: OR 0.47 for delirium; 42% fewer falls; savings US$1,600–3,800 per patient.**
- **RCT-only meta-analysis (2024): delirium ↓ and length of stay ↓, but falls and severity scores unchanged.**
- **mHELP = three nurse-delivered protocols** — orienting communication, oral hydration/ nutrition, early mobilisation; **RR 0.44, LOS 2 days shorter**.
- **ABCDEF bundle** = the ICU equivalent of HELP.
- **HELP-ME** = remote/physically distanced adaptation developed after COVID.
- **4Ms = What Matters, Medication, Mentation, Mobility.**
- **Antipsychotics do not prevent delirium**; benzodiazepines should be avoided.
- **Family at the bedside** — reassure, reorient, feed, mobilise: the low-cost Indian equivalent of the HELP volunteer.
- **Implemented in >200 hospitals worldwide** — the reference standard for delirium prevention.

Q7. Role of the Geriatric Social Worker

Position in the team, assessment, discharge planning, case management, settings and challenges — 15 marks

A. Definition and Position in the Team

1. The **geriatric (gerontological) social worker** is the professionally trained member of the interdisciplinary team responsible for the **social, psychological, economic, environmental and legal dimensions** of an older person's care.
2. Social work is one of the **minimum core disciplines** of every geriatric assessment programme, along with **physicians, nurses and physical and occupational therapists**; **special geriatric expertise among team members is crucial**.
3. The justification is structural: comprehensive geriatric assessment is **multidimensional**, and the **interdisciplinary team conference — the critical step in the process of care** — cannot set priorities without the social perspective.
4. In the **ACE unit model**, care management is deliberately shifted from a **biomedical to a biopsychosocial model**, focusing on the **relationship between the patient and the social structures needed for effective treatment**.

B. Assessment Functions

1. **Social assessment**: past social history, **family relationships and social resources**, living arrangements, personal preferences, finances, housing, and **availability and capability of the caregiver**.
2. **Psychosocial assessment in long-term care**: performed **within 1–2 weeks of admission** and as needed thereafter — identify serious psychosocial symptoms and **refer to a mental health professional**, **assess discharge potential**, and communicate findings to the team. **Knowing the family and their preferences and concerns is critical to good nursing home care.**
3. **Evidence of independent effect**: randomised trials of **social worker assessment and referral in community and outpatient settings** showed **reduced mortality, reduced hospital use, reduced permanent nursing home use and delayed development of disability**.
4. **Safety and protection**: identification of older people at **high safety risk — unsafe driving, elder abuse, neglect, self-neglect, unsafe living conditions** — and development of a plan for assessment or referral.
5. **Caregiver assessment**: burden, **financial stressors, social isolation and loneliness, and spiritual well-being**. Caregivers reporting **emotional stress have significantly increased mortality**, so **identification of the vulnerable caregiver and referral to social work and community resources can be lifesaving**.

C. Intervention and Linkage Functions

1. **Discharge planning — the classic core role.** Good discharge decisions separate two questions: **(i) what type of care will best achieve this patient's goals?** and **(ii) which provider can best deliver that care?** These require entirely different sets of information.
2. **Planning must begin early.** When started late, **availability of placements trumps careful consideration of options**, nursing home discharge is chosen because it is easiest to arrange, and the patient may be committed to an unnecessary lifetime of institutional care.
3. **Matching services to eligibility**: recommending **home health care, day care, assisted living, rehabilitation, nursing home or hospice** based on **clinical needs, personal values, home circumstances, financial resources and programme eligibility**.
4. **Transitional care and information transfer**: ensuring a **written summary of hospital course, discharge medications, cognitive and functional status, advance directives, plan of care**

and follow-up reaches the patient, family and receiving providers — **poor transmission of information drives readmission**.

5. **Counselling**: individual and family counselling, support around placement decisions, mediation of family conflict, **post-diagnostic counselling in memory clinics**, and **bereavement and grief support**.
6. **Resource mobilisation and advocacy**: entitlements, pensions, disability certification, insurance, **legal aid, guardianship, advance directives**, and access to welfare schemes.
7. **Case management**: assessment → care plan → authorisation → coordination → monitoring. This matters because **assessment without follow-up is unlikely to make any difference**; hence "geriatric assessment" has given way to **geriatric evaluation and management**.
8. **Palliative and end-of-life care**: referral to a **palliative care social worker promotes access to services, community resources, volunteers and transport**, and supports families where the support system is already at its limit; hospice programmes provide **bereavement follow-up for about a year after death**.
9. **Team, teaching and service development roles**: participation in team conferences and rounds, **training family caregivers**, running **caregiver support groups**, teaching, research, and advocating for locally missing services. Social workers can obtain **additional certification in gerontology**.

D. Settings and Challenges

1. **Settings**: acute wards and **ACE units, geriatric assessment clinics, geriatric emergency departments** (case management is a listed component), **day hospitals, nursing homes, community mental health teams for older people, home visits and hospices**.
2. **Challenges**: **great time pressure on discharge planners**, shortage of trained gerontological social workers, fragmented services, meagre resources, role overlap with case managers, and the inherent conflict between being both **patient advocate and gatekeeper**.

Latest Updates (2023–Present)

Social connection recognised as a determinant of health

- The **WHO Commission on Social Connection** released *From Loneliness to Social Connection – Charting a Path to Healthier Societies* on **30 June 2025**, finding that **1 in 6 people worldwide is affected by loneliness**, linked to an estimated **100 deaths every hour — more than 871,000 deaths annually**.
- Rates are **highest in low-income countries (about 24%)**. The Commission determined that social connection should be treated as a **"third pillar of health"** alongside physical and mental health, and the **World Health Assembly in May 2025 adopted its first-ever resolution on social connection** as a public health priority.
- In older populations, **social disconnection is associated with cognitive decline and dementia**, and lonely individuals are **twice as likely to experience depression**. Five strategic areas for action are proposed — **policy, research, interventions, measurement and public engagement**. This gives the geriatric social worker's core work — **combating isolation and rebuilding social networks** — a formal public health mandate.

Structured social assessment embedded in clinical pathways

- The **WHO ICOPE approach** is completed by the **assessment and management of social care and support**, covering **daily activities, living conditions, finances, loneliness, elder abuse, social engagement and participation**, together with a **dedicated care pathway to support the caregiver** — the social work domain written into a clinical algorithm.

- The **Age-Friendly Health Systems 4Ms** framework places **"What Matters" — goals-of-care conversations — at its centre**, and the **CMS Age Friendly Hospital Measure** now makes attestation to these practices, including **family caregiver involvement**, a hospital-level quality expectation.
- The **ADS Plus multisite cluster-randomised trial (2024)** across **34 adult day service sites** tested a staff-delivered caregiver support programme — **dementia education, support and validation, referrals and linkages, and strategies for care challenges and self-care** — essentially a structured social-work intervention delivered at scale.

India — the statutory and programmatic basis

- **NPHCE** derives from the **UN Convention on the Rights of Persons with Disabilities, the National Policy on Older Persons (1999) and Section 20 of the Maintenance and Welfare of Parents and Senior Citizens Act, 2007**, which deals with medical care of senior citizens. Its tertiary component, renamed **Rashtriya Varishtha Jan Swasthya Yojana**, runs through **19 Regional Geriatric Centres in 18 states and 2 National Centres for Ageing (AIIMS New Delhi and Madras Medical College, Chennai)**.
- Under the **MWPSC Act, 2007**, a **Tribunal presided over by the Revenue Divisional Officer** has been constituted in each sub-division for speedy disposal of maintenance petitions — maintenance can be claimed through these tribunals or under Section 125 CrPC, with tribunals empowered to order up to **₹10,000 per month**, and older people can seek eviction of abusive or neglectful children from their own property. Guiding families through these remedies is now core geriatric social work in India.
- The **Elder Line (national helpline 14567)** provides **free information, counselling, emotional support and field services** for issues of **care, abandonment, abuse and legal advice**, while the **Integrated Programme for Older Persons** funds NGOs to run **old age homes, day-care centres and mobile medicare units**.
- **Economic vulnerability defines the workload**: the **India Ageing Report 2023 (UNFPA–IIPS)** found **more than 40% of elderly Indians in the poorest wealth quintile and about 18.7% living with no income**, and recommended bringing **all old age homes under regulatory purview** and promoting **in-situ ageing with day-care and elder-creche facilities**.
- The **PM-SPECIAL scheme** of the Ministry of Social Justice and Empowerment is creating a trained cadre through courses such as **Geriatric Caregiver (Institutional and Home Care) and Elderly Care Companion**, though an **EAC-PM working paper** notes that **workforce development remains fragmented without a standardised certification system**, and that models such as **Kerala's Kudumbashree caregiver cooperatives** successfully link training to employment.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Social isolation	Recognised as a caregiver and patient problem	Formal public health priority — **1 in 6 people lonely, 871,000 deaths/year**; **first WHA resolution on social connection (May 2025)**; social connection as the **"third pillar of health"**
Social assessment	Part of CGA, discipline-dependent	**Structured and protocolised** — ICOPE social care and support domain plus a **caregiver pathway**; 4Ms "What Matters"
Caregiver support	Referral to support groups and community resources	

		Manualised, trial-tested programmes delivered by trained staff within day services (ADS Plus)
Accountability	Local practice	**CMS Age Friendly Hospital Measure** makes goals-of-care and caregiver engagement reportable
India	Not addressed	**NPHCE (Section 20, MWPSC Act) with 19 RGCs and 2 NCAs; maintenance tribunals in every sub-division; Elder Line 14567; IPSrC/AVYAY-funded day care and old age homes**
Workforce	Optional certification in gerontology	India lacks **standardised certification**; PM-SPECIAL and community caregiver cooperatives are the emerging response

Exam One-Liners

- **Social work is a minimum core discipline of every geriatric assessment programme.**
- **The interdisciplinary team conference is the critical step** — social work supplies the social perspective.
- **ACE units shift care from a biomedical to a biopsychosocial model.**
- **RCTs of social worker assessment and referral** reduced mortality, hospital use and permanent nursing home use.
- **Psychosocial assessment in long-term care: within 1–2 weeks of admission**, then as needed.
- **Two discharge decisions**: what *type* of care, then which *provider* — different information for each.
- **Late discharge planning means placement by availability, not by need.**
- **Poor information transfer at discharge drives readmission.**
- **Assessment without follow-up makes no difference** — hence geriatric *evaluation and management*.
- **Caregivers with emotional stress have increased mortality** — identifying them can be lifesaving.
- **Advocate versus gatekeeper** — the central role conflict of the social worker/case manager.
- **WHO 2025: 1 in 6 people lonely; ~871,000 deaths a year; ~100 deaths per hour.**
- **ICOPE social domain**: daily activities, living conditions, finances, loneliness, elder abuse, social participation — plus a **caregiver pathway**.
- **India: Elder Line 14567** for information, counselling, abuse, abandonment and legal advice.
- **MWPSC Act 2007** — maintenance tribunals under the RDO in each sub-division; up to **₹10,000 per month**.
- **>40% of Indian elderly are in the poorest wealth quintile; 18.7% have no income.**

Q8. Caregiver Burden, Stress and Burnout — Assessment and Management

Definitions, domains of impact, screening instruments and evidence-based interventions — 15 marks

A. Definitions and Concepts

1. A **caregiver** is a person who provides assistance to a dependent person; the prefix **"family caregiver"** distinguishes the **unpaid** from the paid role. Even unrelated caregivers often regard themselves as **"fictive kin"**.
2. **Caregiver burden** is the **multidimensional strain — physical, psychological, social and financial — arising from the caregiving role**. It must be distinguished from generalised **psychological distress**: strain is role-specific.
3. **Caregiver burnout** = **emotional exhaustion, detachment or depersonalisation from the care recipient, and a reduced sense of accomplishment**. It occurs typically when caregivers **lack the social support systems needed for caregiving tasks and shared decision-making**. **Emotional withdrawal and apathy toward the care recipient are late features and a warning sign of impending neglect or abuse.**
4. Caregiving is **not uniformly negative**. When the caregiver has an **emotionally close relationship** with the recipient, burden is lower; **satisfaction and a sense of personal meaning are protective**. Assessment should therefore also be **strengths-based**.

B. Magnitude of the Problem

1. **Informal care is the backbone of long-term care** — **over 80% of community care is informal**, predominantly by women. Weekly hours range from about **7 hours (Canada) to 24 hours (USA)**, with roughly **25% of caregivers giving over 40 hours per week**.
2. Compared with non-caregivers, caregivers have **higher stress, more depression and lower overall well-being**. **Women report higher stress**, and **spousal caregivers fare worse than those caring for a parent or child**.
3. In India the family is the **default and only provider**; wives and daughters-in-law bear most of the load, often sacrificing employment.

C. Domains of Impact

1. **Physical health**: over **15% of caregivers rate their health as fair or poor** versus 10% of the general population; caregivers **aged ≥50 have increased risk of cardiovascular disease and hypertension**; sleep disturbance, fatigue, pain, appetite change and weight loss are common. **Bathing, transfers and toileting** are the most physically demanding tasks and cause **musculoskeletal pain and injury**.
2. **Mortality**: caregivers reporting **high strain have increased mortality** compared with those reporting low strain — though population-based propensity-matched analyses show caregiving *per se* may be associated with **lower** mortality. **It is the strain, not the role, that kills.**
3. **Mental health**: depression, anxiety and anticipatory grief. Critically, **symptoms do not diminish after institutional placement** — **anxiolytic use rises and nearly half of caregivers are at risk of disabling depression after placing their relative in long-term care**.
4. **Financial**: about **35% report moderate to high financial strain**; out-of-pocket costs for **medicines, equipment and transport**; erosion of pension and retirement funds; **reduced work productivity, early exit from the workforce and difficulty re-entering employment**.
5. **Social and spiritual**: shrinking social networks, isolation and loneliness; the caregiver **gives more support to the recipient while receiving less in return**. **Spiritual and religious coping reduces both burden and depressive symptoms** and is an overlooked resource.

6. **Determinants of high burden**: **behavioural and psychological symptoms of dementia, apathy, incontinence, immobility, night-time disturbance**, high dependency, co-residence, spousal relationship, female sex, poverty and absence of support. **Long-distance caregiving** carries its own emotional and financial strain.

D. Assessment

1. **Screen routinely — early identification of the at-risk caregiver is the single most important preventive step. Identification of the vulnerable caregiver and referral to social work and community resources can be lifesaving**, since emotionally stressed caregivers have significantly increased mortality.
2. **Instruments**:
   - **Zarit Burden Interview (ZBI)** — original 29 items, commonly used **22-item** form, with **12-, 4- and 3-item** versions; developed for dementia but now used across illnesses, and **validated in Brazil, sub-Saharan Africa, Italy and China**.
   - **Caregiver Self-Assessment Questionnaire (CSAQ)** — 18 items, developed by the American Medical Association; also **valid as a screen for depression**.
   - **Rapid Screen for Caregiver Burden** — 7 items (shortened from 25).
   - **Caregiver Well-Being Scale** — 43 items, with 16-item and **6-item Rapid** versions; **strengths-based**, assessing basic needs and activities.
3. Assess **all biopsychosocial-spiritual domains**: physical health, mood, sleep, finances, employment, social support, spirituality, quality of the caregiver–recipient relationship, and **risk of elder abuse or neglect**.

E. Management

1. **General principle** — effective interventions are **multidimensional (psychological + social/emotional + educational)** and target the **dyad**, not the patient alone. A **high-risk caregiver–patient dyad needs higher-intensity care**.
2. **Psychoeducation and skills training**: **cognitive behavioural family intervention**, **behaviour-management training for BPSD**, problem-solving training, contingency planning, and practical skills (**assisting with ADLs, medication administration, symptom management**). **Counselling with ad hoc telephone support, combined with cholinesterase inhibitor therapy in the patient, reduced caregiver depression from moderate to lower levels** — showing that remote formats can enhance or replace face-to-face intervention.
3. **Respite** — **adult day care and day services** are the mainstay; short-term institutional respite where needed. **When carer strain is high, respite is preferable to admission.**
4. **Mind–body interventions**: **Mindfulness-Based Stress Reduction** (formal practice — mindful movement, body scan, sitting meditation; plus informal everyday practice) reduces stress; an **online twice-weekly mindfulness intervention reduced caregiver burden and improved quality of life**, and **yoga with compassion meditation improved quality of life and self-compassion** in caregivers of people with Alzheimer's disease.
5. **Support groups** — two types: **(i) time-limited training groups** and **(ii) ongoing mutual-support forums**. Disease-specific or identity-specific groups improve attendance; **substitute care must be arranged** so the caregiver can actually attend.
6. **Team-based support and cultural sensitivity**: the **occupational therapist** teaches home skills and safety, the **physiotherapist** safe transfers and exercise, the **dietitian** nutrition, the **speech therapist** communication and swallowing, the **social worker** resources, finances and legal help. In **traditional Asian and Latinx cultures, institutional placement is perceived as abandonment**, so suggesting a facility may be experienced as culturally insensitive. **Prepare the caregiver for placement transitions and treat depression and anxiety afterwards.**

Latest Updates (2023–Present)

Global policy recognition

- WHO estimates about **142 million older people worldwide cannot meet basic needs independently**; **unpaid informal care accounts for roughly 80% of all long-term care**; and **support to unpaid caregivers** is now an explicit pillar of the WHO framework for an integrated continuum of long-term care.
- The **WHO Commission on Social Connection report (30 June 2025)** found **1 in 6 people worldwide affected by loneliness**, linked to **871,000 deaths a year (~100 per hour)**, with the **World Health Assembly adopting its first-ever resolution on social connection in May 2025** — directly relevant, since **social isolation is a core component of caregiver burden**. **WHA78 (2025) also extended the Global Dementia Action Plan to 2031**, retaining carer support as a pillar.

Landmark trial evidence — D-CARE

- The **Dementia Care Study (D-CARE)** was a **pragmatic, 18-month, three-armed, assessor-blinded randomised clinical trial** conducted from **June 2019 to August 2023**, comparing **health-system dementia care** (co-management by nurse practitioners or physician assistants), **community-based dementia care** (delivered telephonically by a social worker, nurse or licensed therapist) and **usual care**.
- Across **2,176 patient–caregiver dyads**, there were **no significant differences in patient behavioural symptoms or caregiver strain** between the two active models, nor between either active model and usual care; a prespecified analysis found **no differences in functional status, cognition or quality of life, nor in overall caregiver burden or positive aspects of caregiving**.
- However, **caregiver self-efficacy — confidence in the ability to care — improved**, and **caregiver satisfaction with care was significantly greater in both active arms than usual care from 3 months onward and sustained to 18 months**, with community-based care marginally highest. Higher self-efficacy is thought to help caregivers **obtain more resources and keep the person with dementia at home**.
- **Examination message**: comprehensive dementia care programmes reliably improve **confidence and satisfaction**, but **measurably reducing strain remains difficult** — supporting the emphasis on **respite and multicomponent support** rather than care-coordination alone.

Caregiver support becomes a reimbursed service

- The **CMS GUIDE Model (Guiding an Improved Dementia Experience)**, launched **January 2024**, is an **alternative payment model** funding interprofessional teams to deliver comprehensive dementia care. Required components include **screening and recruitment, comprehensive and home safety assessment, ongoing monitoring, caregiver supports and respite**, with dyads tiered by complexity. **Low-tier dyads receive less frequent outreach, are not eligible for respite funds and attract lower payment**, although early data show their caregivers report comparable burden (Zarit Index) and unmet needs. In one first-year site, **over 35% of eligible beneficiaries used respite services**.

Respite, day services and digital support

- An **updated systematic review (2015–2025)** found regular adult day service use associated with **reduced caregiver stress, improved mood, physiological stress reduction, delayed nursing home placement and cost savings**, with barriers of **cost, awareness, caregiver reluctance and availability**. The **ADS Plus cluster-randomised trial across 34 sites** embedded a staff-delivered caregiver programme — **dementia education, support and validation, referrals and linkage, and strategies for care challenges and self-care** — within day services.

- **WHO iSupport**, an online self-training manual emphasising **education, skill development and caregiver support**, is being adapted and tested across low- and middle-income countries including **Bangladesh**. Meta-analyses of internet-based interventions for dementia caregivers show consistent improvement in **depressive symptoms, perceived stress, anxiety and self-efficacy**, but **no significant improvement in caregiver burden, coping ability or quality of life**.

India

- The **LASI-DAD** (Longitudinal Aging Study in India – Diagnostic Assessment of Dementia) added a **caregiver module**, giving nationally representative data from **4,196 informants** linking caregiver **stress, mental health, positive affect and spirituality** to the care recipient's cognitive function and dementia status. WHO data suggest **India has a higher reported prevalence of informal caregivers than other LMICs**; Indian dementia caregiving is associated with **reduced work hours and poorer health**, and **more caregiving hours predict higher risk of depressive symptoms**.
- A **2024 narrative review of community-based dementia care in India** confirms care is traditionally provided by family members, with studies showing **high caregiving burden and consequent mental health impact**, and identifies **telehealth and online caregiver training as viable alternatives**. It cites the **NITI Aayog report "Senior Care Reforms in India: Reimagining the Senior Care Paradigm" (February 2024)** and the **India Ageing Report 2023**.
- A **Lancet Psychiatry** call for a **national dementia policy** notes India will have **340 million older adults by 2050**, of whom **5.3 million have been living with dementia since 2020**, with persistent shortages of services and trained staff. A systematic review of caregiver burden in Asian LMICs (2025) notes that **about 94% of people with dementia in LMICs are cared for at home**, mostly by family.
- India's structural response is the **PM-SPECIAL scheme** creating a trained cadre of **geriatric caregivers for institutional and home care**, alongside **Elder Line 14567** for counselling and the day-care and respite components of **AVYAY**.

Current Practice Update

Aspect	Textbook Position	Current Practice (2023–2026)
Status of the caregiver	A resource to be supported, assessed opportunistically	**A formal target of health policy** — explicit WHO pillar; caregiver support and respite are **reimbursed services** under the CMS GUIDE Model
Effect of care-coordination programmes	Multicomponent interventions reduce burden and depression	**D-CARE (2,176 dyads)**: no reduction in **caregiver strain or burden**, but improved **self-efficacy and satisfaction with care** — expectations must be recalibrated
Respite	Day care as respite	Strengthened evidence for **reduced caregiver stress, delayed nursing home placement and cost savings**; respite now a funded benefit tied to complexity tier
Digital interventions	Telephone support as an alternative delivery mode	**WHO iSupport** and internet programmes improve **depression, stress, anxiety, self-efficacy**, but **not burden or quality of life**
Screening instruments	ZBI, CSAQ, RSCB, Caregiver Well-Being Scale	Same instruments, now embedded in **programme eligibility and tiering** (Zarit used for GUIDE complexity assessment)

India	Not addressed	**LASI-DAD caregiver module** gives national data; **NITI Aayog senior care reforms (2024)**; **telehealth and online caregiver training** as the scalable model; **PM-SPECIAL** caregiver cadre

Exam One-Liners

- **Caregiver burden = multidimensional strain; burnout = emotional exhaustion, detachment and reduced accomplishment.**
- **Apathy and emotional withdrawal from the care recipient are red flags for neglect and abuse.**
- **>80% of community long-term care is informal**; ~25% of caregivers give **>40 hours a week**.
- **Women and spousal caregivers report the highest stress.**
- **15% of caregivers rate their health fair/poor vs 10% of the general population.**
- **Caregivers ≥50 have increased cardiovascular disease and hypertension.**
- **It is strain, not caregiving itself, that increases mortality.**
- **Distress does not resolve after institutional placement** — anxiolytic use rises; nearly half are at risk of disabling depression.
- **~35% report moderate to high financial strain.**
- **Zarit Burden Interview**: 29 → 22 → 12 → 4 → **3-item** versions; **CSAQ** 18 items (AMA, also screens depression); **Rapid Screen for Caregiver Burden** 7 items; **Caregiver Well-Being Scale** is the strengths-based tool.
- **Emotional closeness reduces burden** — assess positives, not only pathology.
- **Respite is preferable to admission when carer strain is high.**
- **MBSR, yoga and compassion meditation reduce burden and improve quality of life.**
- **Support groups**: time-limited training vs ongoing mutual support; **arrange substitute care so the carer can attend**.
- **Suggesting institutional placement can be culturally insensitive** in Asian and Latinx families.
- **D-CARE (2025)**: comprehensive dementia care improved **self-efficacy and satisfaction** but **not strain or burden**.
- **CMS GUIDE Model (2024)** funds **caregiver education, 24/7 support and respite** as a covered service.
- **94% of people with dementia in LMICs are cared for at home** by family.

Appendix A — Four Frequently Confused Terms

Appendix B — 3D-CAM and CAM-ICU

Part I — Comprehensive Geriatric Assessment and Functional Evaluation

1. Comprehensive Geriatric Assessment — What It Is and Its Usefulness in Clinical Practice

A. 20 High-Yield Points

Definition and Concept

1. **Comprehensive geriatric assessment (CGA)**, also called **multidimensional geriatric assessment**, is a **diagnostic process, usually interdisciplinary**, that determines an older person's **medical, psychosocial, functional and environmental** resources and problems.
2. Its stated objective is to **develop an overall plan for treatment and long-term follow-up**. An assessment **without a linked care plan is NOT a CGA** — a favourite examination point.
3. It **differs from a standard medical evaluation** in three ways: it targets older people with complex problems, it **emphasises functional status and quality of life**, and it uses **interdisciplinary teams with quantitative scales**.
4. A purely psychosocial or environmental home visit **without a medical evaluation** also does not qualify as CGA, because multidimensionality is incomplete.
5. **Historical origin: Dr Marjory Warren**, London infirmary, **late 1930s**. Through evaluation, mobilisation and rehabilitation she got long-bedfast patients out of bed and home, and advocated **assessment and rehabilitation before any long-term institutionalisation**.

Rationale — Why in the Elderly? (five textbook reasons)

6. **Multi-morbidity and complexity** — systematic assessment helps set priorities among multiple conditions.
7. **Unrecognised problems** — many problems are never reported, often because they are **falsely thought to be non-modifiable effects of ageing**.
8. **Chronic conditions** — a diagnosis without information on **functional relevance** is of limited therapeutic value.
9. **Social and environmental interaction** — home layout and social network determine whether a person can stay at home.
10. **Functional status** — the main goal of geriatric medicine is to **prevent or delay functional decline**; benefit is greatest when intervention occurs **early** in the path from robustness to frailty to disability.

Components — What Is Assessed

11. CGA begins with a **functional status "review of systems"** built on three measures: **frailty, basic ADLs, and IADLs**.
12. **Principle of hierarchy / parsimony:** if a patient is **severely ADL-dependent, do not assess frailty**; if the patient is **robust or pre-frail, do not assess basic ADLs**.
13. Frailty is measured by two models — the **phenotype model** (Fried phenotype, Frailty Trait Scale, FRAIL index) and the **cumulative deficit model** (Frailty Index, Clinical Frailty Scale).
14. **Dimensions and tools (Table 96.1):** BADL — **Katz, Barthel, Lawton PSMS**; IADL — **Lawton, OARS**; Social — **Lubben Social Network Scale**; Affective — **Geriatric Depression Scale, Zung**; Cognitive — **MMSE (Folstein), Kahn MSQ**; Gait and balance — **Tinetti, Get-Up-and-Go**; Nutrition — **MNA**; Senses — **whispered voice test, Snellen**; Oral — **GOHAI**.
15. Two screens are **mandatory** in any older person with functional disability: **cognitive impairment and depression**.

Process in Office and Clinic Practice

16. **Step 1 — set priorities:** work first on the problem that **most bothers the patient**, or the problem on which resolution of others depends (**alcoholism, depression**).
17. **Step 2 — task and symptom analysis:** define the exact nature of the impairment and correlate it with **new drugs or dose changes (including over-the-counter), change in living conditions, and intercurrent acute illness**. Then examination, laboratory tests, therapist and social-work input, and a **long-term follow-up / case-management plan**.

Settings and Team

18. **Settings:** home (preventive visits), office and outpatient clinic, **day hospital**, **acute care for the elderly (ACE) unit**, post-acute rehabilitation unit, nursing home (**Resident Assessment Instrument**), and hospital-at-home programmes. Inpatient and day-hospital settings give intensity and speed for the frail; outpatient settings are cheaper.
19. **Team (minimum):** physician, nurse, social worker, physiotherapist, occupational therapist; **optimally** dietician, pharmacist, ethicist, home-care specialist. The **interdisciplinary team conference is critical** — present in most successful trials; teams mature through **forming, storming, norming, performing**.

Evidence of Usefulness — The Exam Core

20. **Proven benefits:** CGA **improves function and survival while reducing healthcare utilisation and costs**.
    Supporting data:

- **Improved diagnostic accuracy — 1 to more than 4 new diagnoses per patient**.

- **1993 Stuck/Rubenstein meta-analysis (28 trials, ~10,000 patients):** mortality down **22%** (hospital-based, 12 months) and **14%** (all programmes); living at home up **47%** (hospital-based) and **26%** (all); readmissions down **12%**; cognitive improvement up **47%**; physical function up **72%** on hospital units.
- **2011 Cochrane meta-analysis:** inpatient CGA increases the likelihood of being **alive and in one's own home**, with potential cost reduction.
- **Better prescribing** — CGA reduces unnecessary and inappropriate medication use.
- **Targeting matters:** best results when patients are at **high risk of deterioration yet retain rehabilitation potential** — exclude those **"too well or too ill."**
- **Programmes with hands-on care and/or long-term follow-up** outperform purely consultative programmes.
- **Weak areas:** outpatient CGA showed **no mortality benefit** in one meta-analysis; **preventive home visits are not recommended routinely** (benefit only with CGA-based extended follow-up in relatively well elders; **number needed to visit about 40** to prevent one nursing-home admission).
- **Oncology (SIOG task force):** CGA detects many problems missed by regular assessment and is associated with **fewer treatment side effects**.

B. Latest Updates (2023–Present)

1. German DGG S3 Guideline on CGA in Hospital (2024) — the first S3-level CGA guideline. Twelve evidence-based and eight consensus-based recommendations. Strongest evidence in **acute geriatric, oncology and orthopaedic/trauma wards**; weaker in emergency departments and general surgery. Core elements: **minimum CGA duration of 15 minutes** and **six core dimensions — self-help ability, mobility, cognitive function/delirium, affect, nutrition and social situation**; the **G8 questionnaire** is recommended for screening mainly in oncology.

2. Italian National CGA Guideline (2024) — 25 scientific societies plus the National Institute of Health, GRADE methodology. Sixteen recommendations from **117 studies** across primary care, clinics, emergency departments, hospital wards and nursing homes. CGA **reduces hospitalisation, mortality, institutionalisation and delirium risk**, improves prescribing appropriateness, and **maintains functional activities**. The **Multidimensional Prognostic Index (MPI)** is specifically recommended to predict negative outcomes.

3. Japanese CGA-Based Healthcare Guidelines 2024. The main objective of CGA is stated to be **personalised care through holistic management plans and targeted interventions — not merely status evaluation or prognostication**.

4. ASCO Geriatric Oncology Guideline Update (2023). Geriatric assessment should be used in **all patients over 65 with cancer**; all older adults with GA-identified deficits should receive **GA-guided management**, and the **Practical Geriatric Assessment (PGA)** is the recommended tool. Evidence base: **GAP70+** and **GAIN** trials.

5. ASCO Global (Resource-Stratified) Geriatric Assessment Guideline (2025) — adapts the 2023 guideline for **resource-limited settings** using ADAPTE methodology. Directly relevant to Indian practice.

6. Cochrane 2022 — Community CGA. Twenty-one studies, 7,893 participants, 10 countries, evaluating domiciliary CGA and CGA in general practice, with outcomes of death, nursing-home admission, unplanned hospital admission and emergency visits.

7. Meta-analysis of CGA in acute hospitalisation (2025) — CGA **may improve short-term survival and reduce readmission rates** after acute hospitalisation.

8. Perioperative CGA is now mainstream. The **2023 World Society of Emergency Surgery guidelines** advocate frailty assessment and multidisciplinary geriatric-surgical management in older trauma patients; the UK **NELA Best Practice Tariff (April 2023)** mandates perioperative team involvement in frailer laparotomy patients. CGA outperforms traditional preoperative risk models in predicting **postoperative delirium, infection and prolonged stay**.

9. Indian context. Evidence is predominantly from high-income countries and hospitalised patients; research on CGA in primary care and community settings in low- and middle-income countries is lacking. Under **NPHCE**, community services are delivered by **ASHA workers** with clinics at PHCs, but implementation is inconsistent. Short culturally adapted tools such as **EHSAS** are being validated for rural India because full CGA is impractical with the available workforce.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Standardisation	Deliberately broad; "no single optimal blueprint"	**Minimum standards defined** — German S3: at least 15 minutes, six mandatory core domains
Prognostic tool	Many scales listed; none preferred	**MPI specifically recommended** (Italian guideline)
Oncology tool	SIOG could not recommend any specific tool	**PGA specifically recommended** (ASCO 2023)
Oncology strength	CGA "possibly" improves survival	**GA mandatory at 65 and above**; GA-guided management proven to cut severe chemotoxicity
Outpatient CGA	"Less impressive"; no mortality benefit	Italian guideline **supports** primary-care CGA for reducing hospitalisation and institutionalisation
Preventive home visits	Cannot be recommended as routine practice	**Largely unchanged** — Cochrane 2022 still shows uncertain benefit
Perioperative CGA	Not covered	Now **embedded in surgical pathways** (NELA BPT, WSES 2023, POPS model)
Emergency department	Not addressed	Recognised as important but **evidence still weak** (German S3)

D. Exam One-Liners

- **CGA without a care plan and follow-up is not a CGA.**
- **Marjory Warren, 1930s London** — mother of CGA and of British geriatrics.
- **Function is the common language of geriatrics; assessment is its core method.**
- **Hierarchy rule:** ADL-dependent, skip frailty testing; robust or pre-frail, skip basic ADL testing.
- **Targeting rule:** benefit is greatest in those **"not too well, not too ill"** — high risk with rehabilitation potential.
- **Hands-on care plus long-term follow-up** separates effective from ineffective programmes.
- **1993 meta-analysis:** mortality down 22%, living at home up 47%, physical function up 72% on hospital units.
- **Two mandatory screens** in functional disability: **cognition and depression**.
- **German S3 six core domains:** self-care, mobility, cognition/delirium, affect, nutrition, social situation.
- **ASCO 2023:** every cancer patient 65 and above gets a geriatric assessment, using the **PGA**.
- **Italian 2024:** use the **MPI** for prognosis.
- **India:** CGA delivery constrained by workforce — hence short screening tools within **NPHCE**.

---

2. Tools of Functional Assessment

A. 20 High-Yield Points

Framework

1. **Functional assessment** measures **what a person actually does in daily life**, not merely what diseases they have. Tools exist to make this measurement **standardised, reproducible and comparable across settings**.
2. **Purpose of using standardised tools:** they allow **information exchange between acute, rehabilitation and community settings**, permit **measurement of effectiveness**, foster **comparison of treatments**, and **minimise repeated collection of identical information** by different team members.
3. **Three levels of measurement (ICF, 2001): impairment** (body function or structure), **activity limitation** (difficulty executing a task), and **participation restriction** (problems in involvement in life situations). Different tools address different levels.
4. **Three functional core measures** in CGA: **frailty, basic ADLs, and IADLs**. The **hierarchy rule** determines which to use — severely ADL-dependent patients are not tested for frailty; robust patients are not tested for basic ADLs.
5. **Two methods of data capture: report** (by the patient or a proxy — tells you what they do under real living conditions) and **performance testing** (tells you what they can do under standard conditions). **Discrepancies between the two are common and informative.**

Basic ADL Tools

6. **Katz Index (1963)** — six items: **bathing, dressing, toileting, transferring, continence, feeding**. Graded independent/dependent, letters A to G. The classic **hierarchy of ADL loss**.
7. **Barthel Index (1965; modified 1988)** — ten items: feeding, bathing, grooming, dressing, bowels, bladder, toilet use, transfer, mobility, stairs. Scored **0–100** (or 0–20). It is an **observation of what the patient does**, and is the **RCP/BGS-endorsed ADL scale**, but has a **ceiling effect in ambulatory patients**.
8. **Lawton Physical Self-Maintenance Scale (PSMS, 1969)** — six items: **toileting, feeding, dressing, grooming, physical ambulation, bathing**. Each graded on **five levels**, dichotomised to a total of **0–6** (6 = independent). Published in the same paper as the Lawton IADL scale.

IADL Tools

9. **Lawton IADL scale (1969)** — eight items: **telephone, shopping, food preparation, housekeeping, laundry, transport, medications, finances**. IADLs need "instruments," and are the **first functions to be lost**.
10. **OARS Multidimensional Functional Assessment Questionnaire** — assesses IADLs alongside social and economic resources; widely used in surveys.
11. **Clinical rule:** if difficulty is reported, always ask **"how does she manage?"** — is the task neglected, or is someone else doing it?

Mobility, Gait and Balance Tools (high-yield numbers)

12. **Gait speed** over a 4-metre track: **below 0.6 m/s is abnormal**; **0.6–0.8 m/s is high-risk**. Each **0.1 m/s fall in gait speed equals a 7% rise in fall risk**.
13. **Timed Get-Up-and-Go (Mathias, Nayak and Isaacs, 1986): more than 12 seconds indicates high fall risk** (sensitivity 77%, positive predictive value 93% in the community).
14. **Tinetti Performance-Oriented Mobility Assessment (1986):** 14 tasks, **score below 24 out of 28 indicates fall risk**; takes 10–15 minutes.
15. **Short Physical Performance Battery (SPPB):** combines gait speed, **30-second chair stand** and the **4-stage balance test** (each position held **10 seconds**). **Berg Balance Scale:** 14 items, 0–56 (0–20 wheelchair-bound, 21–40 walks with assistance, 41–56 independent).

Composite, Global and Domain-Specific Tools

16. **Functional Independence Measure (FIM)** — scores **18 functions** across self-care, sphincter control, mobility, locomotion, communication and social cognition; the standard rehabilitation outcome measure.
17. **RCP/BGS endorsed scales (Table 98.3):** ADL — **Barthel Index**; vision, hearing and communication — **Lambeth Disability Screening Questionnaire**; memory — **Abbreviated Mental Test (10 items)**; depression — **Geriatric Depression Scale (30-item, 15-item short form)**; morale — **Philadelphia Geriatric Center Morale Scale**.
18. **Other domain tools (Table 96.1):** nutrition — **Mini Nutritional Assessment (MNA)**, SNAQ; special senses — **whispered voice test, Hearing Handicap Inventory, Snellen chart**; oral health — **GOHAI**; social network — **Lubben Social Network Scale**; cognition — **MMSE**; mood — **GDS, Zung**.
19. **Frailty tools: Fried phenotype** (weight loss, exhaustion, weakness, slow gait, low activity); **FRAIL scale** (Fatigue, Resistance, Aerobic, Illnesses more than 5, Loss of weight 5%) — answerable in 15–30 seconds; **SOF index** (weight loss, cannot rise from chair 5 times without arms, reduced energy); **Clinical Frailty Scale** (9 points, seconds to apply); **Frailty Index** (30 or more deficits, continuous 0–1).

20. **Screening questions usable at the bedside:** "*Do you need help at home?*" (function) · "*Do you have trouble walking or lose your balance? Have you had a fall? Are you afraid of falling?*" (mobility) · "*Are you sad?*" (mood) · "*Have you lost weight?*" (nutrition) · "*Are you on seven or more medicines?*" (polypharmacy) · "*Do you wet yourself?*" (continence).

B. Master Comparison Table

Domain	Screening tool	Assessment tool	Key threshold
Frailty	FRAIL scale, Clinical Frailty Scale	Fried phenotype, Frailty Index	3 or more of 5 = frail
Basic ADL	—	**Katz, Barthel, Lawton PSMS**	Barthel below 60 = dependent
IADL	—	**Lawton IADL, OARS**	Loss precedes ADL loss
Gait / mobility	Gait speed, TUG	Tinetti POMA, SPPB, Berg	Gait below 0.8 m/s; TUG above 12 s; Tinetti below 24
Cognition	Mini-Cog, AD8	MMSE, MoCA, SLUMS	MMSE below 24
Mood	PHQ-2	GDS-15/30, PHQ-9, CSDD	GDS-15 of 5 or more
Nutrition	MNA-SF, SNAQ	MNA full, BMI, weight loss	MNA-SF 11 or less
Vision	Snellen	Formal ophthalmic review	Below 6/18
Hearing	Whispered voice test	Audiometry, HHIE	Fails at 2 feet
Social	Lubben Social Network Scale	OARS social section	LSNS-6 below 12
Rehabilitation outcome	—	**FIM**	18 items

C. Latest Updates (2023–Present)

1. WHO ICOPE — from deficit to capacity. The ICOPE 5-step pathway (screen, assess, intervene, follow up, community engagement) screens **six domains — mobility, cognition, vitality/nutrition, vision, hearing and psychological well-being** — either by a professional or by self-assessment through the **ICOPE Monitor** app. Step-2 tools are named explicitly: **SPPB for mobility; Mini-Cog, MoCA, MMSE or GPCOG for cognition; MNA, DETERMINE, MUST or SNAQ65+ for nutrition; PHQ-9 for mood; pure tone and speech audiometry for hearing**.

2. Minimum data sets are now mandated. The **German S3 guideline (2024)** requires **six core dimensions in at least 15 minutes**; the **Italian guideline (2024)** recommends the **Multidimensional Prognostic Index (MPI)** for prognosis; **ASCO 2023** mandates the **Practical Geriatric Assessment (PGA)** in oncology. The trend is **domain-mandated but tool-agnostic**.

3. Gait speed is being repositioned as the single best functional marker. A 2025 Age and Ageing study of about 3,600 older adults found that among all components of frailty and sarcopenia, **low physical performance (slow gait speed) was the best single predictor of incident basic and instrumental ADL disability**; sarcopenia as a whole construct was not associated with increased disability risk. **EWGSOP2 defines low physical performance as gait speed of 0.8 m/s or less.**

4. Automated and digital tools. The **electronic frailty index (eFI2)** is replacing the original eFI in English primary care from 2025, allowing **population-level functional risk stratification from routine records**. mHealth and wearable-based functional assessment gives **objective, quantitative data** in place of subjective observer-rated scales, but a 2024 systematic review found **high risk of bias and minimal integration into daily practice**.

5. Diagnostic accuracy data for screening instruments. In emergency-department settings, seven screens pooled across 1,663 participants gave **sensitivity 0.85 and specificity 0.77** against full CGA; **PRISMA-7 was the most sensitive (0.84–0.98)** and the **Clinical Frailty Scale the most specific**, both with AUROC around 0.90.

6. Indian use. LASI applies Katz-type ADL and Lawton-type IADL items; grip strength was the **most discriminant frailty component in Indian men (79.1%)** and physical activity in women (81.6%). **AWGS (not EWGSOP2) cut-offs** should be used for sarcopenia-related functional measures in Indians, and **BIA rather than DXA** is the practical mass-measurement modality.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Choice of tool	Broad menu; "no consensus on the best scale"	**Domain mandated, tool still flexible**, but specific tools named per setting
Gait speed cut-off	Below 0.6 m/s abnormal; 0.6–0.8 high-risk	**0.8 m/s or less** operative threshold (EWGSOP2/AWGS); best single predictor of disability
Who administers	Trained professional or therapist	**Self-assessment and digital screening validated**; community health workers in LMICs
Data source	Interview and bedside observation	**Automated extraction from electronic records** (eFI2); wearables and sensors
Framing	Deficit-based (ADL/IADL loss)	Complemented by **capacity-based** framing (WHO intrinsic capacity)
Sarcopenia link	Not integrated	Functional tools now feed directly into **sarcopenia case-finding** (SARC-F, grip strength, gait speed)

E. Exam One-Liners

- **Katz and Barthel measure ADL; Lawton measures IADL; Tinetti and TUG measure mobility; MNA nutrition; GDS mood; MMSE cognition; Lubben social.**
- **Barthel is what the patient does, not what they can do** — and has a **ceiling effect** in ambulant patients.
- **FIM has 18 items** across six areas and is the rehabilitation standard.
- **TUG above 12 seconds; Tinetti below 24 of 28; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **0.1 m/s slower gait equals 7% higher fall risk.**
- **PSMS has grooming and ambulation; Katz has continence and transferring** — the classic distinguishing point.
- **Report tells you what they do; performance tells you what they can do** — measure both.
- **WHO ICOPE six domains:** mobility, cognition, vitality, vision, hearing, psychological.
- **A tool is only useful if its result changes the care plan.**

---

3. Functional Assessment in the Elderly

A. 20 High-Yield Points

Why Function Matters

1. **Functional assessment** means measuring **what the person actually does in daily life**. In geriatrics, **function is the common language** and assessment is the core method.
2. In an older person, **function predicts outcome better than diagnosis**. There is **no direct relationship between disease and functioning** — the same illness produces very different disability in different people, so function must be measured separately.
3. Functional decline results from **medical, functional, psychological, social and environmental** risk factors acting together. Hence assessment must be **multidimensional**.
4. A **baseline functional measure is essential** so that progress can be monitored and the effect of treatment or rehabilitation judged. **Reassess at least weekly during rehabilitation.**
5. Three levels are assessed: **impairment** (the deficit) → **activity restriction** (ADL/IADL loss) → **participation restriction** (loss of social role). Participation restriction is **unique to the individual** and depends largely on the ability to adapt.
6. Mobility must always be tested — **about half of people aged 85 and over report difficulty walking**, and gait disorders threaten independence and cause falls.

The Core Measures

7. The functional "review of systems" rests on three measures: **frailty, basic ADLs, and IADLs**.
8. **Principle of hierarchy:** if the patient is **severely ADL-dependent, do not test frailty**; if **robust or pre-frail, do not test basic ADLs**. Match the depth of assessment to the patient and the setting.
9. **Basic ADLs (personal care):** bathing, dressing, toileting, transferring, continence, feeding, grooming — **Katz, Barthel, Lawton PSMS**.
10. **IADLs (tasks needing instruments):** cooking, shopping, housework, laundry, telephone, transport, money, medicines — **Lawton IADL, OARS**.
11. **IADLs are lost first, ADLs later**, so IADL loss is the earlier warning sign. Always ask **"how does she manage?"**
12. **Always record premorbid function as well as present function**, especially after acute illness, a fall or hospital admission.

Domains to Cover

13. **Mobility, gait and balance:** gait speed (**below 0.6 m/s abnormal; 0.6–0.8 high-risk**), **TUG above 12 seconds**, **Tinetti below 24 of 28**, 30-second chair stand, 4-stage balance test, SPPB, Berg Balance Scale.
14. **Two screens are mandatory** in any older person with functional disability: **cognition** (MMSE) and **depression** (GDS or Zung).
15. **Other essential domains:** nutrition (**MNA**, SNAQ, weight loss), **special senses** (whispered voice test, Snellen), **oral health** (GOHAI), **continence**, and **social network and support** (**Lubben Social Network Scale**).
16. **Also assess:** pain, polypharmacy (Beers/STOPP-START), continence, sleep, alcohol (CAGE, SMAST-G), caregiver capacity, financial resources, and **home environment**.

How to Do It in Practice

17. Use **both report and performance**. Reports tell you what the person does **under real living conditions**; performance tests tell you what they can do **under standard conditions**.
18. **Grade each task** as: independent without difficulty / independent but with difficulty or an aid / needs human help / unable even with help. Distinguishing "independent with difficulty" adds prognostic value.
19. **Perform a task analysis** of the specific problem. *Example:* "difficulty dressing" may be due to choosing clothes, remembering to finish, buttoning, reaching overhead, or bending for shoes — pointing respectively to **cognitive impairment, poor finger mobility, or shoulder, back or hip disease**. Each demands a different treatment.
20. **Correlate any new functional loss** with **new drugs or dose changes (including over-the-counter)**, **changes in living conditions**, and **intercurrent acute illness (even mild)**. Remember the **cascade** — impaired gait leads to depression and withdrawal, and **immobility of any cause produces deconditioning that persists after the cause is removed**. Finally, **link assessment to a plan**: rehabilitation steps of **assessment, goal setting, therapy, aids and adaptations, education, psychological support, evaluation and follow-up**.

B. Practical Bedside Scheme

Step 1 — History Premorbid and current ADL/IADL status · exact task that fails · duration and rate of decline · pain · falls · continence · drugs (including over-the-counter) · nutrition and weight change · mood and motivation · social support and caregiver capacity · housing and environment.

Step 2 — Examination Postural blood pressure · vision and hearing screening · **observation of gait** · musculoskeletal (tone, power, joint range of motion, feet) · neurological (focal signs, sensation, proprioception) · **skin over pressure areas** · cognition (MMSE/MoCA) and mood (GDS).

Step 3 — Performance testing Gait speed over 4 metres · Timed Up-and-Go · 30-second chair stand · 4-stage balance · grip strength · observed transfer and stair climbing.

Step 4 — Baseline investigations Complete blood count, blood chemistry, **serum calcium (mg/dL), sodium (mEq/L), creatinine (mg/dL)**, thyroid function, vitamin B12, **25-hydroxy vitamin D**, haemoglobin (g/dL), fasting glucose or HbA1c, urinalysis.

Step 5 — Formulate and act Identify **reversible causes** → treat disease and pain → **deprescribe** → refer to physiotherapy, occupational therapy, dietician and social work → prescribe aids and adaptations → set goals with the patient → arrange **follow-up and case management**.

C. Latest Updates (2023–Present)

1. WHO ICOPE and intrinsic capacity. The five-step pathway screens **six domains — mobility, cognition, nutrition/vitality, vision, hearing and psychological well-being** — and can be done by a professional or by self-assessment through the **ICOPE Monitor** app. Reference centiles for intrinsic capacity and real-world screening data were published in *Nature Aging* (2023, 2024).

2. German DGG S3 Guideline (2024) defines minimum requirements — **six core dimensions in at least 15 minutes** — the first guideline to set a floor standard for functional assessment in hospital.

3. Age-Friendly Health Systems "4Ms." What Matters, Medication, Mentation and Mobility. In an eight-hospital 2024 evaluation of 3,103 admissions, patients receiving all 4Ms had **fewer 30-day emergency visits (16% vs 22%)**; **Mobility generated the highest "act-on" rate (83%)** of the four.

4. Gait speed as the single best marker. A 2025 longitudinal study found **slow gait speed the best single predictor of incident ADL and IADL disability**, outperforming both frailty and sarcopenia as constructs.

5. Italian CGA guideline (2024) — across 117 studies, CGA **maintains functional activities** and reduces hospitalisation, mortality, institutionalisation and delirium.

6. Oncology. ASCO 2023 requires geriatric assessment including **physical function** in all patients over 65 on systemic cancer therapy, using the **Practical Geriatric Assessment**.

7. Indian data. LASI wave-1 (31,464 adults aged 60 and above) found **about 3% with severe ADL disability and about 6% with severe IADL disability**, with **7.4% ADL dependency**. Rural surveys show far higher figures — **ADL disability 13.7% and IADL disability 38.7%** in rural Goa — associated with sex, education, financial dependence, comorbidity, alcoholism and **sensory impairment**. Functional tools are being adapted for community health worker delivery under **NPHCE**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Core concept	Function measured as **deficit** (ADL/IADL loss)	**WHO shift to intrinsic capacity** — measure **reserve**, not only deficit
Number of domains	Broad, flexible list	**Standardised minimum sets** — ICOPE six domains; German S3 six dimensions in 15 minutes
Gait speed cut-off	Below 0.6 m/s abnormal	**0.8 m/s or less** widely used; slow gait now the best single predictor of incident disability
Who assesses	Interdisciplinary professional team	**Self-assessment and digital screening validated**; community health worker delivery in LMICs
Hospital framing	ACE units and geriatric assessment programmes	**4Ms Age-Friendly framework** — Mobility as a named, auditable care process
Sarcopenia	Not integrated into functional assessment	Functional assessment now **routinely linked to sarcopenia case-finding**

E. Exam One-Liners

- **Function is the common language of geriatrics.**
- **IADLs go first, ADLs later** — IADL loss is the earlier warning.
- **Two screens you must never omit: cognition and depression.**
- **Hierarchy rule:** ADL-dependent, skip frailty; robust, skip basic ADLs.
- **Record premorbid function, not just current function.**
- **TUG above 12 s; Tinetti below 24; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **New functional decline equals a new drug, a new illness, or a new living situation** until proved otherwise.

- **Task analysis converts a vague complaint into a treatable diagnosis.**
- **WHO ICOPE six domains; 4Ms — What Matters, Medication, Mentation, Mobility.**
- **India (LASI): about 3% severe ADL and 6% severe IADL disability; 7.4% ADL dependency.**
- **Assessment without a linked care plan is not an assessment.**

---

4. Functional Assessment in an 85-Year-Old Lady

A. 20 High-Yield Points

Why Function Matters at 85

1. **Functional assessment** means measuring **what the person actually does in daily life**, not just listing her diseases. In geriatrics, **function is the common language** and assessment is the core method.
2. In an 85-year-old, **function predicts outcome better than diagnosis**. There is **no direct relationship between disease and functioning** — the same illness produces very different disability in different people, so function must be measured separately.
3. Functional decline is caused by **medical, functional, psychological, social and environmental** risk factors acting together. Hence assessment must be **multidimensional**, not just physical.
4. A **baseline functional measure is essential** so that progress can be monitored and the effect of treatment or rehabilitation judged.
5. Three levels are assessed: **impairment** (the deficit) → **activity restriction** (ADL/IADL loss) → **participation restriction** (loss of social role). Participation restriction is **unique to the individual** and depends largely on her ability to adapt.
6. Mobility must always be tested at this age — **about half of people aged 85 and over report difficulty walking**, and gait disorders threaten independence and cause falls.

The Core Functional Measures

7. The functional "review of systems" rests on three measures: **frailty, basic ADLs, and IADLs**.
8. **Principle of hierarchy:** if she is **severely ADL-dependent, do not test frailty**; if she is **robust or pre-frail, do not test basic ADLs**. Match the depth of assessment to the patient and the setting.
9. **Basic ADLs (personal care):** bathing, dressing, toileting, transferring, continence, feeding, grooming. Tools — **Katz Index, Barthel Index, Lawton Personal Self-Maintenance Scale**.
10. **IADLs (tasks needing "instruments"):** cooking, shopping, housework, laundry, telephone, public transport, managing money and medicines. Tools — **Lawton IADL scale, OARS-MFAQ**.
11. **IADLs are lost first, ADLs later** — so IADL loss is the earlier warning sign. If difficulty is reported, always ask **"how does she manage?"** — is the task neglected, or is someone else doing it?
12. **Always record premorbid function as well as present function**, especially after an acute illness, fall or hospital admission.

Domains and Recommended Scales

13. **Mobility, gait and balance — the high-yield numbers:** - **Gait speed** over a 4 m track: **below 0.6 m/s is abnormal**; **0.6–0.8 m/s is high-risk**. Each **0.1 m/s fall in gait speed equals a 7% rise in fall risk**. - **Timed Get-Up-and-Go: more than 12 seconds equals high fall risk** (sensitivity 77%, positive predictive value 93% in the community). - **Tinetti Mobility Scale:** 14 tasks, **score below 24 of 28 indicates fall risk** (10–15 minutes). - **30-second chair stand** and **4-stage balance test** (hold each position **10 seconds**); both feed into the **Short Physical Performance Battery (SPPB)**. - **Berg Balance Scale:** 14 items, 0–56 (0–20 wheelchair-bound, 21–40 walks with assistance, 41–56 independent).
14. **Two screens are mandatory** in any older person with functional disability: **cognition** (Folstein MMSE) and **depression** (Yesavage GDS or Zung). Both are common, treatable causes of apparent functional loss.
15. **Other essential domains:** nutrition (**MNA**, SNAQ, BMI, weight loss), **special senses** (whispered voice test or Hearing Handicap Inventory; Snellen chart), **oral health** (GOHAI), **continence**, and **social network and support** (**Lubben Social Network Scale**, OARS social resources section).
16. **RCP/BGS endorsed scales — memorise this table:**

Domain	Recommended scale	Comment
Basic ADLs	**Barthel Index**	Observation of what the patient *does*; **ceiling effect** in ambulatory patients
Vision, hearing, communication	Lambeth Disability Screening Questionnaire	Postal questionnaire
Memory and cognition	**Abbreviated Mental Test (AMT)**	10 questions
Depression	**Geriatric Depression Scale**	30 items; 15-item short form
Subjective morale	Philadelphia Geriatric Center Morale Scale	Distinct from depression

The **Functional Independence Measure (FIM)** scores **18 functions** — self-care, sphincter control, mobility, locomotion, communication, social cognition — and is used in rehabilitation settings.

17. **Quick screening questions usable at the bedside:** "*Do you need help at home?*" (function) · "*Do you have trouble walking or lose your balance? Have you had a fall? Are you afraid of falling?*" (mobility) · "*Are you sad?*" (mood) · "*Have you lost weight?*" (nutrition) · "*Are you on seven or more medicines?*" (polypharmacy) · "*Do you wet yourself?*" (continence).

How to Do It — Practical Method

18. Use **both report and performance**. Reports (from her or a proxy) tell you what she does **under real living conditions**; performance tests tell you what she can do **under standard conditions**. Discrepancies between the two are common and informative.
19. **Grade each task** into: independent without difficulty / independent but with difficulty or an aid / needs human help / unable even with help. Distinguishing "independent with difficulty" adds prognostic value.
20. **Do a task analysis** of the specific problem, then look for a reversible cause and act on it: - *Example:* "difficulty dressing" may be due to choosing clothes, remembering to finish, buttoning, reaching overhead, or bending for shoes — pointing respectively to **cognitive impairment, poor finger mobility, or shoulder, back or hip disease**. Each demands a different treatment. - Always correlate new functional loss with **new drugs or dose changes (including over-the-counter)**, **changes in living conditions**, and **intercurrent acute illness (even mild)**. - Remember the **cascade**: impaired gait leads to depression and social withdrawal; **immobility of any cause causes deconditioning and loss of musculoskeletal flexibility that persists after the cause is removed**. - **Assessment without a plan is worthless** — link findings to the rehabilitation steps: **assessment → goal setting → therapy → aids and adaptations → education → psychological support → evaluation → follow-up**.

B. Latest Updates (2023–Present)

1. WHO ICOPE and "intrinsic capacity" — the major conceptual shift. The ICOPE 5-step pathway is: screening, in-depth assessment of those screening positive, person-centred interventions, long-term follow-up, and community engagement with caregiver support. The screening tool assesses **six functional domains — mobility, cognition, nutrition/vitality, vision, hearing and psychological well-being** — and can be done by a professional or by self-assessment through the **ICOPE Monitor** application; a confirmed deficit triggers full assessment and a personalised care plan. Reference centiles for intrinsic capacity were published in *Nature Aging* (2023, 2024).

2. German DGG S3 Guideline on CGA in Hospital (2024). Minimum requirements are defined as **six core dimensions — self-help ability, mobility, cognitive function/delirium, affect, nutrition and social situation — with a minimum CGA duration of 15 minutes**. This is the first guideline to set a **floor standard for functional assessment**.

3. Age-Friendly Health Systems "4Ms" framework. The 4Ms are **What Matters, Medication, Mentation and Mobility**. In an eight-hospital 2024 evaluation of 3,103 admissions, patients receiving all 4Ms had **fewer 30-day emergency visits (16% vs 22%)** and a trend to lower readmissions; **Mobility generated the highest "act-on" rate of all four Ms (83%)**.

4. Gait speed is being repositioned as the single best functional marker. A 2025 longitudinal study of about 3,600 older adults found that among all components of frailty and sarcopenia, **low physical performance (slow gait speed) was the best single predictor of incident basic and instrumental ADL disability**, and sarcopenia as a whole construct was not associated with increased disability risk. **EWGSOP2 defines low physical performance as gait speed of 0.8 m/s or less.**

5. Italian National CGA Guideline (2024). Across 117 studies, CGA was shown to **maintain functional activities** and to reduce hospitalisation, mortality, institutionalisation and delirium risk.

6. Oncology — ASCO 2023. Geriatric assessment including **all essential domains, of which physical function is one**, should be used in all patients over 65 with cancer, with the **Practical Geriatric Assessment (PGA)** as the recommended tool.

7. Indian context. Functional assessment tools are being adapted for low-resource, high-volume settings under **NPHCE**. Evidence remains predominantly from high-income countries and hospitalised patients. Short multidimensional community tools such as **EHSAS**, deliverable by community health workers, have been validated for rural India precisely because full CGA is impractical with the available workforce. **LASI** provides the national ADL/IADL disability estimates.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Core concept	Function measured as **deficit** (ADL/IADL loss, disability)	**WHO shift to "intrinsic capacity"** — measure **reserve**, not only deficit
Number of domains	Broad, flexible list	**Standardised minimum sets** — ICOPE six domains; German S3 six dimensions in 15 minutes
Gait speed cut-off	**Below 0.6 m/s abnormal**, 0.6–0.8 high-risk	**0.8 m/s or less** widely used (EWGSOP2/AWGS); slow gait now the **best single predictor of incident disability**
Who does the assessment	Professional, interdisciplinary team	**Self-assessment and digital screening validated** (ICOPE Monitor); community health worker delivery in LMICs
Hospital framing	ACE units, geriatric assessment programmes	**4Ms Age-Friendly framework** — Mobility as a named, auditable care process
Sarcopenia link	Not integrated into functional assessment	Functional assessment now **routinely linked to sarcopenia case-finding** (SARC-F → grip strength → gait speed)
Preventive home visits	"Cannot be recommended as routine practice"	Position unchanged; benefit still uncertain (Cochrane 2022)

D. Exam One-Liners

- **Function is the common language of geriatrics; assessment is its core method.**
- **IADLs go first, ADLs go later** — IADL loss is the earlier warning of decline.
- **Katz and Barthel = ADL; Lawton = IADL; Tinetti and TUG = mobility; MNA = nutrition; GDS = mood; MMSE = cognition; Lubben = social.**
- **Barthel Index** is observation of what she *does*, with a **ceiling effect** in ambulatory patients.
- **TUG above 12 s**, **Tinetti below 24/28**, **gait speed below 0.6 m/s** (Pathy) or **0.8 m/s or less** (EWGSOP2) equals high risk.
- **0.1 m/s slower gait equals 7% higher fall risk.**
- Two screens you must never omit: **cognition and depression**.
- **Hierarchy rule:** ADL-dependent, skip frailty testing; robust, skip basic ADL testing.
- New functional decline equals **a new drug, a new illness, or a new living situation** until proved otherwise.
- **WHO ICOPE 6 domains:** mobility, cognition, vitality/nutrition, vision, hearing, psychological.
- **4Ms:** What Matters, Medication, Mentation, Mobility.
- **Assessment without a linked care plan and follow-up is not an assessment.**

5. Physical Self-Maintenance Scale (PSMS)

Lawton and Brody Personal Self-Maintenance Scale

A. Position in Geriatric Assessment

1. The PSMS is one of the **three named basic-ADL instruments** in the CGA framework — **Katz Index, Lawton Personal Self-Maintenance Scale, Barthel Index**.
2. Its assigned basic context is: **strengths and limitations in self-care, basic mobility and incontinence**.
3. These are **the most widely used tools**, used to detect whether the patient has problems performing **activities people must be able to do to survive in the community without help**.
4. **Clinical implication:** patients unable to perform basic ADLs will generally require **12- to 24-hour caregiver support** — in contrast to IADL loss, which threatens independent living in a house or apartment.
5. **Hierarchy rule:** basic ADL scales like the PSMS are appropriate for patients who are **already dependent or disabled**; in a robust or merely pre-frail person, frailty measures, not basic ADLs, should be used.

B. The Scale Itself

Origin and purpose

- Developed at the **Philadelphia Geriatric Center** by **M. Powell Lawton and Elaine M. Brody, 1969**, published in *The Gerontologist*.
- Purpose: to **gauge disability in older people living in the community or in an institution**, for **planning and evaluating treatment**.
- Deliberately designed so that **items target observable behaviours**, not subjective judgements.
- Published as a **paired instrument**: the **6-item PSMS (basic ADLs)** together with the **8-item IADL scale**. In practice the IADL half became far more famous, but both were introduced in the same 1969 paper.
- **Recommended age group: 60 years and over.** Both an **observer-rated** and a **self-rated** version exist; the self-rated version was later incorporated into the **Philadelphia Geriatric Center Multilevel Assessment Instrument (MAI)**.

The six domains

#	Item	What it assesses
1	**Toileting**	Continence and independent use of toilet or commode
2	**Feeding**	Eating without help, spillage, or need for feeding
3	**Dressing**	Selecting and putting on clothes independently
4	**Grooming**	Face, hair, nails, hands — personal appearance
5	**Physical ambulation**	Walking indoors and outdoors, need for aid or wheelchair, bedbound status
6	**Bathing**	Bathing or showering without assistance

Mnemonic: T-F-D-G-A-B — "*The Frail Do Get Assisted Bathing.*"

Response structure and scoring

- **Each item is graded on a 5-point scale**, running from **complete independence (level 1) to complete dependence (level 5)**, with intermediate levels describing progressively more help needed.
- For summary scoring, each item is **dichotomised: 1 point for the independent level, 0 for the dependent levels**.
- **Total score 0–6. 6 equals fully independent; 0 equals totally dependent.**
- Higher score means better function — the **same direction as Katz**, the **opposite direction to a frailty index**.

Psychometrics (original data)

- **Guttman scale reproducibility coefficient 0.96** for the 6-item PSMS (0.93 for the IADL half) — the items form a genuine **hierarchy of loss**.
- **Test–retest reliability 0.94** (0.88 for the IADL half).
- **Inter-rater validity:** two nurses independently rating 36 patients gave a **Pearson correlation of 0.91**.

C. Comparison with the Other Basic-ADL Scales

Feature	PSMS (Lawton–Brody)	Katz Index	Barthel Index
Year	**1969**	**1963**	1965 (modified 1988)
Items	**6**	**6**	10
Domains	Toileting, feeding, dressing, **grooming**, **ambulation**, bathing	Bathing, dressing, toileting, transferring, continence, feeding	Feeding, bathing, grooming, dressing, bowels, bladder, toilet use, transfer, mobility, stairs
Grading	**5 levels per item**, dichotomised	Independent/dependent (A–G)	0/5/10 or 0/5/10/15 per item
Total	**0–6** (6 = independent)	0–6 or A–G	**0–100** (or 0–20)
Unique items	**Grooming and ambulation**	**Continence and transferring**	**Stairs, bowels, bladder**
Best use	Community and institutional older adults; **paired with IADL scale**	Classic hierarchy of ADL loss	**Rehabilitation and stroke** — most granular
Weakness	Little used alone today; overshadowed by its own IADL twin	Crude two-level grading	**Ceiling effect in ambulant patients**

Key contrast for the exam: the **PSMS includes grooming and ambulation but omits transferring and continence as separate items**; the **Katz Index includes continence and transferring but omits grooming and ambulation**. Barthel is the most detailed and is the **RCP/BGS-endorsed scale for ADL measurement**, but suffers a **ceiling effect** in patients who can already walk.

D. Latest Updates (2023–Present)

1. **The PSMS is now rarely used as a standalone instrument.** Its **IADL half has become the global standard** — "the Lawton–Brody scale" in current trial protocols almost always means the IADL scale — while the ADL half has been largely displaced clinically by the **Barthel Index** and **Katz Index**. Contemporary trials routinely pair **"the Lawton and Brody scale" with the Barthel Index**, using Lawton for IADLs and Barthel for ADLs.
2. **Where it survives is dementia and caregiver research.** The **observer-rated PSMS remains in use** for people with dementia and in caregiver-burden studies, because its 5-level gradations detect **partial dependence** better than a binary scale — relevant to recent dementia home-care trials such as LIVE@Home.Path.
3. **Standardisation pressure from new guidelines.** The **German S3 CGA guideline (2024)** mandates "self-help ability/ADL" as one of six core dimensions but **does not prescribe a specific instrument**; **WHO ICOPE** and **ASCO's Practical Geriatric Assessment (2023)** likewise require an ADL domain without naming the PSMS. The trend is **domain-mandated, tool-agnostic** assessment.
4. **Indian context. LASI** and most Indian epidemiological work use **Katz-type or study-specific ADL items** rather than the PSMS. Indian ADL disability prevalence is around **3% severe ADL disability and 7.4% any ADL dependency** in LASI wave-1, and much higher in rural surveys (about 13.7% in rural Goa).

E. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Status of PSMS	Listed as one of three recommended basic-ADL tools	**Rarely used alone**; its **IADL companion scale dominates**; ADL measurement has moved to Barthel and Katz
Which tool to use	No preference between Katz, Lawton and Barthel	**Domain is mandated, tool is not** (German S3 2024, WHO ICOPE, ASCO PGA)
Grading detail	Not discussed	The **5-level gradation is the PSMS's remaining advantage** — better at detecting partial dependence in dementia and caregiver research
Reporting direction	Not stated	Confusion persists because **Barthel rises with independence out of 100, PSMS out of 6, Katz uses letters** — always state the scale and its direction

F. Exam One-Liners

- **PSMS = Lawton and Brody, 1969, Philadelphia Geriatric Center** — published in the **same paper** as the far more famous Lawton IADL scale.
- **Six items: Toileting, Feeding, Dressing, Grooming, Physical ambulation, Bathing.**
- **Each item graded on 5 levels; dichotomised to give a total of 0–6.**
- **6 equals fully independent, 0 equals totally dependent** — higher is better.
- **Guttman reproducibility 0.96, test–retest 0.94, inter-rater r = 0.91.**
- **PSMS has grooming and ambulation; Katz has continence and transferring** — the classic distinguishing point.
- **Basic ADL loss means 12–24 hour caregiver support; IADL loss means a threat to independent community living.**
- **IADLs are lost first, basic ADLs later** — which is why Lawton's IADL half outlived his ADL half in clinical use.
- **Barthel is the RCP/BGS-endorsed ADL scale** and has a **ceiling effect in ambulant patients**.

Part II — Frailty and Sarcopenia

6. Frailty Syndrome — Etiopathogenesis, Assessment, Management and Prevention

A. 20 High-Yield Points

Definition and Concept

1. **Definition:** Frailty is the condition in which a person **loses the ability to carry out important, practised social activities of daily living when exposed to psychological or physical stress**. It must be **distinguished from disability** — frailty is a state of **pre-disability**, now recognised as a **public health priority**.
2. **Epidemiology:** By Fried's definition, about **6.9% of the older population is frail**. **Females are more often frail than males** of the same age. Sarcopenia, its main substrate, affects **13–24% aged 60–70** and about **50% over age 80**.
3. **Frailty threshold:** Vitality peaks between **20 and 30 years**, then VO2max, cardiac output, balance and muscle strength gradually decline. **Exercise delays** the decline; **disease accelerates** it. If a person lives long enough, **everyone eventually crosses the frailty threshold**.
4. **Pathway: Healthy → Frailty → Disability → Hospitalisation → Institutionalisation → Death**, with **recovery still possible** from the earlier stages. A **stressful event precipitates the frail person into disability**.
5. **Two conceptual models:** the **phenotype model** (a biological syndrome with a pathophysiological substrate) and the **cumulative deficit model** of Rockwood (frailty equals an increasing number of deficits and disabilities; essentially a comorbidity index).
6. **Comparison of the three frailty scales — must memorise:**

Cardiovascular Health Study (Fried)	Study of Osteoporotic Fractures (SOF)	IANA FRAIL scale
Weight loss (**10 lb in a year**)	Weight loss	**F**atigue
Exhaustion (self-report)	Inability to rise from a chair **5 times without using arms**	**R**esistance (climb one flight of stairs)
Weakness (**grip strength, lowest 20%**)	Reduced energy level	**A**erobic (walk one block)
Walking speed (**15 ft, slowest 20%**)	—	**I**llnesses (**more than 5**)
Low physical activity (kcal/week, lowest 20%)	—	**L**oss of weight (**5%**)

Etiopathogenesis

7. **Core mechanism:** In most people frailty results from **failure to generate adequate muscle power** and/or **failure of executive function** to use the available power appropriately. The **backdrop is normal physiological ageing**, which interacts with **genes, lifestyle, environment and disease**.
8. **Five major causes: disease · pain · decreased food intake · decline in executive function · excess muscle loss (sarcopenia)**.
9. **Disease to frailty:** Many diseases produce an **excess of cytokines**, which reduce **muscle mass, food intake and cognitive function**, and also lower the anabolic hormone **testosterone**.
10. **Congestive heart failure — the classic model:** falling VO2max, then left-sided failure causes **intestinal wall oedema → bacterial translocation → endotoxin (lipopolysaccharide)** → immune activation and **TNF-alpha release → anorexia, muscle loss, weight loss, hypoalbuminaemia, hypocholesterolaemia**. - **Best predictors of poor outcome in CHF are weight loss and hypocholesterolaemia.** - **Angiotensin II** cleaves actomyosin, clearing muscle protein via the **ubiquitin–proteasome system**; **ACE inhibitors reverse weight loss and frailty** in some CHF patients.
11. **Other diseases:** - **COPD** — reduced endurance, poor intake, **raised resting metabolic rate and thermic energy of eating**, low testosterone, high cytokines. - **Diabetes mellitus** — low testosterone, raised angiotensin II, raised cytokines, peripheral neuropathy, sarcopenia, reduced executive function, accelerated atherosclerosis; **mortality is increased in frail diabetics**. - **Anaemia** — reduced endurance and strength, orthostasis, falls, reduced mobility, increased disability and mortality; **erythropoietin and darbepoetin-alpha reverse many of these**.
12. **Reversible causes not to be missed: Polymyalgia rheumatica** — painful muscles with proximal myopathy, **raised ESR**, and **corticosteroids completely reverse the frailty**; this **totally reversible condition is often misdiagnosed**. Also **hyperthyroidism, hypothyroidism, hypoadrenalism** (insidious onset) and **arthritis or pain leading to immobility and muscle loss**.
13. **Anorexia of ageing (decreased food intake):** causes are multifactorial — - Social: **isolation, dysphoria** - Sensory: **decline in smell, rise in taste threshold** - Gastric: **decreased fundal compliance and adaptive relaxation** leading to rapid antral filling and **early satiety** - Hormonal: **excess cholecystokinin** from the duodenum after a fatty meal; **high circulating cytokines** - In men: **falling testosterone leads to rising leptin and greater anorexia** — men lose more food intake over the lifespan.
14. **MEALS-ON-WHEELS mnemonic for treatable weight loss: M**edications (digoxin, theophylline, cimetidine) ·

Emotional (depression) · **A**lcoholism, elder abuse, anorexia tardive · **L**ate-life paranoia · **S**wallowing problems · **O**ral factors · **N**osocomial infections (e.g. tuberculosis) · **W**andering and other dementia-related causes · **H**yperthyroidism, hypercalcaemia, hypoadrenalism · **E**nteral problems (gluten enteropathy) · **E**ating problems · **L**ow-salt, low-cholesterol and other therapeutic diets · **S**tones (cholecystitis).

15. **Sarcopenia — the engine of frailty:** - Defined as lean tissue **more than 2 SD below young adults**. - **Best measure is appendicular skeletal mass by DEXA divided by height squared**; MRI, CT, bioelectrical impedance and ultrasound are alternatives. - **Sarcopenic obesity ("fat frail")** — those who stay fat while losing muscle have the **highest future disability and mortality**. - **Myosteatosis** (fat infiltration into muscle) is a **separate condition linked to insulin resistance** via altered insulin-receptor substrate and GLUT transporter function.

16. **Determinants of muscle loss:** best predictors are **age, energy intake, physical activity, IGF-1, testosterone and cytokines**. Also **hypovitaminosis D** (reduced strength, more falls); **testosterone falls about 1% per year from age 30 in men**; **myostatin** acts via activin IIb receptors; **motor unit firing rate falls after age 80**; **CNTF declines**; **TNF-alpha and IL-6 excess** reduce strength; **high homocysteine and peripheral vascular disease** impair muscle blood flow. **Sarcopenia may originate at birth** — grip strength correlates with birth weight in the Hertfordshire cohort.

Assessment

17. **Screen everyone, then assess.** Use a **rapid validated tool** first — the **FRAIL scale** is the simplest and quickest. Then confirm and characterise with a fuller measure. - **Phenotype tools:** Fried phenotype, **Frailty Trait Scale**, **FRAIL index**. - **Cumulative deficit tools: Frailty Index**, **Clinical Frailty Scale**. - Frailty is one of the **three core functional dimensions of CGA**, with basic ADLs and IADLs. Remember the **hierarchy rule** — do not test frailty in someone already severely ADL-dependent. - **Progranulin** is described as a biomarker of frailty.

Management

18. **Management algorithm using the FRAIL screen — the single most examinable table:**

Component	Action
Fatigue	Exclude **depression, sleep apnoea, hypothyroidism, anaemia, hypotension, vitamin B12 deficiency**
Resistance	Treat sarcopenia with **resistance exercise plus adequate protein (1 g/kg/day)**
Aerobic	**Aerobic and balance exercises**
Illnesses	If **more than 5 illnesses**, consider **deprescribing**
Loss of weight	Look for treatable causes — **MEALS-ON-WHEELS**

19. **Principle of management:** Frailty may have a **single reversible cause** — for example **anaemia**, where correction with iron, folate, vitamin B12 or erythropoietin reverses the frailty. More often it is due to the **interplay of hormones and cytokines with disease and poor-quality nutrition**, requiring **careful assessment of causative factors and a multifaceted treatment regimen**.

20. **Prevention and other therapies:** - **Exercise is the central preventive measure** — it delays the slope towards the frailty threshold; **creatine with exercise** may improve muscle performance. - **Testosterone replacement** increases muscle mass **even in non-hypogonadal males**, and pharmacological or replacement doses improve **muscle strength, power and function**. **Selective androgen receptor modulators** — steroidal (nandrolone, oxymetholone, oxandrolone) and non-steroidal (2-quinoline, coumarin, phthalimide, bicalutamide, acetothiolutamide) — are under investigation. - **Vitamin D** — regular sun exposure **15–30 minutes a day** without sunblock, or **800–1000 IU/day**, especially in long-term-care residents. - **Deprescribing and treating reversible disease** are as important as exercise and nutrition.

B. Latest Updates (2023–Present)

1. Kim and Rockwood, NEJM 2024 — the current definitive review. Assessing older patients for frailty enables clinicians to **tailor clinical care, including decisions about stressful treatments**. Management is stratified into **four stages — robust, pre-frailty, frailty and end-stage frailty** — with thresholds such as **Fried phenotype 0, Frailty Index below 0.10, and Clinical Frailty Scale 1–3 defining "robust."** This concept of **"frailty-guided clinical care"** is the major shift since the textbook.

2. NHS England and BGS — proactive frailty care (2023–2025). In December 2023 NHS England published *Proactive care: providing care and support to people living at home with moderate and severe frailty*. The pathway is: identify the cohort (including by **electronic frailty index, eFI**), confirm with the **Clinical Frailty Scale**, then perform a **CGA** covering physical, functional, social, environmental and psychological domains **alongside a medication review**. The original eFI is being replaced nationally by the **eFI2**, available to primary care from 2025. The BGS *Joining the dots* (2023) and *Be proactive* (2024) supersede the 2014 "Fit for Frailty" guidance.

3. ICFSR Global Consensus on Exercise (2025). Structured exercise prescriptions should be **customised and monitored like any other medical treatment**, considering dose–response relationships, with a **multifaceted regimen of aerobic, resistance, balance and flexibility training** through structured and incidental activity.

4. Italian National CGA Guideline (2024). Across 117 studies, CGA reduced hospitalisation, mortality,

institutionalisation and delirium risk, improved appropriateness of drug prescription, and maintained functional activities. **CGA remains the definitive management vehicle for frailty.**

5. WHO ICOPE — intrinsic capacity as the mirror image of frailty. ICOPE screens **six domains — mobility, cognition, nutrition, vision, hearing and psychological well-being** — with confirmed deficits triggering full assessment and a personalised prevention and care plan. Intrinsic capacity (reserve) and frailty (deficits) are two faces of the same coin.

6. Indian data — much higher burden than Western figures. LASI wave-1 (26,058 adults aged 60 and above, Fried phenotype) found **frailty in 29.2% and pre-frailty in 58.8%**, higher among **women (37.3%), the illiterate (37%) and rural residents (31%)**, ranging from **14.5% in Uttarakhand to 41.3% in Arunachal Pradesh**, and strongly associated with depression. A 2025 systematic review and meta-analysis of 330,007 community-dwelling Indians found a **pooled frailty prevalence of 36%** (48% by frailty index, 31% by Fried phenotype). In LASI, the most discriminant frailty component was **grip strength in men (79.1%)** and **physical activity in women (81.6%)**.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Prevalence	**About 6.9%** frail (Fried, Western data)	**India: about 29% frail, 59% pre-frail** (LASI); pooled Indian meta-analysis **36%** — the Western figure badly underestimates Indian burden
Purpose of diagnosis	Identify and treat reversible causes	Additionally **"frailty-guided clinical care"** — deciding intensity of drugs, surgery and screening
Staging	Frail versus not frail	**Four stages** — robust, pre-frail, frail, end-stage frailty — each with different treatment goals
Case-finding	Clinician-led FRAIL screen	**Population-level automated screening** (eFI2) from records, then CFS to confirm
Exercise	"Resistance, aerobic and balance exercises"	**Prescribed like a drug** — specified dose, frequency, progression and monitoring
Anabolic drugs	Testosterone and SARMs presented with optimism	**No approved pharmacotherapy for frailty**; testosterone reserved for symptomatic hypogonadism; SARMs still investigational
Framing	Deficit-based (frailty)	Complemented by **capacity-based** framing (WHO intrinsic capacity)

D. Exam One-Liners

- **Frailty equals pre-disability**; disability is the outcome. Never use them interchangeably.
- **Fried phenotype 5 criteria:** weight loss, exhaustion, weakness, slow gait, low activity. **3 or more equals frail, 1–2 equals pre-frail.**
- **FRAIL:** Fatigue, Resistance, Aerobic, Illnesses (more than 5), Loss of weight (5%).
- **SOF, 3 items:** weight loss, cannot rise from chair 5 times without arms, reduced energy.
- **Two models:** phenotype (Fried) versus cumulative deficits (Rockwood — Frailty Index, Clinical Frailty Scale).
- **CHF frailty chain:** gut oedema → bacterial translocation → endotoxin → TNF-alpha → anorexia plus muscle loss.
- **Best predictors of poor outcome in CHF:** weight loss and hypocholesterolaemia.
- **Never miss polymyalgia rheumatica** — high ESR, and steroids fully reverse the frailty.
- **MEALS-ON-WHEELS** for treatable weight loss.
- **Sarcopenia gold standard measure:** appendicular skeletal mass by DEXA divided by height squared.
- **"Fat frail" (sarcopenic obesity)** carries the worst prognosis.
- **Protein target in frailty: 1 g/kg/day** plus resistance exercise.
- **More than 5 illnesses means deprescribe.**
- **India:** frailty about 29%, pre-frailty about 59% (LASI); higher in women and rural residents.

7. Comparison of the Tests Used to Identify or Screen for Frailty

A. 18 High-Yield Points

The Fundamental Divide

1. **All frailty tools fall into two conceptual families**, and this is the single most important contrast to state: - **Phenotype model** — frailty is a **biological syndrome** with a pathophysiological substrate, expressed as a **limited number of physical domains**. Task and performance based. - **Cumulative deficit model** — frailty is the **accumulation of deficits** (diseases, impairments, abnormal findings) and reflects **biological ageing**. Count based.
2. **Tools by family:** - **Phenotype: Fried frailty phenotype, Frailty Trait Scale, FRAIL index** - **Cumulative deficits: Frailty Index, Clinical Frailty Scale**
3. **A second, equally important divide is purpose: screening or case-finding** (rapid, high sensitivity, applied to everyone) versus **assessment or diagnosis** (detailed, drives the care plan). Screening is never an end in itself — a positive screen must trigger a **comprehensive geriatric assessment**.

The Three Scales Compared Directly

4. Reproduce this table verbatim:

Cardiovascular Health Study (Fried)	Study of Osteoporotic Fractures (SOF)	IANA FRAIL scale
Weight loss (**10 lb in a year**)	Weight loss	**F**atigue
Exhaustion (self-report)	Inability to rise from a chair **5 times without using arms**	**R**esistance (climb one flight of stairs)
Weakness (**grip strength, lowest 20%**)	Reduced energy level	**A**erobic (walk one block)
Walking speed (**15 ft, slowest 20%**)	—	**I**llnesses (**more than 5**)
Low physical activity (**kcal/week, lowest 20%**)	—	**L**oss of weight (**5%**)

5. **Contrast within the table:** Fried requires **equipment (dynamometer, stopwatch, activity questionnaire) and population-based cut-offs (lowest 20%)**; SOF and FRAIL were developed because they are **easier to use in the clinic** and are validated. FRAIL is **purely self-report** — no equipment at all.
6. **Scoring is common to all three: 0 equals robust, 1–2 equals pre-frail, 3 or more equals frail.** This shared cut-off makes them directly comparable even though the items differ.

Contrasting the Individual Tools

7. **Fried phenotype — the reference standard.** Advantages: biologically grounded, identifies a **treatable pre-disability state**, gives the prevalence figure of about **6.9%**. Disadvantages: **time-consuming, needs equipment and normative data**, excludes cognition and mood, cannot be applied to a bed-bound or wheelchair-dependent patient.
8. **SOF index — the pragmatic three-item version.** Advantage: **no grip dynamometer or activity questionnaire**; the chair-stand replaces both. Disadvantage: even narrower domain coverage than Fried.
9. **FRAIL scale — the fastest phenotype screen.** Advantage: **five questions, purely verbal, usable over the telephone**; the "I" item uniquely captures **multimorbidity**, and the tool **maps directly onto a management algorithm**. Disadvantage: self-reported, so subject to recall bias and denial.
10. **Frailty Index (Rockwood–Mitnitski)** — counts deficits and expresses them as a **proportion (deficits present divided by deficits counted)**. Advantages: **continuous variable**, grades severity finely, predicts outcomes well, and can be built from **existing records**. Disadvantages: needs **30 or more variables**, laborious by hand, and it is **not a syndrome** — it deliberately mixes disease, disability and impairment; it **can be considered a comorbidity index**.
11. **Clinical Frailty Scale** — a **global clinical judgement** on a 9-point pictorial scale. Advantages: **seconds to apply**, no equipment, works in acutely unwell patients. Disadvantages: **subjective and rater-dependent**, conflates frailty with disability at the severe end.
12. **Frailty Trait Scale** — phenotype-based but multidimensional; used mainly in research and in ADVANTAGE/ICFSR recommendations.
13. **VES-13 (Vulnerable Elders Survey-13)** — a self-report tool **for identifying vulnerable older people in the community**, measuring **age, self-rated health, physical function and ADL disability**. It has been **compared directly against full CGA** in older men with prostate cancer on androgen deprivation.
14. **aCGA (abbreviated CGA)** — a **pre-screen in older cancer patients**, with published scoring and interpretation. **VES-13 and aCGA screen for vulnerability, not for the frailty phenotype** — they exist to decide **who needs a full CGA**, not to diagnose a syndrome.
15. **SIOG task force position:** screening tools exist and have been used successfully in settings such as the emergency room, **but globally they were poorly tested**, and the task force **could not recommend any specific tool or approach above others** — general geriatric experience should guide the choice.

Choosing Between Them

16. **Principle of hierarchy:** frailty testing is **only worthwhile in the robust-to-pre-frail range**. If a patient is already **severely ADL-dependent, do not measure frailty** — the ADL deficits, not the frailty score, determine risk and management.
17. **Setting dictates the tool.** Adapt the assessment to the patient's complexity and to the place where it is carried out — a brief screen in the office or home, a fuller interdisciplinary work-up in an inpatient or day-hospital setting.
18. **Whichever tool is used, the endpoint is the same:** a positive screen must be followed by a search for the **causative factors** (disease, pain, poor nutrition, sarcopenia, executive dysfunction) and a **multifaceted treatment regimen** — because frailty may have a **single reversible cause** such as anaemia or polymyalgia rheumatica.

B. Master Comparison Table

Tool	Model	Items	Method	Time	Output	Best setting	Main limitation
Fried phenotype (CHS)	Phenotype	5	Performance plus report	10–15 min	3 categories	Research; specialist clinic	Equipment; population cut-offs; excludes cognition
SOF index	Phenotype	3	Performance plus report	~5 min	3 categories	Clinic, community	Very narrow domains
FRAIL scale	Phenotype	5	Self-report only	**15–30 sec**	3 categories	**Primary care, telephone, India and LMICs**	Recall bias
Frailty Index	Deficits	**30 or more**	Record or interview	20–30 min	**Continuous (0–1)**	Research; record-derived	Laborious; not a syndrome
Clinical Frailty Scale	Deficits (judgement)	9 levels	Clinician judgement	**Under 1 min**	Ordinal 1–9	**Acute hospital, ED, surgery**	Rater-dependent
PRISMA-7	Mixed	7	Self-report questionnaire	**Under 2 min**	Score 3 or more equals frail	Community, ED, postal	Age is one item, so over-calls the very old
VES-13	Vulnerability	13	Self-report	~5 min	Score 3 or more equals vulnerable	**Geriatric oncology**, community	Detects disability more than frailty
G8	Vulnerability	8	Self-report	~5 min	14 or less equals abnormal	**Geriatric oncology**	Nutrition-weighted
Gait speed alone	Performance	1	Performance	~1 min	**Below 0.8 m/s**	Any	Single domain
Timed Up-and-Go	Performance	1	Performance	~1 min	**Above 10 s** (frailty) / **above 12 s** (falls)	Any ambulant patient	Needs ambulation
eFI / eFI2	Deficits	36 or more	**Automated from records**	0 min	Continuous or graded	**Population health, primary care**	Data-quality dependent; no clinical judgement

C. The Six Axes of Contrast

Axis	Contrast
1. Model	Phenotype (syndrome, treatable) **versus** cumulative deficits (risk index, prognostic)
2. Purpose	Screen (sensitive, fast) **versus** assess (specific, comprehensive)
3. Method	Self-report **versus** performance-based **versus** clinician judgement **versus** automated record-based
4. Output	Categorical (robust/pre-frail/frail) **versus** ordinal (CFS 1–9) **versus** continuous (FI 0–1)
5. Overlap with disability	Fried and FRAIL **exclude** disability by design; CFS and FI **include** it
6. Actionability	FRAIL maps to an intervention algorithm; FI and CFS mainly stratify **prognosis**

D. Latest Updates (2023–Present)

1. Head-to-head diagnostic accuracy — the emergency department evidence. A systematic review and meta-analysis of prospective diagnostic accuracy studies (2000–2022) covering seven ED frailty screens (PRISMA-7, CFS, VIP, FRESH, BPQ, TRST, ISAR) in 1,663 participants found a **pooled sensitivity of 0.85 and specificity of 0.77** against CGA; **PRISMA-7 was the most sensitive (0.84–0.98) but only moderately specific (0.64–0.78)**, whereas **CFS was the least sensitive but the most specific**.

2. Direct comparison against CGA. In 197 ED attendees aged 70 and above (49% frail by CGA), the **CFS (AUROC 0.91) and PRISMA-7 (AUROC 0.90) were significantly more accurate** than the 3- and 4-item VIP (both 0.84), with **no significant difference between CFS and PRISMA-7**. In a separate cohort of 313 patients (58% frail by CGA), **PRISMA-7 was most accurate (AUC 0.88), followed by CFS (0.83) and ISAR (0.78)**.

3. PRISMA-7 systematic review (2025). PRISMA-7 is completed in **under 2 minutes**, showed an **AUC of 0.85 against the Fried phenotype**, and is a practical alternative to the time-consuming and resource-intensive phenotype.

4. Automated screening has arrived. The **electronic frailty index (eFI2)** is replacing the original eFI across English GP systems, available from 2025. The recommended sequence is now **eFI to identify the cohort → Clinical Frailty Scale to confirm → CGA to assess and plan**. This is the key structural change: **screening is no longer clinician-initiated but population-triggered**.

5. NEJM 2024 frailty-guided care. Kim and Rockwood define **robust** as Fried phenotype 0, **Frailty Index below 0.10**, and **CFS 1–3**, and stratify management across four stages. The tools are now used not just to label but to **decide how intensively to treat**.

6. Guideline position on choice of tool. ICFSR: **all adults aged 65 and over should be offered screening for frailty using a validated rapid frailty instrument suitable to the specific setting or context** (strong recommendation, low certainty), followed by clinical assessment of all who screen positive. In primary care, the **FRAIL scale can be answered in 15 to 30 seconds**, predicted disability and mortality at 9 years, and **performed as well as the Fried phenotype and the SOF index**.

7. Oncology has standardised on a single tool. The German S3 guideline recommends specific screening instruments **mainly in the oncological setting (the G8 questionnaire)**, and ASCO 2023 recommends the **Practical Geriatric Assessment (PGA)**.

8. Indian data — the tool changes the answer. In a meta-analysis of 330,007 community-dwelling Indians, pooled frailty prevalence was **36%**, but varied markedly by instrument — **48% by frailty index versus 31% by Fried phenotype**. In LASI, the most discriminant phenotype component was **grip strength in men (79.1%)** and **physical activity in women (81.6%)**, arguing for sex-specific interpretation.

E. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Which tool to use	No tool preferred; SIOG "could not recommend any specific tool above others"	**Setting-specific standardisation** — FRAIL in primary care, CFS in acute/ED/surgery, G8 or PGA in oncology, MPI for prognosis, eFI2 for population screening
Accuracy data	None given	**PRISMA-7 most sensitive; CFS most specific**; both AUROC about 0.90 against CGA
Who initiates screening	Clinician, opportunistically	**Automated record-triggered** cohort identification (eFI2), then clinician confirmation
Fried phenotype role	The operational definition	Increasingly a **research reference standard**, replaced clinically by rapid proxies
Purpose of the score	Diagnose a treatable pre-disability state	Additionally used to **titrate treatment intensity**
Gait speed	Listed among mobility measures	Emerging as the **best single-item screen**; 0.8 m/s or less the operative threshold

F. Exam One-Liners

- **Two families:** phenotype (Fried, SOF, FRAIL, FTS) versus cumulative deficits (Frailty Index, CFS, eFI).
- **All three classical scales score identically:** 0 robust, 1–2 pre-frail, **3 or more frail**.
- **Fastest self-report screen is FRAIL (15–30 s); fastest clinician screen is CFS (under 1 min).**
- **Most sensitive ED screen is PRISMA-7; most specific is the Clinical Frailty Scale.**
- **Frailty Index needs 30 or more deficits** to predict death, institutionalisation and decline reliably.
- **Fried excludes disability by design; CFS and FI include it** — which is why FI and CFS give higher prevalence.
- **Gait speed below 0.8 m/s, TUG above 10 s, PRISMA-7 of 3 or more** — the three quickest positive triggers.
- **Oncology screens are G8 and VES-13**; the **aCGA** is a pre-screen for full CGA.
- **A screen is never a diagnosis** — every positive screen must be followed by CGA.
- **Do not measure frailty in someone already severely ADL-dependent.**

8. Sarcopenia in Ageing — Diagnostic Criteria, Investigation and Management

A. 18 High-Yield Points

Definition and Concept

1. **Definition:** Sarcopenia is the **excessive loss of muscle mass that occurs in older people**, usually defined as lean tissue **more than two standard deviations below that of young adults**.
2. **Prevalence: 13–24% at ages 60–70**, rising to **about 50% over age 80**.
3. **Relationship to frailty:** Sarcopenia is one of the **five major causes of frailty** and is the **biological substrate of physical frailty** — the two are **two sides of the same "impaired" coin**, and a combined entity, **"physical frailty and sarcopenia,"** is emerging.
4. **Sarcopenia is strongly correlated with disability.** Most sarcopenic people also lose fat, but a subset stay fat while losing muscle — the **"sarcopenic obese" or "fat frail"** — and longitudinally these have the **highest future disability and mortality**.
5. **Myosteatosis is a separate condition** — fat infiltration *into* muscle, related to **insulin resistance**. Mitochondrial failure or high circulating triglycerides cause intramyocellular triglyceride accumulation, altering the **insulin receptor substrate and GLUT transporter**.

Etiopathogenesis

6. **Final common mechanism:** an **imbalance in the everyday renewal cycle of muscle** — either **excess atrophy and apoptosis**, or **reduced hypertrophy and satellite cell production**.
7. **Best epidemiological predictors of muscle mass and strength: age, energy intake, physical activity, IGF-1, testosterone and cytokines**.
8. **Hormonal: Testosterone falls about 1% per year from age 30 in men**, and rapidly between 20 and 40 in women. Testosterone **diverts pluripotential stem cells away from the fat lineage into the muscle lineage**, produces **satellite cells** (essential for muscle repair), **stimulates muscle protein synthesis** and **inhibits the ubiquitin–proteasome pathway**.
9. **Growth factors: Myostatin** is the negative regulator, acting via **activin IIb receptors**; a **soluble activin IIb receptor** scavenges activin and produces muscle and bone hypertrophy in rodents, monkeys and humans. Double myostatin deletion produces the "mighty mouse," and marked hypertrophy in cattle, whippets and one human. **IGF-1 and mechanogrowth factor (MGF)** rise with resistance exercise in young but **not** elderly subjects.
10. **Neural: Motor unit firing rate falls significantly after age 80**. **Ciliary neurotrophic factor (CNTF)** declines with age in parallel with strength. **C-agrin and neurofilament light chain** are raised in a subset of sarcopenic people.
11. **Inflammatory, vascular and developmental: Excess TNF-alpha and IL-6 cause loss of muscle strength**; high CRP and IL-6 correlate with reduced handgrip strength. **Raised homocysteine and peripheral vascular disease** impair muscle blood flow. **Hypovitaminosis D** is associated with decreased strength and falls. In the **Hertfordshire cohort, grip strength correlated with birth weight** — sarcopenia may originate at birth. **ACE I/I** carriers generate more power with exercise than **D allele** carriers.
12. **Signalling pathway:** anabolic limb — **GH/testosterone/creatine → IGF-1/MGF → PI3K → AKT → mTOR → S6K1 → hypertrophy**; catabolic limb — **cytokines → TNFR1 → IKK → NF-kappaB**, and **glucocorticoids/diabetes → FOXO → Atrogin-1 (MAFbx) and MuRF1 → ubiquitin–proteasome → protein degradation → atrophy**; **myostatin → SMAD3** suppresses MyoD, opposed by **follistatin**.

Investigation

13. **Best measure of muscle mass: appendicular skeletal mass measured by DEXA, divided by height in metres squared**. Alternatives: **MRI, CT, or bioelectrical impedance**. **DEXA and MRI measures are highly correlated**, and **ultrasound** is proving to be an excellent measure.
14. **Imaging refinement: MRI with specific protocols is superior to DXA**, particularly for visceral tissues, and can additionally measure **muscle volume, muscle fat infiltration and ectopic fat**. **BIA is accessible even in primary care** but relies on an approximation between total body weight, lean tissue and fat — reasonable for arms and legs, **less precise for visceral regions**.
15. **Circulating biomarkers:** - **P3NP** (procollagen type III N-terminal peptide) — related to muscle mass and strength, stronger in women. - **D3-creatine (methyl-d3) dilution** — urine D3-creatinine enrichment correlates highly with MRI total muscle mass and **may be superior to DXA**. - **C-terminal agrin fragment (CAF)** — a neuromuscular junction breakdown product; associated with **DXA muscle mass, grip strength and gait velocity**. - **Myostatin, follistatin, GDF-11** — inconsistent; the myostatin–muscle mass relationship was confirmed **only in men** in the I-Lan study.

Management

16. **Core treatment: Resistance exercise plus adequate protein (1 g/kg/day)** — the explicit treatment for sarcopenia in the FRAIL management algorithm; plus **aerobic and balance exercise**. **Creatine with exercise** may improve muscle performance.
17. **Pharmacological options: Testosterone replacement increases muscle mass even in non-hypogonadal males**; pharmacological or replacement doses in hypogonadal men **increase muscle strength and power**, with demonstrated **functional improvement**. **Selective androgen receptor modulators** — steroidal (nandrolone, oxymetholone, oxandrolone) and non-steroidal (2-quinoline, coumarin, phthalimide, bicalutamide, acetothiolutamide) — remain investigational.
18. **What NOT to use, and what else to do: Growth hormone is not recommended** — it produced **no positive effect on muscle strength, VO2max or functional capacity**, did not add to resistance training, and **men with the highest GH levels had the highest mortality**. **Vitamin D** — regular sun exposure **15–30 minutes a day** without sunblock, or **800–1000 IU/day**; **25-OH-vitamin D should be above 30 ng/mL**. **Treat the anorexia of ageing** using the **MEALS-ON-WHEELS** mnemonic.

B. Diagnostic Criteria

EWGSOP2 (2019) — the European standard: F-A-C-S

Step	Test	Cut-off
Find	**SARC-F questionnaire**	**4 or more**
Assess (strength)	**Handgrip strength** or **5-time chair stand**	**Below 27 kg (men), below 16 kg (women)**; or **above 15 s**
Confirm (mass)	**ASMI (DXA or BIA)**	**Below 7.0 kg/m2 (men), below 5.5 kg/m2 (women)**
Severity (performance)	**Gait speed**, SPPB, TUG, 400 m walk	**0.8 m/s or less**; SPPB 8 or less; TUG 20 s or more

Diagnostic logic: low strength equals **probable sarcopenia** → plus low mass equals **confirmed sarcopenia** → plus low performance equals **severe sarcopenia**. **Muscle strength, not mass, is the primary parameter.** EWGSOP2 chose round-number cut-offs to foster ease of use.

AWGS 2019 — the Asian standard, more relevant for Indian practice

Case-finding uses **calf circumference (below 34 cm men, below 33 cm women)**, **SARC-F of 4 or more**, or **SARC-CalF of 11 or more**. **"Possible sarcopenia"** is then diagnosed by **handgrip below 28 kg (men) or below 18 kg (women)**, or **5-time chair stand of 12 seconds or more** — and AWGS recommends **starting lifestyle intervention immediately at this stage without waiting for muscle mass measurement**. Low physical performance equals **6-m walk below 1.0 m/s, SPPB 9 or less, or 5-time chair stand 12 s or more**; low muscle mass equals **DXA below 7.0 kg/m2 (men) and below 5.4 kg/m2 (women)**, or **BIA below 7.0 kg/m2 (men) and below 5.7 kg/m2 (women)**.

Head-to-head comparison

Feature	EWGSOP2 (2019)	AWGS 2019	FNIH
Screening	SARC-F 4 or more	**SARC-F / SARC-CalF / calf circumference**	—
Grip strength	**Below 27 / 16 kg**	**Below 28 / 18 kg**	Below 26 / 16 kg
Chair stand	**Above 15 s**	**12 s or more**	—
ASMI (DXA)	**Below 7.0 / 5.5 kg/m2**	**Below 7.0 / 5.4 kg/m2**	ALM adjusted for BMI
Gait speed	**0.8 m/s or less**	**Below 1.0 m/s**	Below 0.8 m/s
Unique feature	Strength is the **primary** criterion; severity staging	**"Possible sarcopenia"** allows treatment in primary care without DXA	Uses **ALM adjusted for BMI**

Exam point: *The criteria set you choose changes the prevalence — Indian data show 48% by frailty/deficit-type indices versus 31% by phenotype criteria. Always state which criteria you are applying.*

C. Investigation — Practical Scheme

Step 1 — Confirm the diagnosis SARC-F / SARC-CalF / calf circumference → grip strength (Jamar dynamometer) → 5-time chair stand → gait speed over 4 metres → DXA or BIA for ASMI.

Step 2 — Exclude mimics and secondary causes (the differential of the weak old person) - **Haemoglobin (g/dL)** for anaemia, **TSH** for thyroid disease, **ESR and CRP** for polymyalgia rheumatica and inflammation - **Serum creatinine (mg/dL) plus eGFR** — beware **masked renal failure**, where creatinine is normal despite severe CKD because of low muscle mass; use **Cockcroft-Gault or cystatin C** - **Fasting glucose or HbA1c**, **serum calcium (mg/dL)**, **vitamin B12**, **25-OH vitamin D (ng/mL)** - **Serum testosterone (ng/dL)** in symptomatic men; **CPK** if myopathy is suspected - **Nutritional assessment** — MNA, SNAQ, weight trend, BMI - **Medication review** — steroids, statins, and Beers/STOPP-START screening

Step 3 — Assess consequences Falls risk, ADL and IADL status, bone mineral density (sarcopenia and osteoporosis co-travel), cognitive and depression screening.

D. Latest Updates (2023–Present)

1. GLIS — the first globally endorsed conceptual definition (2024). The **Global Leadership Initiative in Sarcopenia** defined sarcopenia as a **generalised skeletal muscle condition that is potentially reversible**, applying consistently across conditions, care settings and both clinical and research contexts. Its **core components are muscle mass, muscle strength and muscle-specific strength (strength divided by size)**, while **impaired physical performance is a consequence, not a diagnostic component**. This is the single biggest conceptual change since the textbook.

2. GLIS outcomes consensus (2025). From an individual patient data meta-analysis of 32 databases and 5,116 participants using the SarQoL instrument, people with sarcopenia have **significantly reduced quality of life (mean difference −12.32)**, with the largest difference using **AWGS criteria (−17.65)**.

3. Regional guidelines have proliferated. Australia/New Zealand consensus (2023), Singapore clinical practice guidelines (2022), Chinese guidelines (2025), and an AWGS update. DXA remains a standard but has **limitations in reflecting true muscle quality and predicting outcomes**; **deuterium-labelled creatine dilution** shows promise, and myokine biomarkers (**IL-6, IGF-1, irisin, myostatin, gelsolin**) may improve diagnostic precision.

4. Exercise — now a formal prescription. The **ICFSR global consensus (2025)** states that structured exercise prescriptions should be **customised and monitored like any other medical treatment**, with a **multifaceted regimen of aerobic, resistance, balance and flexibility training**. Combined resistance–aerobic regimens at **2–3 sessions per week** improve muscle strength by **20–35%**.

5. Nutrition — the numbers have firmed up. Optimised protein intake of **1.0–1.5 g/kg/day** with **leucine or vitamin D** enhances muscle synthesis and functional capacity. To overcome the **anabolic resistance** of ageing muscle, **25–30 g of high-quality protein and 2.8–3 g of leucine per meal, at least twice daily**, is recommended; requirements rise to **1.2–1.5 g/kg/day in inflammatory disease**. **HMB 3 g daily** helps **preserve** muscle during illness, immobility or post-surgical recovery — the evidence is stronger for **preventing loss than for building muscle**.

6. Pharmacotherapy — still investigational. SARMs and myostatin inhibitors such as **bimagrumab** increase lean mass by **3–5%** in phase II studies; a single dose of the ActRIIB antibody **bimagrumab** produced a **6–8% increase in muscle mass within a month** with a simultaneous reduction in fat mass. **GDF-15-neutralising antibodies** are emerging as anti-catabolic agents. **No agent is approved for sarcopenia anywhere as of 2026 — exercise plus protein remains the only proven therapy.**

7. Vitamin D — nuance added. Recent trials show **active vitamin D (0.75 microgram/day)** can improve muscle strength and reduce fall risk in sarcopenic individuals, but benefits are largely confined to those who are **deficient**.

8. Indian relevance. Grip strength was the **most discriminant frailty and sarcopenia component in Indian men (79.1%)** in LASI, and **AWGS cut-offs, not EWGSOP2, should be applied** to Indian patients. **BIA is the practical mass-measurement modality** in most Indian centres given limited DXA access — AWGS explicitly provides a BIA cut-off for this reason.

E. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Core definition	**"Excessive loss of muscle mass"** (more than 2 SD below young adults)	**GLIS 2024:** a **muscle disease** defined by **mass plus strength plus muscle-specific strength**; **mass alone is insufficient**
Primary diagnostic parameter	**Muscle mass** (ASM/height squared by DEXA)	**Muscle strength** (EWGSOP2) — mass confirms, performance stages severity
Physical performance	Not part of the definition	EWGSOP2 and AWGS: severity marker; **GLIS: a consequence, not a criterion**
Screening	Not described	**SARC-F, SARC-CalF, calf circumference** now standard entry points
Reversibility	Implied	**GLIS explicitly states sarcopenia is potentially reversible**
Protein target	**1 g/kg/day**	**1.0–1.2 g/kg/day baseline; 1.2–1.5 g/kg/day if inflammatory disease**, with **leucine 2.8–3 g per meal**
Testosterone and SARMs	Presented optimistically	**Not approved**; used only for symptomatic hypogonadism after individualised discussion
New drugs	Not covered	**Bimagrumab, apitegromab, anti-GDF-15** — all investigational
Ultrasound	"Proving to be an excellent measure"	Increasingly used point-of-care; **D3-creatine dilution may surpass DXA**

F. Exam One-Liners

- **Sarcopenia is the biological substrate of physical frailty** — two sides of the same impaired coin.

- **Prevalence: 13–24% at 60–70 years; about 50% over 80.**
- **Textbook gold standard measure:** appendicular skeletal mass by DEXA divided by height squared.
- **EWGSOP2 sequence is F-A-C-S** (Find, Assess, Confirm, Severity); **strength is the primary criterion**.
- **AWGS grip cut-offs: below 28 kg men, below 18 kg women** — use these for Indians. **EWGSOP2: below 27 / 16 kg.**
- **AWGS ASMI (DXA): below 7.0 / 5.4 kg/m2; (BIA): below 7.0 / 5.7 kg/m2.**
- **AWGS "possible sarcopenia" allows treatment to start in primary care without DXA.**
- **Sarcopenic obesity ("fat frail") has the worst prognosis.**
- **Myosteatosis is not sarcopenia** — it is fat *in* muscle, linked to insulin resistance.
- **Atrogin-1 (MAFbx) and MuRF1** are the two key E3 ligases of the ubiquitin–proteasome atrophy pathway.
- **Beware masked renal failure** — normal creatinine with severe CKD because there is no muscle.
- **Only proven treatment is resistance exercise plus adequate protein.** No drug is approved.
- **GH is useless or harmful** — no gain in strength or function; highest GH levels equal highest mortality.

Part III — Disability, Immobility and Rehabilitation

9. Causes of Chronic Disability in the Elderly — Prevention and Management

A. 20 High-Yield Points

Definitions and Framework

1. **Disability is an umbrella term** covering **impairments, activity limitations and participation restrictions** (WHO **ICF, 2001**). **Functioning** is the corresponding positive umbrella term.
2. **The ICF has two parts:** - **Part 1 — Functioning and Disability:** Body Functions and Structures; Activities and Participation - **Part 2 — Contextual Factors:** Environmental Factors; Personal Factors
3. **Key ICF definitions: Impairment** is a problem in body function or structure · **Activity** is the execution of a task · **Activity limitation** is difficulty executing it · **Participation** is involvement in a life situation · **Participation restriction** is a problem in that involvement.
4. **The ICF replaced the older impairment–disability–handicap model** and explicitly recognises that **the social and physical environment shapes functioning** — disability is not a property of the person alone.
5. **The vicious cycle:** Parkinson's disease (impairment) → difficulty with self-care and mobility (activity limitation) → cannot pursue hobbies (participation restriction) → falls and fractures hip → loses confidence → becomes isolated, withdrawn and depressed. **Feedback loops make functioning spiral downwards.**

Causes of Chronic Disability

6. **The major disabling events: stroke, hip fracture, other fall-related injury, and deconditioning following a major illness**.
7. **The major ongoing disabling diseases: osteoarthritis and Parkinson's disease** are named explicitly; also stroke sequelae, amputation, and chronic cardiorespiratory disease.
8. **"Almost any acute or chronic disease can reduce functioning"** — but there is a specific list of **common but easily overlooked causes of dysfunction in older people** that must be memorised: - **Impaired cognition** - **Impaired special senses** (vision, hearing, balance) - **Unstable gait and mobility** - **Poor health habits** (alcohol, smoking, lack of exercise) - **Poor nutrition** - **Polypharmacy** - **Incontinence** - **Psychosocial stress** - **Depression**
9. **The "geriatric giants" as classical causes — the series of I's: Immobility, Instability (falls), Incontinence, Intellectual impairment, Infection, Impairment of vision and hearing, Irritable colon, Isolation (depression), Inanition (malnutrition), Impecunity, Iatrogenesis, Insomnia, Immune deficiency, Impotence.** Morley's **"new geriatric giants"** add **frailty, sarcopenia, anorexia of ageing and cognitive impairment**.
10. **Determinants of ACTIVITY restriction — four factors:** - **Type of impairment** (nature and severity of the disease) - **Presence of associated impairments** (pre-existing problems matter as much as the new one) - **Degree of physiological reserve** - **Level of physical fitness**
11. **Determinants of PARTICIPATION restriction:** - **Intrinsic:** attitude, personality, ability to adjust, cultural issues - **Extrinsic:** financial resources, housing, other resources, **social supports (spouse, family, neighbours, friends, pets)**
12. **The single greatest difference from younger patients is reduced physiological reserve** — recovery is **prolonged and may not return to the premorbid state**. **But note the caution:** even very old people recover from major illness, and **failure to progress can seldom be blamed on reduced reserve alone**. Of **far greater importance is the lack of activity and physical fitness** typical of older people in modern societies.
13. **Site matters as much as size** — in stroke, large lesions in some brain areas may be asymptomatic while **small lesions in strategic areas cause major disability**.
14. **Disability cascades:** impaired gait leads to depression and reduced social functioning; **immobility of any cause — even after the cause is removed — produces secondary impairment from deconditioning and loss of musculoskeletal flexibility**.
15. **Psychological determinants:** onset of impairment provokes a **grief reaction — denial, anger, depression, then acceptance**. **Over 40% of older people become depressed after myocardial infarction**, and this worsens prognosis; high rates also follow stroke despite rehabilitation. At one extreme are **highly motivated** patients; at the other, those who **adopt the "sick role"**, disengage and surrender autonomy.
16. **Kemp's motivation model** — motivation is driven by four elements: the person's **wants, beliefs, rewards for achievement**, and the **cost** (pain and effort). The first three push forward; cost pulls back. The clinician intervenes by **setting goals, challenging incorrect beliefs, establishing rewards and minimising cost**.

Assessment of the Disabled Older Person

17. **Diagnostic approach:** to identify the cause of new disability, look for **(a) worsening of an existing chronic disease, (b) a new acute disease, or (c) one of the common occult diseases listed in point 8**. Do this through a **refocused history guided by the functional deficit** and a **focused examination**.

18. **Examination must always include** — in addition to heart, lungs, extremities and neurology — **postural blood pressure, vision and hearing screening, and careful observation of gait**, plus **MMSE**. **Basic labs:** complete blood count and blood chemistry panel, plus targeted tests.

Prevention and Management

19. **Rehabilitation — the UN definition:** "*a goal-orientated and time-limited process aimed at enabling an impaired person to reach an optimum mental, physical and/or social functional level, thus providing him or her with the tools to change his or her own life*." It may **compensate for lost function (technical aids)** or **facilitate social readjustment**.
20. **The eight steps in the rehabilitation process: 1. Assessment → 2. Setting goals → 3. Therapy → 4. Aids and adaptations → 5. Education → 6. Psychological support → 7. Evaluation → 8. Follow-up.** Attached principles: - **Early intervention is crucial** — anticipate and avoid problems, because once established they may be irremediable (for example, shoulder subluxation in flaccid hemiplegia). - **Goals must be realistic, agreed by the whole team AND the patient**, with **short-term (intermediate) and long-term (final) goals** and flexible time frames. **Patients with ambitious goals make greater progress** — so set **ambitious but achievable** targets. - **Education is a vital component** — it gives the patient knowledge, skills and attitudes to minimise activity and participation restriction, and doubles as **secondary prevention**. - **Age-associated decline is reversible: weight training increases muscle strength and improves functional capacity in older people**, and lifelong trainers have muscle strength comparable to sedentary middle-aged people. - **Assessment must be linked to long-term follow-up and often formal case management.**

B. Structured Classification of Causes

Category	Causes
Neurological	Stroke, Parkinson's disease, dementia, peripheral neuropathy, spinal cord compression, normal-pressure hydrocephalus
Musculoskeletal	**Osteoarthritis**, osteoporosis and fragility fracture (especially hip and vertebral), sarcopenia, polymyalgia rheumatica, amputation
Cardiorespiratory	Heart failure, ischaemic heart disease, COPD, peripheral vascular disease
Sensory	**Cataract, glaucoma, age-related macular degeneration, presbycusis** — the most under-treated reversible causes
Psychological	**Depression**, anxiety, **fear of falling**, adjustment failure or "sick role"
Metabolic and systemic	Diabetes and its complications, hypothyroidism, anaemia, malnutrition, chronic kidney disease
Iatrogenic	**Polypharmacy**, anticholinergic burden, physical restraints, bed rest, unnecessary hospitalisation, catheters
Environmental and social	Poor housing, no grab-bars or rails, inaccessible transport, poverty, isolation, absent carer, elder abuse

C. Prevention — The Three-Level Framework

Primary prevention (prevent the impairment) - **Exercise** — the single most important intervention; multicomponent (aerobic, resistance, balance, flexibility) - Vascular risk control (blood pressure, glycaemic control, lipids, smoking, alcohol) - **Immunisation** (influenza, pneumococcal, herpes zoster, COVID-19) - Osteoporosis and fall prevention; adequate protein and vitamin D - Cognitive and social engagement

Secondary prevention (detect impairment early, before it limits activity) - **Comprehensive geriatric assessment** with periodic functional screening - Screening for the occult causes listed above — cognition, mood, vision, hearing, gait, nutrition, continence - **Medication review and deprescribing** (Beers, STOPP-START) - Preventive home visits — benefits are not definitively confirmed, so not routine practice

Tertiary prevention (prevent activity limitation progressing to participation restriction) - **Early rehabilitation**, aids and adaptations, home modification - Carer training and support; **avoid restraints and unnecessary bed rest** - Social re-engagement, day centres, transport solutions

D. Management — Practical Scheme

1. **Define the disability precisely** — task analysis: which step of dressing, walking or toileting fails?
2. **Search for reversible causes** — a new drug, a new illness, an intercurrent infection, a change in living conditions. *When a reversible cause is found, a simple treatment may eliminate the functional impairment.*
3. **Optimise medical management** — treat the disease, control pain, correct anaemia, thyroid, B12 and vitamin D; **deprescribe**.
4. **Refer to the multidisciplinary team** — physician, nurse, physiotherapist, occupational therapist, social worker; optimally dietician, pharmacist, speech therapist.
5. **Set goals with the patient** — short and long term, ambitious but achievable.
6. **Therapy** — exercise (resistance for strength, aerobic for endurance, balance for falls), gait re-training, ADL re-training.

7. **Aids, appliances and home adaptation** — walking aids, grab bars, raised toilet seat, shower stool, hearing aid, spectacles, footwear.
8. **Address mood and motivation** — treat depression; challenge catastrophic beliefs; use Kemp's framework.
9. **Support the carer** — carer burden is a leading cause of institutionalisation.
10. **Discharge planning, evaluation and long-term follow-up with case management.**

E. Latest Updates (2023–Present)

1. Global burden — the disability picture has shifted. Osteoarthritis is a leading cause of pain and disability among middle-aged and older adults; in 2020 it affected **7.6% of the global population (more than 595 million people)**, with cases projected to rise **60–100% by 2050**, and it is **expected to become the leading cause of disability worldwide by 2030**. Hearing loss ranks as the **third most common cause of years lived with disability globally**, with its age-standardised rate still rising among those aged 60 and above. Regional analyses identify **diabetes mellitus, age-related hearing loss and low back pain** as the leading causes of *disability* in older people, distinct from the leading causes of *death*.

2. Indian data — essential for the exam. LASI wave-1 (31,464 adults aged 60 and above) found **about 3% with severe ADL disability and about 6% with severe IADL disability**. In the same cohort, **44.3% had no geriatric condition, 32.7% had one, 15.9% two and 7.1% had three or more**; specific prevalences were **underweight 26.9%, dizziness 14.5%, impaired vision 13.7%, impaired hearing 9.6%, impaired cognition 9.3%, major depressive disorder 8.2%, injurious falls 5.7% and incontinence 4.0%**, with **7.4% having ADL dependency**. A rural Goa study found much higher figures — **ADL disability 13.7% and IADL disability 38.7%** — associated with sex, education, financial dependence, comorbidities, alcoholism and **sensory impairment**.

3. Multimorbidity combinations matter more than counts. Among 197 multimorbidity combinations in LASI, the combination of **hypertension, arthritis and high depressive symptoms** was associated with **greater ADL–IADL disability than any other combination**; population attributable fractions were about **22.5% for hypertension plus depression, 21.6% for hypertension plus arthritis and 23.5% for arthritis plus depression**. **Adding depression to any physical multimorbidity combination sharply increases disability.**

4. Frailty is the strongest single predictor of incident disability. A systematic review reported a **pooled odds ratio of 9.82 (95% CI 4.71–20.46) for incident ADL disability in frail older adults**; in LASI, frailty was strongly associated with depression (OR 2.09) and ADL difficulty (OR 1.75).

5. Exercise is now prescribed like a drug. The **ICFSR global consensus (2025)** states structured exercise prescriptions should be **customised and monitored like any other medical treatment**, with a **multifaceted regimen of aerobic, resistance, balance and flexibility training**.

6. Proactive, population-level disability prevention. NHS England and BGS proactive care uses the **electronic frailty index** to identify at-risk older people, the **Clinical Frailty Scale** to confirm, and a **CGA covering physical, functional, social, environmental and psychological domains plus a medication review** to plan care. WHO **ICOPE** screens six domains of intrinsic capacity with confirmed deficits triggering a personalised prevention and care plan.

7. CGA reduces disability outcomes. The Italian national CGA guideline (2024), from 117 studies, found CGA reduces hospitalisation, mortality, institutionalisation and delirium risk, improves prescribing appropriateness and **maintains functional activities**.

F. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Leading disabling conditions	Stroke, hip fracture, osteoarthritis, Parkinson's disease	**Osteoarthritis projected to be the world's leading cause of disability by 2030**; **hearing loss third leading cause of YLD**; low back pain and diabetes prominent
Framing	ICF — deficits	Complemented by **WHO intrinsic capacity and functional ability** framing
Who to target	Those with a recent disabling event	**Population-level proactive identification** before the event (eFI2, ICOPE screening)
Depression	Recognised as common post-MI and post-stroke	Quantified as a **major independent driver of disability in multimorbidity combinations** (Indian PAF about 22–24%)
Frailty	A separate concept	The **strongest predictor of incident ADL disability (OR about 9.8)** — the key preventable precursor
Exercise	"Weight training increases strength and improves functional capacity"	**Formal, dose-specified, monitored prescription**
Access	Only 2% of eligible Canadians access pulmonary rehabilitation; 1% musculoskeletal rehabilitation; worse in developing countries	Gap persists; **India relies on NPHCE with inconsistent implementation and ASHA-delivered community screening**

G. Exam One-Liners

- **Disability equals impairment plus activity limitation plus participation restriction** (ICF, 2001).
- **ICF Part 1 is Functioning and Disability; Part 2 is Contextual Factors.**
- **Four determinants of activity restriction:** type of impairment, associated impairments, physiological reserve, physical fitness.
- **Participation restriction is determined mainly by the ability to adapt** — and is largely neglected in clinical practice because it is subjective.
- **Eight steps of rehabilitation:** Assessment, Goals, Therapy, Aids and adaptations, Education, Psychological support, Evaluation, Follow-up.
- **Set ambitious but achievable goals** — ambitious goal-setters progress further.
- **Over 40% of older people are depressed after myocardial infarction**, worsening prognosis.
- **Nine overlooked causes of dysfunction:** cognition, senses, gait, health habits, nutrition, polypharmacy, incontinence, psychosocial stress, depression.
- **"Bed is bad"** — immobility itself causes secondary disability through deconditioning.
- **Frailty confers about a 10-fold risk of incident ADL disability.**
- **In India (LASI): about 3% severe ADL and 6% severe IADL disability; ADL dependency 7.4%.**
- **Hypertension plus arthritis plus depression is the most disabling multimorbidity combination in Indian elders.**
- **Under-investment in rehabilitation is a false economy** leading to avoidable, costly institutional care.

10. Assessment of Disability in Older People and Rehabilitation

A. 20 High-Yield Points

Framework and Terminology

1. **WHO ICF (2001)** replaced the impairment–disability–handicap model. **Disability** is the collective term for **impairments, activity limitations and participation restrictions**; **functioning** is the positive umbrella term. - **Part 1 — Functioning and Disability:** Body Functions and Structures; Activities and Participation - **Part 2 — Contextual Factors:** Environmental Factors; Personal Factors
2. **Key definitions: Impairment** — problem in body function or structure · **Activity** — execution of a task · **Activity limitation** — difficulty executing it · **Participation** — involvement in a life situation · **Participation restriction** — problem in that involvement · **Environmental factors** — the physical, social and attitudinal environment.
3. **Vicious cycles:** Parkinson's disease → difficulty with self-care and mobility → cannot pursue hobbies → falls and fractures hip → loses confidence → isolated, withdrawn, depressed. Rehabilitation can interrupt the cycle **at any point** — preventing progression of impairment to activity restriction, of activity restriction to participation restriction, and preventing further impairments.
4. **Rehabilitation (UN definition):** "*a goal-orientated and time-limited process aimed at enabling an impaired person to reach an optimum mental, physical and/or social functional level, thus providing him or her with the tools to change his or her own life.*"
5. **Determinants — must reproduce:**

Determinants of ACTIVITY restriction	Determinants of PARTICIPATION restriction
Type of impairment (nature and severity of disease)	**Intrinsic:** attitude · personality · ability to adjust · cultural issues
Presence of associated impairments	**Extrinsic:** financial resources · housing · other resources · **social supports (spouse, family, neighbours, friends, pets)**
Degree of physiological reserve	
Level of physical fitness	

6. **The greatest difference from younger patients is reduced physiological reserve** — recovery is prolonged and may not reach premorbid level. **But** even very old people recover from major illness, and **failure to progress can seldom be attributed to reduced reserve alone**; of **far greater importance is lack of activity and physical fitness**. Weight training increases strength and improves functional capacity even in old age.

Assessment

7. **Assess BEFORE entry into a rehabilitation programme** — to confirm the problems are remediable and to plan management. **Patient selection is difficult:** it is unfair to subject someone who cannot benefit to a demanding programme and raise false expectations; equally, **those who can benefit even to a limited extent must not be denied access**.
8. **Assess "both the problem in the individual and the individual with the problem."** Determine the nature and severity of **all** impairments, new and long-standing.
9. **Obtain a baseline measure of functional status** so progress can be monitored and efficacy reviewed. **Reassess at least weekly.**
10. **Assessment of activity restriction:** - Begin with the **clinical history** — determine **premorbid as well as current** function. - Use **ADLs** (washing, grooming, dressing, toileting, eating) and **IADLs** (meals, telephone, laundry, housework, gardening, shopping, public transport). - If difficulty is reported, **ask how the person manages** — is the task neglected, or does someone help? - **Busy clinicians can estimate the extent of restriction with a few simple questions and observations**; detailed standardised scaling is generally left to therapists and social workers. - No consensus exists on the best scale; **highly valid and reliable scales are resource-intensive or intrusive**, and the lack of uniformity inhibits comparative research.
11. **RCP/BGS endorsed standardised scales — high-yield table:**

Domain	Recommended scale	Comment
Basic ADLs	**Barthel Index**	Observation of what the patient *does*; **ceiling effect** in ambulatory patients
Vision, hearing, communication	Lambeth Disability Screening Questionnaire	Postal questionnaire
Memory and cognition	**Abbreviated Mental Test (AMT)**	10 questions from the Roth–Hopkins test
Depression	**Geriatric Depression Scale**	30 items; 15-item short form
Subjective morale	Philadelphia Geriatric Center Morale Scale	Distinct from depression, some overlap

Value of standardised scales: they allow **information exchange across acute, rehabilitation and community settings**, permit measurement of effectiveness, foster comparison of treatments, and **minimise repeated collection of identical information**. The **Functional Independence Measure (FIM)** scores **18 functions** — self-care, sphincter control, mobility, locomotion, communication, social cognition.

12. **Assessment of participation restriction:** each person interacts uniquely with their environment, so participation restriction is **unique to the individual** and determined mainly by the **ability to adapt**. Some redefine rather than lose their social role, and a few people's lives are **enriched** by developing an impairment. Because such measurements are **subjective and unstable over time (influenced by mood)**, assessing participation restriction is **largely neglected in both clinical and research settings**.

The Rehabilitation Process

13. **Eight steps — the single most examinable table: 1. Assessment → 2. Setting goals → 3. Therapy → 4. Aids and adaptations → 5. Education → 6. Psychological support → 7. Evaluation → 8. Follow-up.** The steps **overlap, occur simultaneously and must be regularly revisited**.

14. **Two overarching principles:** - **Early intervention is crucial** — avoidable restriction develops soon after impairment onset and, once established, may be irremediable. *Flaccid hemiplegia risks shoulder subluxation; proper handling and limb positioning immediately post-stroke minimises this.* - **A team approach is essential — doctors manage impairment, remedial therapists manage activity restriction, social workers manage participation restriction**; nursing has a holistic brief influencing both. Teams need co-location for informal exchange plus **regular formal meetings** to review progress, revise goals, plan discharge and organise follow-up.

15. **Goal setting:** goals must be **realistic**, account for premorbid status, and be agreed by **all team members and particularly the patient** — a programme is seriously compromised if key people differ on the target. Sometimes **modest goals** are right (wheelchair independence rather than walking for an amputee). **Patients with ambitious goals make greater progress**, so the pragmatic approach is **"ambitious but achievable."** Set **short-term (intermediate) and long-term (final)** goals with **flexible, regularly reviewed time frames**.

16. **Therapy — team roles: Doctors** manage the presenting problem and coexisting impairments, minimise risk factors and anticipate complications (in embolic stroke: monitor anticoagulation, control hypertension, manage angina and diabetes). **Occupational therapists** assess and enhance ADL competence. **Physiotherapists** target cardiorespiratory, neuromuscular and locomotor function. **Speech and language therapists** address communication and swallowing. Plus clinical psychologists, podiatrists, dieticians.

17. **Aids and adaptations:** - **A caution:** providing an aid is **not always best — it can foster dependence rather than independence**. Conversely, **those in real need often do not obtain even basic aids**. - **Match the adviser to the aid:** occupational therapists for general aids, physiotherapists for mobility aids, speech therapists for communication aids, audiologists for hearing aids, continence advisors for continence aids — and they must **follow up to ensure aids are used and maintained**. - **Prostheses** replace body parts; **orthoses** are applied externally to support, improve function, or restrict or promote movement. - **Home adaptation:** handrails, ramps, improved shower and toilet access. **Early occupational therapy input, often including a home visit**, ensures modifications are appropriate and timed to facilitate discharge.

18. **Education and psychological support:** - **Education is a vital component and doubles as secondary prevention** — patients must understand their disease, its implications, prospects of recovery, risk factors and lifestyle modification; **family should be included**. - Psychological support requires **good listening skills**; people fear the unknown, and explanation reduces anxiety. Patients may fear **future** events (another stroke) as much as the present one. - **Regular reassurance and positive feedback are simple and effective**; a **careless negative remark can profoundly demoralise** a patient. Feedback must never become dishonest or generate false expectations. - Support **spouses and relatives** too; hospital settings foster a **"therapeutic community"**, and **self-help groups** provide ongoing support after discharge.

19. **Discharge planning, evaluation and follow-up:** - **Discharge is a transition in rehabilitation, not its conclusion.** Many benefit from continuing outpatient therapy to gain further or prevent loss of gains. **Some follow-up is essential.** - Programmes are **resource-intensive and must demonstrate effectiveness** — at minimum compare patients on entry and at discharge, using increasingly standardised data.

20. **Settings and specific programmes:** - **Settings:** stand-alone rehabilitation hospitals · designated rehabilitation units · undifferentiated wards · nursing and residential homes · **day hospitals** · community day centres · outpatient centres · **the patient's own home**. Ideally a **range of options** should be available. - **Co-location by condition** (stroke units, ortho-geriatric units) fosters expertise, research and training. **Stroke units improve survival and functional outcomes; evidence for ortho-geriatric units is less convincing.** - **Intermediate care** is intensive, short-term, community- or home-based rehabilitation to prevent hospitalisation, facilitate early discharge and maximise independent living. **Community-based rehabilitation only suits the least disabled and well-supported.** - **Cardiac rehabilitation** — SIGN's **four phases**; exercise-based programmes reduce **all-cause mortality by 27%**. After uncomplicated infarct, **feed self from the outset, sit out of bed within 24 hours, walk to the toilet within 48 hours**. - **Pulmonary rehabilitation** reduces dyspnoea and fatigue, increases exercise capacity, improves quality of life and may prevent hospitalisation; benefits are seen in the **"old old"**, and **the greatest benefits are in the most**

impaired patients. Exercise: **at least 3 times a week, at least 20 minutes, heart rate at least two-thirds of maximum, for at least 6 weeks and preferably 3 months**. Gains are lost without a maintenance programme. - **Musculoskeletal disorders** — multidisciplinary rehabilitation is of **proven benefit only in chronic back pain, other chronic pain, and after hip fracture in frail elderly people**. - **The elderly amputee** — most lower-limb amputations follow **peripheral vascular disease**. **Perioperative mortality 10–30%, two-year survival 40–50%, five-year survival 30–40%** — unchanged over 50 years. **Preserving the knee is critical:** it takes **40% more energy to walk with an above-knee than a below-knee prosthesis**. **Prescription of a prosthesis is almost always indicated regardless of age**, yet older amputees are less likely to receive one even after adjusting for comorbidity and function. - **Emerging technologies** — remote sensors and wearables give **objective, quantitative** data (existing scales are subjective and prone to observer variability), **virtual reality and video-capture platforms**, video games for post-stroke upper limb (must give feedback, avoid a sense of failure, and match challenge to capability), and GPS, robotics and mobile systems enabling **early transfer from hospital to home-based rehabilitation**.

B. Latest Updates (2023–Present)

1. Rehabilitation is now a recognised global public health priority. A **World Health Assembly resolution endorsed in May 2023** marked the first time in 75 years that rehabilitation was recognised as a **core global public health priority**, aligned with the Rehabilitation 2030 action areas; WHO has supported approximately **78 countries** to strengthen rehabilitation services. At the **3rd Global Rehabilitation 2030 meeting (July 2023)** the **World Rehabilitation Alliance** was launched with 82 founding organisations, along with the **Package of Interventions for Rehabilitation (PIR)** — evidence-based interventions for **20 health conditions** produced with Cochrane Rehabilitation — plus the Rehabilitation Competency Framework and health-financing and workforce guidance.

2. EuGMS definition of geriatric rehabilitation. Geriatric rehabilitation is **"a multidimensional approach of diagnostic and therapeutic interventions, the purpose of which is to optimize functional capacity, promote activity and preserve functional reserve and social participation in older people with disabling impairments"** — a definition following the WHO ICF framework. Common admission diagnoses are **stroke, hip fracture, post-orthopaedic surgery, osteoarthritis and other musculoskeletal disease, movement disorders, oncological disease and cardiopulmonary conditions**.

3. Predictors of successful geriatric rehabilitation are now defined. Discharge back to the community is associated with **higher cognition, better mobility at admission, higher baseline functional independence, lower multimorbidity, fewer acute hospitalisation days and greater social support**. In those over 90, **higher functional independence at admission and fewer medications** predict community discharge, whereas **multiple comorbidities, hospital admission in the past year and lack of social work involvement** predict readmission.
