4. "No rehabilitation potential" is no longer acceptable. Rehabilitation for older people **reduces hospital admissions, length of stay and carer burden while improving functional outcomes**. The 2024 British Geriatrics Society report "*Reablement, Rehabilitation and Recovery: everyone's business*" argued that **rehabilitation should be a component of all services caring for older people**, and that rationing access on the dubious basis of "no rehabilitation potential" should be a thing of the past.

5. Meta-analytic evidence. A 2024 systematic review and meta-analysis in *BMC Medicine* of randomised trials in adults 65 and above undergoing inpatient or geriatric day-hospital rehabilitation versus usual care assessed **mortality, care-home admission and functional status** as primary outcomes.

6. Prehabilitation — a new stage before rehabilitation. Structured pre-operative exercise and education programmes are being trialled in older surgical patients; **cognitive prehabilitation** is being evaluated for its effect on **postoperative delirium and delayed neurocognitive recovery**. Evidence for physical prehabilitation before hip replacement remains **conflicting**.

7. Digital and mHealth rehabilitation. A systematic review of mHealth in geriatric rehabilitation found most outcomes improved in both arms with a **majority favouring the intervention**, but with **high risk of bias and minimal reporting of integration into daily practice**.

8. Assessment tools converging with CGA standards. The **German S3 guideline (2024)** sets six mandatory CGA dimensions — **self-help ability, mobility, cognition/delirium, affect, nutrition and social situation**. **WHO ICOPE** screens **mobility, cognition, nutrition, vision, hearing and psychological well-being**.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Status of rehabilitation	"Lack of investment is a false economy" — an advocacy point	**WHA resolution (May 2023)** — rehabilitation formally a **core global public health priority** and part of universal health coverage
Definition	UN definition (goal-orientated, time-limited)	**EuGMS definition** specific to geriatric rehabilitation — adds **preserving functional reserve** and **social participation**
Patient selection	"Assess to ensure problems are remediable"	**"No rehabilitation potential" rejected as a basis for rationing**; predictors of success now evidence-based
Assessment scales	Barthel, AMT, GDS, FIM	Supplemented by **standardised CGA minimum domain sets** and **objective digital and wearable measures**
Participation restriction	"Largely neglected in clinical and research settings"	Foregrounded by ICF-aligned WHO PIR and patient-reported outcome measures
Technology	Virtual reality, video capture and sensors "emerging"	**mHealth in routine geriatric rehabilitation** — positive but with high risk of bias; not yet standard
Timing	Early intervention after the disabling event	**Prehabilitation** — intervention *before* the planned insult, including **cognitive prehabilitation**
Ortho-geriatric units	"Evidence less convincing" than stroke units	Now embedded in **NELA and hip fracture best-practice tariffs** with mandated perioperative geriatric input

D. Exam One-Liners

- **ICF 2001:** disability equals impairment plus activity limitation plus participation restriction.
- **Doctors treat impairment; therapists treat activity restriction; social workers treat participation restriction.**
- **Eight steps:** Assessment, Goals, Therapy, Aids and adaptations, Education, Psychological support, Evaluation, Follow-up.
- **Two cardinal principles: early intervention and the team approach.**
- **Set ambitious but achievable goals** — disagreement about goals wrecks programmes.
- **Barthel Index** is observation of what the patient *does*; **ceiling effect** in ambulatory patients.
- **FIM has 18 functions** across self-care, sphincter control, mobility, locomotion, communication and social cognition.
- **Participation restriction is subjective, mood-dependent and therefore largely unmeasured.**
- **An aid can foster dependence** — but those in real need often go without.
- **Prosthesis replaces a body part; orthosis supports an existing one.**
- **Stroke units improve survival and function; ortho-geriatric unit evidence is weaker.**
- **Cardiac rehabilitation reduces all-cause mortality by 27%**; sit out of bed within 24 hours and walk to the toilet within 48 hours after uncomplicated myocardial infarction.
- **Pulmonary rehabilitation: at least 3 times a week, at least 20 minutes, at least two-thirds maximum heart rate, at least 6 weeks (preferably 3 months)** — greatest benefit in the most impaired.
- **An above-knee prosthesis costs 40% more energy than below-knee** — preserve the knee.
- **Discharge is a transition, not the end, of rehabilitation.**

11. Immobility in the Elderly — Causes, Complications and Management

A. 20 High-Yield Points

Definition and Significance

1. **Definition:** Immobility is the state in which an individual has a **limitation in independent, purposeful physical movement** of the body or of one or more lower extremities. A complementary definition is the **restriction of time spent out of bed or chair** by **medical orders, restrictive devices, chemical restraints (for example antipsychotics), lack of mobility aids, or lack of human assistance or encouragement**.
2. **Why it matters:** Immobility triggers a **cascade of further disease, pain, disability and impaired quality of life**. Small improvements in mobility reduce complications, improve wellbeing and **cut the cost and burden of caregiving**. Immobility and sedentary time are independently associated with **all-cause mortality**.
3. **Scale of the problem: One-third of older patients are restricted to bed or chair rest during hospitalisation. 15–76%** of hospitalised elders have diminished performance in at least one ADL at discharge; of these, **only half recover function at three months**, and for many the decline means **permanent loss of independent living**. **Functional decline is a profound marker of morbidity and mortality**, causing longer stays, higher costs and increased nursing-home placement.
4. **"Spiralling immobility" (Tinetti and Ginter)** — a **catch-22**: an older person perceived to be at risk of falling is restrained to prevent falls, and then **cannot ambulate again safely because of the immobilising consequences of the restraint itself**.

Causes

5. **Musculoskeletal: arthritides (degenerative joint disease is the commonest)**, osteoporosis, **fractures (especially hip and femur)**, podiatric problems, Paget's disease. Degenerative joint disease pain and joint changes cause contractures and progressive immobility if untreated.
6. **Neurological: stroke**, **Parkinson's disease**, neuropathies, **normal-pressure hydrocephalus**, dementias, cerebellar dysfunction.
7. **Cardiovascular: severe congestive heart failure**, coronary artery disease with frequent angina, **peripheral vascular disease with claudication** — all limit activity through **lack of cardiovascular endurance**. In older diabetics, peripheral vascular disease causes claudication, neuropathy and altered balance together.
8. **Pulmonary:** severe **chronic obstructive lung disease**.
9. **Sensory: impaired vision**, **decreased kinaesthetic sense**, **decreased peripheral sensation**.
10. **Environmental: forced immobility in hospitals and nursing homes**, **inadequate mobility aids**, cluttered environments, uneven surfaces, unsuitable chair or bed height, **stairs**, absent handrails and grab bars.
11. **Psychological: depression**, **fear of falling**, apathy, **lack of motivation**, and **health beliefs** — particularly the belief that **rest and immobility aid recovery**.
12. **Iatrogenic and caregiving: well-meaning caregivers who do things *for* the patient rather than optimise their function** — inappropriate wheelchair use, bathing and dressing people who could do it themselves — directly produce deconditioning.
13. **Drugs: sedatives and hypnotics** (drowsiness, dizziness, delirium, ataxia); **typical antipsychotics** (extrapyramidal rigidity); **antihypertensives** (orthostatic hypotension, bradycardia, dizziness).
14. **Other: deconditioning after prolonged bed rest**, malnutrition, **severe systemic illness such as widespread malignancy**, and acute and chronic pain.

Complications — System-Wise

15. **The complete complication table:**

System	Complications
Skin	**Pressure ulcers**
Musculoskeletal	Muscular **deconditioning and atrophy** · reduced fibre size, diameter and capillarity · **contractures** · **disuse osteoporosis** · degenerative joint disease · balance and coordination problems
Cardiovascular	**Deconditioning** · **orthostatic hypotension** · **deep vein thrombosis and pulmonary embolism**
Pulmonary	Decreased tidal volume and ventilation · **atelectasis** · **aspiration pneumonia** (supine position)
Gastrointestinal	Anorexia · **constipation** · **faecal impaction and incontinence**
Genitourinary	**Urinary infection** · **retention** (cannot void lying down; impaction obstructs flow) · **bladder calculi** · incontinence
Metabolic	**Negative nitrogen and calcium balance** · **decreased plasma volume** · **impaired glucose tolerance** · **altered drug pharmacokinetics** · hypercalcaemia
Psychological	**Sensory deprivation** · **delirium** · **depression** · anxiety

16. **Key mechanistic points:** - **Muscle atrophy severity is proportional to the duration and magnitude of activity limitation**; unchecked it causes **permanent muscle damage**. - Immobility causes a **rapid and sustained increase in bone resorption with decreased bone formation**; reduced bone mass then makes any fall more likely to fracture. - **Deconditioned cardiovascular reflexes plus reduced plasma volume produce postural hypotension**, which impairs rehabilitation and predisposes to **falls, stroke and myocardial infarction**. - **Contracture** is fixation of muscle *and* joint in flexion from structural shortening of muscles adjacent to a major joint, leading to **permanent loss of range of motion**; highly prevalent in nursing homes. - **"The bed is a very dangerous place for an older person."**

Assessment

17. **History:** nature and duration of the disability · contributing medical conditions · **pain** · **drugs affecting mobility** · **motivation and psychological factors** · **environment, physical and social, especially caregiving interactions** · the patient's and carer's **perceived** cause of immobility. **Nutrition:** check **protein status and 25-hydroxy vitamin D (ng/mL)**, both linked to muscle weakness, poor performance, balance problems and falls.
18. **Examination: skin** (bony prominences, areas pressed by bed, chair, splint, shoe or device) · **cardiopulmonary status including postural blood pressure and pulse** · **musculoskeletal** (muscle tone and strength, joint range of motion, foot deformities and lesions) · **neurological** (focal weakness, sensory and perceptual deficits, cognition). **Levels of mobility — assess and re-assess serially: bed mobility → transfers (bed to chair, toilet) → wheelchair mobility → standing balance → gait → stair climbing**, noting **pain with movement, fear, resistance and endurance**. Use **standardised repeated muscle-strength grading (MRC 0–5)** to gauge progress.

Management

19. **General principles:** - **Treat the underlying cause** and **relieve pain** — pain and fear of falling must be addressed *before* engaging the patient in exercise. - **Careful assessment of function and underlying capability**; **set realistic goals**. - **Prevent secondary disabilities and complications of immobility.** - **Evaluate the environment; adapt the environment to the patient and the patient to the environment.** - **Ongoing motivation of both the patient and the caregivers is critical.** - **Restorative philosophy of care** — maintain the highest level of function and increase time spent in physical activity; a **core element of geriatric practice**.
20. **Team-based management:**

Discipline	Role
Physiotherapy	**Objectives:** relieve pain · evaluate, maintain and improve **joint range of motion** · improve **strength, endurance, motor skills and coordination** · improve **gait and stability** · assess need for and teach use of **assistive devices**. **Modalities: active (isometric, isotonic) and passive exercise**, **sitting exercise programmes**, heat (hot packs, paraffin, diathermy, ultrasound), **hydrotherapy**, **TENS**
Occupational therapy	Focus on **functional abilities, especially ADLs and IADLs**; detailed mobility assessment; **aids, adaptations and home modification**
Physician	Treat underlying disease; **deprescribe sedatives, typical antipsychotics and offending antihypertensives**; correct anaemia, thyroid disease, B12 and vitamin D deficiency; **analgesia**
Nursing	Two-hourly turning · skin care · **early mobilisation, sitting out for meals, own clothes** · continence and bowel care · **avoid restraints and catheters**
Dietician	Protein and calorie adequacy; **vitamin D and calcium (mg/dL)**

System-specific prevention: - **Skin — prevention is the cornerstone.** Three contributory factors: **pressure, shearing forces and friction**. Shearing occurs when the **head of the bed is elevated and the torso slides down**, transmitting pressure to the sacrum. **More than 90% of pressure ulcers occur in the lower body** — sacral and coccygeal, ischial tuberosities and greater trochanter. Risk scored by **Braden or Norton scale**. **The area of damage below the ulcer is often much larger than the ulcer itself.** Management equals pressure relief (**alternating pressure mattresses and overlays are equally effective**), regular cleansing and drying, nutrition and hydration. **The most important factor is simply the attention the skin receives.** - **Chest:** upright positioning, breathing exercises, incentive spirometry, aspiration precautions. - **Venous thromboembolism:** early mobilisation, graduated compression stockings, thromboprophylaxis. - **Bowel and bladder:** timed toileting, avoid indwelling catheters, treat constipation and impaction. -

Metabolic and musculoskeletal: daily passive and active range-of-motion exercises to prevent contractures, weight-bearing where possible, adequate protein and vitamin D. - **Psychological:** treat depression, provide sensory stimulation and orientation, prevent delirium. - **Avoid restraints:** physical restraints and **full-enclosure siderails** are associated with numerous negative outcomes including **strangulation and asphyxiation**, and **research demonstrates they can be safely eliminated**. Success requires **long-term, organisation-level education plus clear policy backed by regulation** — short educational programmes alone do not work.

B. Latest Updates (2023–Present)

1. "Hospital-associated deconditioning (HAD)" is now a named, defined syndrome. A **2025 BMJ Open scoping review** set out to establish **agreed diagnostic criteria for hospital-acquired deconditioning** and to distinguish it from other immobility-linked syndromes — the central limitation of previous reviews being the absence of any consensus definition. Current working figures: **muscle deconditioning begins within two days**, with a **2–5% decline in muscle mass per day** of leg inactivity and **up to 20% loss of baseline strength in one week**.

2. "End PJ Paralysis" — the strongest recent implementation evidence. The Alberta multicomponent inpatient ambulation initiative, analysed across **32,884 discharge abstracts** using interrupted time series (2024), showed **length of stay reduced by 1.8 days**, **inpatient falls reduced by 2.2 events**, and an increasing percentage discharged home. The interventions **safely mitigated immobility-induced complications including deconditioning and hospital-acquired disability**.

3. BGS "Sit up, get dressed, keep moving!" remains the endorsed UK campaign, now paired with the **Royal College of Physicians' 2024 National Audit of Inpatient Falls report, "Don't stop moving: optimising safety while staying active in hospital"** — explicitly rejecting immobilisation as a falls-prevention strategy. **Fear of falls must not be a barrier to mobilisation**; patients must be supported to maintain independence **from the moment of arrival**.

4. Cochrane 2024 updated the evidence on **falls prevention interventions in older people**, relevant because immobilisation is still wrongly used as a falls-prevention measure.

5. International Pressure Injury Guideline — 4th edition (2025). NPIAP, EPUAP and PPPIA, with **more than 240 clinical experts and consumer representatives** and GRADE evidence-to-decision methodology. Released in **staged online chapters** — prevention from February 2025, treatment after September 2025 — with refreshed quick-reference guides, superseding the 2019 edition.

6. Pressure injury — points that have changed: - Terminology: **"pressure injury"** replaces "pressure ulcer or sore"; **reverse staging is not valid**. - **Adjunctive therapies (negative pressure wound therapy, hyperbaric oxygen, laser, electrotherapy, therapeutic ultrasound) have no good evidence of improving healing.** - **Diagnosing infection:** classic signs (purulent exudate, erythema, heat, oedema) and foul odour are **not helpful**; **increasing pain is the most useful sign (likelihood ratio 11–20)**. Confirm with a **quantitative swab using the Levine technique** — rotate the swab over 1 x 1 cm for 5 seconds with enough pressure to express fluid. - **"Skin failure"** is now recognised — in overall patient decline with irreversible conditions, wounds on bony prominences are **not preventable pressure injuries**, and care should prioritise **infection risk reduction and pain control**.

7. Age-Friendly Health Systems 4Ms. Mobility is one of the four Ms. In a 2024 eight-hospital evaluation, **Mobility generated the highest "act-on" rate of all four Ms (83%)**, and patients receiving all 4Ms had **fewer 30-day emergency visits (16% vs 22%)**.

C. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Concept	"Immobility" as a geriatric syndrome or presenting problem	Reframed as **hospital-associated deconditioning / hospital-acquired disability** — a *preventable adverse event*, with a 2025 push for formal diagnostic criteria
Speed of onset	"Deconditioning can occur rapidly"	**Quantified: begins within 2 days; 2–5% muscle mass loss per day; up to 20% strength loss in 1 week**
Falls versus mobility	Restraints and bed rest historically used for "safety"	**RCP 2024: "Don't stop moving"** — immobilisation is *not* falls prevention
Intervention model	Individual physiotherapy or occupational therapy referral	**Whole-system campaigns** — End PJ Paralysis, Sit Up Get Dressed Keep Moving, 4Ms Mobility, with measurable outcomes
Pressure ulcers	2019 international guideline; Braden and Norton; stages I–IV	**4th edition International Guideline (2025)**; "pressure injury"; adjunctive therapies unsupported; **increasing pain is the best sign of infection**; concept of **"skin failure"**
Restraints	Described as declining but persistent	Evidence confirms **safe elimination**; requires **long-term organisational education plus policy plus regulation**

D. Exam One-Liners

- **"The bed is a very dangerous place for an older person."**
- **One-third of hospitalised older patients are on bed or chair rest**; 15–76% lose an ADL by discharge and **only half**

recover by 3 months.

- **Deconditioning starts within 48 hours** — 2–5% muscle loss per day, about 20% strength loss per week.
- **Spiralling immobility** — restrained to prevent falls, then cannot walk, then more falls.
- **Commonest musculoskeletal cause is degenerative joint disease**; commonest neurological cause is stroke.
- **Three drug classes that immobilise:** sedative-hypnotics, typical antipsychotics, antihypertensives.
- **Complications by system:** skin (pressure injury) · musculoskeletal (atrophy, contractures, disuse osteoporosis) · cardiovascular (orthostasis, DVT and PE) · respiratory (atelectasis, aspiration pneumonia) · gastrointestinal (constipation, impaction) · genitourinary (UTI, retention, calculi) · metabolic (negative nitrogen and calcium balance, impaired glucose tolerance) · psychological (delirium, depression, sensory deprivation).
- **Contracture equals muscle plus joint fixation in flexion** and permanent loss of range of motion.
- **Pressure injury triad: pressure plus shear plus friction**; **more than 90% occur in the lower body**; risk scored by **Braden or Norton**.
- **Alternating pressure mattresses and overlays are equally effective** — what matters most is the attention the skin receives.
- **Increasing pain, not pus or erythema, is the best sign of chronic wound infection.**
- **Assess mobility in a ladder:** bed mobility, transfers, wheelchair, standing balance, gait, stairs.
- **Restraints can be safely eliminated** — but only with sustained organisational education and policy.

Part IV — Cognition, Mood and Decisional Capacity

12. Tests of Cognition and Rating Scales

A. 20 High-Yield Points

Principles

1. **Purpose of cognitive testing:** to establish **strengths and weaknesses of various functions relative to a standardised, norm-referenced scoring system**, so that the **nature and extent of cognitive deficits** can be determined, informing diagnosis and management and acting as a **comparator for past and future assessments**.
2. **A cognitive screen is not a diagnosis.** The MMSE and similar tools give an overall assessment of cognitive function, but **their use alone is not sufficient to establish a diagnosis of Alzheimer's disease or any dementia**.
3. **Cognitive screening is one of only two mandatory screens** (with depression) in any older person with functional disability.
4. **Key aspects of the mental status examination:** state of consciousness · general appearance and behaviour · orientation · **memory (short and long term)** · language · visuospatial function · **executive control functions** · other cognitive functions (calculations, proverb interpretation) · **insight and judgement** · thought content · mood and affect.
5. **Test all three components of memory: immediate recall** (repeating digits), **recent memory** (recalling three objects after a few minutes), and **remote memory** (details of early life).
6. **Executive function** involves the **planning, sequencing and execution of goal-directed activities**, and is **critical to the ability to perform IADLs**. Screen with the **clock-drawing test** (a component of the Mini-Cog) or **verbal fluency** (listing 12 animal names in one minute is normal).
7. **Interpretation depends on education and age.** The MMSE score is **dependent on sociocultural level and subject to a ceiling effect** — a crucial caveat in the Indian population, where illiteracy is common.
8. **Assess premorbid intellectual status** where possible (for example the National Adult Reading Test) to interpret other test scores correctly.
9. **Adapt tests to deficits.** In language impairment or dyspraxia, **recognition memory tests reduce the demand for expressive language** required by recall tests.
10. **Always include a standardised measure of mood** — depression is the commonest mimic of cognitive impairment.

Screening and Assessment Tools

11. **Recommended tools in primary care (Table 72.2):** - **Delirium: Confusion Assessment Method (CAM)** - **Dementia screening: AD8**, **Mini-Cog** - **Dementia assessment: SLUMS**, **MMSE**, **MoCA**
12. **Mini-Cog** screens **both memory (three-item recall) and executive function (clock drawing)** — quick, and relatively education-independent.
13. **MoCA and Addenbrooke's Cognitive Examination-Revised (ACE-R)** are described as **well-validated screening options**; ACE-R **incorporates the MMSE and clock-face drawing**.
14. **MMSE severity bands in Alzheimer's disease: mild 20–24, moderate 10–19, severe below 9.**
15. **Global staging scales combining cognition and ADLs: Global Deterioration Scale (GDS, Reisberg)** and the **Clinical Dementia Rating (CDR) scale**.
16. **Severe Impairment Battery (SIB)** was developed for subjects **too cognitively impaired for standard testing**.
17. **Memory-specific screens:** the **five-word test** and the **Memory Impairment Screen (MIS)** assess **anterograde verbal memory** at an initial consultation. For detailed evaluation, **free and cued recall** paradigms — the **Grober and Buschke test (Free and Cued Selective Reminding Test)** and the **California Verbal Learning Test** — distinguish mild Alzheimer's disease from healthy subjects with **more than 90% precision**, even when MMSE scores are similar.
18. **Domain-specific battery (Table 62.4 — Cardiff memory clinic):**

Domain	Tests
Premorbid ability	**National Adult Reading Test (NART)**
Cognitive screen / battery	**MMSE, MoCA, RBANS, Frontal Assessment Battery (FAB)**
Attention and concentration	Digits forward, digits backward, digit span
Language	**Boston Naming Test**, Irving Names Learning Test
Memory	Story recall (immediate and delayed), Kendrick tests, **California Verbal Learning Test**
Executive function	**Trail-Making Test A and B**, clock drawing
Visuospatial function	**Rey–Osterrieth Complex Figure**, clock drawing
Mood	**GDS-15**

Delirium Instruments

19. **Confusion Assessment Method (CAM)** — the standard; **sensitivity 94%, specificity 89%** with high inter-rater reliability. **Inattention** is tested at the bedside by **months of the year backwards, days of the week backwards, or**

digit span 3 or 4 backwards. - **3D-CAM:** a structured **three-minute** screen — **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% in those without**. - **Best single item: "months of the year backwards"** (sensitivity 83%, specificity 69%). Best two items: months backwards plus "what is the day of the week?" (sensitivity 93%, specificity 64%). - **CAM-ICU** for intubated patients — inattention tested by squeezing on the letter A in "SAVEAHAART"; level of consciousness by **RASS score other than 0**.

Practical Conduct of Testing

20. Tests must be **acceptable to the person and contain nothing belittling**. **Consent must be obtained**, the purpose explained, and **sensory and physical limitations accommodated** — adequate lighting, earphone amplifiers, suitable seating, minimal distractions. Provide **realistic reassurance with positively phrased feedback that highlights strengths as well as weaknesses**, and at the end **allow patients to comment on their own performance**. Ideally an experienced psychologist or neuropsychologist performs formal testing, though **much useful information can be obtained by any suitably trained professional**. Introduce questions **non-threateningly**, because many patients with early deficits respond defensively.

B. Comparison of the Main Cognitive Tools

Tool	Items / time	Domains	Main strength	Main limitation
AMT (Hodkinson)	10 questions, 2 min	Orientation, memory	Very quick; RCP/BGS endorsed	Crude; misses executive and visuospatial deficits
Mini-Cog	3 min	3-word recall + clock drawing	**Relatively education-independent**; screens executive function	Screen only
AD8	8 items, informant	Change over time	Informant-based, detects change	Needs a reliable informant
MMSE	30 points, 10 min	Orientation, registration, attention, recall, language, construction	Most widely known; severity bands defined	**Education- and culture-dependent; ceiling effect; poor for executive function**; copyrighted
MoCA	30 points, 10–15 min	Adds executive, abstraction, visuospatial, attention	**Superior for mild cognitive impairment and executive dysfunction**	Lower specificity; education adjustment (+1 if 12 years or less)
SLUMS	30 points, 10 min	Adds executive and clock tasks	Free to use; education-stratified cut-offs	Less international validation
ACE-R / ACE-III	100 points, 20 min	Five domains; incorporates MMSE	Differentiates **Alzheimer's from frontotemporal dementia**	Long
RBANS	30 min	Repeatable battery	Serial testing without practice effect	Requires training
Frontal Assessment Battery	6 items	Frontal/executive	Detects subcortical and frontal deficits	Narrow
CAM / 3D-CAM / CAM-ICU	3–5 min	Delirium	**Gold standard for delirium**	Needs training; misses hypoactive cases if hurried
GDS (Reisberg) / CDR	Interview	Global staging	Combines cognition and function	Time-consuming
SIB	40 min	Severe dementia	Usable when MMSE floor is reached	Specialist tool

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria — Alzheimer's disease is now defined biologically. Diagnosis rests on **Core 1 biomarkers** — a positive **plasma p-tau217**, a positive **amyloid PET**, or abnormal **CSF ratios (p-tau181/Aβ42, t-tau/Aβ42, Aβ42/40)**. Cognitive testing now defines the **clinical stage**, not the disease itself. This is the single biggest conceptual change in the field.

2. Blood-based biomarkers have entered clinical use. Diagnostic models combining **plasma p-tau217 with age and ApoE genotype** achieve **AUC around 0.94** for Alzheimer's disease. In very elderly nursing-home and hospital populations, **plasma p-tau181, p-tau217 and GFAP differ significantly between cognitively normal and probable Alzheimer's groups**, while **Aβ42, Aβ40 and the Aβ42/40 ratio do not** — an important practical point, since amyloid ratios perform poorly in the oldest old.

3. Cognitive screens are being repositioned as triage. Rather than diagnosing, MMSE and MoCA increasingly serve to **decide who proceeds to biomarker testing**. Clinical trials now use combinations such as **CDR global score 0.5–1.0 plus MMSE 21 or above plus a positive Core 1 biomarker** for entry.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — has emerged as an **early**

indicator of dementia risk that may precede measurable cognitive decline, and is being studied alongside plasma p-tau217.

5. Digital and mobile cognitive assessment. Mobile cognitive assessment systems have demonstrated **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening; future direction is **composite risk scores combining digital tests, wearables and plasma p-tau217**. Regulatory and ethical frameworks for data security, algorithmic transparency and equitable access are still being established.

6. Standardised inclusion in assessment frameworks. Cognition/delirium is one of the **six mandatory core dimensions** of the German S3 CGA guideline (2024); **cognition** is one of the **six WHO ICOPE domains**, with **Mini-Cog, MoCA, MMSE or GPCOG** named as step-2 assessment tools; **Mentation** is one of the **4Ms** of Age-Friendly Health Systems.

7. Indian context. In LASI wave-1, **impaired cognition was present in 9.3%** of adults aged 60 and above. Culture- and education-fair instruments are essential: **Hindi Mental State Examination (HMSE)**, **Vernacular MoCA versions**, **Rowland Universal Dementia Assessment Scale (RUDAS)**, **Indian Council of Medical Research Neuro-Cognitive Tool Box**, and **AIIMS Comprehensive Neuropsychological Battery in Hindi** are used in place of a directly translated MMSE, because **the standard MMSE penalises illiteracy heavily**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Basis of Alzheimer's diagnosis	Clinical, supported by cognitive tests and imaging	**Biological — 2024 NIA-AA criteria** based on Core 1 biomarkers
Role of MMSE/MoCA	Screening and severity grading	**Staging and triage** to biomarker testing; no longer diagnostic on their own
Biomarkers	CSF amyloid and tau "in some centres"	**Plasma p-tau217 in routine diagnostic pathways**; AUC around 0.94 with age and ApoE
Amyloid ratios	Presented as useful	**Aβ42/40 performs poorly in the oldest old**; p-tau217 and GFAP superior
Delivery	Face-to-face testing by trained staff	**Mobile and computerised assessment shown equivalent to MMSE/MoCA**
Preclinical detection	Subjective cognitive decline and MCI	Adds **mild behavioural impairment (MBI)** as an early neurobehavioural marker
Indian practice	MMSE with education caveat	**Education-fair tools mandatory** — HMSE, RUDAS, vernacular MoCA, ICMR NCTB

E. Exam One-Liners

- **A cognitive screen is not a diagnosis** — MMSE alone cannot diagnose Alzheimer's disease.
- **MMSE bands:** mild 20–24, moderate 10–19, severe below 9.
- **MMSE is education- and culture-dependent with a ceiling effect** — the key limitation in India.
- **MoCA beats MMSE for mild cognitive impairment and executive dysfunction.**
- **Mini-Cog = 3-word recall plus clock drawing** — screens memory and executive function in three minutes.
- **Clock drawing and verbal fluency screen executive function**, which drives **IADL** performance.
- **CAM sensitivity 94%, specificity 89%; 3D-CAM takes three minutes.**
- **Best single delirium item: months of the year backwards.**
- **ACE-R incorporates the MMSE and clock drawing** and helps separate Alzheimer's from frontotemporal dementia.
- **Free and cued recall (Grober–Buschke) separates mild Alzheimer's from normal with over 90% precision** even at similar MMSE scores.
- **Global staging: Reisberg GDS and CDR** combine cognition with function.
- **SIB is for patients too impaired for standard testing.**
- **2024 NIA-AA: Alzheimer's disease is now a biological diagnosis** — plasma **p-tau217**, amyloid PET, or CSF ratios.
- **Always pair cognitive testing with a mood scale**, and obtain consent and premorbid ability first.

13. Cognitive Assessment Tools

A. 20 High-Yield Points

Classification — the Framework to Open With

1. Cognitive assessment tools fall into **four functional groups**, and stating this classification first earns marks: - **Delirium instruments** — CAM, 3D-CAM, CAM-ICU, 4AT - **Brief screening tools** — Mini-Cog, AD8, AMT, GPCOG, MIS, six-item screener - **Cognitive screening batteries** — MMSE, MoCA, SLUMS, ACE-III, RUDAS - **Detailed neuropsychological batteries and staging scales** — RBANS, CVLT, Trail-Making, FAB, Boston Naming, Rey–Osterrieth; CDR and Reisberg GDS for staging
2. **A second axis is the informant dimension** — **performance-based** (patient does the task: MMSE, MoCA) versus **informant-based** (a relative reports change: **AD8, IQCODE**). Informant tools detect **change from a personal baseline** and are invaluable when education confounds performance tests.
3. **The tool must match the question:** *Is this delirium?* → CAM. *Is there any cognitive problem?* → Mini-Cog or AD8. *How severe and in which domain?* → MoCA, MMSE, SLUMS. *Which dementia is it?* → ACE-III with a full battery. *How advanced is it?* → CDR or Reisberg GDS.

Delirium Tools

4. **CAM** — sensitivity **94%**, specificity **89%**, high inter-rater reliability. Four features: **acute onset and fluctuating course, inattention, disorganised thinking, altered level of consciousness** (features 1 and 2 plus either 3 or 4).
5. **Inattention testing at the bedside: months of the year backwards, days of the week backwards, digit span 3 or 4 backwards**; or the examiner may simply observe **inappropriate distraction or loss of the thread of conversation**.
6. **3D-CAM** — three-minute structured version: **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% without dementia**. **CAM-ICU** for intubated patients uses the "SAVEAHAART" letter-A task and the **RASS**.

Brief Screens

7. **Mini-Cog — three-item recall plus clock drawing**; screens **memory and executive function** in about three minutes and is **relatively education-independent**, making it the most practical screen in Indian outpatient settings.
8. **AD8** — an **eight-item informant questionnaire** detecting change over time; useful when the patient's education level makes performance testing unreliable.
9. **Abbreviated Mental Test (Hodkinson, 10 items)** — the **RCP/BGS-endorsed** memory and cognition screen; extremely fast but crude.
10. **Memory Impairment Screen and the five-word test** assess **anterograde verbal memory** specifically at a first consultation.

Screening Batteries

11. **MMSE (Folstein, 1975)** — 30 points across orientation, registration, attention/calculation, recall, language and construction. **Interpretation is complex because thresholds depend on education and age**; it has a **ceiling effect** and **tests executive function poorly**. Severity bands: **mild 20–24, moderate 10–19, severe below 9**.
12. **MoCA (Nasreddine, 2005)** — 30 points; adds **trail-making, cube copy, clock drawing, verbal fluency, abstraction and delayed recall**, so it detects **mild cognitive impairment and executive/subcortical dysfunction far better than the MMSE**. **Add 1 point if formal education is 12 years or less.**
13. **SLUMS (Saint Louis University Mental Status)** — 30 points; free of charge, with **separate cut-offs for those with and without a high-school education**.
14. **ACE-R / ACE-III** — 100 points across **attention/orientation, memory, verbal fluency, language and visuospatial function**; ACE-R **incorporates the MMSE and clock-face drawing**, and the **VLOM ratio helps separate Alzheimer's disease from frontotemporal dementia**.
15. **RUDAS (Rowland Universal Dementia Assessment Scale)** — designed to be **culturally and linguistically fair**, needing no literacy; highly relevant to multilingual, variably literate Indian populations.

Detailed and Domain-Specific Tools

16. **Domain mapping (Table 62.4):** premorbid ability — **NART**; screening battery — **MMSE, MoCA, RBANS, FAB**; attention — **digit span forward and backward**; language — **Boston Naming Test**; memory — **story recall, California Verbal Learning Test**; executive — **Trail-Making A and B, clock drawing**; visuospatial — **Rey–Osterrieth Complex Figure**; mood — **GDS-15**.
17. **Free and cued recall tests** — the **Grober and Buschke test** and the **CVLT** — separate mild Alzheimer's disease from normal ageing with **more than 90% precision**, even when MMSE scores are identical, because they demonstrate a **hippocampal amnestic pattern (cueing does not improve recall)**.
18. **Staging scales: Clinical Dementia Rating (CDR)** and the **Reisberg Global Deterioration Scale** combine cognition with ADL impact. The **Severe Impairment Battery** is used when impairment is too severe for standard testing.

Rules of Use

19. **Practical conduct:** obtain **consent**, explain the purpose, ensure **adequate lighting, hearing amplification, suitable seating and no distractions**, introduce questions **non-threateningly**, phrase feedback **positively**, and give the patient a chance to comment on their own performance at the end. Assess **premorbid intellectual status** first, and **always add a mood scale**.
20. **Two cardinal caveats:** - **Depression and delirium must be excluded before any score is attributed to dementia** — screening tools become unreliable in delirium, and depression is the commonest reversible mimic. - **No cognitive screening test is appropriate for determining decision-making capacity.** Screens of **executive function** such as the **clock-drawing test** or the **Executive Interview** correlate better with decisional capacity than the MMSE, but capacity requires its own task-specific assessment.

B. Comparison Table — Choosing the Right Tool

Clinical question	Tool of choice	Time	Notes
Is this delirium?	**CAM / 3D-CAM / CAM-ICU**	3–5 min	Sensitivity 94%, specificity 89%
Rapid screen in a busy clinic	**Mini-Cog**	3 min	Education-independent; memory + executive
Screen when the patient cannot be tested	**AD8 or IQCODE** (informant)	3 min	Detects change from baseline
General cognitive assessment	**MoCA**	10–15 min	Best for MCI; add 1 point if education 12 years or less
Severity grading in known dementia	**MMSE**	10 min	Mild 20–24, moderate 10–19, severe below 9
Free alternative with education cut-offs	**SLUMS**	10 min	Education-stratified
Differentiating dementia subtypes	**ACE-III**	20 min	VLOM ratio; Alzheimer's vs frontotemporal
Illiterate or multilingual patient	**RUDAS, HMSE, vernacular MoCA**	10 min	Culture- and literacy-fair
Detecting early Alzheimer's memory pattern	**Grober–Buschke, CVLT**	20–30 min	Cueing fails to improve recall
Frontal or subcortical deficit	**FAB, Trail-Making B, verbal fluency**	5–10 min	Subcortical screen
Global staging	**CDR, Reisberg GDS**	Interview	Combine cognition and function
Severe dementia	**SIB**	40 min	Below the MMSE floor

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria define Alzheimer's disease **biologically** through **Core 1 biomarkers — plasma p-tau217, amyloid PET, or CSF p-tau181/Aβ42, t-tau/Aβ42 or Aβ42/40**. Cognitive tools now **stage the disease rather than diagnose it**.

2. Plasma p-tau217 is the practice-changing test. Models combining **plasma p-tau217, age and ApoE genotype** achieve **AUC about 0.94**. In the very elderly, **p-tau181, p-tau217 and GFAP discriminate probable Alzheimer's from normal cognition, while Aβ42, Aβ40 and the Aβ42/40 ratio do not** — so amyloid ratios should not be relied on in the oldest old.

3. Digital cognitive assessment. Mobile cognitive assessment systems show **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening. Future work is on **composite scores integrating digital tests, wearables (for example sleep fragmentation) and plasma p-tau217**, with cross-ethnic validation and regulatory frameworks still pending.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — is now recognised as an early dementia-risk indicator that may **precede measurable cognitive decline**, and is being validated against plasma p-tau217.

5. Mandated inclusion in assessment frameworks. German S3 CGA guideline (2024): cognition and delirium is one of six core dimensions. **WHO ICOPE:** cognition is one of six intrinsic-capacity domains, with **Mini-Cog, MoCA, MMSE and GPCOG** as named step-2 tools. **Age-Friendly 4Ms:** cognition sits under **Mentation**. **ASCO 2023 Practical Geriatric Assessment** includes a cognitive domain for every cancer patient aged 65 and above.

6. Indian tools and data. LASI wave-1 found **impaired cognition in 9.3%** of those aged 60 and above. Because the MMSE penalises illiteracy heavily, Indian practice uses the **Hindi Mental State Examination (HMSE)**, **RUDAS**, **vernacular MoCA versions**, the **ICMR Neuro-Cognitive Tool Box**, and the **AIIMS Comprehensive Neuropsychological Battery in Hindi**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
What the tools do	Screen for and grade cognitive impairment	**Stage the disease** and **triage to biomarker testing**
Diagnosis of Alzheimer's	Clinical, supported by imaging and sometimes CSF	**Biological (2024 NIA-AA)** — Core 1 biomarkers
Blood tests	Not diagnostically useful	**Plasma p-tau217 in routine pathways**; GFAP adds value
Amyloid measures	CSF amyloid used in some centres	**Aβ42/40 unreliable in the oldest old**
Mode of testing	Paper-and-pencil, face to face	**Mobile and computerised testing equivalent to MMSE/MoCA**
Preclinical markers	Subjective cognitive decline, MCI	Adds **mild behavioural impairment**
Cross-cultural use	MMSE with an education caveat	**Literacy-fair instruments mandatory** in India — RUDAS, HMSE, vernacular MoCA

E. Exam One-Liners

- **Four groups of tools:** delirium instruments, brief screens, screening batteries, detailed batteries and staging scales.
- **CAM for delirium; Mini-Cog or AD8 to screen; MoCA or MMSE to assess; ACE-III to subtype; CDR or Reisberg GDS to stage.**
- **Mini-Cog = 3-word recall plus clock drawing**, and is relatively education-independent.
- **AD8 and IQCODE are informant-based** — they measure change from the person's own baseline.
- **MoCA detects MCI and executive dysfunction better than MMSE; add 1 point if education is 12 years or less.**
- **MMSE has a ceiling effect, is education-dependent, and tests executive function poorly.**
- **RUDAS, HMSE and vernacular MoCA are the literacy-fair choices for Indian patients.**
- **Grober–Buschke free and cued recall demonstrates the hippocampal amnestic pattern of Alzheimer's disease.**
- **ACE-R incorporates the MMSE and clock drawing.**
- **Exclude delirium and depression before interpreting any cognitive score.**
- **No cognitive screening test determines decision-making capacity** — executive tests correlate better than the MMSE, but capacity needs its own assessment.
- **2024 NIA-AA: plasma p-tau217, amyloid PET or CSF ratios define the disease; cognition defines the stage.**

14. Depression Rating Scales in the Elderly

A. 20 High-Yield Points

Which Scale, and When

1. **A fundamental distinction must open the answer:** - **Screening scales** (detect possible cases) — **GDS, CES-D, PHQ-2 and PHQ-9** - **Severity and monitoring scales** (measure change once diagnosed) — **MADRS (preferred), HDRS** - **Special-population scale** (severe cognitive impairment) — **Cornell Scale for Depression in Dementia (CSDD)**
2. **Diagnosis is clinical.** Formal diagnostic interviews such as the **Composite International Diagnostic Interview (CIDI)**, aimed at establishing a DSM diagnosis, are **very time-consuming and require extensive training** — so the diagnosis is usually made clinically, with or without a screening instrument.
3. **Screening in primary care is critical** — not only because depression is frequent, but because **suicidal ideation can be detected by screening**.
4. **The key cognitive threshold:** in **severe cognitive impairment (MMSE below 18)**, the GDS and CES-D become **less reliable**, and the **Cornell Scale for Depression in Dementia is advised** instead.
5. **Monitoring rule:** once depression is diagnosed, severity **must be evaluated with a depression scale before starting treatment and at least every three months during treatment**, and **at least every three months for every older person started on any antidepressant treatment — drug or non-drug**.
6. **MADRS is the preferred severity scale** (Montgomery and Asberg, 1979) because it was **designed to be sensitive to change**.
7. **The Hamilton Depression Rating Scale (HDRS, 1960) is widely used but has a specific geriatric flaw:** it contains **relatively many somatic items**, so **somatic comorbidity can cause over-reporting** of depression severity.
8. **This flaw has distorted the literature.** The frequently repeated claim that late-life depression presents more somatically rests on a **meta-analysis based on studies using the HDRS** — so it is unclear how much of the "somatic presentation" is really an artefact of comorbid physical disease inflating somatic items. **This is a first-class critical-appraisal point.**
9. **Always accompany a depression scale with a cognitive scale** — objectify cognition with the **MMSE (Folstein) or MoCA (Nasreddine)** whenever depression is assessed in an older person.

Standardised Scales Recommended in Primary Care

10. **Depression:** - **Screening tool: PHQ-2** - **Assessment tools: PHQ-9**, **GDS-15 and GDS-30**, **SLU AMSAD** (Saint Louis University AM SAD), **CSDD**
11. **The rest of the recommended primary-care set, often asked as a whole:** - **Delirium:** Confusion Assessment Method (**CAM**) - **Dementia screening: AD8**, **Mini-Cog** · **Dementia assessment: SLUMS**, MMSE, MoCA - **Alcohol: CAGE** (screen), then **SMAST-G** (Short Michigan Alcohol Screening Test – Geriatric version) - **Agitation in dementia: Cohen-Mansfield Agitation Inventory – short form**

Where the Scales Sit in Geriatric Assessment

12. In the CGA framework, the **mental health and affective dimension** is measured by the **Geriatric Depression Scale (Yesavage)** and the **Zung Self-Rating Depression Scale**. Both are **in wide use**, and **shorter screening versions are available without significant loss of accuracy**.
13. **A depression screen is one of only two mandatory screens** in any older person with functional disability — the other being **cognitive screening**.
14. **RCP/BGS endorsed scales for rehabilitation:** depression is measured by the **Geriatric Depression Scale — 30 items, with a 15-item short form**. The **Philadelphia Geriatric Center Morale Scale** measures *subjective morale*, which is **distinct from depression though with some overlap**.
15. **Disease-specific scales:** - **Dementia → Cornell Scale for Depression in Dementia** (Alexopoulos, 1988) - **Stroke → Stroke Aphasic Depression Questionnaire, Signs of Depression Scale, Visual Analogue Mood Scale** - **Primary care → PRIME-MD** (5 questions mapping to DSM categories)
16. **The GDS family** is available as **30-item, 15-item, 5-item and 2-item** versions. **The 2-item version is used for preliminary screening, followed by a longer version if positive.**
17. **PHQ-2 detail:** asks how often over the **last 2 weeks** the person has had **(1) little interest or pleasure in doing things** and **(2) feeling down, depressed or hopeless**. Responses: not at all / several days / more than half the days / nearly every day. **Score 0–6; 3 or more indicates depression.**
18. **Before attributing symptoms to depression, exclude physical illness.** Because of symptom overlap and the close association of depression with medical conditions, older patients presenting with apparent depression need careful physical evaluation — this also **builds trust with the patient and family**.
19. **Baseline investigations in a depressed older patient: complete blood count, ESR, serum electrolytes (sodium**

mEq/L), glucose and calcium (mg/dL), renal and liver function, thyroid function, vitamin D, vitamin B12 or methylmalonic acid, folate, syphilis serology, urinalysis.

20. **Risk factors to elicit alongside the score:** female sex, previous depression, chronic physical illness and **ADL limitations**, cognitive disorders, personality problems, **loss of partner**, lack or loss of social contacts, **subjective loneliness**, recent life events, genetic factors, and **drugs commonly used by older people** that can cause mood disorder.

B. The Scales in Detail

Geriatric Depression Scale (GDS) — Yesavage, Brink et al., 1983

Feature	Detail
Design	Purpose-built for older adults
Format	Simple **yes/no** answers — deliberately chosen for ease of use, including in mild cognitive impairment
Key innovation	**Somatic items were deliberately excluded**, avoiding the false positives that physical illness produces on general scales
Versions	GDS-30 (original) · **GDS-15 (1986, the workhorse)** · GDS-10 · GDS-5 · GDS-4 · GDS-2
Scoring GDS-15	1 point per depressive answer; **0–4 normal, 5–9 mild, 10 or more moderate to severe**
Scoring GDS-30	**0–9 normal, 10–19 mild, 20–30 severe**
Translations	Over **30 languages**; validated Hindi, Tamil, Bengali, Malayalam and Kannada versions exist

Diagnostic accuracy (meta-analysis, 53 studies, 17,018 participants): - **GDS-30:** sensitivity **82%**, specificity **76%**, AUC **0.85** - **GDS-15:** sensitivity **86%**, specificity **79%**, **AUC 0.90 — the best of the family** - **GDS-10:** sensitivity 87%, specificity 75%, AUC 0.83 - **GDS-4:** sensitivity 74%, specificity 71%

The shorter GDS-15 and GDS-10 outperform the original GDS-30. An earlier primary-care meta-analysis confirmed the **GDS-15 correctly identifies more patients than the GDS-30 (77.6% versus 71.2%)** and rated the GDS-15 as **"good" for screening** but **"poor" for case-finding** — it rules out, it does not rule in.

Limitation: accuracy **falls in cognitive impairment** — specificity decreases below MMSE 28, and below MMSE 18 the scale should be abandoned for the CSDD.

Comparison of All the Major Scales

Scale	Items	Type	Best use in geriatrics	Key limitation
GDS-30 / GDS-15	30 / 15	Self-report, **yes/no**	**First-line screening** in any older person	Unreliable if **MMSE below 18**
GDS-5 / GDS-4 / GDS-2	5 / 4 / 2	Self-report	Ultra-rapid screening in busy or low-resource settings	Lower specificity
PHQ-2 then PHQ-9	2 then 9	Self-report	**Two-step primary-care pathway**; PHQ-9 also grades severity and asks about suicide	Contains **somatic items**
CES-D	20	Self-report	Epidemiological and population studies	Not geriatric-specific
Zung SDS	20	Self-report	Listed in the CGA dimension table	Dated; somatic items
CSDD	19	**Two-part interview — informant plus patient**, observation-based	**Depression in dementia** — the *only* scale validated when MMSE is below 18	Needs an informant; takes about 30 minutes
MADRS	10	Clinician-rated	**Severity monitoring — the preferred scale**; sensitive to change	Requires a trained rater
HDRS / HAM-D	17 / 21	Clinician-rated	Historic trial standard	**Too many somatic items — over-scores physically ill elders**
BASDEC	19 cards	Deck of cards	**Deaf or hard-of-hearing** inpatients	Not widely available
PGC Morale Scale	17	Self-report	**Morale, not depression** (RCP/BGS endorsed)	Different construct

MADRS 10 items: apparent sadness, reported sadness, inner tension, reduced sleep, reduced appetite, concentration difficulties, lassitude, inability to feel, pessimistic thoughts, suicidal thoughts. Each 0–6; **total 0–60**. Cut-offs: **0–6 normal, 7–19 mild, 20–34 moderate, 35 or more severe.** Its geriatric advantage is that **only 2 of 10 items are somatic** (sleep, appetite) — far fewer than the HDRS.

C. Latest Updates (2023–Present)

1. USPSTF 2023 — the headline guideline change. Clinicians should **screen all adults, including those 65 and older, for major depressive disorder (Grade B)**, and screen adults aged 19–64 for anxiety disorders. Critically, the USPSTF **concluded there was insufficient evidence to recommend for or against screening for anxiety disorders**

in adults 65 years or older, or for **suicide risk in any adult**. The tools specifically examined were the **PHQ (any version), CES-D, EPDS for perinatal persons, and the GDS for older adults**. This replaces the 2016 depression and 2014 suicide-risk statements.

2. The paradox to quote: depression screening in the elderly is now a **Grade B recommendation**, but **suicide-risk screening remains Grade I (insufficient evidence)** — despite older men having the highest suicide rates of any group. The PHQ-9 includes a question assessing suicidal thoughts, so many patients still receive de facto suicide-risk screening.

3. GDS-15 remains the geriatric standard, with an updated cut-off debate. At the recommended **cut-off of 5 or more**, pooled **sensitivity 0.89 and specificity 0.77**. An updated 2000–2019 review found pooled sensitivity **0.80**, specificity **0.79**, **AUC 0.89** — and flagged that **diagnostic accuracy is lower in older adults with cognitive impairment**. A head-to-head study against structured clinical interview found **AUC 0.97 for GDS-15 versus 0.95 for PHQ-9**, with **GDS-15 of 6 or more giving sensitivity 94% and specificity 88%**, while the standard **PHQ-9 cut-off of 10 or more was too high for older people** (specificity 95% but sensitivity only 71%).

4. Practical implication: the conventional **GDS-15 cut-off of 5 or more misses very few cases of major depression but performs less well for minor depression**; some validation work in the very old supports **6 or more**. For the **PHQ-9, the standard adult cut-off of 10 may be too high in older adults** — consider a lower threshold.

5. Ultra-short versions are now meta-analytically validated. GDS-4 and GDS-5 were assessed across 23 studies (5,048 participants): at **cut-off 2**, **GDS-5 sensitivity 0.85, specificity 0.75**; **GDS-4 sensitivity 0.77, specificity 0.75**. These are the appropriate choices for **resource-limited and high-volume Indian settings**.

6. Screening is now embedded in structural frameworks: - **German S3 CGA guideline (2024): "affect" is one of the six mandatory CGA core dimensions**. - **WHO ICOPE: psychological well-being** is one of the six intrinsic-capacity domains screened, with **PHQ-9** as the step-2 tool. - **ASCO 2023 Practical Geriatric Assessment:** includes a **psychological and depression domain** for every cancer patient aged 65 and above. - **Age-Friendly 4Ms:** depression falls under **Mentation**, alongside dementia and delirium.

7. Indian context. LASI wave-1 found **major depressive disorder in 8.2%** of adults aged 60 and above. Depression is also the **critical multiplier of disability**: the combination of **hypertension plus arthritis plus high depressive symptoms** was associated with **greater ADL–IADL disability than any other multimorbidity combination**, with population attributable fractions of about **22–24%**. In practice, **screening for depression is itself a disability-prevention intervention**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Who to screen	"Screening in primary care is critical"	**USPSTF 2023: universal depression screening, all adults including 65 and above, Grade B**
Suicide screening	"Suicidal ideation can be detected by screening"	**USPSTF 2023: Grade I — insufficient evidence** for standalone suicide-risk screening
Anxiety in the elderly	Covered as a clinical entity	**Insufficient evidence to screen for anxiety in those 65 and above**, unlike younger adults
Best GDS version	GDS-30 with a 15-item short form	**GDS-15 outperforms GDS-30** (AUC 0.90 versus 0.85); GDS-5 validated for rapid use
GDS cut-off	Not stated	**5 or more** conventional; **6 or more** may be better in the very old; a "good screening, poor case-finding" tool
PHQ-9 in the elderly	Listed as an assessment tool	**Standard cut-off of 10 or more may be too high in older adults** — sensitivity falls to about 71%
Cognitive threshold	**MMSE below 18 means use CSDD**	Unchanged and reaffirmed; GDS accuracy declines even below MMSE 28
Severity monitoring	**MADRS preferred; reassess at least 3-monthly**	Unchanged — remains best practice

E. Exam One-Liners

- **Screening is not severity.** GDS, PHQ and CES-D screen; **MADRS and HDRS measure severity and change**; **CSDD** is for dementia.
- **GDS equals Yesavage and Brink, 1983**; yes/no format; **somatic items deliberately omitted**.
- **GDS-15: 0–4 normal, 5–9 mild, 10 or more moderate to severe. GDS-30: 0–9 normal, 10–19 mild, 20–30 severe.**
- **GDS-15 beats GDS-30** — sensitivity 86%, specificity 79%, **AUC 0.90**.
- **GDS-15 is "good for screening, poor for case-finding"** — it rules out, it does not rule in.
- **MMSE below 18 means abandon the GDS and use the Cornell Scale for Depression in Dementia.**
- **CSDD is the only depression scale validated in dementia** and uses **both informant and patient interview**.
- **HDRS over-scores physically ill older people** because of its many somatic items — and this artefact may explain the "somatic presentation of late-life depression."

- **MADRS is preferred for monitoring** — 10 items, 0–60, sensitive to change, only 2 somatic items.
- **Reassess severity before treatment and at least every 3 months** on any antidepressant, drug or non-drug.
- **PHQ-2 of 3 or more out of 6 is positive**, then proceed to PHQ-9.
- **USPSTF 2023: screen everyone 65 and above for depression (Grade B); suicide-risk screening Grade I.**
- **PGC Morale Scale measures morale, not depression** — overlapping but distinct constructs.
- **Always pair a depression scale with MMSE or MoCA**, and exclude thyroid disease, B12 deficiency, anaemia and hypercalcaemia first.

15. Assessment of Decisional Capacity in an Older Person

A. 20 High-Yield Points

Concepts and Definitions

1. **Capacity and competence are not the same.** A **clinician evaluates a patient's capacity to make a decision**; **competence is a legal term** implying that a person **has been deemed competent or incompetent by a court of law**. Someone not competent to act on their own behalf **requires an agent to act for them**.
2. **Competence** refers to a person's ability to **act reasonably after understanding the nature of the situation being faced**.
3. **Capacity is decision-specific and time-specific.** A patient may have capacity for one decision and not another, and may regain capacity later.
4. **Capacity is presumed until proved otherwise.** A **diagnosis of dementia — even by type — is not a sufficient indicator of a person's ability to comprehend and express a meaningful preference**. Intellectual deficits are **spotty**: a person may get lost or forget things yet still make decisions **with appropriate prompting**.
5. **The ethical foundation is autonomy** — the capacity of each adult and cognitively competent individual to **process information and freely decide on a course of action that best suits their own values, preferences, goals and desires**. Respect for autonomy underpins **informed consent**.
6. **Preconditions of valid informed consent: competence to understand and decide**, and **voluntariness in deciding**. The **information element** is **disclosure of relevant information** about the condition and the proposed course of action.
7. **An unwise decision is not incapacity.** In a patient with capacity, autonomy means "*you may not do things to me without my permission*" — **even if a patient's decision to refuse treatment seems unwise, if they have capacity their refusal stands**, and the clinician's **duty of care does not diminish**; all other care continues without prejudice.
8. **Just as it is wrong to infantilise patients** by directing questions to others who answer faster, **it is equally wrong to prejudge their ability to participate in decisions about their own care**.

The Four Elements of Decisional Capacity

9. **Decisional capacity is predicated on four elements** — the single most examinable list: - **Understanding** — the ability to comprehend the disclosed information about the nature of the situation or medical problem, the procedures involved, and the risks and benefits of undergoing or not undergoing testing or treatment. - **Appreciation** — of the significance of the disclosed information and the potential risks and benefits **for one's own situation and condition**. - **Reasoning** — the ability to engage in a reasoning process about the risks and benefits. - **Choice** — being able to **express a choice** whether or not to undergo further testing or treatment.
10. **The four US legal standards for determining decisional capacity** (a parallel, equally examinable list): - The patient is **aware of the treatment options and expresses a treatment preference clearly and consistently**. - The patient can give a **conventionally understandable reason** for the decision that is **consistent with their past behaviour**. - The patient **remembers and can tell back the information** about diagnosis, prognosis and treatment options given by the practitioner. - The patient can **state what their decision means for their own state of health**.
11. **The sliding-scale principle (Figure 95.1):** the **standard of decisional capacity required rises with the risk of the intervention**. A **fully cognisant patient with good health literacy** can consent to high-risk options such as a **phase 1 clinical trial**; a **cognitively impaired patient lacking decisional capacity could not consent to experimental treatment** and, given reduced life expectancy in advanced dementia, would be unlikely to benefit from highly toxic therapy even if it is standard of care. **The area between is the domain of best clinical judgement.** Hence **"staging the ageing is as important as staging the cancer."**

Assessment in Practice

12. **Distinguish memory from understanding** — a person may fail a memory test yet understand the decision at hand.
13. **No cognitive screening test is appropriate to determine decision-making capacity.** Screening tools that focus on **executive function** — the **Clock Drawing Test** or the **Executive Interview** — are **more likely to be associated with decisional capacity** than the MMSE.
14. **Formal capacity instruments exist but are difficult for older adults**, because they require consideration of **hypothetical situations and complex abstract thinking**. Examples: **MacCAT-T (MacArthur Competence Assessment Tool for Treatment — the reference standard)**, **Aid to Capacity Evaluation (ACE)**, **Capacity to Consent to Treatment Instrument (CCTI)**, **Hopemont Capacity Assessment Interview**, **Understanding Treatment Disclosures**.
15. **A useful practical criterion** in routine informed consent is to **recheck with the patient after an interval** to be certain that they **understand the situation and consistently state the same preference**.
16. **Maximise capacity before declaring its absence.** Before deciding a person cannot decide: correct **sensory deficits**

(a deaf patient may need a hearing aid, many older people need glasses), **treat delirium, depression, pain and infection**, review sedating drugs, use **simple language, repetition and rephrasing**, choose a **quiet, distraction-free environment**, and involve a familiar person. Written material must be legible — a leaflet is useless if **the typeface is too small, the colour contrast is poor, or there is no white space**.

17. **Formal assessment of mental state may be necessary**, but **no specific score is associated with an inability to make decisions about one's personal healthcare** — this is an important negative statement to write in an examination.
18. **Where capacity is absent:** consult any **advance care directive** and the **surrogate or proxy decision-maker**. A proxy may be formally appointed through an **enduring power of attorney**, or the patient's wishes may be recorded in an **advance directive**; if none exists, the lead clinician must decide in the patient's **best interests**, or apply for **guardianship**.
19. **Hierarchy of treatment decision-makers** (Australian model, quoted in the textbook): **enduring guardian with authority → guardian with authority → adult son or daughter → parent → sibling → primary unpaid carer → other person with a close personal relationship and frequent contact**. The clinician goes to the first person who is **18 or older, has full legal capacity, and is reasonably available and willing**.
20. **Communication and documentation:** - **Relatives must not be given the impression that the decision is theirs to make** — they may suffer significant distress from the emotional burden. Their role is to provide **valuable information about what would be in the patient's best interests**. - Where families cannot bear to decide, the humane option is **"informed assent"** — explicitly offering them the choice to **defer to the provider's judgement**, documented clearly in the record. - **Anticipate decisions early in admission** so the patient can be involved as much as possible and **proxy decision-making is avoided**. - Clinicians must disclose: **the condition being treated; the nature of the proposed treatment or procedure; anticipated results; recognised alternatives; and recognised serious risks, complications and benefits, including of non-treatment.** - **Document the assessment, the reasoning and the outcome.**

B. Structured Approach to a Capacity Assessment

Step	Action
1. Define the decision	Capacity is **decision-specific** — state exactly which decision is in question
2. Presume capacity	Start from presumption; a diagnosis alone never establishes incapacity
3. Optimise the person	Treat delirium, pain, depression, infection; correct vision and hearing; review sedatives; choose the best time of day and a quiet setting
4. Disclose	Condition, proposed treatment, expected outcome, alternatives, serious risks, and the consequences of non-treatment — in **plain language**
5. Test the four elements	**Understanding** ("tell me in your own words") · **Appreciation** ("what does this mean for you?") · **Reasoning** ("how did you weigh those up?") · **Choice** ("so what would you like to do?")
6. Apply the sliding scale	Higher risk demands a higher standard of capacity
7. Recheck	Re-ask after an interval to confirm **consistency** of preference
8. Conclude and act	If capacity present, the decision stands even if unwise. If absent, consult advance directive, then surrogate, then best interests or guardianship
9. Document	Record the specific decision, the disclosure made, the four elements, the conclusion and the reasoning

C. The Indian Legal Framework

1. **Mental Healthcare Act (MHCA), 2017** is the governing statute across India and was rewritten after India ratified the **UNCRPD in 2007**. Capacity has a **pivotal role**.
2. **Section 4, MHCA 2017:** every person is **presumed to have the capacity to make mental healthcare and treatment decisions** if they can **understand the information, appreciate the foreseeable consequences of the decision, or communicate the decision by speech, gesture or any other means**.
3. **Memory loss, cognitive deficits, or even a formal diagnosis of dementia do not imply incapacity automatically** — the Act emphasises **establishing capacity**, and gives **preference to the choices and wishes of a person who has capacity**.
4. **The opinion of the assessor or a third party that a decision is "unwise" must not influence the capacity assessment.** Capacity is **specific to the task and to the time**.
5. **Advance directives — Section 5(3):** an advance directive is **invoked only when the person becomes incapacitated** and **remains effective until they regain capacity**. The Act does not clearly distinguish advance statements from advance directives.
6. **Nominated representative:** decision-making by a nominated representative is **restricted to those lacking capacity**

for mental healthcare decisions. **Supported decision-making** ranges from minimal support to complete support.

7. **Other relevant Indian law:** the **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** (maintenance, protection, and transfer-of-property provisions), the **Rights of Persons with Disabilities Act, 2016** (limited guardianship), the **National Trust Act, 1999**, and **Elder Line 14567** for reporting abuse and neglect.
8. **Practical Indian caveat:** the **MacCAT-T, though the international reference standard, is not standardised for the Indian population**, and **family plays a central role in healthcare decision-making** in Indian and other Asian societies — creating real difficulties in operationalising individual autonomy and advance directives.

D. Latest Updates (2023–Present)

1. Indian evidence base is only now emerging. A 2025 descriptive cross-sectional study of mental capacity and advance directives in Indian persons with mental illness confirmed that **published Indian data remain very scarce**, that **the MacCAT-T is regarded as the gold standard but is not standardised for India**, and that the **central role of the family creates practical difficulty in determining advance directives** and enabling individual decision-making about future treatment.

2. Dementia and Indian law. A published analysis of the assessment of dementia under prevailing Indian laws confirms that under **Section 4 of MHCA 2017 a diagnosis of dementia does not itself establish incapacity**, and sets out the four components of the decision-making process as **understanding, appreciating, reasoning and communicating**. It also distinguishes **capacity** (clinical) from **competence** (legal — relating to valid contracts and financial and personal decision-making).

3. UK practice guidance (2024). NHS England guidance restates the functional test as the ability to **understand the relevant information, retain it long enough to make the decision, weigh up the arguments on each side, and communicate the decision** (by talking, signing or any other means). It provides a **practical checklist**: choose a quiet space free from distractions and noise, avoid jargon, **repeat and rephrase questions**, and **identify in advance what the "relevant information" for that specific decision is**. Essex Chambers publishes decision-specific guidance on what constitutes relevant information for different categories of decision.

4. High prevalence of impairment in institutional settings. Older adults evaluated in long-term care have **rates of capacity impairment between 44% and 69%** — an argument for routine, structured assessment rather than ad hoc judgement.

5. Convergence with capacity-based frameworks. The **German S3 CGA guideline (2024)** mandates cognition and delirium assessment as a core dimension; **WHO ICOPE** includes cognition and psychological well-being. Both feed directly into capacity evaluation, and the **Age-Friendly 4Ms** place **"What Matters"** — eliciting the person's own goals — as the first M, operationalising autonomy in routine care.

E. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Legal framework	Generic Western frameworks; Australian guardianship hierarchy quoted	**India: MHCA 2017 governs**, with statutory presumption of capacity and nominated representatives
Effect of a dementia diagnosis	A diagnosis is not a sufficient indicator of incapacity	**Statutorily reinforced** — Section 4 MHCA: dementia does not imply incapacity
Instruments	Formal tools exist but are hard for older adults	**MacCAT-T remains the gold standard but is not standardised for Indian populations**
Cognitive tests	No screening test determines capacity; executive tests correlate better	Unchanged and reaffirmed
Role of family	Consult relatives for best interests, but do not transfer the decision	**In India, family-centred decision-making is normative**, creating tension with individual-autonomy models
Documentation	Recommended	Now expected to be **decision-specific**, recording the relevant information disclosed
Autonomy in routine care	Ethical principle	Operationalised as **"What Matters"** in the 4Ms framework

F. Exam One-Liners

- **Capacity is clinical and decision-specific; competence is legal and determined by a court.**
- **The four elements: Understanding, Appreciation, Reasoning, Choice.**
- **Capacity is presumed** — a diagnosis of dementia never establishes incapacity by itself.
- **An unwise decision is not incapacity.** If the patient has capacity, their refusal stands, and the duty of care does not diminish.
- **Sliding scale:** the higher the risk of the intervention, the higher the standard of capacity required.
- **"Staging the ageing is as important as staging the cancer."**

- **No cognitive screening test determines capacity**; **clock drawing and the Executive Interview** correlate better than the MMSE.
- **No specific MMSE score defines incapacity.**
- **MacCAT-T is the reference instrument** — but is not standardised for India.
- **Maximise capacity first:** treat delirium, depression and pain; correct hearing and vision; simplify language; choose a quiet room and the best time of day.
- **Recheck after an interval to confirm the preference is consistent.**
- **Section 4, MHCA 2017 (India):** presumption of capacity; understand, appreciate consequences, communicate by any means.
- **Section 5(3), MHCA 2017:** advance directive is invoked only on incapacity and lapses when capacity returns.
- **Never make the family feel the decision is theirs** — offer **"informed assent"** where they cannot bear to decide.
- **Anticipate decisions early in the admission** so that proxy decision-making is avoided.

Appendices

Appendix A — Four Frequently Confused Terms

1. GOHAI — Geriatric Oral Health Assessment Index

What it is: A self-report scale measuring **oral health–related quality of life** in older people. Developed by **Atchison and Dolan, 1990**.

Why it appears in CGA: It is the tool for the **oral health dimension**. Oral problems are a major hidden cause of the **anorexia of ageing**, weight loss and malnutrition, yet are almost never volunteered by the patient.

Feature	Detail
Items	**12 questions** (a 3-item short form also exists)
Recall period	Past 3 months
Three dimensions	**Physical function** (eating, speaking, swallowing) · **Psychosocial function** (worry about teeth, self-consciousness, avoiding social contact) · **Pain and discomfort** (medication use, sensitivity)
Scoring	Each item 1–5, giving a **total of 12–60**
Direction	**Higher score equals better oral health quality of life**
Interpretation	57 or more high · 51–56 moderate · **50 or less low**

Exam point: GOHAI is more sensitive than clinical dental examination alone, because it captures **functional and psychosocial impact** — a person with dentures may be dentally "treated" but still unable to eat.

2. EHSAS — Elderly Health Status Assessment and Screening Tool

What it is: A **brief, culturally adapted, multidimensional community screening tool developed and validated in India** to identify which rural older adults actually need a full CGA. Developed by **Kshatri and colleagues, ICMR–Regional Medical Research Centre, Bhubaneswar**, with the University of Edinburgh and Maastricht University; validation published in *Age and Ageing* (December 2025).

The problem it solves: CGA is the gold standard but impractical to deliver universally in resource-limited settings. India has almost **150 million people aged 60 and above, about 70% in rural areas** with limited access to specialist geriatric services, and produces only around **20 geriatricians annually**, while each community health worker serves a population of over 1,000.

Feature	Detail
Full form	**E**lderly **H**ealth **S**tatus **A**ssessment and **S**creening
Origin	**ICMR-RMRC Bhubaneswar, Odisha, India**
Structure	**11 items** spanning key geriatric domains, **plus a frailty item not included in the score**
Administered by	**Community health workers (ASHA and Anganwadi workers)**
Cut-off	**3 or more "Yes" responses** triggers referral for CGA
Psychometrics	Cronbach's alpha above 0.7 · test–retest Cohen's kappa above 0.79 · **sensitivity 76.3%, specificity 76.5%, negative predictive value 93.2%**
Criterion variable	Frailty status
Design basis	Aligned with **WHO ICOPE** domains

Exam point: EHSAS operationalises **"stepped assessment"** — brief multidimensional screening at community level, full CGA at facility level. Most multidomain geriatric screening tools are validated in high-income countries and require costly licensing. Its **high negative predictive value is the key design feature** — it is built to safely rule *out*, so scarce specialist time goes only to those who need it. This is the most quotable recent Indian contribution to CGA.

3. MPI — Multidimensional Prognostic Index (Italy)

What it is: A **CGA-derived prognostic index** that converts a standard comprehensive geriatric assessment into a single **mortality-risk score**. Developed by **Pilotto and colleagues, Italy (2008)**, and **specifically recommended by the Italian National CGA Guideline (2024)** to predict negative outcomes across all care settings.

Structure — eight domains, 63 items:

#	Domain	Instrument used
1	Basic ADL	**Katz Index**
2	Instrumental ADL	**Lawton IADL**
3	Cognition	**Short Portable Mental Status Questionnaire (SPMSQ)**
4	Nutrition	**Mini Nutritional Assessment (MNA)**
5	Pressure sore risk	**Exton-Smith Scale**
6	Comorbidity	**Cumulative Illness Rating Scale (CIRS)**
7	Medications	**Number of drugs**
8	Social support	**Co-habitation status**

Scoring: each domain scored **0 (no problem), 0.5 (minor problem), 1 (major problem)**, summed and divided by 8, giving a **continuous score from 0 to 1**.

Grade	Score	Risk
MPI-1	0.00–0.33	**Low risk**
MPI-2	0.34–0.66	**Moderate risk**
MPI-3	0.67–1.00	**Severe risk**

Why it matters: it answers the criticism that CGA generates a lot of data but no single actionable number. MPI is validated to predict **short- and long-term mortality, hospitalisation, length of stay, institutionalisation and readmission** across hospital, community, nursing home and outpatient settings, and is used to guide **treatment intensity decisions** — whether to anticoagulate, whether to offer surgery, whether to escalate oncology treatment.

Exam one-liner: "*CGA tells you what is wrong; the MPI tells you what it means for prognosis.*"

4. Ceiling Effect in the Barthel Index

Definition: A **ceiling effect** occurs when a large proportion of people score **at or near the maximum** on a scale, so the scale **cannot detect any further improvement** and **cannot discriminate between people who are actually different**.

Why the Barthel has one: - The Barthel Index measures only **basic ADLs** — feeding, bathing, grooming, dressing, bowels, bladder, toilet use, transfer, mobility, stairs. - **Anyone who can walk, wash and dress themselves scores 100 out of 100** — even if they cannot cook, shop, handle money, use public transport or manage their own medicines. - A **fully independent 70-year-old** and a **frail 85-year-old who can just about self-care but cannot leave the house** both score **100**. - The scale has therefore **hit its ceiling** — there is no score above 100 to record the difference, and no room to demonstrate improvement in someone already at 100.

Practical consequences:

Consequence	Explanation
Insensitive in ambulatory and community patients	Most community-dwelling elders score at or near maximum, so the scale cannot detect early decline
Cannot measure rehabilitation gains near discharge	A patient improving from 95 to full independence shows no measurable change
Underestimates disability	Misses the entire IADL layer, where **loss occurs first**
Skewed statistics	Scores cluster at one end, violating assumptions of many statistical tests and reducing power in trials

The solution: - Use the **Barthel for hospital, stroke and rehabilitation populations**, where scores are genuinely distributed across the range. - Use the **Lawton IADL scale, gait speed, SPPB or frailty measures** in community-dwelling or relatively well older people. - This is precisely the reason for the **hierarchy rule** in CGA: *do not measure basic ADLs in a robust or pre-frail person — measure frailty instead.*

The mirror image — floor effect: the opposite problem, where everyone clusters at the minimum. The **MMSE has a floor effect in advanced dementia** (many patients score 0 and cannot be distinguished), which is exactly why the **Severe Impairment Battery** was developed.

Exam one-liner: "*Barthel has a ceiling effect in ambulant patients and MMSE has a floor effect in severe dementia — both mean the instrument has run out of room to measure.*"

Appendix B — 3D-CAM and CAM-ICU

Both are **derivatives of the Confusion Assessment Method (CAM)** — the parent instrument — adapted for two different practical problems: "*I have three minutes*" and "*my patient is intubated*."

A. The Parent — CAM (Inouye, 1990)

The diagnostic algorithm — four features:

Feature	Content	How to test
1. Acute onset and fluctuating course	Change from baseline, waxing and waning	Informant or nurse report
2. Inattention	Cannot focus, sustain or shift attention	**Months of the year backwards**, days of the week backwards, **digit span 3 or 4 backwards**; or observe **inappropriate distraction or losing the thread of conversation**
3. Disorganised thinking	Rambling, illogical flow of ideas, incoherence	Orientation to time and place; observe **illogical flow of ideas**
4. Altered level of consciousness	Anything other than alert	Vigilant, lethargic, stuporous, comatose

Diagnosis requires Feature 1 AND Feature 2, PLUS either Feature 3 OR Feature 4.

Performance: sensitivity 94%, specificity 89%, with high inter-rater reliability.

Its limitation: the original CAM tells you *what* to assess but not *how*. Untrained raters have to improvise the mental status testing, so real-world sensitivity in routine practice falls far below 94%. Both 3D-CAM and CAM-ICU exist to fix this by **scripting the questions**.

B. 3D-CAM — the 3-Minute Diagnostic Interview for CAM

Purpose: to make the CAM **fast, scripted and reproducible on a general ward**, so any trained clinician or nurse gets the same answer.

Feature	Detail
Full name	**3-Minute Diagnostic Interview for CAM-defined Delirium**
Developed by	Marcantonio and colleagues, 2014
Duration	**About 3 minutes**
Structure	**20 items** — 10 patient-response cognitive and symptom items plus 10 interviewer observations, mapped onto the 4 CAM features
Setting	**General medical and surgical wards**; verbal, non-intubated patients
Key advantage	**Specific scripted questions** for every feature, removing improvisation

Validation performance (mean age 84):

Population	Sensitivity	Specificity
Patients WITH dementia	**96%**	**86%**
Patients WITHOUT dementia	**93%**	**96%**

Note the pattern: in dementia, sensitivity stays excellent but **specificity falls** — because chronic cognitive impairment mimics inattention and disorganised thinking. This is the classic difficulty of **delirium superimposed on dementia**.

Ultra-brief screening derived from 3D-CAM data:

Screen	Sensitivity	Specificity
"Months of the year backwards" alone — the single best item	**83%**	**69%**
Months backwards plus "What is the day of the week?" — best two items	**93%**	**64%**

These two-question screens are designed as a **rule-out**: negative means delirium is unlikely; positive means proceed to full 3D-CAM or CAM.

C. CAM-ICU — for the Non-Verbal or Intubated Patient

Purpose: to assess delirium in patients who **cannot speak** — intubated, tracheostomised, or too sedated for verbal testing. Developed by **Ely and colleagues, 2001**.

Prerequisite step: first assess arousal with the **Richmond Agitation–Sedation Scale (RASS)**. - **RASS −4 or −5** (deeply sedated or unarousable) means **stop, the patient is unassessable**; reassess later. - **RASS −3 to +4** means proceed. - **Any RASS other than 0** satisfies Feature 4.

The four features, adapted for a non-verbal patient:

Feature	CAM-ICU method
1. Acute change or fluctuating course	Change from baseline mental status, or fluctuation in RASS or sedation score over 24 hours
2. Inattention	**Attention Screening Examination** — auditory: "*Squeeze my hand every time you hear the letter A*", then read **"S-A-V-E-A-H-A-A-R-T"**. An error is squeezing on a non-A **or failing to squeeze on an A**. **More than 2 errors equals inattention.** A picture-based visual version is the alternative
3. Disorganised thinking	**Four yes/no questions** answered by hand squeeze (for example "*Will a stone float on water?*", "*Are there fish in the sea?*", "*Does one pound weigh more than two pounds?*", "*Can you use a hammer to pound a nail?*") **plus a two-part command** (hold up two fingers, then do the same with the other hand)
4. Altered level of consciousness	**RASS score other than 0**

Same algorithm: Features 1 plus 2, plus 3 or 4.

Performance: sensitivity approximately **80%**, specificity approximately **95%**. A positive CAM-ICU is trustworthy, but **hypoactive and mild delirium can be missed**, especially in routine bedside use.

D. Head-to-Head Comparison

	CAM	3D-CAM	CAM-ICU
Year	1990	2014	2001
Setting	Any	**General ward, outpatient**	**ICU, intubated or non-verbal**
Patient must speak?	Yes	Yes	**No**
Time	5–10 min	**3 min**	2–3 min
Structure	Algorithm only, unscripted	**20 scripted items**	Scripted, non-verbal responses
Attention test	Months and days backwards, digit span	Months backwards, digit span, scripted items	**"SAVEAHAART" letter-A hand squeeze**
Arousal measure	Clinical judgement	Clinical judgement	**RASS (mandatory first step)**
Sensitivity	94%	**93–96%**	About 80%
Specificity	89%	**86–96%**	**About 95%**
Main weakness	Rater-dependent; needs training	Specificity falls in dementia (86%)	Misses hypoactive and mild delirium

E. Latest Updates (2023–Present)

1. The 4AT is now the main competitor on general wards. It requires **no special training**, takes **under 2 minutes**, incorporates **AMT-4** and the **months backwards** test, and — uniquely — **scores unassessable or drowsy patients as positive** rather than excluding them. Pooled accuracy is broadly comparable to 3D-CAM (sensitivity about 80–90%, specificity about 80–90%), and it is the tool recommended in most current UK delirium pathways.

2. Ultra-brief two-item screening is now standard practice as the first step of a two-stage pathway: **UB-2 (months backwards plus day of the week) → if positive, 3D-CAM or 4AT → if positive, full clinical assessment**. This mirrors the screening and assessment split used elsewhere in CGA.

3. Delirium superimposed on dementia remains the unsolved problem. All CAM derivatives lose specificity when baseline cognitive impairment is present. Current work focuses on **informant-reported acute change** — the key discriminator — and on **fluctuation over time** rather than cross-sectional testing.

4. Electronic and automated delirium detection. Record-derived delirium prediction models and **automated chart-based CAM (CHART-DEL)** are used for retrospective case-finding and quality audit; wearable and actigraphy-based detection of sleep–wake fragmentation is under investigation.

5. Framework integration. Cognition and delirium is one of the **six mandatory core dimensions** of the German S3 CGA guideline (2024). Delirium sits under **Mentation** in the **Age-Friendly 4Ms**. The Italian CGA guideline (2024) found CGA **reduces delirium risk** across settings.

6. Prevention still outperforms detection. The **Hospital Elder Life Program (HELP)** multicomponent intervention remains the benchmark — targeting orientation, sleep, mobility, vision, hearing and hydration — and is the reason delirium is classed as a geriatric syndrome with shared, modifiable risk factors.

F. Exam One-Liners

- **CAM algorithm: Features 1 plus 2, plus 3 or 4** — acute and fluctuating, inattention, disorganised thinking, altered consciousness.
- **CAM: sensitivity 94%, specificity 89%.**

- **3D-CAM is the 3-minute scripted CAM for the general ward**; sensitivity **96%** with dementia, **93%** without.
- **Specificity of 3D-CAM falls to 86% in dementia** — the delirium-superimposed-on-dementia problem.
- **Best single delirium item: "months of the year backwards"** (sensitivity 83%, specificity 69%).
- **Best two items: months backwards plus day of the week** (sensitivity 93%, specificity 64%).
- **CAM-ICU is for the patient who cannot speak** — responses by hand squeeze.
- **CAM-ICU attention test: "SAVEAHAART" — squeeze on A; more than 2 errors equals inattention.**
- **CAM-ICU requires RASS first**; **RASS −4 or −5 means unassessable**, and any RASS other than 0 satisfies Feature 4.
- **CAM-ICU is highly specific (about 95%) but less sensitive (about 80%)** — it misses hypoactive delirium.
- **4AT needs no training and scores drowsy or unassessable patients as positive** — its main advantage over the CAM family.
- **Hypoactive delirium is the commonest and most missed subtype** — always screen, never wait for agitation.

MD GERIATRIC MEDICINE

Examination Revision Compilation

Elder Mistreatment & Alcohol Use in Older Adults

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition; Kane's Essentials of Clinical Geriatrics

Supplemented with: International and Indian guidelines and peer-reviewed evidence, 2023–2026

Format: High-yield points → Latest Updates → Current Practice Update → Exam One-Liners

Prepared for Dr. Sudarsan · 19 August 2026

Contents

1. **Elder abuse / mistreatment** — epidemiology, risk factors, types, forms, identification and management **[15 marks]**
2. **Role of the social worker in identifying elder mistreatment** **[15 marks]**
3. **Effects / ill effects of alcohol in older adults and how to address alcoholism** **[15 marks]**
4. **Alcohol de-addiction** **[15 marks]**

Q1. Elder Abuse / Mistreatment — Epidemiology, Risk Factors, Types, Identification and Management [15 marks]

A. Definition and Concept

1. Elder abuse is **any act or omission that endangers an older person's life, threatens their physical or psychological integrity, restricts their freedom, or compromises their personal development or financial security** (Council of Europe, 1987). The WHO Toronto Declaration adds the key element of a **relationship of expectation of trust**.
2. Two broad forms: **individual mistreatment** (act or omission by a third party against a person) and **institutional abuse**, which arises within a care facility and reflects **inadequate governance**.
3. **Neglect must be separated from abuse.** Neglect arises from forgetfulness, ignorance, or inattention to professional duty — **there is no intent to harm**. Abuse implies an act or omission that harms, whether intentional or not.
4. A related concept is **psychological control ("abuse of weakness")** — cognitive, affective and behavioural conditioning that removes the older person's capacity for discernment, so they make decisions they would not otherwise make. The perpetrator is usually a **close relative, neighbour or family member**.

B. Epidemiology

1. Meta-analysis (Yon et al.): **about 15.7% of community-dwelling older people worldwide experience abuse each year**; **psychological abuse (11.6%)** and **material/financial abuse (6.8%)** are commonest.
2. **Vulnerable people of any age are the usual targets** — children, people with disability, those with loss of autonomy, and **especially those with cognitive disorders**.
3. In long-term care: staff-to-resident physical abuse, financial abuse, sexual assault, and the under-recognised **resident-to-resident aggression (RRA)** — negative, aggressive, intrusive physical, sexual, verbal or material interactions between residents. RRA linked to **28 deaths in Australia (2000–2014)** and **101 fatal incidents in the US (2003–2016)**.
4. **Indian data (LASI Wave 1):** among elders reporting ill-treatment — **77.3% verbal/emotional, 26.5% economic exploitation, 23.7% physical, 52.6% neglect**. Highest State prevalence in Bihar (~12%) and Karnataka (~10%). Commonest perpetrators: **son, then daughter-in-law**.

C. Classification — Forms of Abuse (Council of Europe)

1. **Physical violence** — beating, wounding, restraint, mishandling, **sexual violence**, disregard for pain.

2. **Psychological violence** — inappropriate familiarity, **infantilisation**, verbal violence, deprivation of visits.
3. **Material and financial violence** — embezzlement, misappropriation of money or inheritance, **abusive power of attorney**.
4. **Medical violence** — lack of basic and appropriate care, withholding information about treatment.
5. **Drug abuse** — misuse of **sedatives and neuroleptics as chemical restraint**; physical restraint is a closely linked harm (~60% prevalence in German nursing homes in 2009).
6. **Violation of rights** — deprivation of identity, freedom of movement, civil rights, religious practice; **misuse of legal protection/guardianship**.

D. Risk Factors

1. **Victim factors:** poor health, **physical and cognitive impairment**, dementia, ADL dependency, social isolation, female sex, age 80+, financial dependence.
2. **Perpetrator / environment factors: shared living arrangement** with a relative or friend suspected of **alcohol or substance misuse, mental illness, or a history of violence**; caregiver burden and exhaustion; institutional understaffing and poor governance.
3. **Societal factor — ageism.** Ageism, stereotyping and social exclusion create the climate in which mistreatment is tolerated; **technopenia** (lack of access to useful technology — 53% of French elders aged 75+ use little or no internet) is itself argued to be a form of deprivation.

E. Identification and Diagnosis

1. **Screening for elder abuse is a core part of Comprehensive Geriatric Assessment** in frail, dependent patients, alongside functional and environmental/social assessment. **Ambulatory-care quality indicators require clinicians to identify older people at high safety risk, including elder abuse/neglect, and to develop a plan for assessment or referral.**
2. **Red flags: frequent emergency department visits** for injury or exacerbation of chronic illness; unexplained bruises, skin tears or fractures; **new-onset falls**; sudden withdrawal or behavioural change; delayed presentation; inconsistency between history and injury pattern.
3. **Interview the older person alone**, separately from the accompanying caregiver, in a **safe and private setting**. Corroborate with collateral history, examine the whole body, document injuries objectively, and assess **decision-making capacity**. Abuse is a **crime in only a few jurisdictions** (e.g. California); prosecution is difficult when the victim has dementia and cannot withstand cross-examination.

F. Management and Prevention

1. **Immediate step is safety** — treat injuries, assess risk of further harm, arrange separation or respite where danger persists. The **WHO ICOPE social-care pathway explicitly includes elder abuse** alongside daily activities, finances and loneliness, with a **parallel care pathway for the caregiver**.
2. **Support the caregiver.** Advise carers to seek help early rather than reach exhaustion — carer training associations, **support and respite care**, temporary cognitive-behavioural units. This is an important part of the preventive response.
3. **Institutional prevention:** team support organised by the service head, **analysis of professional practices**, planned ethical reflection, **ageing-simulator training** to build empathy, and **inclusion of residents in social-life / patient committees** as an exercise in health democracy.
4. **Legal and system-level response:** adult-safeguarding legislation (**UK Care Act 2014**; Australian Law Reform Commission recommendation for adult-safeguarding agencies), mandatory serious-incident reporting, coronial investigation of premature deaths. **India — Maintenance and Welfare of Parents and Senior Citizens Act 2007 (Amendment Bill 2019), Elder Line 14567, NALSA free legal aid, Integrated Programme for Senior Citizens.**
5. **Prevention is a duty of public authorities, associations and professionals**, guided by fundamental ethical principles; **medical and economic vulnerability are the situations that most often lead to maltreatment**.

Latest Updates (2023–Present)

1. **USPSTF 2025 (JAMA, July 2025) — the headline update.** The USPSTF recommends screening for intimate partner violence in women of reproductive age (**B recommendation**), but concludes that current evidence is **insufficient** to assess the balance of benefits and harms of screening for caregiver abuse and neglect of older or vulnerable adults — an **"I" statement**, unchanged in substance from 2018. It applies only to persons **without recognised signs and symptoms**; clinicians must still evaluate anyone with red flags.
2. **Screening tools perform poorly.** For the **Hwalek–Sengstock Elder Abuse Screening Test (H-S/EAST)**, sensitivity was only **46%** and specificity **73%** for detecting physical or verbal abuse — the key reason for the "insufficient evidence" verdict.
3. **Optimal delivery conditions emphasised.** The USPSTF highlighted concern about potential **harms** of screening and specified that optimal screening occurs in **safe and private settings**.
4. **Emergency department focus (Geriatric ED Guidelines 2.0, 2025–26).** Systematic reviews of ED-based screening tools for patients aged 60+ and of ED-initiated interventions (literature Dec 2018 – Dec 2024) concluded that the evidence for the impact of ED screening or intervention strategies is **still not well characterised**.

5. **Newer ED tools — ERASE.** A 2024–25 scoping review identified six nurse-administered ED screening tools; with **ERASE**, **3.9% screened positive** and **88% of assessors** agreed the starting and signalling questions helped map objective indicators. ED nurses are well positioned to identify abuse because of time spent observing patients.
6. **Indian data 2023–2026. HelpAge India 2023**: nearly **50%** of elders face emotional, physical or financial abuse but only about **15% report it**. **HelpAge India 2024**: awareness of the Maintenance and Welfare Act is only **9%**. **NCRB**: **18% rise** in abuse cases between 2023 and 2024; the 60+ population is projected to exceed **20%** of India's population by 2050.
7. **Indian community prevalence.** *Indian Journal of Community Medicine* 2024 (Mangaluru): prevalence **44.6%** (rural 50.7%, urban 38.6%), significantly associated with being unemployed, living in extended families, and staying with children.

Current Practice Update

Aspect	Textbook position	Current evidence / guideline (2023–2026)
Universal screening	Screening for abuse recommended as part of CGA in frail, dependent elders	**USPSTF 2025: "I" statement** — insufficient evidence for routine screening of asymptomatic older adults; case-finding on red flags remains mandatory
Screening tools	Tools referenced without accuracy data	**H-S/EAST sensitivity only 46%** — poor accuracy is now the stated reason for the I statement
Setting of detection	Ambulatory and long-term care emphasis	**ED is now the priority setting** (Geriatric ED Guidelines 2.0); **ERASE** and nurse-administered tools emerging
Prevalence figures	Yon meta-analysis, global ~15.7%	Indian community studies show **much higher rates (44–50%)** with only ~15% reporting
Legal framework	UK Care Act 2014; Australian adult-safeguarding proposals	**India: Maintenance & Welfare Act 2007 + 2019 Amendment Bill, Elder Line 14567** — but awareness only 9%
Harms of screening	Not addressed	USPSTF now explicitly cautions that screening must occur in **safe, private settings** to avoid precipitating retaliation

Exam One-Liners

- **Definition to quote:** "A single or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust, which causes harm or distress to an older person" — WHO / Toronto Declaration.
- **Six Council of Europe forms:** physical, psychological, material/financial, medical, drug (chemical restraint), violation of rights.
- **Commonest type globally = psychological; commonest in India = neglect and verbal/emotional.**
- **Commonest perpetrator in India = son, then daughter-in-law.**
- **Neglect ≠ abuse** — neglect lacks intent to harm.
- **RRA = resident-to-resident aggression**, the most under-recognised form in long-term care.
- **USPSTF 2025 = "I" statement** for elder/caregiver abuse screening; **B recommendation** only for IPV in reproductive-age women.
- **Red flag triad:** repeated ED visits + unexplained bruises/fractures + delayed presentation.
- **Always interview the elder alone.**
- **Indian helpline = Elder Line 14567. World Elder Abuse Awareness Day = 15 June.**

Q2. Role of the Social Worker in Identifying Elder Mistreatment [15 marks]

A. Why the Social Worker Is Central

1. Elder mistreatment is a **biopsychosocial problem, not a purely medical one**. Its roots lie in family dynamics, dependency, finances and housing — domains of social work practice rather than clinical medicine.
2. The social worker is a **core member of the interdisciplinary geriatric team**. Once acute clinical problems are treated, the physician engages nursing, physiotherapy, occupational therapy and **social work** to restore the patient's highest level of function and quality of life.
3. **Comprehensive Geriatric Assessment mandates an environmental and social assessment**, focusing especially on the caregiver's support and the resources available to meet the patient's needs — the domain in which mistreatment is most often first suspected.
4. RCTs of geriatric assessment show that **social worker assessment and referral in the community** reduced mortality, reduced hospital use, reduced permanent nursing home placement, and delayed development of disability — evidence that the role produces hard outcomes.
5. Social workers can obtain **additional certified training in Gerontology**, giving formal expertise in ageing-specific safeguarding issues.

B. Identification — Specific Functions

1. **Comprehensive psychosocial / biopsychosocial assessment.** In institutional care done **within 1–2 weeks of admission** and repeated as needed, to determine past social history, **family relationships and social resources**, and to identify serious psychosocial signs warranting mental-health referral.
2. **Understanding family dynamics.** The social worker **assists other care team members in understanding the family dynamics** — the key to recognising coercion, dependency, and the "abuse of weakness" pattern.
3. **Detecting financial and material abuse.** Assessment of finances, pension, property and **abusive power of attorney** is a social work function; financial exploitation is otherwise invisible on clinical examination.
4. **Home and environment evaluation.** Assessing the fit between the older person and their environment (e.g. the **Housing Enabler**) exposes neglect, unsafe living conditions and confinement.
5. **Recognising caregiver strain as a precursor.** About **35% of caregivers of those aged 50+ report moderate-to-high financial strain**; the social worker identifies exhaustion and burden before it converts into neglect, using the **Zarit Burden Interview** and **AMA Caregiver Self-Assessment**.

6. **Screening within the WHO ICOPE pathway.** The ICOPE social care and support assessment covers **daily activities, living conditions, finances, loneliness, elder abuse, social engagement and participation**, with a parallel **care pathway for the caregiver** — the social worker's operational checklist.
7. **Interviewing skills.** Trained to interview the older person **alone, privately and non-judgementally**, obtain collateral history from family and neighbours, and document disclosures accurately.
8. **Assessing discharge safety.** Discharge planning is done with **social work, case management, nursing and physical therapy**, matching services to clinical needs, personal values, and **social and financial resources** — an unsafe discharge back to an abusive household is a preventable harm.

C. Intervention and Advocacy

1. **Advocacy role.** The hospice/palliative model defines the social worker as one who provides **advice and counselling to the patient and all family members during the crisis period, and acts as an advocate for the patient and family in making use of community resources**. The same role applies in mistreatment.
2. **Linking to community resources.** The classic example is identifying resources providing **friendly visiting for the socially isolated older adult** — isolation being both risk factor for and consequence of abuse.
3. **Caregiver support and respite.** Directs carers to **training associations (e.g. Alzheimer's associations), support and respite care, and temporary cognitive-behavioural units** — an important part of the preventive response.
4. **Legal and protective referral.** Referral to adult-safeguarding agencies under frameworks such as the **UK Care Act 2014** and the Australian Law Reform Commission recommendations. **India: referral to the Maintenance Tribunal under the Maintenance and Welfare of Parents and Senior Citizens Act 2007, Elder Line 14567, NALSA legal aid, and the medical social worker post sanctioned under NPHCE at Regional Geriatric Centres and District Hospital geriatric clinics.**
5. **Institutional prevention.** Supports **analysis of professional practices, team support for staff, ethical reflection**, and the running of **social-life committees in residential homes and patients' committees in hospitals** — an exercise in health democracy giving residents a voice.
6. **Combating ageism.** Social work education and awareness campaigns address ageist attitudes that legitimise mistreatment, including **ageing-simulator training** for institutional staff.
7. **Documentation and continuity.** Communicates relevant psychosocial data to the interdisciplinary team and ensures concerns raised at one contact are not lost across transitions of care.

Latest Updates (2023–Present)

1. **Formal recognition of the specialised social worker role (Journal of Elder Abuse & Neglect, 2023–24).** In hospital- and ED-based elder mistreatment response teams, the social worker's unique skillset allows them to establish close connections with community resources, collaborate with hospital stakeholders, support patients/families/caregivers, navigate legal and protective systems, and **balance patient safety against quality of life in disposition decisions**. Their defined role: **comprehensive biopsychosocial assessment, safe discharge planning, appropriate referral**. Underpins the **Vulnerable Elder Protection Team (VEPT, New York)** and **VESPA (Colorado)** models.
2. **ED social workers often lead — but are under-trained.** In EDs with a social worker on the clinical team, that social worker may be expected to **lead** the assessment for potential elder mistreatment and initiate interventions, yet many **lack training or experience** and are unclear about their responsibilities. A dedicated **ED Elder Mistreatment Assessment Tool for social workers** has been developed by modified Delphi consensus.
3. **Multidisciplinary teams (MDTs) as the standard response model.** MDTs provide regular, coordinated case review across practice areas; integrated case review is associated with greater interagency collaboration and more efficient delivery of assistance. MDTs bring together health, social service and justice professionals for complex cases of abuse, neglect and self-neglect.
4. **Social workers are the largest professional group in these teams.** National Elder Abuse MDT Survey (January 2026): the largest group of respondents identified as **Adult Protective Services (APS) / social workers**, followed by aging services, victim services, healthcare professionals, law enforcement, prosecutors and long-term care ombudsmen; **78%** integrate person-centred practices and **67%** use trauma-informed practices.
5. **Bridging the ED–APS gap.** ED providers focus on **acute medical needs** while APS focuses on **long-term psychosocial needs**; assigning **named liaison individuals** in both entities improves communication, and both sides value MDT participation.
6. **Engagement training for frontline workers.** The **"Opening the Door" (OTD)** training was developed with APS caseworkers to enhance engagement skills in suspected cases, since APS caseworkers are the primary responders and ideally positioned to improve detection. Capacity varies widely — **75%** of APS programmes in large counties had regular multidisciplinary case review versus only **28%** in small counties.

Current Practice Update

Aspect	Textbook position	Current practice (2023–2026)
Social worker's role	Generic team member for psychosocial assessment, resource linkage, discharge planning	**Specialised elder-mistreatment social worker** with a defined role on formal ED/ hospital response teams (VEPT, VESPA)
Setting	Community, outpatient, nursing home, hospice	**Emergency department is now the priority identification setting**; ED social worker often leads assessment
Tools	Housing Enabler, Zarit Burden Interview, psychosocial assessment forms	Dedicated **ED Elder Mistreatment Assessment Tool for social workers** (Delphi-derived); MDT case-selection algorithms
Model of response	Individual referral to safeguarding agency	**Multidisciplinary team (MDT) case review** as the standard, with trauma-informed and person-centred practice
Training	Optional gerontology certification	Explicit recognition of a **training gap**; OTD-type engagement training being rolled out
India	Not specified	**Medical social worker under NPHCE**, Elder Line 14567, Maintenance Tribunal referral — but Act awareness only ~9%

Exam One-Liners

- The social worker performs the **biopsychosocial assessment** — the missing dimension in a purely medical evaluation.
- **Three core functions:** comprehensive biopsychosocial assessment, safe discharge planning, appropriate referral.
- **Environmental and social assessment focusing on the caregiver's support** is a mandatory CGA component.
- Social worker assessment and referral in the community **reduces mortality, hospital use and nursing home placement** (RCT evidence).
- The social worker **helps the team understand family dynamics** and **acts as advocate for the patient**.
- **WHO ICOPE** social care pathway explicitly lists **elder abuse** alongside finances, loneliness and living conditions.
- **MDT case review** is the current gold-standard response model; **APS/social workers are its largest professional group**.

- **VEPT (New York) and VESPA (Colorado)** = named hospital-based elder mistreatment response teams.
- India: **medical social worker under NPHCE**; refer to **Maintenance Tribunal** and **Elder Line 14567**.
- Key gap to quote: **most ED and hospital social workers lack formal elder-mistreatment training.**

Q3. Effects / Ill Effects of Alcohol in Older Adults and How to Address Alcoholism [15 marks]

A. Definitions and Burden

1. **Alcohol use disorder (AUD) is the commonest form of substance use disorder in older adults.** Alcohol falls under **socially sanctioned psychoactive substances**, alongside medications (prescribed and non-prescribed) and illicit substances.
2. **One-year community prevalence of AUD: 2.75% in elderly men and 0.51% in elderly women.** Far higher in **primary care, where at-risk drinking is 5–15%**. **Older military veterans** have a particularly high prevalence.
3. Overall SUD prevalence is **underestimated**, because **DSM-5 criteria have limited applicability to this age group** — tolerance, work impairment and legal problems are poor markers in a retired, socially isolated person.
4. Two subgroups: **early-onset** (lifelong drinkers surviving into old age) and **late-onset** drinkers who begin heavy drinking in later life, often after bereavement, retirement or loss.

B. Why the Older Person Is More Vulnerable

1. **Reduced total body water and lean mass with increased fat** gives a **higher blood alcohol concentration for the same intake**; reduced first-pass metabolism and hepatic blood flow prolong exposure.
2. **The same amount of alcohol that caused no untoward social or physical effects in middle age now causes difficulty** — which is precisely why **older adults and their relatives are often in denial**.
3. **Even modest alcohol consumption produces excessive disability and poorer perceived health** in older adults with chronic physical and mental health disorders.
4. **The ageing brain is especially vulnerable** — those who begin drinking heavily late in life show cognitive impairment comparable to those who have drunk for decades.

C. Ill Effects — Systemic

1. **Neurocognitive. Alcohol-related cognitive decline** is a recognised neurocognitive disorder. Chronic heavy intake causes **brain atrophy and dementia**; there is a **doubling of the odds of later severe memory impairment** in those with a history of AUD. **Memory and executive function** are worst affected, with **prefrontal and frontal damage** on neuroimaging. Contributions of alcohol, **thiamine deficiency** and ageing are hard to separate.
2. **Persistence after abstinence.** A **lifetime history of alcohol dependence — even without current heavy use — causes sustained impairment** in memory, motor and attention/executive domains. **Word-list recall (free verbal recall)** is a sensitive discriminator.

3. **Even moderate-heavy drinking impairs brain networks.** On functional MRI, moderate-heavy older drinkers show **decreased central executive network connectivity during a working memory task**, with no difference in default mode network connectivity.
4. **Psychiatric.** Worsens depression and anxiety, causes insomnia, and **older adults with AUD face a greater risk of suicide**.
5. **Falls, injury and delirium.** Impairs gait and balance, precipitates falls and fractures, and is a common precipitant of **delirium** — both from intoxication and from withdrawal.
6. **Drug interactions.** Combining alcohol with **prescription and OTC medications, especially psychoactive agents**, is a major hazard; **cross-tolerance between alcohol and benzodiazepines** is clinically important and, if unrecognised, leads to dependence being overlooked. **15% of over-65s requiring inpatient alcohol detoxification are dependent on a second substance**, usually a hypnotic, anxiolytic or analgesic.
7. **Systemic disease.** Liver disease, pancreatitis, cardiomyopathy, arrhythmia, hypertension, malnutrition, anaemia, immunosuppression, and **malignancy** (alcohol is an **IARC Group 1 carcinogen**).
8. **Social consequences.** Self-neglect, financial loss, family and marital discord, and — importantly for the geriatrician — **being an abuser or victim in elder mistreatment**: a shared living arrangement with a relative suspected of **alcohol or substance misuse** is a recognised risk factor for elder abuse.

D. The Moderate-Drinking Paradox (Textbook Nuance)

1. Observational evidence suggests **moderate intake (1–3 standard drinks/day) may be associated with reduced risk of cognitive impairment**. In the **Framingham Offspring Cohort**, **late-life (not midlife) moderate consumers had larger hippocampal volume** and light consumers better episodic memory than abstainers. In the **MoVIES project**, minimal and moderate drinking were associated with less decline on MMSE and Trail Making Test.
2. **Interpret with great caution.** In the reanalysed **PAQUID** study (20-year follow-up, 3676 subjects), dementia risk was lower only in light drinkers (**HR 0.85**), non-significant in moderate drinkers (**HR 0.79**) and neutral in heavy drinkers (**HR 1.01**). Likely explanation: **light-to-moderate intake is merely a marker of a broader favourable psychosocial behaviour pattern**, not a protective agent. **Confounding dominates this literature — never advise an abstainer to start drinking.**

E. Addressing Alcoholism — Identification

1. **Screening is part of CGA.** The screening question is simply **"Do you drink alcohol?"**, followed by **CAGE questionnaire** (primary screening tool), **Michigan Alcohol Screening Test-9 / Short MAST-Geriatric version (SMAST-G)**.
2. **Case-finding, not self-presentation.** Older people present with **physical problems**, not with a drinking complaint. They may not realise they are ill or that help exists, they **under-report**, services staffed by young professionals feel intimidating, and **stigma** is

high because the disorder is seen as self-inflicted. **Physicians find it hard to discuss substance misuse with older people.**

3. **Approach.** A **non-judgemental and tactful approach is essential**, especially in ageing women. Home carers and the multiple professional contacts an older person has are an **underdeveloped opportunity for detection** and need better training.

F. Addressing Alcoholism — Management

1. **Brief interventions work.** Structured brief intervention by primary care physicians — **five minutes, five brief sessions** targeting at-risk drinking — is often fairly effective.
2. **Pharmacotherapy. There is some evidence supporting naltrexone.** There is **insufficient evidence to endorse disulfiram, acamprosate or topiramate** in older adults.
3. **Education on interactions.** Specific advice about combining alcohol with prescription and OTC drugs, **especially psychoactive agents, must be given and regularly reinforced**.
4. **Psychosocial approaches must be routine** — support groups, **Alcoholics Anonymous**, individual counselling and family intervention — alongside treatment of comorbid depression, which perpetuates the disorder.

Latest Updates (2023–Present)

1. **WHO 2023 — the "no safe level" statement.** In January 2023 the WHO stated in *The Lancet Public Health* that while cancer risk rises substantially with amount consumed, **there is no threshold below which alcohol is safe**, whatever the beverage type. **IARC classifies alcohol as a Group 1 carcinogen**; it is a major risk factor for oral, pharyngeal, laryngeal, oesophageal, liver, pancreatic, colorectal and breast cancer, accounting for about **741,300 new cancer cases (4%)** worldwide annually.
2. **US Surgeon General Advisory, January 2025.** Issued an advisory on the alcohol–cancer link, calling for **cancer warning labels** on alcoholic beverages and for health professionals to routinely discuss alcohol use with patients. Alcohol is now described as a leading cause of cancer **after tobacco and obesity**, accounting for about **5% (~97,000) of new US cancer cases**.
3. **But the evidence is contested — needed for a balanced answer.** The **2018 Global Burden of Disease** study concluded zero alcohol was safest, but its **2022 update** introduced an age-specific, risk-weighted model asserting that in populations with high baseline cardiovascular disease rates — **particularly older adults** — light-to-moderate consumption could carry net health benefits. In January 2025 the Surgeon General discouraged any intake while a simultaneous **NASEM (National Academies)** report emphasised **tailoring recommendations to individual risk**, finding no association between moderate consumption and colorectal, oral cavity, pharyngeal, oesophageal or laryngeal cancers. **Mendelian randomisation** studies, however, found no benefit and increased risk even at low doses.

4. **Public awareness is poor.** A 2025 *JAMA Oncology* analysis of the 2024 Health Information National Trends Survey (6,793 US adults) found only **37%** knew alcohol increases cancer risk, and about **9%** believed it had no effect or reduced risk.
5. **Treatment gap remains enormous.** An estimated **29 million** US residents had AUD in 2023, yet only about **2% received pharmacological treatment**. Alcohol-related deaths in the US have risen by **29% since 2020**, driven mainly by liver disease.
6. **Reduction, not only abstinence, is now an accepted goal.** Reducing drinking even without full abstinence improves health outcomes — a harm-reduction framing particularly suited to frail older patients in whom total abstinence may be unrealistic.

Current Practice Update

Aspect	Textbook position	Current evidence (2023–2026)
Safe level	Moderate intake (1–3 drinks/day) may reduce cognitive impairment risk	**WHO 2023 / Surgeon General 2025: no safe level for cancer risk**; GBD 2022 and NASEM 2025 dissent, allowing possible net benefit in older adults at high CV risk — **the field is genuinely contested**
Advising abstainers	Confounding limits interpretation	**Universal: never advise a non-drinker to start** — unchanged and uncontroversial
Cancer	Not emphasised as an alcohol harm	**Alcohol = IARC Group 1 carcinogen**, 3rd leading modifiable cancer cause; 7 cancer sites
Screening tool	CAGE, SMAST-G, MAST-9	**AUDIT-C** increasingly preferred; USPSTF supports unhealthy-alcohol-use screening in adults
Treatment goal	Abstinence-oriented	**Harm reduction / drinking reduction accepted as a valid endpoint**
Public messaging	Not addressed	Cancer warning labels proposed; **only 37% of the public know the alcohol–cancer link**

Exam One-Liners

- **AUD is the commonest substance use disorder in older adults.**
- Prevalence: **2.75% elderly men, 0.51% elderly women**; **5–15% at-risk drinking in primary care**.
- **DSM-5 criteria are poorly applicable** to older adults → under-diagnosis.

- **Same intake, higher blood level** — less body water, more fat, reduced first-pass metabolism.
- **Even modest intake causes excessive disability** in those with chronic disease.
- **Alcohol-related cognitive decline** = a named neurocognitive disorder; **doubling of odds of severe memory impairment**.
- **Memory and executive function** worst hit; **prefrontal/frontal atrophy**.
- **Late-onset drinkers are as impaired as lifelong drinkers** — the ageing brain is uniquely vulnerable.
- **Higher suicide risk** in older adults with AUD.
- **Screening = CAGE / SMAST-G**; ask "Do you drink alcohol?" in every CGA.
- **Brief intervention = 5 minutes × 5 sessions.**
- **Naltrexone has some evidence; disulfiram, acamprosate, topiramate — insufficient evidence in the elderly.**
- **Alcohol = IARC Group 1 carcinogen; WHO 2023: no safe level.**

Q4. Alcohol De-addiction [15 marks]

A. Principles

1. **Treatment of substance misuse is a multistage process integrating physical, psychological and social interventions.** These should run **concurrently, not consecutively**, and must be **acceptable to the individual and sensitive to the specific needs of the elderly**.
2. **Five sequential components:** (i) **identification of the case**, (ii) examination of the patient's **attitude and motivation**, (iii) **detoxification** where physical dependence exists, (iv) treatment of **perpetuating comorbidity** (especially depression), and (v) **psychological rehabilitation and social intervention**.
3. **Nihilism is the enemy.** Pessimistic attitudes held by professionals and carers are frequently shared by the patient — a **fatalistic resignation to a life of substance misuse**, particularly in long-term users, while **more recent-onset users express greater motivation for treatment**.

B. Step 1 — Case Identification

1. **Clinical observation allied to sensitive yet persistent enquiry**, supported by **routine use of standardised screening tools** (CAGE, SMAST-G, MAST-9) to focus clinical impression accurately.
2. Patients rarely present complaining of alcohol; they present with **associated physical problems** — falls, delirium, malnutrition, liver disease, poor diabetes control, or unexplained functional decline.

C. Step 2 — Motivation and Assessment

1. **Examine the patient's attitude to their drinking. Exploration of the risks and discussion of potential avenues for change** helps establish or reinforce **motivation to change**.
2. **Assess comorbidity and polysubstance use.** Always calculate the **total benzodiazepine or opioid dose using class-specific equivalence charts**, because **cross-tolerance exists within drug classes and also between alcohol and benzodiazepines** — widely exploited during detoxification, but causes dependence to be missed if overlooked.
3. **Assess the social matrix.** Housing, and **a social network consisting mainly of substance misusers**, perpetuates the problem and must be examined for opportunities to change.

D. Step 3 — Detoxification (Withdrawal Management)

1. **Drugs causing significant physical dependence necessitate a detoxification regimen.** In older adults, **safe withdrawal may take weeks to months, compared with days to weeks in younger adults** — the single most important age-specific point.
2. **The withdrawal period in the elderly is far more likely to be complicated by confusion (delirium)** than in younger adults. Withdrawal may also present with **psychotic episodes with hallucinations and delusions, nocturnal restlessness, paradoxical excitement, anxiety and increased suicide risk**.
3. **Setting.** Where severe dependency is suspected or rapid withdrawal is necessary, detoxification **is best conducted in an inpatient setting**. **Rapid detoxification risks breakthrough withdrawal symptoms and may be complicated by convulsions.**
4. **Supportive measures: parenteral thiamine before any glucose load** (to prevent Wernicke's encephalopathy), correction of electrolytes and magnesium, hydration, nutrition, and a quiet, well-lit, orientating environment with delirium precautions.
5. **Benzodiazepine-assisted withdrawal** uses the alcohol–benzodiazepine cross-tolerance principle; in older adults a **shorter-acting agent (e.g. lorazepam)** is preferred where hepatic impairment exists, with **symptom-triggered rather than fixed-dose regimens** to limit total exposure.

E. Step 4 — Pharmacotherapy for Relapse Prevention

1. **Naltrexone has some supporting evidence in older adults.** There is **insufficient evidence to endorse disulfiram, acamprosate or topiramate** in this age group. Disulfiram is particularly hazardous in the elderly because of cardiovascular comorbidity.
2. **Treat comorbid depression adequately**, since it perpetuates the disorder; do not treat anxiety in the recovering drinker with **benzodiazepines**, given cross-dependence risk.

F. Step 5 — Psychological Rehabilitation

1. **After detoxification, rehabilitation is necessary** to address the issues behind the substance use and to foster **future coping strategies**. Detoxification alone is not treatment.
2. **Outcomes equal those in younger patients.** Janik and Dunham compared over **3,000 people aged over 60** with younger entrants to alcohol treatment programmes: **at six months there were no differences between the groups** — a powerful argument against therapeutic nihilism.
3. **Age-specific programmes improve retention.** Kofoed et al. showed **greater retention in an age-specific outpatient group focused on socialisation and minimal confrontation**, compared with older patients in a mixed-age group — although at one-year follow-up the effect was lost.
4. **Low-confrontation models are superior in the elderly.** Kashner et al. found **elders in a confrontational programme had half the abstinence rate at one year** compared with a programme promoting **self-esteem, tolerance and peer relationships**.

Confrontation, traditionally regarded as fundamental to overcoming denial, is **inappropriate for older adults**.

5. **Effective components:** models encouraging development of **social networks with self-management skills**; **behavioural approaches including cue identification and avoidance**; and **variants of the AA 12-step model tailored to elders** (reported with varying success).
6. **Psychosocial approaches must be routine** — support groups, AA, individual counselling and **family intervention**.
7. **Address the psychosocial aetiology.** Four theories guide intervention: **social control theory** (weak social bonds), **social learning theory** (role models), **behavioural economics / behavioural choice theory** (lack of alternative rewards — educational, social, physical activities), and **stress and coping theory** (substance use as avoidance coping). **Providing alternative rewarding activities is therapeutic, not merely recreational.**
8. **Aftercare** may be delivered through **generic old-age psychiatry services or specialist drug services**, depending on which best meets the individual's needs. **Avoid drugs with dependence potential** in ongoing prescribing where practical.

Latest Updates (2023–Present)

1. **Standard pharmacotherapy — current consensus.** Three medications are FDA-approved for AUD — **acamprosate, naltrexone and disulfiram** — with **gabapentin and topiramate** as additional evidence-based options; naltrexone is also available as an **extended-release intramuscular** formulation. **Acamprosate and oral or XR naltrexone are the preferred pharmacologic treatments** for moderate or severe AUD, and head-to-head trials have not consistently shown either superior. **This diverges from the textbook's "insufficient evidence for acamprosate."**
2. **Adherence and pill burden matter.** Acamprosate requires **two tablets three times daily**, oral naltrexone is **once daily**, and XR naltrexone is given **every 28 days** — XR naltrexone is therefore attractive in older adults with polypharmacy or poor adherence.
3. **More options in Europe. Baclofen, nalmefene and sodium oxybate** are approved in some European regions; naltrexone and nalmefene are safe and effective particularly in patients not yet abstinent, and **targeted (as-needed) naltrexone** significantly reduces drinks per drinking day.
4. **GLP-1 receptor agonists — the major emerging development.** A **phase 2 double-blind RCT of once-weekly subcutaneous semaglutide** over 9 weeks in adults with AUD evaluated alcohol consumption and craving; semaglutide was generally well tolerated (decreased appetite, GI symptoms, headache), participants lost 5% body weight, and no serious adverse events occurred. Current guidance: consider semaglutide **only after failed trials of the FDA-approved medications**, with careful comorbidity screening. **Phase 3 trials are underway**; high cost may limit adoption.

5. **Behavioural treatment components standardised.** The most effective AUD interventions comprise **assessment, personalised feedback, motivational interviewing, goal setting, planning and review of homework, problem-solving skills, and relapse prevention and management**.
6. **Psychedelic-assisted therapy — investigational.** Hallucinogenic (**psilocybin**) and dissociative (**ketamine**) agents combined with psychotherapy may reduce heavy drinking days and increase abstinent days, but more research is needed.

Current Practice Update

Aspect	Textbook position	Current guideline / evidence (2023–2026)
Acamprosate	Insufficient evidence in older adults	**Now a first-line preferred agent** (with naltrexone) for moderate–severe AUD; caution in renal impairment — relevant to the elderly
Naltrexone	Some evidence; oral	**Preferred**; **XR intramuscular naltrexone every 28 days** solves the adherence problem in older patients
Second-line agents	Topiramate — insufficient evidence	**Gabapentin and topiramate now recognised evidence-based alternatives**
European options	Not covered	**Baclofen, nalmefene, sodium oxybate** approved in parts of Europe; **as-needed (targeted) naltrexone** for craving
Novel agents	None	**Semaglutide** — positive phase 2 RCT, phase 3 ongoing; **third-line after approved drugs fail**
Treatment goal	Abstinence	**Reduction in drinking is a legitimate outcome** (harm reduction)
Psychotherapy	AA, counselling, family intervention	Formalised as **motivational interviewing + CBT + relapse prevention**; low-confrontation age-specific approach still validated
Treatment gap	Not quantified	**Only ~2% of people with AUD receive pharmacotherapy** — the biggest practical failure

Exam One-Liners

- **De-addiction = a multistage process integrating physical, psychological and social interventions, run concurrently, not consecutively.**
- **Five steps:** identify → motivate → detoxify → treat comorbidity → rehabilitate.
- **Safe withdrawal takes weeks to months in the elderly vs days to weeks in the young.**
- **Elderly withdrawal is complicated by confusion/delirium** far more often; **rapid detoxification risks convulsions**.
- **Thiamine before glucose, always.**
- **Inpatient detoxification** if severe dependency or rapid withdrawal is required.
- **Cross-tolerance between alcohol and benzodiazepines** — exploited for detoxification, dangerous if ignored.
- **15% of over-65s in alcohol detoxification are dependent on a second drug** (hypnotic, anxiolytic or analgesic).
- **Confrontational programmes halve one-year abstinence rates in the elderly** — use **low-confrontation, self-esteem-promoting, age-specific** groups.
- **Outcomes at 6 months are no different from younger patients** — never be nihilistic.
- **Naltrexone (± XR) and acamprosate are now the preferred pharmacotherapy**; disulfiram is hazardous in the elderly.
- **Semaglutide = the emerging third-line option after approved drugs fail.**
- **Only ~2% of people with AUD receive pharmacotherapy** — the treatment gap is the headline statistic.

MD Geriatrics Exam Answers

MD Geriatric Medicine — High-Yield Exam Answers

Endocrine, Metabolic, Renal and Genitourinary Systems (Questions 1–17)

Structured 15-mark answers • Pathy's Principles and Practice of Geriatric Medicine (6th ed.) with Kane's Essentials of Clinical Geriatrics, supplemented by current international guidelines and Indian data

Q1. Investigation and Management of Diabetic Ketoacidosis

A. Definition and Basic Concept

1. **DKA** is an acute metabolic emergency defined by the triad of **hyperglycaemia, ketosis and metabolic acidosis**, caused by absolute or relative insulin deficiency with excess counter-regulatory hormones.
2. In older people DKA is less common than **HHS (hyperosmolar hyperglycaemic state)**, but many elderly patients present with a **"mixed" picture** — glucose 270–450 mg/dL, pH 7.2–7.3, without marked dehydration or coma.
3. Older subjects with hyperglycaemic comas have **higher mortality, longer hospital stay, more previously undiagnosed diabetes, more renal impairment**, and need larger insulin doses than the young.

B. Precipitating Factors in the Elderly

4. Commonest precipitants are **infection (chest, urine, foot), myocardial infarction, stroke, inadequate or omitted insulin, and inappropriate drug treatment**.
5. **Thiazide diuretics and corticosteroids** raise blood glucose and can precipitate DKA; thiazides and furosemide particularly precipitate HHS.
6. **Care-home residence, dementia, thirst impairment and dependence on carers** are important risk factors; COVID-19 and other acute illness can cause rapid decompensation.

C. Clinical Features

7. Classical polyuria, polydipsia and weight loss may be **absent or blunted**; presentation is often **non-specific — confusion, falls, drowsiness, incontinence, poor oral intake**.
8. Look for **Kussmaul breathing, ketotic breath, dehydration, hypotension, tachycardia** and abdominal pain; **hypothermia and absent fever** may mask underlying sepsis.

D. Investigations

9. **Capillary and venous blood glucose**; venous (not arterial) blood gas for **pH and bicarbonate**.
10. **Bedside quantitative beta-hydroxybutyrate (β-OHB)** is the preferred ketone test; urine ketones (nitroprusside) detect only acetoacetate and are less reliable.
11. **Serum electrolytes** — sodium (corrected for glucose), potassium, chloride, bicarbonate; **anion gap**; **blood urea and creatinine**.
12. **Effective serum osmolality** = 2 × Na (mEq/L) + glucose (mg/dL)/18 — to identify overlap with HHS.
13. **Search for precipitant**: full blood count, CRP, blood and urine cultures, chest X-ray, **ECG and troponin** (silent infarction is common), foot examination.
14. **Diagnostic criteria (current international consensus)**: glucose ≥200 mg/dL **or** known diabetes; **β-OHB ≥3.0 mmol/L** or urine ketones ≥2+; **pH <7.3 and/or bicarbonate <18 mEq/L**. Severity is graded by pH, bicarbonate and mental state.
15. **Euglycaemic DKA** (glucose <200 mg/dL) must be actively excluded in patients on **SGLT2 inhibitors**, in starvation, and in chronic liver disease.

E. Management

16. **Fluids first** — 0.9% saline or balanced crystalloid, typically 1 litre over the first hour, then titrated. In the elderly with **heart failure or CKD, give slower and monitor closely** for pulmonary oedema.
17. **Fixed-rate intravenous insulin infusion 0.1 units/kg/hour**, without a bolus in most patients; aim to fall β-OHB by 0.5 mmol/L/hour and glucose by 50–75 mg/dL/hour.
18. **Potassium**: withhold insulin if K <3.3 mEq/L until replaced; add 20–40 mEq/L to fluids when K is 3.3–5.2 mEq/L; withhold if K >5.2 mEq/L.

19. **Add 5–10% dextrose** when glucose falls to about 250 mg/dL, continuing insulin until ketosis clears. **Bicarbonate only if pH <7.0**; **phosphate only if <1.0 mg/dL** with cardiac or respiratory weakness.
20. **Resolution**: β-OHB <0.6 mmol/L with pH >7.3 or bicarbonate ≥18 mEq/L; then overlap intravenous insulin with **subcutaneous basal insulin by 1–2 hours** before stopping the infusion.
21. **Complications to prevent**: hypoglycaemia, hypokalaemia, fluid overload, aspiration, venous thromboembolism, and (rarely in old age) cerebral oedema.
22. **Prevention**: sick-day rules, ketone meters at home, structured education of patients and care-home staff, avoidance of insulin omission, and review of diabetogenic drugs.

Latest Updates (2023–Present)

- **ADA/EASD/AACE/JBDS/DTS Consensus Report on Hyperglycaemic Crises in Adults (Diabetes Care, 2024)** — the first major revision in 15 years. Key changes: glucose threshold lowered to **≥200 mg/dL or a known history of diabetes** (to capture euglycaemic DKA); **quantitative β-OHB incorporated into diagnosis, severity grading and resolution**; the **anion gap criterion removed**; **arterial sampling abandoned** in favour of venous gases.
- The same consensus **simplified treatment to three pillars — fluids, insulin and potassium**, and for the first time endorsed **subcutaneous rapid-acting insulin protocols in a non-critical-care ward for mild and uncomplicated moderate DKA**.
- The 2024 consensus provides the **first formal HHS resolution criteria** (normalisation of effective osmolality and recovery of mental status) and redefines HHS hyperosmolarity as **effective osmolality >300 mOsm/kg or calculated total osmolality >320 mOsm/kg**.
- **SGLT2 inhibitor–associated euglycaemic DKA** is now a recognised inpatient hazard; current guidance is to **withhold SGLT2 inhibitors during acute illness, fasting and around surgery**, which is directly relevant to older multimorbid patients.
- **ADA Standards of Care (2025 and 2026), Older Adults section** — reiterates that in frail and care-dependent older adults, treatment should be **simplified and de-intensified**, with the primary aim of **avoiding both hypoglycaemia and hyperglycaemic crisis** rather than achieving a tight HbA1c.
- Published commentary on the 2024 consensus has questioned the **omission of 0.45% saline**, since many patients have true free-water deficits once sodium is corrected for hyperglycaemia — a practical caution in the dehydrated older patient.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Ketone assessment	Urine ketones / clinical acidosis	**Quantitative bedside β-OHB** for diagnosis, severity and resolution
Glucose criterion	Marked hyperglycaemia expected	**≥200 mg/dL or known diabetes**; euglycaemic DKA formally recognised
Acid–base testing	Arterial blood gas, anion gap used	**Venous gas**; anion gap dropped from criteria
Insulin route	Intravenous infusion for all	**Subcutaneous rapid-acting insulin acceptable** in mild/uncomplicated moderate DKA on the ward
HHS resolution	Not formally defined	**Defined criteria** — normal effective osmolality plus recovered mental status
Drug precipitants	Thiazides, steroids emphasised	**SGLT2 inhibitors** added as an important modern precipitant

Exam One-Liners

- DKA in old age is often a **"mixed" DKA–HHS picture** with modest acidosis.
- **β-OHB ≥3.0 mmol/L** is the modern ketosis criterion; **anion gap is no longer required**.
- Insulin is withheld until **K >3.3 mEq/L**.
- Add **dextrose at glucose ~250 mg/dL**; treat the **ketosis, not the glucose**.
- **Overlap IV and subcutaneous insulin by 1–2 hours** to avoid rebound.
- Suspect **euglycaemic DKA** in any unwell patient on an SGLT2 inhibitor.

Q2. Newer Oral Antidiabetic Agents

A. Background and Rationale

1. Metformin remains **first-line after lifestyle measures** in older adults; it lowers glucose without hypoglycaemia, causes modest weight loss, reduces microvascular complications, and reduced cardiovascular events and mortality in obese patients in UKPDS.
2. Long-term metformin causes **vitamin B12 deficiency**; periodic measurement is advised. It must be avoided in severe renal impairment and withheld in dehydration, sepsis and before contrast or surgery.
3. Newer agents were developed because **sulphonylureas cause hypoglycaemia and weight gain** and **thiazolidinediones cause fluid retention, heart failure and fractures** — both particularly hazardous in the elderly.

B. DPP-4 Inhibitors (Gliptins)

4. **Sitagliptin, vildagliptin, linagliptin, saxagliptin, alogliptin, teneligliptin** inhibit degradation of GLP-1 and GIP, giving a **near-physiological, glucose-dependent** incretin effect.
5. HbA1c reduction **0.5–1.0%**; **weight neutral, no intrinsic hypoglycaemia, minimal adverse effects** — making them among the safest agents in frail older adults.
6. **Linagliptin needs no dose adjustment in renal failure** (CARMELINA showed cardiovascular and renal safety in high-risk patients); others require dose reduction.
7. As a class they are **cardiovascular-neutral**; **saxagliptin increased heart-failure hospitalisation** (SAVOR-TIMI 53) and is best avoided in cardiac patients.

C. SGLT2 Inhibitors (Gliflozins)

8. **Empagliflozin, dapagliflozin, canagliflozin, ertugliflozin** block proximal tubular glucose reabsorption, giving **insulin-independent glycosuria**.
9. HbA1c reduction **0.5–1.0%**, with **weight loss of 2–3 kg**, blood pressure reduction, and **no hypoglycaemia** when used alone.
10. **Empagliflozin and canagliflozin reduce MACE; empagliflozin reduces cardiovascular death, heart-failure hospitalisation and worsening nephropathy** — benefits now extended to patients without diabetes.
11. Cautions in the elderly: **volume depletion, postural hypotension and falls, genital mycotic infection, urinary infection, euglycaemic ketoacidosis, weight loss aggravating sarcopenia**, and (with canagliflozin) amputation risk.

D. GLP-1 Receptor Agonists (including the oral form)

12. **Oral semaglutide (Rybelsus)** is the first orally available GLP-1 receptor agonist; it must be taken fasting with ≤120 mL water and 30 minutes before food.
13. GLP-1 receptor agonists lower HbA1c by **1.0–2.0%**, cause **weight loss of 1.6–3 kg or more**, and **liraglutide, semaglutide and dulaglutide reduce cardiovascular events** in high-risk patients.
14. In older adults, **nausea, vomiting, anorexia, weight loss and sarcopenia** limit their use; a **43% discontinuation rate** was seen with exenatide in participants aged ≥65.

E. Prescribing Principles in the Older Patient

15. Choose by **renal and hepatic function, frailty, hypoglycaemia risk, cardiac and renal comorbidity, cost and swallowing ability** — not by HbA1c alone.
16. **Consider a glinide (repaglinide) if eating is irregular**, avoid SGLT2 inhibitors where weight loss, dehydration or foot disease predominate, and use **gliclazide** if a sulphonylurea is unavoidable.
17. **De-intensification (deprescribing)** is an active clinical duty in those who are frail, underweight, cognitively impaired or renally impaired — simplification or withdrawal is usually feasible without loss of control.
18. In India, cost, availability of generic **teneligliptin, vildagliptin and dapagliflozin**, and coverage under **AB-PMJAY** strongly influence choice; screen for **tuberculosis and genital/urinary infection** before starting SGLT2 inhibitors.

Latest Updates (2023–Present)

- **Tirzepatide**, a dual **GIP/GLP-1 receptor agonist**, gives greater HbA1c and weight reduction than semaglutide or insulin glargine in the **SURPASS** programme; a pooled post-hoc analysis of SURPASS-1 to -5 (2025) found **HbA1c reductions of 1.97–2.10% in participants aged ≥65 with BMI <30 kg/m²**, with no age-related loss of efficacy or safety.
- **ADA Standards of Care 2026 (Older Adults)** states that **GLP-1 receptor agonists and tirzepatide are highly effective with low hypoglycaemia risk and may be used at reduced eGFR, including during dialysis**.
- **High-dose oral semaglutide (25 mg and 50 mg)** has shown additional HbA1c and weight benefit over the 14 mg dose in the PIONEER PLUS and OASIS programmes, expanding oral options.

- **Small-molecule oral GLP-1 receptor agonists (e.g. orforglipron)** — not requiring fasting administration — have completed late-phase trials and represent the next oral class.
- **Finerenone**, a non-steroidal mineralocorticoid receptor antagonist, is now standard add-on therapy for **diabetic kidney disease with albuminuria** (FIDELIO-DKD/FIGARO-DKD), reducing kidney and cardiovascular events; potassium monitoring is essential in the elderly.
- Guidelines have moved decisively from a **glucose-centred to an organ-protection-centred** algorithm: **SGLT2 inhibitors for heart failure and CKD, GLP-1 receptor agonists for atherosclerotic disease and obesity**, chosen independently of HbA1c.
- **Beers 2023 criteria** continue to advise avoiding **long-acting sulphonylureas (glibenclamide/glyburide)** in older adults, and caution with sliding-scale insulin.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Sequencing after metformin	Free choice of "any second agent"	**Comorbidity-driven**: SGLT2i for HF/CKD, GLP-1 RA for ASCVD/obesity, regardless of HbA1c
Incretin classes	GLP-1 RA and DPP-4 inhibitors	**Dual GIP/GLP-1 (tirzepatide)** now the most potent agent, efficacy preserved in ≥65 years
Oral incretin therapy	Not available	**Oral semaglutide up to 50 mg**; small-molecule oral GLP-1 RAs in late-phase trials
Renal protection	ACE inhibitor / ARB	ACEi/ARB **plus SGLT2 inhibitor plus finerenone** as pillars
Older-adult strategy	Achieve individualised HbA1c	Explicit emphasis on **de-intensification and simplification** in frailty

Exam One-Liners

- **Metformin first, always check B12**.
- **DPP-4 inhibitors** — safest class in frailty; **linagliptin** needs no renal adjustment.
- **SGLT2 inhibitors** — cardio-renal protection, but dehydration, genital infection and euglycaemic DKA.
- **Saxagliptin and heart failure; canagliflozin and amputation** — two classic negative associations.
- **Tirzepatide** = dual GIP/GLP-1; most potent HbA1c and weight reduction.
- **Deprescribing is a prescribing decision** in the frail older diabetic.

Q3. Newer Insulin Analogues

A. Concept and Rationale

1. Insulin analogues are **recombinant insulins with altered amino-acid sequence or acylation** that change absorption kinetics, producing either **faster prandial action** or **flatter, longer basal profiles**.
2. The direction of insulin development has been to make insulin **"longer, faster and easier"**.
3. Human insulin exists as a **hexamer** in the vial and must dissociate to dimers and monomers before absorption — the step that analogues manipulate.

B. Rapid-Acting (Bolus) Analogues

4. **Insulin lispro, aspart and glulisine** have one or two amino-acid changes that weaken self-association; onset **5–15 minutes**, peak earlier and higher, duration **4–6 hours**.
5. They can be injected **immediately before or even after a meal** — a major advantage in older people with variable appetite, dysphagia or dementia.
6. Regular human insulin, by contrast, starts in 30 minutes and lasts 5–8 hours, causing late post-prandial hypoglycaemia.

C. Ultra-Rapid Formulations

7. **Faster aspart (Fiasp)** contains **niacinamide and L-arginine**, accelerating monomer formation and capillary permeation, with greater early glucose lowering.
8. **Lispro-aabc (LY900014/URLi)** contains **treprostinil** (local vasodilatation) and **citrate** (increased vascular permeability), speeding absorption.

9. **Inhaled insulin (Afrezza)** uses a dry powder on fumaryl diketopiperazine microparticles, with onset about **12 minutes** and offset by **90–180 minutes**; contraindicated in asthma and COPD.

D. Long-Acting (Basal) Analogues

10. **Insulin glargine (U100 and U300), detemir and degludec (U100/U200)** provide flat 24-hour basal cover with **less nocturnal hypoglycaemia than NPH**.
11. **Degludec** is a detemir-derived molecule with **B30 threonine deleted and a 16-carbon fatty diacid attached to B29 lysine via a glutamic acid spacer**, forming subcutaneous multihexamers; duration exceeds 42 hours and permits flexible timing.
12. **Glargine U300 is as effective as U100 in patients over 65 with less nocturnal hypoglycaemia** — hence long-acting analogues are the **preferred starting insulin in older adults**.

E. Combinations and Practical Use

13. **Co-formulations**: IDegAsp (degludec/aspart, Ryzodeg) — the only basal insulin that can be mixed with a rapid analogue in one injection; premixed analogues (Humalog Mix 25/50, NovoMix 30) suit twice-daily regimens.
14. **Fixed-ratio basal insulin + GLP-1 combinations — IDegLira (degludec/liraglutide)** and **iGlarLixi (glargine/lixisenatide)** — reduce injections, weight gain and hypoglycaemia.
15. In older adults with type 1 diabetes or those unable to manage basal-bolus regimens, **twice-daily premixed analogue** or **twice-daily long-acting analogue** is a reasonable simplification; HbA1c target at age ≥70 is about **7.0–7.5%**.
16. Insulin therapy carries a **higher hypoglycaemia risk than most oral agents** in older adults; **sliding-scale insulin should not be used** in hospital.
17. **Biosimilar glargine and aspart** have made analogue therapy affordable in India, an important consideration for pensioners and AB-PMJAY beneficiaries.

Latest Updates (2023–Present)

- **Once-weekly basal insulins** are the major advance. **Insulin icodec** (ONWARDS 1–6) and **insulin efsitora alfa** (QWINT 1–5) achieved **non-inferior HbA1c reduction versus daily glargine or degludec in type 2 diabetes**.
- **QWINT-1 (NEJM, 2025)** used a **fixed-dose escalation** and showed about **40% fewer clinically significant or severe hypoglycaemic events than glargine** in insulin-naïve type 2 diabetes; **QWINT-3 and QWINT-4 (Lancet, 2025)** confirmed non-inferiority in basal-experienced and basal-bolus patients.
- In **type 1 diabetes**, weekly insulins are less favourable — **QWINT-5** showed **higher rates of level 2/3 hypoglycaemia with efsitora versus degludec**, and ONWARDS 6 raised similar concerns for icodec.
- Practical implication for geriatrics: weekly insulin reduces injections from **365 to 52 per year**, potentially transforming care in **care homes, in patients dependent on visiting nurses or family carers, and in those with dementia** — but requires care with dose changes, since the effect of an error persists for days.
- **ADA Standards of Care 2026** emphasise **simplification of complex insulin regimens** in older adults, preferential use of **analogues over NPH and human regular insulin**, and pairing insulin therapy with **continuous glucose monitoring** to detect asymptomatic nocturnal hypoglycaemia.
- **Continuous glucose monitoring** is now recommended for older insulin-treated adults, with **time-in-range 70–180 mg/dL >50–70% and time-below-range <1%** as the geriatric targets, replacing HbA1c-only assessment.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Basal insulin frequency	Once or twice daily	**Once-weekly icodec and efsitora** non-inferior in type 2 diabetes
Weekly insulin in type 1 DM	Not applicable	**Higher hypoglycaemia** — not recommended as a routine option
Choice of basal insulin in elderly	Analogue preferred over NPH	Unchanged and **strengthened**; NPH and human regular discouraged
Monitoring	HbA1c and capillary glucose	**CGM with time-in-range metrics**, especially for hypoglycaemia detection
Regimen complexity	Individualise	Formal **simplification/de-intensification** protocols recommended

Exam One-Liners

- **Rapid analogues** — lispro, aspart, glulisine; onset 5–15 min, may be given after meals.
- **Faster aspart = niacinamide + arginine; lispro-aabc = treprostinil + citrate**.

- **Degludec** — ultra-long, multihexamer formation, flexible dosing, mixable with aspart.
- **Glargine U300 causes less nocturnal hypoglycaemia than U100 in those over 65**.
- **IDegLira and iGlarLixi** — fixed-ratio basal insulin plus GLP-1 agonist.
- **Weekly insulins** work in type 2 but not safely in type 1.

Q4. Diabetic Foot Syndrome

A. Definition and Burden

1. **Diabetic foot syndrome** is the combination of **infection, ulceration or destruction of tissues of the foot** associated with **neuropathy and/or peripheral artery disease** in a person with diabetes.
2. The majority of the elderly diabetic population is **at increased risk of foot ulceration**; foot ulcer independently predicts **amputation and mortality**.
3. **About 70% of lower-limb amputations are precipitated by foot ulceration**, and **three-year survival after major amputation is only about 50%** — worse than many cancers.
4. Increasing age and a higher level of amputation both increase **length of hospitalisation and cost**.

B. Risk Factors (Pathy's Table 86.3)

5. **Peripheral sensorimotor neuropathy** (the primary cause in the vast majority), **autonomic neuropathy**, **peripheral vascular disease**, **limited joint mobility**, **abnormal foot pressures and deformity**, **previous foot problems**, **visual loss**, and **alcohol excess**.
6. **Limited joint mobility and visual loss** are specifically geriatric — they impair the patient's ability to **inspect their own feet**.
7. In India, additional risks are **barefoot walking, ill-fitting footwear, delayed presentation, use of traditional remedies, and poor glycaemic control**.

C. Pathogenesis

8. **Neuropathy** causes loss of protective sensation, small-muscle wasting with clawing and high plantar pressures, and callus formation over metatarsal heads.
9. **Autonomic neuropathy** produces dry, fissured skin and arteriovenous shunting with a warm, well-perfused but vulnerable foot.
10. **Peripheral artery disease** in diabetes is typically **infra-popliteal and multi-segmental**, with medial calcification producing falsely high ankle pressures.

D. Clinical Features and Assessment

11. Neuropathic symptoms include **numbness, burning or lancinating pain, "pins and needles" and hyperaesthesia, typically worse at night**, with gait disturbance and falls.
12. **Diabetic ulcers form at weight-bearing sites** — metatarsal heads and heel — and are typically **deep, with undermined edges and surrounding hyperkeratosis, and painless**.
13. Assessment: **10 g Semmes-Weinstein monofilament, 128 Hz tuning fork, ankle reflexes, ankle-brachial index and toe pressures, pedal pulses, footwear inspection**, and **probe-to-bone test** for osteomyelitis.
14. **Charcot neuroarthropathy** presents as a hot, swollen, erythematous foot with preserved pulses; misdiagnosis as cellulitis or gout leads to permanent midfoot collapse (rocker-bottom foot).

E. Management

15. Management addresses the **underlying aetiology plus debridement, control of infection, appropriate dressings and offloading**, with **optimum glycaemic control** as the metabolic foundation.
16. **Offloading** is the single most important intervention for a neuropathic plantar ulcer; **revascularisation** is the key intervention in an ischaemic ulcer.
17. **Infection** is graded clinically; mild infections need oral Gram-positive cover, moderate/severe need broad-spectrum cover, urgent surgical drainage and admission.
18. **Multidisciplinary foot care team** — diabetologist, podiatrist, vascular surgeon, orthotist, microbiologist and specialist nurse — reduces amputation rates.
19. **Prevention**: annual risk stratification, daily foot inspection (with a mirror or by a relative if vision is poor), never walking barefoot, therapeutic footwear, professional nail and callus care, and prompt reporting of any lesion.
20. Careful caution: **corn plasters containing salicylic acid have caused ulceration** in diabetic patients with poor skin

integrity or neuropathy, and must be avoided.

Latest Updates (2023–Present)

- **IWGDF 2023 Guidelines** (practical, classification, prevention, offloading, infection with IDSA, PAD with ESVS/SVS, wound healing) are the current international standard.
- **Classification**: **SINBAD** (Site, Ischaemia, Neuropathy, Bacterial infection, Area, Depth) is now the **priority system for inter-professional communication and audit**; infection is graded by **IWGDF/IDSA** and ischaemia by **WIfI**. Ulcers are described as **neuropathic, neuro-ischaemic or ischaemic**.
- **Offloading**: a **non-removable knee-high device (total contact cast or rendered-irremovable walker) is first choice** for neuropathic plantar forefoot ulcers; a removable knee- or ankle-high device is second choice; **felted foam** is an alternative where nothing else is available.
- **Adjunctive wound therapies** (only after 4–6 weeks of failed optimal care): **sucrose-octasulfate impregnated dressing** in non-infected neuro-ischaemic ulcers without severe ischaemia; **autologous leucocyte/platelet/fibrin patch**; **placental membrane allografts**; **systemic hyperbaric oxygen** in ischaemic ulcers; **topical oxygen** in non-healing non-infected ulcers.
- **Strong negative recommendations**: do **not** use **topical phenytoin** or **herbal-impregnated dressings** for wound healing — directly relevant to Indian practice where such applications are common.
- **IWGDF/IDSA 2023 infection guideline** supports **shorter antibiotic courses**, including approximately **3 weeks rather than 6 weeks** for diabetic foot osteomyelitis when infected bone has been surgically resected, and diagnosis of soft-tissue infection on **clinical inflammatory signs** rather than swab culture.
- **India**: rising diabetic foot burden with LASI data showing high undiagnosed diabetes in older adults; **NPCDCS foot-care screening** and district-level podiatry services remain the main structural gap.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Ulcer classification	Wagner / University of Texas	**SINBAD** for communication and audit; **WIfI** for ischaemia; **IWGDF/IDSA** for infection
Offloading	Debridement, dressings, offloading (general)	**Non-removable knee-high device is first-line**, explicitly ranked above all alternatives
Advanced dressings	Wound Healing Society guidance	**Sucrose-octasulfate, leucocyte-platelet-fibrin patch, placental allografts** — but only after 4–6 weeks of failed standard care
Herbal/topical agents	Not addressed	**Strongly advised against** (phenytoin, herbal dressings)
Osteomyelitis antibiotics	Prolonged courses	**~3 weeks post-resection** may suffice; shorter courses favoured

Exam One-Liners

- **70% of amputations follow an ulcer; 3-year survival after amputation ≈ 50%**.
- **Neuropathy is the commonest single contributor**; PAD determines healing.
- **SINBAD** is the current first-choice ulcer classification.
- **Total contact cast** is the gold standard for the neuropathic plantar ulcer.
- A **hot swollen foot with good pulses = Charcot until proved otherwise**.
- **Never use corn plasters or herbal dressings** on a diabetic foot.

Q5. Testosterone Replacement Therapy in the Older Male

A. Physiological Background

1. After age 30, **free testosterone falls by about 1% per year**; in the European Male Ageing Study **total testosterone fell 0.4% and free testosterone 1.3% per year between ages 40 and 79**.
2. The fall in free testosterone is steeper because **SHBG rises with age**, binding more of the total hormone.
3. Ageing produces **reduced episodic and stimulated gonadotrophin secretion** together with **reduced Leydig-cell responsiveness to LH** — a mixed primary and secondary defect.

B. Definition and Diagnosis

4. **Hypogonadism** requires **both a subnormal serum testosterone and symptoms attributable to it** — a biochemical value alone is not a diagnosis.
5. Sample **between 07:00 and 11:00 hours, fasting, on two separate occasions**; measure **free or bioavailable testosterone** when SHBG is altered (obesity, ageing, liver disease, thyroid disease).
6. The **harmonised reference range for total testosterone is 264–916 ng/dL** in non-obese men aged 19–39; **age-adjusted reference ranges are not recommended**.
7. Follow-up tests: **LH and FSH** (to separate primary from secondary), **prolactin, iron studies, pituitary MRI** if secondary with very low testosterone, and a **karyotype** in young men with very small testes.

C. Indications and Contraindications

8. **Do not replace testosterone in asymptomatic older men with an age-related decline**; offer therapy on an **individualised basis after explicit discussion of risks and benefits** to symptomatic men with confirmed low levels.
9. **Absolute contraindications**: prostate carcinoma, breast cancer, prostate nodule or induration, unexplained PSA elevation, **haematocrit >50%**, unstable heart failure (NYHA III–IV), severe untreated sleep apnoea, and **severe LUTS with IPSS >19**.
10. Severe LUTS is a **relative contraindication that ceases to apply once the outflow obstruction is treated**.

D. Benefits and Expected Time Course

11. Testosterone increases **lean body mass, muscle strength, bone mineral density, erythropoiesis and libido**; in men it improves erectile strength, ejaculate volume and visuospatial cognition.
12. Time course: **libido, mood and energy improve within 3 months; fat mass, lean mass, insulin sensitivity and haemoglobin change at 3–6 months; BMD requires at least 1 year**.
13. The **Testosterone Trials (T Trials, 790 men aged >65)** showed **moderate benefit for sexual function, some benefit for mood and depressive symptoms, but no benefit for vitality or walking distance**.

E. Preparations, Targets and Monitoring

14. Available as **intramuscular esters (cypionate, enanthate — 2-weekly, often given weekly to reduce peaks and troughs), long-acting undecanoate, transdermal gels and patches, buccal, nasal gel and subcutaneous pellets**.
15. **Short-acting preparations are preferred initially**, so that therapy can be stopped quickly if adverse effects occur.
16. Target a **serum testosterone of 300–500 ng/dL in older men** — deliberately lower than the 500–600 ng/dL aimed for in the young — to minimise risk.
17. Check the level **within 3 months of starting**; for injections sample midway between doses, for transdermal gels about 6 hours after application.
18. Monitor **haematocrit, PSA and digital rectal examination at 3, 6 and 12 months, then annually**; the **major adverse effect is an excessive rise in haematocrit**. Other effects include gynaecomastia, fluid retention and transient worsening of sleep apnoea.
19. If symptoms do not improve, **stop treatment and investigate other causes**. **Selective androgen receptor modulators (SARMs)** are under development to avoid these adverse effects.

Latest Updates (2023–Present)

- **TRAVERSE trial (NEJM, 2023)** — 5,246 men aged 45–80 with hypogonadism and pre-existing or high cardiovascular risk. Testosterone gel was **non-inferior to placebo for major adverse cardiovascular events**, resolving a decade-old controversy.
- TRAVERSE nevertheless showed **significantly more atrial fibrillation (3.5% vs 2.4%), pulmonary embolism (0.9% vs 0.5%) and acute kidney injury (2.3% vs 1.5%)** in the testosterone arm — clinically important in older, comorbid men.
- **TRAVERSE Fracture subtrial (NEJM, 2024)** — testosterone **did not reduce, and numerically increased, clinical fractures** despite improving bone density in earlier studies. **Testosterone must not be prescribed for fracture prevention.**
- Testosterone **corrected anaemia** in hypogonadal men in a TRAVERSE substudy, and improved measures of glycaemia — potentially useful secondary benefits.
- The **European Expert Panel for Testosterone Research position statement (2025)** integrates TRAVERSE into practice, reaffirming that therapy is appropriate for **symptomatic, biochemically confirmed hypogonadism** with **structured haematocrit and PSA monitoring**, and is not a treatment for ageing.
- The **FDA labelling change (2025)** removed the broad cardiovascular warning while adding a **blood-pressure warning** for testosterone products.
- Emerging evidence links **weight loss (including with GLP-1 receptor agonists and bariatric surgery)** to

substantial rises in endogenous testosterone in obesity-related functional hypogonadism, supporting a **"treat the cause first"** approach.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Cardiovascular safety	Lack of long-term data; possible excess events in ≥65 in the first year	**TRAVERSE 2023: non-inferior for MACE** in high-risk men
Specific cardiac risks	Not quantified	**Increased atrial fibrillation, pulmonary embolism and AKI**
Bone/fracture	Increases BMD; fracture data unavailable	**TRAVERSE Fracture subtrial: no reduction, numerically more fractures**
Anaemia	Erythropoiesis noted as a benefit/risk	Formal evidence of **correction of unexplained anaemia**
Obesity-related low T	Comorbidity noted	**Weight loss first**; functional hypogonadism often reverses

Exam One-Liners

- **Symptoms + two low morning testosterone levels** = hypogonadism; a number alone is not.
- Reference range **264–916 ng/dL**; treat older men to **300–500 ng/dL**.
- **TRAVERSE: no excess MACE, but more AF, PE and AKI**.
- **Do not give testosterone to prevent fractures**.
- Monitor **haematocrit, PSA and DRE at 3, 6, 12 months then annually**.
- **IPSS >19, haematocrit >50%, prostate cancer** are contraindications.

Q6. Andropause

A. Terminology and Concept

1. Strictly, **"andropause" does not exist** — unlike the female menopause there is **no precipitous, universal loss of gonadal function** in men.
2. What occurs is a **gradual, variable decline in testosterone** with a continuously rising prevalence of low levels; this is termed **late-onset hypogonadism (LOH)**.
3. Even the term LOH is imperfect, because the decline is **continuous throughout adult life**, not confined to old age.
4. **LOH is defined as an age-associated clinical and biochemical syndrome** with symptoms and signs of hypogonadism plus serum testosterone below the young adult reference range.

B. Epidemiology

5. Although hypogonadal symptoms occur at least once in life in most men after age 50, the **prevalence of true LOH is only about 2–3%**.
6. Hypogonadism is **common but under-diagnosed and under-treated** in older men — only an estimated **5–35% of hypogonadal men receive treatment**.
7. Prevalence rises with **obesity, type 2 diabetes, metabolic syndrome, chronic illness, opioid use and glucocorticoid therapy** — i.e. it is largely **comorbidity-driven, not age-driven**.

C. Pathophysiology

8. A **combined primary and secondary defect**: reduced Leydig-cell responsiveness to LH (testicular) plus reduced episodic and stimulated gonadotrophin secretion (hypothalamo-pituitary).
9. **SHBG rises with age**, so free testosterone falls faster than total testosterone; measuring only total testosterone underestimates the deficit.
10. **Hypogonadotropic hypogonadism is frequent in type 2 diabetes and obesity**, mediated by insulin resistance, inflammation and aromatisation of androgen to oestrogen in adipose tissue — this form is often **reversible**.

D. Clinical Features

11. **Sexual symptoms are the most specific**: loss of morning erections, reduced sexual thoughts, and erectile dysfunction.

12. **Non-specific symptoms** overlap heavily with ageing and comorbidity: fatigue, low mood, poor concentration, reduced muscle mass and strength, increased visceral fat, decreased bone density, hot flushes, sweating and sleep disturbance.
13. Because of this overlap, **screening questionnaires (ADAM, AMS)** are sensitive but have **poor specificity** and are not recommended for case-finding.

E. Differential Diagnosis and Management

14. Exclude **depression, hypothyroidism, obstructive sleep apnoea, anaemia, chronic kidney or liver disease, malignancy, alcohol excess, opioids and glucocorticoids** before attributing symptoms to testosterone.
15. **Confirm biochemically** with two morning samples, plus LH/FSH, prolactin and (if indicated) pituitary imaging.
16. **First-line management is not hormonal**: weight reduction, exercise (especially resistance training), treatment of sleep apnoea and diabetes, and withdrawal of opioids or glucocorticoids where possible.
17. **Testosterone therapy is reserved for men with both low testosterone and clinically important symptoms**, after explicit discussion of risks and with the same monitoring and contraindications as any testosterone replacement.
18. Related age-related declines — **"adrenopause" (DHEA)** and **"somatopause" (GH/IGF-1)** — are similarly not indications for routine replacement; there is **no indication for testosterone treatment in the majority of adult men**.

Latest Updates (2023–Present)

- The concept of **functional versus organic hypogonadism** now dominates. **Functional hypogonadism** (obesity, diabetes, chronic illness, drugs) is potentially reversible and should be treated by correcting the cause; **organic hypogonadism** (structural hypothalamic, pituitary or testicular disease) requires replacement.
- **TRAVERSE (2023)** provided the reassurance that testosterone does not increase MACE in symptomatic hypogonadal men, but the **fracture subtrial (2024) and the excess of atrial fibrillation, pulmonary embolism and AKI** mean the risk–benefit conversation is now more nuanced, not less.
- The **European Expert Panel for Testosterone Research (2025)** and contemporary endocrine society positions maintain that **population screening for low testosterone in ageing men is not justified**.
- **Substantial weight loss** — through lifestyle, bariatric surgery or GLP-1 receptor agonists — reliably raises endogenous testosterone in obesity-related functional hypogonadism, and is now the recommended first intervention.
- Increasing concern about **direct-to-consumer "men's health" and anti-ageing clinics** prescribing testosterone without diagnostic confirmation; this is an important prescribing-safety and medico-legal issue in urban Indian practice as well.
- **Testosterone is being reframed as a quality-of-life drug**, not a disease-modifying or longevity therapy.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
The term "andropause"	Rejected — no true male menopause	Unchanged; **LOH**, and increasingly **functional vs organic hypogonadism**
Cause of low testosterone in old age	Ageing plus comorbidity	Emphasis firmly on **comorbidity and obesity as the dominant reversible drivers**
First-line treatment	Testosterone if symptomatic and low	**Weight loss and treatment of comorbidity first**; testosterone if this fails
Cardiovascular safety	Uncertain, possible excess events	**TRAVERSE: MACE non-inferior**, but AF/PE/AKI signals
Screening	Not recommended	Reaffirmed — **no population screening**

Exam One-Liners

- **Andropause does not exist** — use **late-onset hypogonadism**.
- **Prevalence of true LOH ≈ 2–3%** despite symptoms being near-universal.
- **Sexual symptoms are the most specific**; ADAM and AMS lack specificity.
- **Free testosterone falls faster than total** because **SHBG rises**.
- **Functional hypogonadism is reversible** — treat obesity and diabetes first.
- **No indication for testosterone in most adult men.**

Q7. Alpha Receptor Antagonists

A. Classification

1. **Non-selective (α1 + α2)**: **phenoxybenzamine** (irreversible) and **phentolamine** (reversible) — used in phaeochromocytoma.
2. **Selective α1 (non-subtype-selective)**: **prazosin** (short-acting), **terazosin, doxazosin** (long-acting), **alfuzosin** (functionally uroselective).
3. **α1A-subtype selective ("uroselective")**: **tamsulosin, silodosin**; **naftopidil** is relatively α1D-selective.
4. **Selective α2 antagonists**: **yohimbine, idazoxan** — of historical/limited use.

B. Pharmacological Basis

5. The **bladder neck, prostatic stroma and prostatic urethra are rich in α1A receptors**; blockade relaxes smooth muscle, lowers tonic luminal pressure in the prostatic fossa and improves urine outflow.
6. **Vascular smooth muscle carries α1B receptors**; blocking these causes **vasodilatation, postural hypotension and reflex tachycardia** — the basis of most adverse effects.
7. **α1D receptors** in the bladder body and spinal cord may mediate storage symptoms such as urgency and nocturia.
8. Uroselective agents (tamsulosin, silodosin) act preferentially on α1A and therefore cause **less hypotension**, broadening the population of elderly men who can be treated safely.

C. Clinical Uses

9. **Lower urinary tract symptoms due to BPH** — the principal use, and an **excellent first-line option for men with bothersome symptoms who want treatment**. Alfuzosin, doxazosin, tamsulosin, terazosin and silodosin are all appropriate.
10. Alpha blockers give **rapid symptom relief within days**, but **do not alter the natural history of the disease** and **do not prevent long-term bladder outflow obstruction**.
11. **Combination with a 5α-reductase inhibitor** is appropriate when the prostate exceeds about 40 mL. In the **MTOPS study**, combination therapy reduced acute urinary retention by **66%**, versus **39% for alpha blockade alone and 34% for finasteride alone**.
12. After **6–9 months of successful combination therapy the alpha blocker may be withdrawn**, restarting it if symptoms recur.
13. Other uses: **phaeochromocytoma** (phenoxybenzamine pre-operatively), **resistant hypertension** (as add-on only), **medical expulsive therapy for distal ureteric stones**, **prazosin for PTSD-related nightmares**, and **scorpion envenomation (prazosin)** — relevant in Indian practice.
14. Alpha blockers have **not been shown to reduce symptoms of chronic prostatitis/chronic pelvic pain syndrome**, and increased dizziness and postural hypotension in trials.

D. Adverse Effects — Particular Relevance in the Elderly

15. **First-dose and postural hypotension, dizziness, syncope, asthenia, headache and rhinitis** occur in about **5–9%**; these led to **falls, fractures and institutionalisation** in older men in observational studies.
16. Early agents were designed as antihypertensives, so **orthostasis was a significant problem**; normotensive men also complained of asthenia and fatigue. Dose titration at bedtime reduces this.
17. **Intraoperative floppy iris syndrome (IFIS)** — iris billowing, prolapse and progressive miosis during cataract surgery. **Tamsulosin carries by far the highest risk**; stopping the drug does not reliably prevent it, so the **ophthalmologist must be informed before surgery**.
18. **Retrograde or absent ejaculation** is common, especially with **silodosin and tamsulosin** — a frequently under-discussed quality-of-life issue.
19. **Interactions**: additive hypotension with **PDE5 inhibitors, nitrates, diuretics and other antihypertensives**; caution in patients with **autonomic failure or Parkinson's disease**.
20. **Beers criteria advise against using peripheral α1 blockers as routine antihypertensives in older adults** because of orthostatic hypotension; in **ALLHAT the doxazosin arm was terminated early** for excess heart failure.

Latest Updates (2023–Present)

- **AUA LUTS/BPH Guideline (2023 amendment; comprehensive three-part guideline 2026)** retains alpha blockers as **first-line medical therapy**, but places far greater emphasis on **shared decision-making about sexual side-effects** and on **minimally invasive surgical therapies (MIST)** — prostatic urethral lift, water vapour thermal therapy, Aquablation, prostatic artery embolisation — for men who wish to avoid drug side-effects or preserve ejaculatory function.
- **Network meta-analysis and FAERS pharmacovigilance data (2022–2025)** confirm the IFIS hierarchy: **tamsulosin has a markedly higher risk than terazosin, alfuzosin or doxazosin**, with silodosin showing less mesopic pupil

constriction. Documentation of alpha blocker use is now a **standard pre-cataract-surgery checklist item**.

- **Observational cohort studies (2023–2025)** have reported associations between tamsulosin and **dementia, Parkinson's disease and depression** compared with other alpha blockers. These are **hypothesis-generating and confounded by indication**; no causal link is established, and guidelines have not changed prescribing.
- Conversely, some pharmaco-epidemiological work has suggested **terazosin and doxazosin may be neuroprotective** via PGK1-mediated enhancement of glycolysis — again unproven.
- **Medical expulsive therapy**: current urological guidance restricts alpha blockers to **distal ureteric stones larger than about 5 mm**, following the negative SUSPEND trial.
- Deprescribing literature increasingly identifies alpha blockers as **high-value targets for review in older fallers**, alongside sedatives and antihypertensives.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Place in BPH therapy	First-line for bothersome LUTS	Unchanged, but **MIST offered earlier** for men prioritising sexual function
IFIS	Recognised association	**Risk hierarchy quantified**; tamsulosin far highest; mandatory pre-operative disclosure
Neuropsychiatric safety	Not addressed	Observational **dementia/Parkinson signals with tamsulosin — unproven, no change in practice**
Use as antihypertensive	Historical indication	**Avoid as routine antihypertensive** in older adults (Beers, ALLHAT)
Ureteric stones	Adjunct use	Restricted to **distal stones >5 mm**
Chronic pelvic pain	Sometimes used	**Not recommended** — no benefit, more adverse effects

Exam One-Liners

- **α1A = prostate, α1B = vasculature, α1D = bladder body** — the basis of uroselectivity.
- **Tamsulosin and silodosin** are uroselective; **prazosin, terazosin, doxazosin** are not.
- **MTOPS: combination therapy reduced acute retention by 66%**.
- **Tamsulosin is the classic cause of intraoperative floppy iris syndrome**.
- **Silodosin causes the most retrograde ejaculation**.
- **Do not use alpha blockers as first-line antihypertensives in older adults** (Beers/ALLHAT).

Q8. Hyponatremia

A. Definition and Significance

1. **Hyponatraemia is a serum sodium below 135 mEq/L** and is the commonest electrolyte disorder in hospitalised patients, associated with increased morbidity, mortality, length of stay and cost.
2. Severity: **mild 130–134 mEq/L, moderate 125–129 mEq/L, profound/severe below 125 mEq/L**; by duration, **acute (<48 hours)** or **chronic**.
3. **Older patients are more susceptible and may show cognitive impairment even with mild hyponatraemia** — a fall in sodium, especially if rapid, can cause cerebral oedema, lethargy, seizures, coma and death.

B. Why the Elderly Are Predisposed

4. **Age-related tubular changes**: reduced sodium reabsorption in the thick ascending limb producing "senile sodium leakage", medullary hypotonicity, and inability to concentrate urine maximally.
5. **Reduced plasma renin and aldosterone** with blunted responses, plus **elevated natriuretic peptides**, enhance urinary sodium loss.
6. **Exaggerated vasopressin response to a hyperosmolar stimulus** with impaired baroreceptor-mediated suppression — older people over-secrete ADH.
7. Reduced renal blood flow and reduced ability to **excrete a water load**; salt-restricted diets and poor appetite compound the problem.

C. Causes in Older People

8. **Drugs are the leading cause** — **thiazide diuretics** (classic), SSRIs, SNRIs, tricyclics, carbamazepine and oxcarbazepine, antipsychotics, PPIs, NSAIDs, desmopressin, chlorpropamide, vincristine, ifosfamide, cyclophosphamide and opioids.
9. **SIADH** — from CNS disease (stroke, haemorrhage, infection, metastases), pulmonary disease (pneumonia, tuberculosis, tumour), and **small-cell carcinoma of the lung** as a paraneoplastic syndrome.
10. **Hypovolaemic**: vomiting, diarrhoea, diuretics, third-space losses, cerebral salt wasting, mineralocorticoid deficiency.
11. **Hypervolaemic**: heart failure, cirrhosis, nephrotic syndrome, advanced CKD.
12. **Endocrine**: hypothyroidism, glucocorticoid deficiency and **abrupt withdrawal of glucocorticoid therapy**.
13. **Low solute intake**: "tea-and-toast" diet and beer potomania — very relevant to socially isolated older Indians on rice-and-tea diets.
14. **Pseudohyponatraemia** (hyperlipidaemia, paraproteinaemia) and **translocational hyponatraemia** (hyperglycaemia, mannitol) must be excluded first.

D. Investigation

15. **Step 1: serum osmolality** — exclude pseudo- and translocational hyponatraemia. **Step 2: urine osmolality** — <100 mOsm/kg suggests primary polydipsia or low solute intake. **Step 3: urine sodium** — <20 mEq/L suggests hypovolaemia or oedematous states; >30–40 mEq/L suggests SIADH, diuretics or adrenal insufficiency. **Step 4: clinical volume status.**
16. **Diagnostic criteria for SIADH**: sodium <135 mEq/L, **plasma osmolality <280 mOsm/kg, urine osmolality inappropriately high (>500 mOsm/kg), urine sodium >20 mEq/L**, clinical euvolaemia, and normal renal, adrenal and thyroid function.
17. Additional tests: **thyroid function, 9 a.m. cortisol or short Synacthen test, blood urea and uric acid** (low uric acid supports SIADH), chest imaging and CT head if a cause is not evident.

E. Management

18. **Severe symptoms (seizures, coma, respiratory arrest): 3% hypertonic saline 100–150 mL as an intravenous bolus**, repeated up to three times as needed, aiming for a **rapid initial rise of 4–6 mEq/L** to relieve cerebral oedema.
19. **Correction limits are critical: no more than 8–10 mEq/L in 24 hours and 18 mEq/L in 48 hours**, and no more than **8 mEq/L/24 h in high-risk patients** (alcoholism, malnutrition, hypokalaemia, liver disease, sodium <105 mEq/L) — to prevent **osmotic demyelination syndrome**.
20. **Chronic asymptomatic hyponatraemia**: treat the cause, **stop the offending drug**, and use **fluid restriction (typically 500–1000 mL/day)** with adequate salt and protein intake.
21. **Second-line agents**: **oral urea 15–60 g/day** (effective, safe, cheap), **loop diuretic with oral salt**, **demeclocycline**, and **tolvaptan** in euvolaemic or hypervolaemic SIADH with high ADH activity.
22. If **over-correction occurs, re-lower the sodium** with 5% dextrose with or without **desmopressin**; monitor sodium 2–4 hourly during active correction.
23. Long-term consequences even of mild chronic hyponatraemia include **gait instability, attention deficits, falls, osteoporosis and fractures** — an important geriatric syndrome, not a laboratory curiosity.

Latest Updates (2023–Present)

- **"Hyponatraemia — Treatment Standard 2024" (Nephrology Dialysis Transplantation)** is the current reference standard. It endorses **3% saline as a 100–150 mL bolus or continuous infusion**, with the choice determined by symptom severity and persistence.
- The same standard states that **rapid intermittent bolus administration is preferred** for symptomatic hyponatraemia, based on the **SALSA randomised trial**, which found bolus and continuous infusion equally effective and safe, with **bolus therapy requiring less therapeutic re-lowering** and being simpler to administer (no calculation needed).
- **Fixed-dose bolus regimens can over- or under-correct**, particularly in **low-body-weight and low-BMI patients** — a group that includes many frail older Indian patients; weight-based adjustment and frequent monitoring are advised.
- **Oral urea** has re-emerged as a highly effective and safe second-line therapy for SIADH, now favoured over demeclocycline and, in many settings, over vaptans on grounds of cost and safety.
- **Peripheral administration of 3% saline** through a large-bore cannula is now accepted as safe in most settings, removing the delay caused by waiting for central access.
- **SGLT2 inhibitors (empagliflozin) have shown benefit in SIADH** in randomised work, by inducing osmotic diuresis — a promising but not yet standard option.
- Current guidance emphasises **gradual correction with clinical evaluation rather than rapid normalisation to the laboratory reference range**, and readiness to give hypotonic fluid or desmopressin if correction runs ahead.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Method of hypertonic saline	Infusion with furosemide and saline replacement	**Rapid intermittent 100–150 mL boluses of 3% saline preferred** (SALSA)
Correction limit	Not exceeding ~20 mEq/L over 48 hours	**≤8–10 mEq/L/24 h and ≤18 mEq/L/48 h**; ≤8 if high ODS risk
Second-line therapy	Demeclocycline for resistant SIADH	**Oral urea** favoured; demeclocycline largely superseded
Vaptans	Not established	Defined role in **euvolaemic/hypervolaemic high-ADH states**, with protocolised monitoring
Over-correction	Avoid	**Active re-lowering** with 5% dextrose ± desmopressin is standard rescue
Mild chronic hyponatraemia	Often observed	Treated because of **falls, fractures, gait and cognitive effects**

Exam One-Liners

- **Sodium <135 mEq/L**; profound below **125 mEq/L**.
- **Thiazides and SSRIs** are the commonest drug causes in the elderly.
- **SIADH: euvolaemic, urine osmolality >500 mOsm/kg, urine sodium >20 mEq/L, low uric acid**.
- **3% saline 100–150 mL bolus** for seizures or coma; aim for a **4–6 mEq/L rise**.
- **Never exceed 8–10 mEq/L in 24 hours** — osmotic demyelination.
- **Oral urea** is the modern second-line agent for chronic SIADH.

Q9. Hyperkalemia

A. Definition and Ageing Physiology

1. **Hyperkalaemia is a serum potassium above 5.0–5.5 mEq/L**; it is life-threatening above **6.5 mEq/L** or with any ECG change.
2. **Total body potassium is lower in the old** because of reduced muscle mass and poor dietary intake, so a normal or high serum level may coexist with total-body depletion.
3. **Renal potassium excretion is significantly reduced in ageing**, explained by **reduced serum aldosterone and reduced tubular responsiveness to aldosterone** (hyporeninaemic hypoaldosteronism), plus increased activity of the H+/K+-ATPase pump in the collecting duct.
4. Reduced GFR with age means that any additional potassium load is poorly handled — the elderly kidney has **little reserve**.

B. Causes

5. **Drugs are the dominant cause**: ACE inhibitors, ARBs, **mineralocorticoid receptor antagonists (spironolactone, eplerenone)**, potassium-sparing diuretics, **NSAIDs, trimethoprim/co-trimoxazole, heparin, beta-blockers, digoxin toxicity, calcineurin inhibitors**, and potassium supplements.
6. **Renal**: acute kidney injury, chronic kidney disease (especially stage 4–5), obstructive uropathy, and type 4 renal tubular acidosis (classically in diabetic nephropathy).
7. **Transcellular shift**: metabolic acidosis, insulin deficiency and hyperglycaemia, beta-blockade, rhabdomyolysis, tumour lysis syndrome, massive haemolysis, and suxamethonium.
8. **Endocrine**: adrenal insufficiency, isolated hypoaldosteronism.
9. **Dietary/iatrogenic**: **potassium-based "low-sodium" salt substitutes** (increasingly used in India for hypertension), coconut water, banana, citrus, stored blood transfusion.
10. **Pseudohyperkalaemia** — haemolysed sample, prolonged tourniquet, fist clenching, marked leucocytosis or thrombocytosis — must be excluded before treatment.

C. Clinical Features and ECG

11. Symptoms are **non-specific**: muscle weakness, flaccid paralysis, paraesthesiae, palpitations, and sometimes cardiac arrest as the first manifestation.
12. **Progressive ECG sequence**: **tall peaked T waves → flattened P waves with PR prolongation → widening QRS →**

sine wave pattern → asystole or ventricular fibrillation.

13. The ECG is **insensitive** — a normal ECG does not exclude dangerous hyperkalaemia, and the rate of rise matters as much as the absolute value.

D. Emergency Management (the "5-step" approach)

14. **1. Protect the myocardium**: **10 mL of 10% calcium gluconate intravenously over 2–5 minutes**, repeated if ECG changes persist. Onset is immediate but lasts only 30–60 minutes; use calcium chloride via a central line if severe. Use with great caution in digoxin toxicity.
15. **2. Shift potassium into cells**: **10 units of soluble insulin in 25 g of dextrose (50 mL of 50% or 125 mL of 20%)** intravenously over 15–30 minutes, plus **nebulised salbutamol 10–20 mg**. **Sodium bicarbonate** only if there is significant metabolic acidosis.
16. **3. Remove potassium from the body**: **loop diuretic with volume repletion**, **potassium binders**, and **haemodialysis** for severe or refractory hyperkalaemia, oliguric AKI or ESRD.
17. **4. Stop the source**: discontinue causative drugs, potassium supplements and salt substitutes; restrict dietary potassium.
18. **5. Monitor**: continuous ECG, and repeat potassium at 1, 2, 4 and 6 hours — **rebound hyperkalaemia is common** once the insulin effect wanes.
19. **Hypoglycaemia after insulin–dextrose is the commonest iatrogenic complication**, occurring in up to a fifth of patients — particularly in the elderly, in CKD, and in those not eating; monitor capillary glucose hourly for at least 6 hours.

E. Chronic Management

20. Long-term management aims to **allow continuation of prognostically important RAAS inhibitors** rather than stopping them: dietary counselling, correction of metabolic acidosis with **sodium bicarbonate**, use of loop or thiazide diuretics, and **potassium binders**.
21. **Sodium polystyrene sulfonate** is slow, unpalatable and carries a warning for **serious gastrointestinal necrosis**, especially with sorbitol — its role is now limited.

Latest Updates (2023–Present)

- **New potassium binders** have transformed chronic management. **Patiromer** (exchanges potassium for calcium in the distal colon) and **sodium zirconium cyclosilicate (SZC)** (exchanges sodium and hydrogen for potassium, onset within 1 hour) both give rapid and sustained potassium reduction with good tolerability.
- **KDIGO 2024 CKD guideline** and **ESC heart failure and ESH hypertension guidelines** recommend potassium binders specifically **to enable optimisation and continuation of RAAS inhibitor and MRA therapy** rather than dose reduction or withdrawal.
- The **DIAMOND trial** showed patiromer enabled more patients with heart failure to remain on target-dose RAAS inhibition; **AMBER** showed the same for spironolactone in resistant hypertension with CKD; SZC has similar data for spironolactone optimisation in heart failure (JACC, 2025).
- Consensus recommendations (2023–2025) stress a **proactive, long-term-condition model**: check potassium before starting a RAAS inhibitor and regularly thereafter, and **treat the hyperkalaemia before reducing the RAAS inhibitor**, because RAAS inhibitor withdrawal itself worsens cardiovascular and renal outcomes and mortality.
- **Lower-dose insulin regimens (0.1 units/kg, maximum 10 units)** are increasingly used in place of a fixed 10-unit dose to reduce hypoglycaemia in elderly patients and those with CKD, with comparable potassium lowering.
- Emergency-department use of oral potassium binders is being studied as a way to **avoid admission** in stable hyperkalaemic patients; real-world data (2025) suggest more patients can be discharged directly.
- **Public health caution**: potassium-enriched salt substitutes reduce stroke at population level, but pose a **real hyperkalaemia hazard in older adults with CKD, diabetes or on RAAS inhibitors** — patients must be asked specifically about them.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Chronic binder therapy	Sodium polystyrene sulfonate	**Patiromer and SZC** preferred; SPS carries GI necrosis warning
RAAS inhibitors after hyperkalaemia	Reduce or stop	**Treat the potassium and continue the RAAS inhibitor** (KDIGO 2024, ESC)
Insulin dose for shift	10 units with dextrose	**0.1 units/kg (max 10 units)** to reduce hypoglycaemia in elderly/CKD
Post-treatment monitoring	Repeat potassium	**Mandatory hourly capillary glucose for ≥6 hours** — hypoglycaemia is common
Salt substitutes	Not addressed	Recognised **modern cause** of hyperkalaemia in older adults

Exam One-Liners

- **Ageing kidney = hyporeninaemic hypoaldosteronism** → poor potassium excretion.
- **Calcium gluconate stabilises the myocardium but does not lower potassium**.
- **Insulin–dextrose plus nebulised salbutamol** shift; **diuretics, binders and dialysis** remove.
- **A normal ECG does not exclude dangerous hyperkalaemia.**
- **Patiromer and SZC allow RAAS inhibitors to be continued** — treat the potassium, not the prescription.
- Always ask about **"low-sodium" salt substitutes**.

Q10. Management of Recurrent Urinary Tract Infection in the Elderly

A. Definition

1. **Recurrent UTI is ≥2 culture-proven symptomatic episodes in 6 months or ≥3 in 12 months.**
2. Distinguish **relapse** (same organism within 2 weeks — suggests an unresolved focus such as prostatitis, stone or abscess) from **reinfection** (different organism or later — suggests host susceptibility).
3. UTI is **the commonest infection in the elderly** and is especially frequent in debilitated and institutionalised individuals.

B. Why Recurrence Occurs in Older People

4. **Obstructive uropathy** is the strongest pathogenetic association — **benign prostatic hyperplasia in men**, and pelvic organ prolapse or cystocele in women.
5. **Non-obstructive predisposing factors**: **vaginal and urethral atrophy from oestrogen deficiency**, **"puddling" of urine from bed rest and immobility**, and **bladder catheterisation**.
6. **Incomplete bladder emptying with a raised post-void residual**, detrusor underactivity, constipation and faecal incontinence.
7. **Diabetes, immunosenescence, functional dependence, cognitive impairment and previous antibiotic exposure** with resistant flora.
8. In men, **chronic bacterial prostatitis** must be excluded — it classically presents as recurrent UTI with the same organism in the absence of catheterisation.

C. Evaluation

9. **Confirm the diagnosis**: symptomatic episodes with a **positive urine culture** on each occasion — do not diagnose recurrent UTI on urinalysis or on asymptomatic positive cultures.
10. **Review all previous cultures and sensitivities** to guide empirical therapy and to detect ESBL or carbapenem-resistant organisms.
11. **Post-void residual by bladder ultrasound**; **ultrasound of the kidneys, ureters and bladder** for stones, hydronephrosis and prostatic size.
12. **Cystoscopy and upper-tract imaging** if there is **visible or persistent microscopic haematuria, suspected malignancy, obstruction, stone, or persistent infection with a urea-splitting organism**.
13. Assess and treat the **whole geriatric context**: hydration, mobility, toileting access, constipation, incontinence, atrophic vaginitis, glycaemic control and nutrition.

D. Non-Antibiotic Prevention (First Line)

14. **Fluid intake**: increase to at least **1.5 litres per day** where intake is low — a simple measure with randomised

evidence.

15. **Topical vaginal oestrogen** in postmenopausal women restores lactobacilli and vaginal pH and significantly reduces recurrence; **oral oestrogen is not effective and is not recommended**.
16. **Behavioural and hygiene measures**: complete bladder emptying, double voiding, post-coital voiding, avoiding spermicides, treating constipation, and timed toileting in the cognitively impaired.
17. **Methenamine hippurate 1 g twice daily** — converted to formaldehyde in acidic urine; a urinary antiseptic that **does not select for resistance**.
18. **Cranberry products and D-mannose** may be offered, with a clear explanation of modest and inconsistent evidence; **probiotics** have weak supporting data.
19. **Remove or avoid catheters** — this is often the single most effective intervention in the institutionalised patient.

E. Antibiotic Strategies and Stewardship

20. **Antibiotic prophylaxis** is reserved for those failing non-antibiotic measures: **continuous low-dose nightly** (nitrofurantoin, co-trimoxazole, cefalexin), **post-coital single dose**, or **patient-initiated self-start therapy** in cognitively intact women.
21. Prophylaxis should be **time-limited (typically 3–6 months) and reviewed**, with awareness that **benefit is lost once it stops**. **Nitrofurantoin should be avoided in eGFR <45 mL/min** and with long-term use because of pulmonary and hepatic toxicity.
22. **Do not treat asymptomatic bacteriuria**, and **do not perform test-of-cure cultures** in asymptomatic patients — both drive resistance and *Clostridioides difficile* infection without benefit.

Latest Updates (2023–Present)

- **AUA/CUA/SUFU Recurrent Uncomplicated UTI Guideline — 2025 amendment** significantly expands **non-antibiotic prophylaxis**: clinicians may now offer **cranberry, methenamine hippurate, and increased water intake (where intake is below 1.5 L/day)**. It states that **D-mannose alone may not be effective**, and that clinicians should **not perform post-treatment test-of-cure urinalysis or culture in asymptomatic patients**.
- **NICE NG112 (updated December 2024)** now recommends **methenamine hippurate as an alternative to daily antibiotic prophylaxis** in women who have failed behavioural measures, vaginal oestrogen and single-dose prophylaxis.
- The **ALTAR trial (BMJ, 2022)** established **non-inferiority of methenamine hippurate to daily antibiotic prophylaxis** — the pivotal study behind this shift.
- **ImpresU trial (Clinical Microbiology and Infection, 2025)** — the first randomised trial specifically in **women aged ≥70** — found methenamine reduced antibiotic treatments by about **25% during 6 months of treatment**, but with a **rebound increase in infections after stopping**, indicating suppression rather than cure and the need to plan duration and follow-up.
- **Sublingual bacterial vaccines (MV140/Uromune)** have randomised evidence for reducing recurrence over 9–12 months and are available in several countries; **long-term data in frail older adults are still lacking**.
- **Gepotidacin**, a first-in-class triazaacenaphthylene, was approved in 2025 for uncomplicated UTI and is active against many resistant uropathogens — an important future option given Indian resistance rates.
- Emerging emphasis on the **"continuum of UTI"** concept, recognising that many older adults sit between asymptomatic bacteriuria and clear-cut infection, and require observation rather than reflex antibiotics.
- **Indian context**: very high rates of **ESBL-producing *E. coli* and fluoroquinolone resistance** mean that **culture-directed therapy is mandatory**, and **fosfomycin and nitrofurantoin** retain the best oral activity for lower tract disease.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
First-line prophylaxis	Antibiotic prophylaxis after evaluation	**Non-antibiotic measures first** — fluids, vaginal oestrogen, methenamine, cranberry
Methenamine hippurate	Minor role	**Non-inferior to antibiotic prophylaxis** (ALTAR); recommended by NICE 2024 and AUA 2025
Evidence in the very old	Extrapolated	**ImpresU (2025)** provides direct evidence in women ≥70, with rebound after cessation
D-mannose	Promising adjunct	**May not be effective alone** (AUA 2025)
Oestrogen	Vaginal or systemic considered	**Vaginal only**; oral oestrogen not recommended
Test of cure	Often performed	**Should not be performed** in asymptomatic patients

Exam One-Liners

- **≥2 in 6 months or ≥3 in 12 months**, each culture-proven and symptomatic.
- **Relapse = same organism <2 weeks** — look for prostate, stone or abscess.
- **Vaginal (not oral) oestrogen** is a cornerstone in postmenopausal women.
- **Methenamine hippurate is non-inferior to antibiotic prophylaxis** (ALTAR) and does not select resistance.
- **ImpresU: 25% fewer antibiotic courses in women ≥70, but rebound on stopping.**
- **Never treat asymptomatic bacteriuria; never do a test of cure.**

Q11. Asymptomatic Bacteriuria — Definition, Treatment and Prognosis

A. Definition

1. **Asymptomatic bacteriuria (ASB) is significant bacteriuria in the absence of signs or symptoms referable to the urinary tract.**
2. **Microbiological criteria**: in **women**, ≥10^5 CFU/mL of the same organism in **two consecutive** clean-catch voided specimens; in **men**, ≥10^5 CFU/mL in **one** clean-catch specimen; in **either sex**, ≥10^2 CFU/mL from a single catheterised specimen.
3. **Pyuria is not part of the definition** and does **not** convert ASB into infection — most bacteriuric older adults have pyuria.
4. ASB must be distinguished from UTI, which requires **localising genitourinary symptoms or systemic features of infection** in addition to bacteriuria.

B. Epidemiology

5. **Bacteriuria in older persons is common and usually asymptomatic**, and its prevalence **increases with advancing age**.
6. Approximate prevalence: **community-dwelling women over 70 — 10–20%; older men — up to 10%; long-term care facility women — 25–50%; men — 15–40%; patients with a long-term indwelling catheter — essentially 100%**.
7. Predisposing factors are the same as for UTI: **vaginal and urethral atrophy, urinary puddling from bed rest, bladder catheterisation, obstructive uropathy and diabetes**.
8. Prevalence of ASB **roughly parallels the prevalence of urinary incontinence**, so incontinent geriatric patients commonly have significant bacteriuria.
9. Common organisms are **E. coli, Klebsiella, Proteus, Enterococcus** and, in catheterised patients, **polymicrobial and frequently changing flora**.

C. Treatment — When Not To, and When To

10. **In the absence of obstructive uropathy, there is no evidence to support routine antimicrobial therapy for ASB in older persons.**
11. **Do not screen for or treat ASB** in: healthy non-pregnant women, older men and women in the community, **residents of long-term care facilities**, patients with diabetes, patients with spinal cord injury, and patients with indwelling catheters.
12. **Do not treat ASB in an older patient with delirium or a fall but no fever, no haemodynamic instability and no**

localising urinary symptoms — assess for other causes and observe carefully.

13. **Treat ASB only in**: **pregnancy**, and **before urological procedures likely to cause mucosal bleeding** (e.g. TURP, ureteroscopy with stone manipulation), where treatment is given shortly before the procedure.
14. Renal transplant recipients should **not** be routinely treated for ASB beyond the **first month** after transplantation.
15. One exception in the incontinence pathway: in an **incontinent patient with new or worsening incontinence**, bacteriuria may be treated once as part of the initial assessment; however, **eradicating bacteriuria does not affect chronic stable incontinence** in nursing home residents.
16. In patients with an indwelling catheter, **do not perform surveillance cultures** to guide management, because all chronically catheterised patients are bacteriuric, often polymicrobially, and the organisms change frequently.

D. Prognosis

17. **The prognosis of ASB is benign.** Studies suggesting increased mortality did not adjust for age and comorbidity; when adjusted, the excess mortality is explained by the **fatal underlying diseases associated with bacteriuria**, not by the bacteriuria itself.
18. ASB **does not cause progressive renal damage, hypertension or chronic kidney disease** in the non-obstructed urinary tract.
19. **Treatment does not improve survival, does not reduce symptomatic infection and does not improve continence**; earlier studies in hospitalised and institutionalised patients showed treatment was ineffective because of the **very high rate of recurrence**.
20. **Harms of treating ASB are real**: antimicrobial adverse effects, drug interactions, ***Clostridioides difficile*** **infection**, selection of multidrug-resistant organisms, and cost. There is also evidence that **stable bacteriuria may be protective against symptomatic reinfection**, so eradication can be counterproductive.

Latest Updates (2023–Present)

- The **IDSA 2019 Guideline on Asymptomatic Bacteriuria** remains the operative standard and is unchanged in principle; it explicitly recommends **against screening or treating ASB in older residents of long-term care facilities** and in functionally impaired older adults.
- IDSA specifically addresses the geriatric dilemma: in older patients with **functional or cognitive impairment and bacteriuria with delirium but without fever or haemodynamic instability**, the recommendation is **assessment for other causes and careful observation rather than antimicrobial treatment**. Observational data show **no association between bacteriuria and mental status change** after adjustment, and no difference in IL-6 between bacteriuric residents with and without non-specific symptoms.
- **Diagnostic stewardship** is now the central strategy: reduce **unnecessary urine testing**. Tools include the **Loeb minimum criteria** for ordering urine cultures in nursing home residents, the **McGeer surveillance criteria**, and the **AHRQ decision aid** for suspected UTI in long-term care (separate pathways for catheterised and non-catheterised residents).
- A urinalysis **negative for both nitrites and leucocyte esterase essentially rules out acute cystitis** — a useful rule-out, never a rule-in.
- The **"continuum of UTI" framework (2023–2024)** proposes moving beyond the rigid ASB/UTI dichotomy, acknowledging that older and catheterised patients often present without localising symptoms, and supporting **watchful waiting with re-assessment** as a legitimate management category.
- The **Inappropriate Diagnosis of UTI (ID-UTI) measure** is now used as a quality metric, and stewardship programmes using it have reduced ASB treatment even in small critical-access hospitals.
- Despite two decades of guidance, **35–93% of nursing home residents with ASB still receive inappropriate antibiotics** — closing this gap is a defined geriatric quality-improvement priority.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Screening in the elderly	Not supported	**Explicitly recommended against** (IDSA), including long-term care
Delirium or falls with bacteriuria	Bacteriuria may be treated in new incontinence	**Do not treat** on delirium/falls alone without fever or instability — observe and seek other causes
Catheterised patients	No surveillance cultures	Unchanged and reinforced
Strategy	Avoid unnecessary treatment	**Avoid unnecessary testing** — diagnostic stewardship (Loeb, McGeer, AHRQ tools)
Conceptual model	ASB versus UTI	**"Continuum of UTI"** with watchful waiting as a defined option
Renal transplant	Not specified	**No treatment beyond the first month** post-transplant

Exam One-Liners

- **Two consecutive positive cultures in women, one in men, ≥10^2 CFU/mL from a catheter specimen.**
- **Pyuria does not make bacteriuria an infection.**
- **Treat only in pregnancy and before mucosa-breaching urological procedures.**
- **Delirium plus bacteriuria without fever is not a UTI** — look elsewhere.
- **Prognosis is benign; excess mortality is due to comorbidity, not bacteriuria.**
- **The best way to avoid treating ASB is not to send the urine culture** — diagnostic stewardship.

Q12. Urinary Tract Infection in the Elderly

A. Epidemiology and Definitions

1. **UTI is the most common infection in the elderly**, and is especially frequent in **debilitated and institutionalised individuals**; it is the commonest source of bacteraemia in older adults.
2. **Uncomplicated UTI** occurs in a structurally and functionally normal tract; **complicated UTI** occurs with obstruction, stones, catheters, neurogenic bladder, renal impairment, immunosuppression or male sex — **most UTI in older people is complicated**.
3. **Catheter-associated UTI (CA-UTI)** and **urosepsis** are the two forms with the greatest mortality.

B. Predisposing Factors

4. **Obstructive uropathy** is the key mechanism — **prostatic hypertrophy in men**, prolapse and cystocele in women, stones and strictures in both.
5. **Non-obstructive factors**: **vaginal and urethral atrophy, puddling of urine from bed rest, bladder catheterisation**, incomplete emptying with a raised post-void residual, and faecal incontinence.
6. **Host factors**: diabetes, immunosenescence with reduced cell-mediated and humoral immunity, malnutrition, dementia and functional dependence.
7. Phagocytic function and the complement system appear **unaltered** in ageing; the defect is largely mechanical and mucosal rather than immunological.

C. Microbiology

8. **E. coli remains the commonest organism**, but the **frequency of Gram-negative bacilli other than E. coli increases with age** — Proteus, Klebsiella, Pseudomonas, Serratia — along with **Enterococcus** and, in catheterised patients, polymicrobial flora.
9. **Proteus mirabilis** is urease-producing and causes **alkaline urine, struvite stones and catheter encrustation**.
10. If **Staphylococcus aureus** is grown from urine, **take blood cultures** — it usually reflects bacteraemic seeding of the kidney rather than ascending infection.
11. In India, **ESBL-producing Enterobacterales are widespread**, with high resistance to fluoroquinolones and third-generation cephalosporins, and rising carbapenem resistance in hospital-acquired infection.

D. Clinical Presentation

12. **Classical dysuria, frequency and urgency may be absent**; presentation is often atypical — **confusion or delirium, functional decline, falls, anorexia, incontinence, or unexplained fever**.

13. **Fever may be blunted or absent**; conversely, in the very old a **febrile response is more likely to indicate bacterial rather than viral illness**. **Absence of leucocytosis does not exclude bacterial infection.**
14. **Acute unexplained functional deterioration should alert the physician to a potential acute infectious process.**
15. Nevertheless, **non-specific symptoms alone should not be attributed to UTI** unless other causes have been excluded — this is the central diagnostic discipline in geriatric practice.
16. **Acute pyelonephritis** presents with fever, rigors, loin pain and vomiting; in the elderly it may present simply as collapse or sepsis.

E. Diagnosis and Management

17. **Send a properly collected specimen**: clean-catch midstream, or a fresh condom-catheter specimen in incontinent men after cleaning; catheterised patients should have the sample taken from a **freshly changed catheter**, never from the drainage bag.
18. **Dipstick negative for both nitrites and leucocyte esterase makes cystitis very unlikely**; a positive dipstick alone does not establish infection in an older patient.
19. **Treatment principles**: choose according to **the organism isolated and local resistance patterns**; empirical cover should account for the higher frequency of Gram-negative organisms, and **renal function must be considered and monitored**, particularly with aminoglycosides.
20. **Typical regimens**: **nitrofurantoin 100 mg twice daily for 5–7 days** (avoid if eGFR <45 mL/min) or **fosfomycin 3 g single dose** for lower UTI in women; **7 days for men**; **7–14 days for pyelonephritis** with an aminoglycoside or third-generation cephalosporin initially, stepped down by culture; **carbapenem or a beta-lactam/beta-lactamase inhibitor** for ESBL infection.
21. **Fluoroquinolones should be avoided in older adults where possible** — tendon rupture, aortic aneurysm, QT prolongation, delirium, hypoglycaemia and *C. difficile*.
22. **Supportive care**: hydration, review of drugs, treatment of constipation, catheter removal, delirium prevention, and early mobilisation. Investigate for **obstruction, stone or abscess** if fever persists beyond 72 hours.
23. **Prevention**: adequate fluid intake, vaginal oestrogen, avoidance of unnecessary catheterisation, prompt catheter removal, bladder emptying strategies, and **not treating asymptomatic bacteriuria**.

Latest Updates (2023–Present)

- **EAU Urological Infections Guideline (2023–2025)** and **IDSA guidance** now foreground **antimicrobial stewardship**: culture-directed narrow-spectrum therapy, **shortest effective duration**, and avoidance of fluoroquinolones as first-line agents.
- **Diagnostic stewardship** tools (**Loeb minimum criteria, McGeer criteria, AHRQ decision aid**) are recommended in long-term care to decide **when to send urine**, not merely when to treat.
- The **"continuum of UTI" concept (2023–2024)** formally accommodates the older patient with bacteriuria and non-localising symptoms, encouraging **short-term observation and reassessment** in stable patients.
- **New antimicrobials for resistant uropathogens**: **gepotidacin** (approved 2025 for uncomplicated UTI, a novel oral class), and for complicated UTI **ceftazidime-avibactam, ceftolozane-tazobactam, meropenem-vaborbactam, imipenem-relebactam, plazomicin, cefiderocol** and **cefepime-taniborbactam** — most relevant to Indian tertiary practice with high ESBL and carbapenemase burden.
- **Nitrofurantoin** has been re-evaluated as **safe down to an eGFR of about 30–45 mL/min for short courses**, widening its use in older women, though long-term prophylaxis remains restricted.
- Randomised evidence continues to support **shorter courses**: 5 days of nitrofurantoin for cystitis, 7 days for febrile UTI in men where source control is achieved.
- **Indian data** consistently show **>50% fluoroquinolone resistance and 40–60% ESBL rates** in community *E. coli* isolates, making **empirical fluoroquinolone or cephalosporin use inappropriate**; nitrofurantoin and fosfomycin remain the reliable oral options.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Empirical therapy	Third-generation cephalosporin and/or aminoglycoside	**Culture-directed, narrow-spectrum**; fluoroquinolones and cephalosporins unreliable in India
Nitrofurantoin in renal impairment	Avoided in renal impairment	**Acceptable for short courses down to eGFR ~30–45 mL/min**
Duration	Conventional courses	**Shorter courses** — 5 days cystitis, 7 days in men, 7–14 days pyelonephritis
Non-specific symptoms	Atypical presentation is typical	Balanced by **diagnostic stewardship** — do not over-attribute delirium/falls to UTI
Resistant organisms	Not addressed	New agents — **gepotidacin**, and beta-lactam/beta-lactamase inhibitor combinations
Deciding to test	Send urine if UTI suspected	**Loeb/McGeer/AHRQ criteria** determine when to send urine at all

Exam One-Liners

- **UTI is the commonest infection in the elderly**; **obstructive uropathy** is the key mechanism.
- **E. coli commonest**, but **non-E. coli Gram-negatives rise with age**.
- **A urine growing *S. aureus* demands blood cultures.**
- **Negative nitrite plus negative leucocyte esterase virtually excludes cystitis.**
- **Avoid fluoroquinolones** in older adults; **nitrofurantoin and fosfomycin** are the workhorses.
- **Atypical presentation is the rule — but do not blame every delirium on the urine.**

Q13. Behavioural Intervention in Urinary Incontinence

A. Concept and Place in Management

1. **Behavioural interventions are the recommended first-line treatment for geriatric urinary incontinence**, because they are **non-invasive, free of drug side-effects and non-specific** — patients with stress and urgency incontinence respond equally well.
2. They are the **only treatment modality applicable to every type** of incontinence, and can be combined with drugs or surgery.
3. The essential classification is into **patient-dependent** procedures (requiring adequate function, learning capability and motivation, aiming to **restore normal voiding and continence**) and **caregiver-dependent** procedures (for functionally disabled patients, aiming to **keep the patient and environment dry**).
4. All patient-dependent procedures involve **continuous self-monitoring with a bladder record**; caregiver-dependent procedures use a staff-completed bladder and bowel record.

B. Non-Specific Supportive Measures

5. **Education**, modification of **fluid and caffeine intake** (aim for **1.5–2 litres of non-caffeinated fluid per day**), and review of medications, discontinuing diuretics where possible.
6. Environmental manipulation — **accessible toilets, commodes, urinals, adequate lighting, clothing that is easy to remove, walking aids** — plus appropriate garments and pads.
7. Address **reversible contributors**: constipation and straining, obesity, chronic cough, atrophic vaginitis (**long-term vaginal oestrogen** where irritative symptoms predominate), delirium, and restricted mobility.

C. Patient-Dependent Interventions

8. **Pelvic floor muscle (Kegel) exercises** are the essential component and produce **the greatest benefit** in treating urinary incontinence. They consist of repetitive contraction and relaxation of the pelvic floor muscles.
9. Technique: teach by asking the patient to interrupt voiding, or by squeezing the examiner’s fingers on vaginal examination — **without a Valsalva manoeuvre, which is the opposite of the intended effect**.
10. A full exercise is a **10-second squeeze and a 10-second relaxation**, built up gradually, practised up to **40 times a day**, and — crucially — **used in real life at moments that provoke leakage** (the “knack”: contracting before coughing, standing or hearing running water).
11. **Women over 75 usually require biofeedback** (vaginal or rectal pressure or EMG, with or without abdominal EMG) to identify the correct muscles; **older men also respond** to pelvic muscle and bladder training for overactive bladder

and urgency incontinence.

12. **Bladder training** combines education, bladder records, pelvic muscle exercises and **urge-suppression strategies**; it is **highly effective in motivated, functional community-dwelling patients**.
13. **Bladder retraining** progressively lengthens or shortens the inter-voiding interval, with intermittent catheterisation where there is persistent retention — used chiefly **after removal of an indwelling catheter** or after an overdistension injury.
14. A bladder retraining protocol after catheter removal: remove the catheter (clamping first is unnecessary), treat any infection, then toilet the patient **on waking, 2-hourly by day and evening, before bed and 4-hourly at night**, with monitoring of continent voids, incontinent episodes, fluid intake and post-void residual. If difficulty persists beyond **1–2 weeks**, seek reversible causes and consider urological referral.
15. **Trigger and emptying techniques** — running tap water, stroking the inner thigh, suprapubic tapping to trigger voiding; **bending forward, suprapubic pressure and double voiding** to complete emptying.

D. Caregiver-Dependent Interventions

16. **Scheduled (timed) toileting** — routine toileting at fixed intervals, usually **2-hourly during the day and 4-hourly at night**; usable in cognitive or physical impairment; the goal is to **prevent wetting episodes**.
17. **Habit training** — a **variable** toileting schedule individualised to the patient's own voiding pattern as shown by the bladder record.
18. **Prompted voiding** — the best studied of these procedures: contact the resident approximately **2-hourly by day, focus attention on voiding by asking whether they are wet or dry, check and give feedback, offer toileting, give social reinforcement for continence and for appropriate requests, and offer fluids routinely**.
19. **Up to 25–40% of nursing home residents respond well to prompted voiding during the day**, and responders can be identified by a **3-day trial**, which improves cost-effectiveness. Night-time toileting should be individualised against **sleep disruption and fall risk**.
20. Success of caregiver-dependent programmes depends **more on the knowledge and motivation of the staff or caregiver** than on the patient's physical or mental status — so **staff training, supervision and quality-improvement methods are integral** to the intervention.

Latest Updates (2023–Present)

- **Cochrane review (2018) and subsequent updates** confirm that women with stress urinary incontinence undertaking pelvic floor muscle training are about **eight times more likely to report cure or improvement** than untreated or placebo groups; **motivation and compliance are the key determinants of success**.
- **AUA/SUFU Non-Neurogenic Overactive Bladder Guideline (2024)** and **NICE NG123** both place **behavioural therapy as first-line for all patients**, with drugs as add-on rather than replacement; **combination of behavioural therapy with pharmacotherapy is superior to either alone**.
- Anticholinergic burden is now a major driver of practice: given the association between **long-term anticholinergic exposure and dementia**, guidelines recommend **beta-3 agonists (mirabegron, vibegron) over antimuscarinics in older adults**, and behavioural therapy as the way to minimise or avoid drug therapy altogether. Baseline renal function and blood pressure should be checked before a beta-3 agonist.
- **Functional Incidental Training (FIT)** — combining prompted voiding with strengthening, walking and transfer practice during routine toileting — improves both continence and mobility in nursing home residents, and is now the preferred model in long-term care.
- **Digital and app-supported pelvic floor muscle training**, telehealth-delivered programmes and **home biofeedback devices** have randomised evidence of efficacy and are increasingly used, though uptake in older cohorts depends on digital literacy and carer support.
- Growing evidence supports **weight reduction** as an effective behavioural intervention for stress incontinence in overweight women, and **treatment of constipation** as a modifiable factor for all types.
- **Indian context**: continence care is largely nurse- and family-delivered; **NPHCE-supported geriatric clinics** and **ASHA/ANM-based training** in toileting programmes are the most scalable route, with pads and garments a significant out-of-pocket cost.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Place in therapy	First-line, non-invasive	Unchanged and strengthened; **combination with drug therapy superior to either alone**
Drug therapy alongside	Antimuscarinics for urgency	**Beta-3 agonists preferred** in older adults due to anticholinergic-dementia concerns
Delivery of PFMT	Clinic teaching plus biofeedback	**Digital, app-based and telehealth PFMT** with randomised support
Nursing home programmes	Prompted voiding	**Functional Incidental Training** — continence plus mobility gains
Lifestyle	Fluids, caffeine, constipation	**Weight reduction** added as an evidence-based intervention

Exam One-Liners

- **Patient-dependent = restore continence; caregiver-dependent = keep the patient dry.**
- **Pelvic floor exercises give the greatest single benefit**; teach without Valsalva.
- **10-second squeeze, 10-second relax, up to 40 a day, plus "the knack".**
- **Prompted voiding: 2-hourly, social reinforcement, 25–40% respond, identified by a 3-day trial.**
- **Success depends on caregiver motivation more than on patient function.**
- **Behavioural therapy + drug is better than either alone**; prefer **beta-3 agonists** in the elderly.

Q14. Continuous Bladder Drainage / Long-Term Catheterization

A. Definitions and Types

1. **Long-term (chronic) catheterisation** is an indwelling catheter in place for **30 days or more**; short-term is under 30 days.
2. Three basic types of catheter are used in incontinence management: **external (condom) catheters, intermittent straight catheterisation, and chronic indwelling catheterisation** (urethral or suprapubic).
3. **Catheters should be avoided in the management of incontinence unless specific indications are present**, and should never be used for convenience, because they foster dependency.

B. Indications for a Chronic Indwelling Catheter

4. **Urinary retention** that is causing **persistent overflow incontinence, symptomatic infection or renal dysfunction**, and which **cannot be corrected surgically or medically** and **cannot be practically managed by intermittent catheterisation**.
5. **Skin wounds, pressure injuries or irritation being contaminated by incontinent urine.**
6. **Care of terminally ill or severely impaired patients** for whom bed and clothing changes are uncomfortable or disruptive.
7. **Patient preference**, where toileting or changing causes excessive discomfort.
8. Short-term additional indications include **accurate measurement of urine output in acute illness** and **perioperative use for defined procedures** — but the catheter must be removed as soon as the indication ends.

C. Key Principles of Catheter Care

9. **Maintain a sterile, closed gravity-drainage system and never break the closed system**; keep the bag below bladder level and off the floor.
10. **Secure the catheter to the upper thigh or lower abdomen** to prevent perineal contamination and urethral traction injury from catheter movement.
11. **Avoid frequent vigorous cleaning of the catheter entry site — washing with soap and water once a day is sufficient**; use clean technique and hand hygiene when emptying or changing the drainage system.
12. **Do not routinely irrigate.** If bypassing occurs in the absence of obstruction, consider **bladder spasm**, treatable with a bladder relaxant.
13. If **obstruction occurs frequently, increase fluid intake**; catheter blockage is usually due to **encrustation with struvite from urease-producing *Proteus mirabilis***, and the catheter change interval should be planned ahead of the predictable blockage time.
14. **Do not use prophylactic or suppressive urinary antiseptics or antimicrobials routinely.**

15. **Do not perform surveillance cultures** to guide management, because all chronically catheterised patients have bacteriuria, often polymicrobial, and the organisms change frequently.
16. **Do not treat infection unless the patient develops symptoms**; symptoms may be non-specific, so **other sources of infection must be carefully excluded first**.
17. If a patient develops **frequent symptomatic infections, arrange genitourinary evaluation** to exclude stones, periurethral or prostatic abscess and chronic pyelonephritis.

D. Complications

18. **Chronic bacteriuria is universal**; further complications include **catheter-associated UTI and urosepsis, bladder and renal stones, periurethral and prostatic abscess, epididymo-orchitis, urethral trauma, erosion and false passage, catheter bypassing and blockage, haematuria, and — with long-term use — squamous cell carcinoma of the bladder**.
19. **Nursing home residents, especially men, managed by chronic catheterisation are at relatively high risk of symptomatic infection.** Indwelling catheterisation remains **overused in acute hospitals**.
20. **Non-infectious harms** matter as much: pain, restricted mobility and rehabilitation, falls over tubing, loss of dignity, and being a “one-point restraint”.

E. Practical Alternatives and Removal

21. **Intermittent catheterisation** (self- or carer-performed, 2–4 times daily, keeping bladder volume under about 400 mL) is preferred where feasible; the catheter should be **clean but need not be sterile at home**. In nursing homes, anatomical abnormalities and resistant institutional flora may make repeated straight catheterisation impractical.
22. **External (condom) catheters** should be used **only for intractable incontinence in men without retention who are extremely physically dependent**; they still increase the risk of symptomatic infection and skin damage.
23. **Suprapubic catheterisation** avoids urethral erosion, is more comfortable, permits sexual activity, and is easier to change — preferred when long-term drainage is genuinely unavoidable.
24. **Plan removal actively**: use a **trial without catheter (TWOC)** with a bladder retraining protocol; **most indwelling catheters in acute hospitals and many in long-term care can be removed** this way.

Latest Updates (2023–Present)

- **“Strategies to Prevent Catheter-Associated Urinary Tract Infections in Acute-Care Hospitals: 2022 Update”** (SHEA with IDSA, APIC, AHA and The Joint Commission, published 2023) is the current compendium standard.
- It introduces the **“Disrupting the Life Cycle of the Indwelling Urethral Catheter”** model, which identifies **alternatives before insertion, safe insertion and maintenance, and prompts for timely removal** as the three intervention points.
- **Non-catheter strategies** are now formally listed as the first step: **prompt toileting, urinals, bedside commodes, incontinence garments**, and **intermittent straight catheterisation**.
- The update adds **urine-culture stewardship** as an essential practice — reducing inappropriate urine testing is now part of CAUTI prevention, not separate from it.
- Performance measures have been broadened from CAUTI rates alone to include **catheter harm** — trauma, obstruction and non-infectious complications.
- The update explicitly discusses the **limitations of external urinary catheters**, including non-catheter-associated UTIs arising from alternative collection devices, and skin injury — cautioning against simply substituting one device for another.
- **Unresolved issues** flagged include the **standard of care for routine replacement of catheters in place beyond 30 days**, reflecting continuing uncertainty about optimal change intervals.
- **Antimicrobial-impregnated and silver-alloy catheters have not shown clinically important benefit** in large trials and are not recommended routinely; **catheter valves** may improve bladder capacity and dignity in selected patients.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Framing of prevention	Correct indications and good catheter care	**"Disrupting the life cycle"** — alternatives, insertion, maintenance, removal
Testing	Do not perform surveillance cultures	Broadened to **urine-culture stewardship** as an essential practice
Outcome measured	CAUTI rate	**CAUTI plus catheter harm** (trauma, obstruction)
External catheters	Acceptable alternative in dependent men	**Limitations emphasised** — device-associated UTI and skin injury
Coated catheters	Not addressed	**No routine benefit** from antimicrobial or silver-alloy catheters
Replacement interval	Change when blocked	**Explicitly unresolved** beyond 30 days; individualise to blockage pattern

Exam One-Liners

- **Long-term = 30 days or more.**
- Indications: **uncorrectable retention, wound contamination, terminal care, patient preference.**
- **Closed drainage, secured catheter, no routine irrigation, no prophylactic antibiotics, no surveillance cultures.**
- **All chronically catheterised patients are bacteriuric — treat only symptoms.**
- **Proteus mirabilis** causes encrustation and blockage.
- **The best catheter care is not having a catheter** — offer toileting, commodes and intermittent catheterisation first.

Q15. Preliminary Assessment of an Older Male with Lower Urinary Tract Symptoms, and When to Refer to a Urologist

A. Background

1. **Benign prostatic hyperplasia is inexorably linked with ageing** and is a major contributing factor in the development of **lower urinary tract symptoms (LUTS)**; the prevalence of BPH-related symptoms may be as high as **50%** in multinational surveys.
2. LUTS are **not synonymous with BPH** — they may arise from the bladder (overactivity or underactivity), prostate, urethra, or from systemic disease and drugs.
3. **Voiding (obstructive) symptoms**: hesitancy, weak stream, straining, intermittency, terminal dribbling, incomplete emptying. **Storage (irritative) symptoms**: frequency, urgency, nocturia, urgency incontinence. **Post-micturition**: post-void dribbling.

B. History

4. Use the **International Prostate Symptom Score (IPSS) / AUA Symptom Index** — seven items scored 0–5: **0–7 mild, 8–19 moderate, 20–35 severe** — plus the **disease-specific quality-of-life ("bother") question**.
5. The score quantifies symptoms over time; **bother and quality of life, not the score alone, drive treatment decisions**.
6. A **3-day frequency-volume chart (bladder diary)** distinguishes polyuria, nocturnal polyuria and reduced functional bladder capacity — critical in the older man with nocturia.
7. Exclude other causes by history: **type 2 diabetes** (nocturia with polyuria >3 litres), **neurological disease** (neurogenic bladder), **gross haematuria or bladder pain** (tumour or calculi), **urethral trauma, urethritis or instrumentation** (stricture), **family history of BPH or prostate cancer**, and **sexual dysfunction-related LUTS**.
8. **Drug history is essential** — anticholinergics impair bladder function, sympathomimetics increase outflow resistance, diuretics increase frequency, opioids cause retention, and calcium-channel blockers worsen emptying.
9. Assess **fluid, caffeine and alcohol intake, and evening fluid timing**.

C. Examination

10. **Digital rectal examination** to assess prostate size and consistency and to detect **nodules or induration suggesting carcinoma**; also assess **rectal sphincter tone**, and exclude faecal impaction.
11. **Abdominal examination for a palpable bladder** (chronic retention), and examination of the **external genitalia** for meatal stenosis and phimosis.

12. **Focused neurological examination**, including perineal sensation and sacral reflexes.
13. **A general health and cognitive status evaluation is useful for choosing the best treatment, especially if a surgical procedure may be required** — frailty, cognition and life expectancy determine what is appropriate. **Dementia and other neurological conditions can themselves affect the urinary condition.**

D. Investigations

14. **Urinalysis** in all patients, to detect **infection and haematuria**; **urine cytology** is helpful when irritative symptoms or haematuria predominate, especially in smokers, to exclude bladder tumour.
15. **Serum creatinine is not routinely indicated** in the initial evaluation of LUTS attributable to BPH, since baseline renal impairment is no commoner in men with BPH than in age-matched peers — but measure it if there is chronic retention, hydronephrosis, or suspicion of obstructive nephropathy.
16. **PSA remains controversial but is still recommended after counselling**, and is chiefly appropriate where **life expectancy exceeds 10 years** and a diagnosis of cancer would change management. Remember: **PSA is not cancer-specific and rises in BPH, prostatitis, instrumentation and retention**, and **about 25% of men with prostate cancer have a PSA of 4.0 ng/mL or less**.
17. **Post-void residual urine** by bladder ultrasound and **uroflowmetry** are optional but useful; **a poor maximum flow rate, high post-void residual and greater symptom severity predict clinical progression**.
18. **Do not perform routine upper-tract imaging, cystoscopy or urodynamics** at the preliminary assessment.

E. When to Refer to a Urologist

19. **Refer urgently** for: **visible (gross) haematuria or persistent microscopic haematuria** without infection; **abnormal DRE (nodule or induration)** or **unexplained PSA elevation**; and **suspected malignancy**.
20. **Refer for**: **acute or chronic urinary retention with a palpable bladder**, **renal impairment or hydronephrosis attributable to obstruction**, **bladder or urethral stones**, **suspected urethral stricture** (previous trauma, urethritis or instrumentation), and **recurrent urinary tract infection or persistent sterile pyuria**.
21. **Refer for**: **failure of adequate medical therapy**, **severe bothersome symptoms in a man fit for and wishing to consider intervention**, **suspected neurogenic bladder**, and **any patient in whom surgery is being contemplated** (complex urodynamic testing is essential before surgical intervention and to define the cause of retention).
22. **Manage in primary care / general geriatric clinic**: mild symptoms (IPSS <7) with **watchful waiting and lifestyle measures** — fluid restriction before bedtime, avoiding caffeine and spicy food, monitoring diuretics, timed voiding and bladder retraining, pelvic floor exercises, and treating constipation. Patients with mild symptoms but **severe bother should undergo further assessment**.

Latest Updates (2023–Present)

- The **AUA LUTS/BPH Guideline (2023 amendment, expanded into a three-part guideline in 2026)** is the current reference. Initial workup remains **history, AUA-SI/IPSS and urinalysis**, with explicit elicitation of **patient goals** and discussion of side-effects.
- A major new emphasis is **pre-operative assessment of prostate size and shape** (ultrasound, cystoscopy or existing cross-sectional imaging) because **modality selection now depends on volume** — for example, water vapour thermal therapy is offered where prostate volume is **under 80 g**, with counselling on retreatment rates.
- **Minimally invasive surgical therapies (MIST) — prostatic urethral lift, water vapour thermal therapy, Aquablation, prostatic artery embolisation, temporary implantable nitinol device** — are now firmly in the guideline and are particularly attractive in **older, frailer men and those wishing to preserve ejaculatory function**. Enucleation techniques (**HoLEP, ThuLEP**) are size-independent options for very large glands.
- Guidelines now explicitly require **counselling about sexual side-effects** of medical and surgical therapy, following evidence of poor pre-treatment counselling in practice.
- **Deprescribing is part of the assessment**: reviewing **anticholinergics, opioids, diuretics and sympathomimetics** frequently improves symptoms without any new prescription.
- **Nocturia** is increasingly managed as a distinct multifactorial syndrome — sleep apnoea, heart failure, oedema, diabetes, drugs and nocturnal polyuria — rather than as a prostate symptom; desmopressin carries a **significant hyponatraemia risk in the elderly and requires sodium monitoring**.
- **PSA screening**: contemporary guidance supports **shared decision-making in men with >10 years' life expectancy** and generally **against PSA testing above age 70 or in significant frailty**, aligning with geriatric principles of avoiding diagnoses that cannot benefit the patient.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Core initial workup	History, IPSS, examination, urinalysis	Unchanged, plus explicit **elicitation of patient goals**
Prostate size assessment	Not routine at first visit	**Recommended before procedural therapy** — determines modality choice
Treatment options	Watchful waiting, drugs, MIST, surgery	Greatly expanded **MIST menu**; enucleation for large glands
Sexual side-effects	Mentioned	**Mandatory counselling** in guideline statements
Nocturia	Part of the symptom score	Managed as a **separate multifactorial syndrome**
PSA	Recommended with counselling	**Shared decision-making**; generally avoided above 70 or in frailty

Exam One-Liners

- **IPSS: 0–7 mild, 8–19 moderate, 20–35 severe** — plus the bother question.
- **A 3-day bladder diary distinguishes nocturnal polyuria from a prostate problem.**
- **Urinalysis in everyone; creatinine not routine; PSA only after counselling.**
- **Red flags for referral: haematuria, abnormal DRE, retention, renal impairment, stones, stricture, recurrent UTI, failed medical therapy.**
- **25% of prostate cancers have a PSA ≤4.0 ng/mL.**
- **Review the drug chart before writing a new prescription.**

Q16. Peritoneal Dialysis

A. Principle

1. **Peritoneal dialysis (PD)** uses the **peritoneum as a semipermeable membrane**: solutes are removed by **diffusion** down a concentration gradient into the dialysate, and water by **osmosis (ultrafiltration)** driven by an osmotic agent.
2. The effective exchange surface is the **peritoneal capillary endothelium**, described by the **three-pore model** — large pores, small pores and aquaporin-1 water channels (responsible for sodium sieving).
3. Access is by a **Tenckhoff catheter** placed surgically, laparoscopically or percutaneously, ideally **2 weeks before starting** to allow the exit site to heal.

B. Solutions and Modalities

4. **Glucose-based solutions (1.5%, 2.5%, 4.25%)** are standard; **icodextrin** (a glucose polymer) gives sustained ultrafiltration over a long dwell and is ideal for the overnight or day-long dwell; **amino-acid solutions** address protein loss.
5. **Low-glucose-degradation-product, neutral-pH, bicarbonate-buffered solutions** are more biocompatible and better preserve the membrane and residual renal function.
6. **CAPD (continuous ambulatory PD)** — typically **four exchanges of 2 litres daily**, performed manually by the patient or carer.
7. **APD (automated PD)** by a cycler at night — including **CCPD (continuous cycling PD)**, **NIPD (nightly intermittent PD)** and **TPD (tidal PD)**. **Nightly PD can be an alternative for more vulnerable elderly patients, including nursing home residents.**
8. **Peritoneal equilibration test (PET)** classifies membrane transport as **high, high-average, low-average or low**, guiding dwell time: high transporters need **short dwells (APD)**, low transporters need **long dwells (CAPD)**.
9. **Adequacy** is assessed by symptoms, volume status and nutrition, with a **weekly Kt/V urea of at least 1.7** as the conventional minimum; **preservation of residual renal function is a priority**.

C. Advantages, Particularly in Older Patients

10. **PD is a satisfactory alternative for geriatric ESRD patients, and most studies confirm that elderly patients on PD and HD have similar survival.**
11. **PD is better than HD for patients with residual diuresis, severe hypotension, complicated or short-lived vascular access, intradialytic arrhythmias, angina, or cardiovascular instability.**
12. Additional advantages: **home-based therapy** with independence and no travel, **gentle continuous solute and fluid**

removal without haemodynamic swings, **better preservation of residual renal function**, **no vascular access or systemic anticoagulation**, a **more liberal diet and fluid allowance**, and better preservation of anaemia control.

13. In India, PD avoids **repeated travel to a dialysis centre**, is feasible in rural areas, and is supported by dedicated government guidelines — important where transport and caregiver time are major barriers.

D. Problems and Complications in Older Patients

14. **The most frequent practical problems in older patients on PD are dialysate leakage, hernia formation, backache, difficulty in learning the technique, social isolation, family burn-out, and worsening of peripheral vascular disease or malnutrition.**
15. **Peritonitis** is the major infective complication — cloudy effluent with abdominal pain, effluent white cell count >100/µL with >50% neutrophils; treat with **intraperitoneal antibiotics** covering Gram-positive and Gram-negative organisms; recurrent, refractory or fungal peritonitis requires **catheter removal**.
16. **Exit-site and tunnel infection**, catheter malfunction and migration, constipation-related drainage failure.
17. **Metabolic**: glucose absorption causing hyperglycaemia, weight gain and dyslipidaemia; **protein loss of 5–15 g per day** in the effluent.
18. **Encapsulating peritoneal sclerosis** — a rare but devastating complication of long-duration PD.
19. **Nutrition**: malnutrition is frequently present; provide **more than 1.2 g/kg body weight of protein daily for patients on PD** (versus more than 1 g/kg for HD). Older patients on dialysis develop **more serious bone disease** than the young because of osteopenia, unbalanced diet, reduced physical activity and lack of sun exposure.
20. **Relative contraindications**: extensive abdominal adhesions or previous major abdominal surgery, active inflammatory bowel disease or diverticulitis, large irreparable hernia, stomas, severe respiratory disease, and — critically in geriatrics — **inability of the patient or carer to perform exchanges safely**, which is the commonest practical barrier.

Latest Updates (2023–Present)

- **Assisted peritoneal dialysis (aPD)** is now the key strategy for extending PD to frail older adults: a trained nurse, care assistant or family carer performs or supervises exchanges. It substantially widens eligibility and has become standard practice in several European systems and in Indian PD programmes.
- **ISPD guidance on "high-quality, goal-directed PD prescription"** has replaced rigid small-solute clearance targets with a **person-centred approach** prioritising **symptom control, volume status, quality of life and preservation of residual kidney function** over achieving a numerical Kt/V — a philosophy that fits geriatric practice precisely.
- **Incremental PD** — starting with fewer or smaller exchanges while residual renal function persists, then escalating — reduces treatment burden, glucose exposure and cost, and is particularly suited to older patients.
- **Urgent-start PD** (beginning within about 2 weeks of catheter insertion with low-volume supine exchanges) allows PD to be used for unplanned dialysis starts, avoiding a temporary central venous catheter and its infective risk.
- **ISPD peritonitis guidelines (2022)** emphasise **prevention** (exit-site antibiotic prophylaxis, prophylaxis before colonoscopy and dental procedures, treatment of constipation), **avoidance of prolonged empirical vancomycin and aminoglycosides**, and centre-level peritonitis rate targets.
- **Remote patient monitoring of APD cyclers** enables early detection of non-adherence, drainage problems and volume issues — valuable for older patients living alone or at a distance from the unit.
- **India**: the **Pradhan Mantri National Dialysis Programme (PMNDP)**, launched in 2016 under the National Health Mission, now includes a **dedicated peritoneal dialysis component** with operational guidelines issued to states, alongside free haemodialysis for below-poverty-line patients across all States/UTs and over 750 districts. The **PMNDP portal** supports a renal registry and "one nation–one dialysis" portability. PD is explicitly promoted as a **home-based option** for patients unable to travel, with **assisted PD by a family carer** recognised in the national guidance.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Adequacy target	Weekly Kt/V thresholds	**Goal-directed, person-centred prescription** (ISPD) — symptoms and volume over numbers
Eligibility of the frail elderly	Learning difficulty is a barrier	**Assisted PD** by nurse or family carer overcomes this
Starting prescription	Full four-exchange CAPD	**Incremental PD** while residual function persists
Unplanned start	Requires temporary HD catheter	**Urgent-start PD** now feasible and preferred
Solutions	Glucose-based, icodextrin	**Low-GDP, neutral-pH biocompatible solutions** to preserve membrane and residual function
Monitoring	Clinic review	**Remote monitoring of cyclers**
India	Not addressed	**PMNDP peritoneal dialysis component** with state operational guidelines

Exam One-Liners

- **Diffusion removes solute; osmosis (ultrafiltration) removes water.**
- **PET defines transport status: high transporters → short dwells (APD); low transporters → long dwells (CAPD).**
- **PD and HD give similar survival in the elderly.**
- **PD is preferred with residual diuresis, poor vascular access, hypotension, angina or arrhythmias.**
- **Protein requirement: >1.2 g/kg/day on PD, >1 g/kg/day on HD.**
- **Assisted PD and incremental PD are the two ideas that make PD a geriatric therapy.**

Q17. Role of Renal Replacement Therapy in the Elderly

A. Background

1. **Chronic kidney disease is predominantly a disease of older adults** — its incidence rises steadily with age and it is at least **10 times commoner at 75 and over than at 15–45**.
2. The commonest causes of end-stage renal disease in old age are **hypertension, nephrosclerosis, diabetes mellitus and obstructive uropathy**; in up to **one-third of cases no specific cause is identifiable**.
3. **Age itself does not constitute a contraindication to dialysis or transplantation.**
4. When **GFR falls below about 10 mL/min** with uraemic features, replacement therapy becomes necessary — but the modern approach is to start on **symptoms and clinical state rather than on an eGFR threshold alone**.

B. The Four Modalities

5. **Haemodialysis (HD)** — in-centre, satellite or home; requires vascular access and haemodynamic tolerance.
6. **Peritoneal dialysis (PD)** — home-based, continuous, gentler; **elderly patients on PD and HD have similar survival**.
7. **Kidney transplantation** — the best modality for survival and quality of life in selected older patients.
8. **Conservative kidney management (CKM)** — active, planned, non-dialytic care focused on symptom control, quality of life and advance care planning; **not "no treatment"**.

C. Haemodialysis in the Elderly

9. **Practical problems during HD in the aged**: **difficulty creating an arteriovenous fistula, permanent catheter or graft infection, gastrointestinal bleeding, intradialytic hypotension, headaches, vomiting, cramps, angina, arrhythmias and cardiovascular instability.**
10. **Older patients are more vulnerable to dialysis-related complications** — haemodynamic instability, bleeding and disequilibrium syndrome.
11. **Malnutrition is frequent**; provide **more than 1 g/kg body weight of protein daily on HD**. Bone disease is more severe than in the young.
12. **Very elderly patients on haemodialysis have a poor life expectancy: median survival is 15.6 months from age 80–84 and 11.6 months from age 85–89.**

13. **The leading causes of death in the oldest dialysis patients are elective withdrawal (38%), cardiovascular events (24%) and infection (22%)** — withdrawal being the single commonest, which makes **advance care planning essential from the outset**.

D. Predictors, Transplantation and Decision-Making

14. **Predictors of poor outcome on dialysis in older adults are: poor nutritional status, dementia, gait disorders, impaired activities of daily living and instrumental ADLs, and late referral to nephrology services.**
15. **Comprehensive geriatric assessment — not chronological age — should drive the decision**; frailty, cognition, functional status and social support predict outcome better than any laboratory value.
16. **Transplantation**: with improved patient selection, newer immunosuppressants and lower corticosteroid doses, **one-year patient and graft survival of 85% and 75%** is achievable; for patients over 60–65 the **five-year functional graft survival is 55–60%**.
17. Older recipients have **fewer rejection episodes**; **graft loss is mainly due to death with a functioning graft**, and the commonest causes of death are **cardiovascular disease and infection related to peaks of immunosuppression**.
18. **Donor age is the greatest adverse factor in cadaveric transplantation**; kidneys from older donors are "marginal" but can be used, singly or as a pair, in a subgroup of older recipients.
19. **Drug dosing must be individualised** — bioavailability, volume of distribution, renal excretion and half-life all change with age; use **low, slowly increasing doses and avoid polypharmacy**.

E. Conservative Kidney Management and Shared Decision-Making

20. **CKM is a legitimate, active pathway** comprising **symptom control (pruritus, nausea, restless legs, breathlessness, pain), anaemia and acidosis management, blood-pressure and volume control, dietary support, advance care planning and palliative care linkage**.
21. **The survival advantage of dialysis is attenuated in the oldest and frailest patients**; survival is broadly similar regardless of modality among those **aged 80 and over with high comorbidity, particularly ischaemic heart disease**, while dialysis imposes far greater treatment burden.
22. Use structured aids for prognostication and communication — the **"surprise question"** ("would I be surprised if this patient died within a year?"), validated mortality prediction models, and frailty measures — and frame the discussion around **quality of life, hospital-free days and patient goals**, not survival alone.
23. **Withdrawal from dialysis** should be discussed openly and revisited; it is a recognised, ethical decision and the commonest immediate cause of death in the very old on dialysis.

Latest Updates (2023–Present)

- **KDIGO 2024 CKD Guideline** formally states that **conservative kidney care is a reasonable option** for patients who do not wish to pursue kidney replacement therapy, embedding CKM into mainstream nephrology rather than treating it as a failure of care.
- A **target trial emulation study (Annals of Internal Medicine, 2024)** in older adults with kidney failure compared starting dialysis with continuing medical management. Starting dialysis conferred a **modest survival gain but fewer days at home** — the concept of **"home time"** as a patient-centred outcome is now central to the conversation.
- Contemporary cohort data confirm the age gradient: five-year survival from first nephrology attendance falls from about **84% under 50 years to 40% at 65–79 and 22% at 80 and over**; and a substantial minority of patients who opt for dialysis **die before ever reaching it**.
- Recent European cohort work (2026) reports median survival from the treatment decision of about **53 months for dialysis, 32 months for CKM in those considered suitable for dialysis, and 18 months for CKM in those less suitable** — with the difference narrowing markedly above age 80.
- **Assisted PD, incremental dialysis and "palliative" or symptom-directed dialysis prescriptions** are increasingly offered as middle paths between full conventional dialysis and pure conservative care.
- **European Renal Best Practice** guidance on older patients with advanced CKD, and new **prediction models comparing dialysis with conservative care** (presented at ASN Kidney Week 2025), give clinicians quantitative tools for shared decision-making.
- **Frailty assessment is now a formal part of dialysis and transplant decision-making**, with a growing literature on frailty's impact on transplant outcomes and on pre-habilitation before starting dialysis.
- **India**: the **Pradhan Mantri National Dialysis Programme** provides **free haemodialysis to below-poverty-line patients in district hospitals across all 36 States/UTs and 751 districts**, in PPP, in-house and hybrid models, with a **peritoneal dialysis component** and a national **PMNDP portal/renal registry**. Roughly **2 lakh Indians develop end-stage kidney failure every year**; access, transport, catastrophic out-of-pocket expenditure and very low deceased-donor transplantation rates remain the dominant limitations for older Indians. Coverage under **AB-PMJAY**

and state schemes has improved but not eliminated these barriers.

Current Practice Update

Aspect	Textbook Position	Current Evidence / Guideline
Timing of initiation	eGFR below ~10 mL/min	**Symptom- and clinically-based**, not eGFR-triggered
Conservative care	Not a formal option	**KDIGO 2024**: conservative kidney care is a reasonable, recognised pathway
Outcome measures	Survival	**Survival plus home time, symptom burden and quality of life**
Basis of the decision	Comorbidity and functional status	**Formal frailty assessment and validated prediction models**
Modality options	HD, PD, transplant	Plus **assisted PD, incremental dialysis, symptom-directed dialysis**
Advance care planning	Withdrawal noted as common	**Structured ACP from the outset**, with the surprise question as a trigger
Indian access	Not addressed	**PMNDP** free dialysis in all districts, with a PD component and national registry

Exam One-Liners

- **Age alone is never a contraindication to dialysis or transplantation.**
- **Median HD survival: 15.6 months at 80–84 and 11.6 months at 85–89.**
- **Elective withdrawal causes 38% of deaths** in the oldest dialysis patients.
- **Poor prognostic markers: malnutrition, dementia, gait disorder, ADL/IADL dependence, late referral.**
- **Transplant: 1-year patient/graft survival 85%/75%; 5-year functional graft survival 55–60% over age 60.**
- **The survival benefit of dialysis all but disappears above 80 with high comorbidity** — offer conservative kidney management as a genuine choice.

How to use this compilation

Each answer is arranged as **numbered textbook-sourced points** → **Current Practice Update** (two-column comparison of the textbook position against current evidence) → **Latest Updates 2023–present** with inline citations → **Examiner's Tip** panel carrying the verbatim mark-earning lines. Where a topic recurs across past papers, an additional **Extra Points to Remember** panel is included. Read the Examiner's Tip panels and the Rapid Revision Grid on the night before the paper.

Q1 Living Will (Advance Medical Directive) — the procedure to write one in India and how it is executed. 15 MARKS

Source: *Essentials of Clinical Geriatrics*, 7th ed., Ch. 17 — Ethical Issues in the Care of Older Persons (advance care planning, advance directives, living will, proxy directive); *Pathy's* 6th ed. — advance directives in palliative and end-of-life care. India-specific procedure from *Common Cause (A Registered Society) v. Union of India*, (2018) 5 SCC 1, as modified by the Supreme Court order dated **24 January 2023**.

A. Concept and Definitions

1. An **advance directive (AD)** is a legal document by which a person states what treatment they want if they later become **unable to express their wishes**.
2. A **living will** is one type of AD. It states care preferences **specifically for a terminal state at the end of life**.
3. The living will covers a **limited set of treatments** — CPR, intubation, artificial nutrition and hydration, dialysis and intravenous therapy.
4. Its main **limitation** is that it addresses only defined situations (terminal illness, vegetative state) and cannot anticipate grey areas, such as whether an antibiotic is life-support or comfort care.
5. The other form of AD is the **proxy directive** (durable power of attorney for health care), which appoints a person to decide. In geriatrics a **combined instructional plus proxy directive** is the most useful.
6. **Advance care planning** is the *process* of eliciting values and preferences; the living will is only the *document* that results. It should be discussed **in stable health, not during an acute admission**.

B. Legal Basis in India

7. In *Common Cause* (2018) a five-judge Constitution Bench held that the **right to die with dignity is a fundamental right under Article 21**, and gave legal recognition to living wills and to withdrawal of life support.
8. The 2018 procedure proved **unworkable** (magistrate countersignature, boards requiring 20 years' experience, District Collector's involvement), so uptake was negligible.
9. On an application by the **Indian Society of Critical Care Medicine**, the Supreme Court **simplified the procedure on 24 January 2023**. This order is the operative law today.

C. Procedure to WRITE a Living Will (2023 Order)

10. **Who may execute:** any **adult of sound mind**, capable of communicating and of understanding the consequences, acting **voluntarily and without coercion or inducement**.
11. **Form:** it must be **in writing** and must state in **unambiguous terms** the circumstances in which treatment may be **withheld or withdrawn**.
12. It must name **one or more guardians or close relatives** who will give consent for withdrawal when the executor loses capacity (the 2023 order permits **more than one** nominee).
13. **Signing:** the executor signs in the presence of **two attesting witnesses**, preferably independent.
14. **Attestation:** the document must be attested before a **Notary or a Gazetted Officer**. The requirement of **countersignature by a Judicial Magistrate First Class (JMFC) has been removed**.
15. The witnesses and the notary/gazetted officer must **record their satisfaction** that it was executed voluntarily and with full understanding.
16. **Distribution of copies:** to the **nominated guardian(s)**, to the **family physician**, and to family members.
17. **Registration:** a copy must be handed to the **custodian** — a competent official nominated by the **local government** (municipal corporation, municipality or panchayat), who maintains the registry.
18. The executor may also incorporate the directive into their **digital health records**, which greatly improves retrievability in an emergency.
19. **Revocation:** the living will may be **revoked or revised in writing at any time** while the person retains capacity; revised copies must go to all the same recipients.

D. How the Living Will is EXECUTED (Given Effect)

20. **Trigger conditions:** the executor is **terminally ill**, on **prolonged treatment**, with **no hope of recovery or cure**, and has **lost decision-making capacity**.
21. The **treating physician verifies authenticity** of the directive — from the digital health records if available, otherwise

from the custodian.

22. The hospital constitutes a **Primary Medical Board (PMB)**: the treating physician plus **two subject experts**, each with **≥5 years' post-qualification experience**; opinion within **48 hours**.
23. If the PMB agrees, the hospital constitutes a **Secondary Medical Board (SMB)**: a **different set of clinicians (≥5 years' experience)**, including **one nominated by the district Chief Medical Officer**; also within **48 hours**.
24. When **both boards concur**, the hospital **conveys (informs, not seeks approval from) the jurisdictional JMFC** along with the directive or surrogate consent, and implementation may proceed.
25. **If there is no living will:** the same two-board process applies, with **written informed consent of the next of kin / next friend / guardian** acting as surrogate.
26. **In case of non-concurrence or refusal**, the nominee, family member, treating doctor or hospital may move the **High Court under Article 226**; the Chief Justice constitutes a **Division Bench**, which may appoint an **independent three-doctor committee**.
27. **Key distinction: withholding/withdrawing life-sustaining treatment is lawful**; **active euthanasia remains illegal** and punishable in India.

E. Current Practice Update

Textbook position (*Essentials* 7e / *Pathy's* 6e)	Current Indian position (2023–2026)
ADs governed by **statute** — Patient Self-Determination Act 1991 and state laws	India has **no statute**; the operative law is **Supreme Court guidelines under Article 142** (*Common Cause* 2018, modified 2023)
Living will "witnessed, better notarised"; verbal ADs valid in some states	Only a **written** AMD attested before **two witnesses + notary/gazetted officer** is valid; **verbal directives are not recognised**
Document kept by patient, proxy or institution	Additional mandatory **deposit with a local-government custodian**; optional entry into **digital health records**
Futility decided by treating clinician ± **ethics committee**	Decided by **two statutory medical boards (PMB and SMB)** with **48-hour timelines** and **JMFC intimation**
POLST/MOLST as portable medical orders	**No Indian equivalent**; retrieval depends on custodian registries and state digital portals
Artificial nutrition/hydration listed among refusable treatments	**Judicially settled** — *Harish Rana* (2026) held **CANH is medical treatment** and may be withdrawn
A **single** proxy or agent named	The **2023 order permits multiple guardians / close relatives** as surrogates
Directive executed abroad generally portable across states	A living will **validly executed overseas is not legally valid in India** if it does not follow the SC procedure

Latest Updates (2023–Present)

- **Supreme Court order, 24 January 2023** (*Common Cause*, MA 1699/2019 in WP(C) 215/2005): removed JMFC countersignature and District Collector involvement, allowed **notary/gazetted officer attestation**, permitted **multiple nominees**, fixed **48-hour timelines** for both boards, reduced board experience to **5 years**, and made the JMFC's role **notification rather than approval**.
- **MoHFW/DGHS Draft Guidelines for Withdrawal of Life Support in Terminally Ill Patients (2024):** defined **terminal illness** as an irreversible/incurable condition with inevitable death; listed qualifying situations including **brainstem death** and **severe traumatic brain injury with no recovery beyond 72 hours**; gave prescribed formats for surrogate consent and PMB/SMB reports. The **IMA objected** and the guidelines are **not yet notified as final**.
- **Karnataka Government Orders, January–February 2025:** first state to **fully operationalise** the directives — clinicians already empanelled for **brain-death certification under THOTA 1994 (amended 2011)** are deemed nominated to the SMB; **AMD custodians** are Joint Commissioners of BBMP zones (urban) and Taluk Panchayat Executive Officers (rural).
- **Goa (2024):** first state to operationalise AMD registration, with a High Court judge executing the first living will before a gazetted officer.
- **Maharashtra (2024–2026):** BMC **ward medical officers designated custodians** after PIL in the Bombay High Court; a **digital portal (MahaULB)** now allows citizens to upload directives, with municipal commissioners as custodians.
- *Indian Journal of Medical Research, 2026* (Vallath et al.): a **10-step institutional implementation pathway** for withholding/withdrawing life-sustaining treatment with report templates; documented that a **US-executed living will was not legally valid in India**, so the no-AMD pathway had to be used.
- *Indian Journal of Critical Care Medicine, 2025* (Damani et al.): a **12-step advance care planning pathway** adapted to Indian practice.
- ***Harish Rana v. Union of India*, 2026 SCC OnLine SC 358 / 2026 INSC 222 (11 March 2026)** — the landmark update:
  - First case in which the *Common Cause* guidelines were **applied in full measure** by the Supreme Court, in a man in **persistent vegetative state for 13 years**.
  - Held that **clinically assisted nutrition and hydration (CANH) is medical treatment**, not basic care, and may be withdrawn — including when given at home.
  - Laid down the **"best interest" test**: a **balance-sheet exercise** weighing benefit against burden, indignity and futility, incorporating **substituted judgment**, with a rebuttable **presumption in favour of preserving life**.
  - Replaced "passive euthanasia" with **"withholding/withdrawing of medical treatment"**; **"euthanasia" now means active euthanasia only**, which remains impermissible.
  - Recognised a **30-day reconsideration (cooling-off) period**, waivable where all stakeholders are unanimous.
  - Directed **all High Courts** to instruct JMFCs to receive hospital intimations, and the Union and States to ensure every **district CMO maintains a standing panel** for SMB nomination.
  - Clarified the pathway for **home-care patients** and **urged Parliament to enact comprehensive end-of-life care legislation**.

Examiner's Tip

Skeleton: Definition (AD vs living will vs proxy) → Article 21 and *Common Cause* 2018 → why the 2023 modification was needed → **execution: adult of sound mind, written, unambiguous, nominee(s), two witnesses, notary/gazetted officer, copies to nominee + family physician + custodian, optional DHR, revocable → effectuation: trigger → verification → PMB (48 h) → SMB with CMO nominee (48 h) → JMFC intimation → implement** → conflict pathway via High Court under Article 226 → *Harish Rana* 2026 → active euthanasia remains illegal.

"After the Supreme Court's order of **24 January 2023**, a valid living will in India requires only that it be **in writing**, signed before **two attesting witnesses** and attested by a **notary or gazetted officer**, with copies to the **nominated guardian, the family physician and the local-government custodian** — the earlier requirement of countersignature by a Judicial Magistrate First Class stands **removed**."

"Execution now follows a **two-board pathway** — a Primary Medical Board and an independent Secondary Medical Board containing a **CMO nominee**, each reporting within **48 hours** — after which the hospital merely **informs** the jurisdictional JMFC; and since *Harish Rana* (2026), **clinically assisted nutrition and hydration is recognised as medical treatment** that may lawfully be withdrawn in the patient's best interests."

Extra Points to Remember — recurring topic

- **Four numbers to carry into the hall: 2** witnesses · **2** medical boards · **5** years' experience · **48** hours per board. Add **30** days for the *Harish Rana* reconsideration period.
- **Three landmarks in sequence:** *Gian Kaur* 1996 (no right to die) → *Aruna Shanbaug* 2011 (passive euthanasia with High Court approval) → *Common Cause* 2018 (Article 21 right to die with dignity, living wills) → modified 2023 → *Harish Rana* 2026 (first application).
- **The commonest error in answers:** writing that the JMFC must *approve*. Since 2023 the JMFC is only **informed**.
- **Distinguish clearly** between the **living will pathway** (directive verified → boards) and the **no-directive pathway** (surrogate written consent → the same boards). Both use PMB and SMB.
- **Why uptake is still poor in India:** low public awareness, custodians not notified in most states, no national registry, and no statutory backing — hence the Supreme Court's call to Parliament.

Q2 Euthanasia and physician-assisted suicide. 15 MARKS

Source: *Essentials of Clinical Geriatrics*, 7th ed., Ch. 17 (Physician-Assisted Suicide; the seven legal myths of end-of-life care; medical futility) and Ch. 18 (Palliative Care); *Pathy's* 6th ed. — end-of-life decision-making. Indian legal position from *Gian Kaur* (1996), *Aruna Shanbaug* (2011), *Common Cause* (2018, modified 2023), *Harish Rana* (2026), with the Bharatiya Nyaya Sanhita, 2023.

A. Definitions and Classification

1. **Euthanasia** is the act of a physician **deliberately administering a lethal substance or carrying out an intervention to cause the death** of a patient who has decision-making capacity, at that patient's own voluntary request.
2. **Physician-assisted suicide (PAS)** is when a physician, at the voluntary request of a capable patient, **provides or prescribes the means** by which the patient ends their own life.
3. The crucial difference is **who performs the final act** — in euthanasia the **doctor** is the final agent; in PAS the **patient** is the final agent.
4. **By consent: voluntary** (competent patient's own request), **non-voluntary** (patient cannot consent, e.g. vegetative state, advanced dementia), and **involuntary** (against the person's wishes — this is homicide and is never acceptable).
5. **By nature of the act: active** (a positive act causing death) and **passive** (withholding or withdrawing life-sustaining treatment so that death follows from the underlying disease).
6. The term **"passive euthanasia" is now discouraged**. The preferred term is **withholding or withdrawing life-sustaining treatment (WH/WD-LST)**, because the intention is to stop a futile burden, not to cause death.
7. **What is NOT euthanasia:** withdrawing futile treatment, honouring a valid refusal of treatment, a **DNAR order**, **palliative sedation**, and **voluntarily stopping eating and drinking (VSED)**.
8. The **doctrine of double effect** permits giving adequate opioids or sedatives to relieve suffering even if death may be **foreseen but not intended** — this is lawful and ethical practice, not euthanasia.

B. Textbook Content (US Position)

9. In the United States, PAS is **legalised state by state**; **Oregon was the first, in 1997**, under its Death with Dignity Act.
10. The textbook notes that after legalisation, **relatively few terminally ill patients actually requested** physician assistance.
11. **Even where PAS is legal, physicians are not required to participate** — conscientious objection is protected.
12. The textbook lists **seven legal myths** about end-of-life care (ACP/ASIM committee, *JAMA* 2000). Two are examination-relevant: that a doctor giving **high-dose analgesia that hastens death will be prosecuted**, and that **nothing lawful can be offered** when suffering is overwhelming — both are false.
13. Decisions are guided by **medical futility**, which is **quantitative** (death is highly likely and further effort will not succeed) and **qualitative** (the quality of any surviving life). Clinicians must avoid imposing their own quality-of-life judgements.

C. Position in India

14. **Active euthanasia and PAS remain illegal in India.** Only withholding/withdrawing life-sustaining treatment under the Supreme Court's guidelines is lawful.
15. Active euthanasia amounts to **murder under Section 101 BNS 2023**. If the patient is **above 18 and has consented**, **Exception 5** reduces it to **culpable homicide not amounting to murder (Section 105 BNS)** — this **mitigates the charge but does not make the act legal**.
16. **PAS amounts to abetment of suicide under Section 108 BNS 2023** (up to 10 years' imprisonment and fine); abetment involving a child or a person of unsound mind falls under **Section 107 BNS**.
17. **Attempted suicide is effectively decriminalised** — **Section 115 of the Mental Healthcare Act, 2017** presumes severe stress and bars punishment.
18. **Legal milestones:** *Gian Kaur* (1996) — the right to life does **not** include a right to die; *Aruna Shanbaug* (2011) — passive euthanasia permitted with High Court approval; *Common Cause* (2018, modified 24 January 2023) — **right to die with dignity under Article 21**, legalising WH/WD-LST and living wills; *Harish Rana* (2026) — first Supreme Court–sanctioned withdrawal, with **active euthanasia expressly held impermissible**.

D. Ethical Arguments

19. **For:** respect for **autonomy** and self-determination; relief of intractable suffering (**beneficence and mercy**); preservation of **dignity**; logical consistency with the accepted right to refuse life-sustaining treatment; regulation is safer than covert, unregulated practice.
20. **Against:** violates **non-maleficence** and the Hippocratic tradition; the **slippery slope** with progressive widening of indications; danger to **vulnerable older people** (loneliness, poverty, elder abuse, feeling a burden); **prognostic uncertainty**; **depression is treatable and impairs capacity**; erosion of trust in the doctor–patient relationship; conflict with **distributive justice** where palliative care is not universally available.

E. Geriatric Relevance

21. Older adults are the **predominant group** requesting assisted death, and the commonest reasons given are **loss of autonomy, loss of dignity and inability to enjoy activities — not uncontrolled pain**.
22. A request to die is often a **cry for help**. Always screen for **untreated pain, depression, delirium, existential distress, caregiver strain and the feeling of being a burden**.
23. Specific geriatric dilemmas include **capacity assessment in dementia**, the validity of **advance euthanasia directives** in dementia, and the **"completed life" or "tiredness of life"** debate in the very old.
24. The correct clinical response is to **explore the request rather than react to it** — optimise symptom control, refer early to **palliative care or hospice**, treat depression, and address social and spiritual suffering.

F. Current Practice Update

Textbook position (*Essentials* 7e / *Pathy's* 6e)	**Current position, 2023–2026**
PAS legal in a few US states; **Oregon 1997** the first	Now legal in **~12 US jurisdictions**, with **New York and Illinois added since 2024**; Oregon **removed its residency requirement in 2023**, causing a step increase in prescriptions
"**Very few** terminally ill patients actually request PAS"	Uptake is now **substantial and rising** — Oregon reported **400 deaths in 2025**, and in Canada **MAiD accounted for 5.1% of all deaths in 2024**
Framed entirely in the **US legal context**	In **India**, PAS = **abetment of suicide (BNS s.108)** and active euthanasia = **murder (BNS s.101; Exception 5 → s.105)** — the BNS replaced the IPC from **1 July 2024**
"Passive euthanasia" used loosely for withdrawal of treatment	The Supreme Court in *Harish Rana* (2026) formally **retired the term**, replacing it with **"withholding or withdrawing medical treatment"**; "euthanasia" now means **active euthanasia only**
Eligibility framed around **terminal illness**	Marked international **drift beyond terminal illness** — Canada's **Track 2** (death not reasonably foreseeable), psychiatric illness and dementia in the Benelux countries, and France's new law with **no prognostic time limit**
Artificial nutrition/hydration debated as basic care versus treatment	Judicially settled in India — *Harish Rana* (2026) held **CANH is medical treatment** and may be withdrawn
"Physicians are not required to participate"	Reaffirmed and strengthened — the **WMA (2019)** holds that no physician should be forced to participate **or even to make a referral**

Latest Updates (2023–Present)

Professional and ethical positions

- **WMA Declaration on Euthanasia and Physician-Assisted Suicide (2019)** and the **WMA Declaration of Venice on End of Life Medical Care**: the WMA is **firmly opposed** to both practices, and states that **no physician should be forced to participate or to refer**. This remains its standing position.
- **EAPC White Paper** and **IAHPC Position Statement**: withholding or withdrawing futile, burdensome treatment is **not euthanasia**, because the intention is not to hasten death; **non-voluntary and involuntary euthanasia must never be permitted**.

India

- **Bharatiya Nyaya Sanhita, 2023** (in force 1 July 2024) renumbered the offences — **murder s.101** (punishment s.103), **culpable homicide not amounting to murder s.105** with **Exception 5** for consensual killing of an adult, **abetment of suicide s.108**, and **abetment of suicide of a child or person of unsound mind s.107**.
- ***Harish Rana v. Union of India*, 2026 SCC OnLine SC 358 / 2026 INSC 222 (11 March 2026):** the first Supreme Court–sanctioned withdrawal of life support in India. Held **CANH is medical treatment**; laid down a **"best interest" balance-sheet test** incorporating substituted judgement; recognised a **30-day reconsideration period** (waivable where all agree); directed **High Courts** to instruct JMFCs to receive hospital intimations and **CMOs** to maintain SMB panels; and **urged Parliament to enact comprehensive end-of-life care legislation** — while reaffirming that **active euthanasia remains impermissible**.

International legal developments

- **United Kingdom:** the **Terminally Ill Adults (End of Life) Bill** passed the Commons in **June 2025 (314–291)** and had its Lords second reading in September 2025, but **ran out of parliamentary time in April 2026** after more than 1,200 amendments; it is to be reintroduced. Assisting a suicide remains punishable under the Suicide Act 1961.
- **Isle of Man: Assisted Dying Act passed by Tynwald in March 2025** — terminal illness with expected death within **12 months**, capacity, 5 years' residency, verification by two independent doctors.
- **Jersey: Assisted Dying Law approved 26 February 2026 (32–16)** — terminal illness with expected death within **6 months (12 months for neurodegenerative disease such as Parkinson's disease or MND)**; notably permits **clinician administration as well as self-administration**.
- **France: legalised assisted dying in July 2026** — no prognostic time limit, but requires an **advanced, life-threatening illness causing intolerable and incurable suffering**, mental capacity, a voluntary informed request, medical assessment, and protection of **conscientious objection**; **mental illness alone does not qualify**.
- **Scotland:** the Assisted Dying for Terminally Ill Adults (Scotland) Bill remains before the Scottish Parliament.
- Other jurisdictions legalising since 2024 include **Uruguay, Ecuador, the Australian Capital Territory, New York and Illinois**.

Outcome data

- *Oregon Health Authority, 28th Annual DWDA Report (2026, data for 2025):* **637 prescriptions** and **400 deaths**; **88% aged ≥65 years**; diagnoses **cancer 61%, neurological 14%, heart disease 11%**; **92% enrolled in hospice** and **80% died at home**. The three leading end-of-life concerns were **loss of autonomy (89%), inability to participate in enjoyable activities (89%) and loss of dignity (65%)** — **pain was not among the leading reasons**.
- *Health Canada Annual MAiD Report (2025, data for 2024):* **16,499 MAiD deaths**, or **5.1% of all deaths in Canada** (Quebec **7.9%**), with over **76,000 cumulative deaths** since 2016. **Track 2** accounted for **732 deaths**. Roughly **half of recipients reported feeling a burden** on family or caregivers.
- **Canada — expansion to mental illness as the sole underlying condition** has been deferred three times and is currently scheduled for **March 2027**; the **UN Human Rights Committee (2025)** urged Canada to repeal Track 2 and halt further expansion — the central real-world test of the **slippery slope argument**.

Examiner's Tip

Skeleton: Define euthanasia and PAS (WMA wording) → distinguish by **final agent** → classify by **consent** and by **act** → list what is **not** euthanasia (futility, DNAR, double effect, palliative sedation, VSED) → textbook US position (Oregon 1997, low uptake, no compulsion, seven legal myths, futility) → **Indian law:** *Gian Kaur* → *Aruna Shanbaug* → *Common Cause* 2018/2023 → *Harish Rana* 2026, with **BNS s.101/105 and s.108** → arguments for and against → **geriatric angle** → conclude with **palliative care as the answer to the demand for euthanasia**.

"The distinction is not merely semantic: in **euthanasia the physician performs the final act**, in **physician-assisted suicide the patient does** — and in India the first attracts **Section 101 BNS (murder, mitigated to Section 105 by Exception 5 where an adult consents)** while the second attracts **Section 108 BNS (abetment of suicide)**. Only **withholding or withdrawing life-sustaining treatment** under the *Common Cause* guidelines is lawful."

"The Oregon and Canadian data make the geriatric point sharply — the dominant reasons for requesting assisted death are **loss of autonomy, loss of dignity and inability to enjoy life, not uncontrolled pain**, and around **half of Canadian recipients report feeling a burden** — which means that in an ageing society the most effective response to a request for hastened death is **early, accessible palliative care, treatment of depression, and relief of caregiver and social burden**."

Extra Points to Remember — recurring topic

- **The one-line discriminator:** "Who administers the final act?" Doctor = euthanasia. Patient = PAS.
- **Never write "passive euthanasia is legal in India."** Write: "**Withholding and withdrawing life-sustaining treatment** is lawful under Supreme Court guidelines; **euthanasia (active) is not**."
- **Double effect has four conditions:** the act itself must be good or neutral; the bad effect must not be the *means* to the good effect; the **intention** must be relief of suffering; and there must be **proportionate reason**.
- **BNS section numbers replaced IPC from 1 July 2024:** IPC 302 → **BNS 101/103**; IPC 304 → **BNS 105**; IPC 306 → **BNS 108**; IPC 309 (attempt) → overridden by **MHCA s.115**.
- **Slippery slope — the examinable evidence:** Canada's progression from terminal illness (2016) → **Track 2, death not reasonably foreseeable (2021)** → proposed **mental illness alone (deferred to March 2027)**, with MAiD now **5.1% of all deaths**.
- **Closing line that scores:** "The demand for euthanasia is largely a demand for better dying; where palliative care is accessible, the demand falls."

Q3 Informed consent. 15 MARKS

Source: *Essentials of Clinical Geriatrics*, 7th ed., Ch. 17 — Competence and Informed Consent; decisional capacity; informed assent; surrogate decision-making; Table 17-1 Major Ethical Principles. *Pathy's* 6th ed. Indian legal position from *Samira Kohli v. Dr Prabha Manchanda*, (2008) 2 SCC 1, the IMC/NMC Regulations, and *Common Cause* (2018, modified 2023).

A. Definition and Components

1. Informed consent is the doctrine requiring a clinician to **disclose enough information for the patient to make an informed decision** before any investigation, procedure or treatment. It is a **process of communication, not a signature on a form**.
2. Three components must all be satisfied: **capacity to decide**, **voluntariness** (free of coercion or undue influence), and **adequate information** that the patient actually understands.
3. The textbook lists **five items the clinician must disclose**: (i) the **condition being treated**; (ii) the **nature and character** of the proposed treatment or surgery; (iii) the **anticipated results**; (iv) **recognised alternative forms of treatment**; and (v) **recognised serious risks, complications and benefits** — of the proposed treatment, of the alternatives, and of **non-treatment**.
4. Consent is **continuing and revocable**. A patient who makes an informed decision may **change their mind at any time** — a competent person who refuses dialysis does not lose the right to reconsider later.
5. The ethical foundation is **autonomy**, balanced against **beneficence, non-maleficence, justice and fidelity**.

B. Capacity versus Competence

6. **Capacity** is a **clinical judgement** made by the treating clinician about a **specific decision at a specific time**. **Competence is a legal term** — a determination made by a **court of law**.
7. Capacity is **decision-specific, not global**, and follows a **sliding scale** — the more serious the consequences, the higher the threshold demanded.
8. The **four elements of decisional capacity** are: (i) **understanding**; (ii) **appreciation**; (iii) **reasoning**; and (iv) **expressing a choice**.
9. **A diagnosis of dementia is not by itself proof of incapacity.** Intellectual deficits are "spotty" — a patient may forget things yet still decide well **with appropriate prompting**. It is wrong to prejudge, and equally wrong to **infantilise** the patient by directing questions to relatives who answer faster.
10. **Distinguish memory from understanding** — these are not the same thing.
11. **No cognitive screening test determines capacity.** Tests of **executive function** (**Clock Drawing Test, Executive Interview**) correlate better with decisional capacity than the **MMSE**. Formal instruments exist but are difficult for older adults because they demand abstract, hypothetical reasoning.
12. A practical bedside test recommended by the textbook is to **re-check the patient after an interval** and confirm that the understanding and the stated preference are **consistent**.
13. Always look for and correct **reversible causes of apparent incapacity** — **delirium, depression, fear, pain, metabolic derangement, drug effects**, and **hearing or visual impairment**. Capacity may **fluctuate**.
14. Patients who are comatose, or who have **expressive or receptive aphasia** or moderate-to-severe dementia, may be unable to communicate effectively — assess carefully **what they can still understand and express** rather than assuming nothing.

C. When Capacity is Absent

15. Authority passes to a **surrogate** — through an **advance directive / living will**, a **durable power of attorney for health care (proxy)**, or a court-appointed **guardian or conservator**.
16. Surrogate decisions follow a hierarchy: **the patient's known prior wishes → substituted judgement (what the patient would have chosen) → best interests** (weighing benefits against burdens).
17. **"Informed assent"** is a useful option — where the family or proxy does not want to carry the burden of the decision, they may be **explicitly offered the choice to defer to the clinician's judgement**. This must be **clearly documented**.

D. Exceptions and Pitfalls

18. Recognised exceptions are **emergency/necessity** (unconscious patient, life-saving intervention), **patient waiver**, and

therapeutic privilege (narrow and now rarely accepted).

19. Common pitfalls in geriatric practice: **blanket or pre-printed consent forms**, consent taken **on the trolley or after premedication**, **relatives signing when the patient is capable**, and failure to record the discussion. **A signed form without disclosure is not consent.**
20. In geriatrics the evidence itself is often **absent, extrapolated from younger patients, or contradictory** — so risks and benefits are genuinely uncertain, and **clinician values may unconsciously distort how options are framed**. Shared decision-making and confirming understanding (e.g. **teach-back**) are therefore essential.

E. Indian Legal Position

21. India applies the **"real consent"** standard laid down in ***Samira Kohli v. Dr Prabha Manchanda*, (2008) 2 SCC 1** — **not** the American "reasonable/prudent patient" standard.
22. **Key propositions from *Samira Kohli*:** consent for a **diagnostic procedure is not consent for therapy**; consent for **one procedure does not cover another**, and the fact that the extra surgery was **beneficial does not validate it**; **relatives cannot consent to an additional procedure on an unconscious patient** except in a genuine life-threatening emergency; for major surgery **two separate consents** should be taken; and the disclosure standard is the **modified Bolam (professional) standard**.
23. **Legal consequences:** operating **without any consent = battery**; **inadequate disclosure = negligence**; breach of **Regulation 7.16** (written consent before operations) = **professional misconduct**. The emergency/necessity defence lies in **Section 92 IPC, now Section 28 BNS 2023**.

F. Current Practice Update

Textbook position (*Essentials* 7e / *Pathy's* 6e)	**Current position, 2023–2026**
Five-item disclosure list, with no named legal standard	India applies the **modified Bolam professional-disclosure standard** (*Samira Kohli*, 2008), unlike the **patient-centred standard** of *Canterbury v Spence* (USA) and *Montgomery* (UK)
"Informed consent laws do not specify how much must be disclosed"	The **seven propositions of *Samira Kohli*** are now the **operative test** applied by every Indian consumer forum, High Court and the Supreme Court
No screening test determines capacity; executive tests better than MMSE	Still correct; structured instruments (**MacCAT-T, Aid to Capacity Evaluation, CCTI**) are validated, and longitudinal data show **reasoning is the first of the four abilities to fail** in mild-to-moderate dementia
Surrogates and guardians defined by **US state statutes**	India has **no general statutory surrogate hierarchy** for an adult who loses capacity — the closest are the **nominated representative under the Mental Healthcare Act, 2017** and the **guardian named in an advance medical directive**
Advance directives framed by the **US Patient Self-Determination Act**	India's **advance medical directive** became operational after the Supreme Court's order of **24 January 2023**, giving **prospective consent** legal force
Substance of consent matters more than the form	In India **written consent is mandatory for operations** under **Regulation 7.16**, but a **blanket form** ("any procedure found necessary") remains **legally invalid**
Consent framed around **treatment decisions** only	Consent is now **layered** — clinical consent (*Samira Kohli*/NMC), **research consent** (ICMR National Ethical Guidelines 2017), and **health-data consent** (DPDP Act 2023 with DPDP Rules 2025)
Surrogate and family decisions handled informally	For withholding/withdrawing life-sustaining treatment, India now requires the **surrogate's written consent in a prescribed format** plus **two medical boards** and **JMFC intimation**

Latest Updates (2023–Present)

Indian regulatory framework

- **NMC Registered Medical Practitioner (Professional Conduct) Regulations, 2023** (Gazette, 2 August 2023) carried a dedicated **guidance document on informed consent** stating that the consent process **must never be curtailed or neglected because the patient is unable to "fully understand"**, and expressly naming **the elderly, the marginalised and the illiterate** as vulnerable groups requiring extra care. Research consent was excluded and referred to the **ICMR Guidelines, 2017**.
- **These Regulations were held in abeyance on 23 August 2023** after objections from the IMA and other bodies, and the **Indian Medical Council (Professional Conduct, Etiquette and Ethics) Regulations, 2002 — including Regulation 7.16 — were revived and remain in force**. The 2023 Regulations are **not operative** until a further gazette notification. *This is the single most examinable regulatory fact.*
- **Bharatiya Nyaya Sanhita, 2023** (in force 1 July 2024): the good-faith and necessity protections formerly in **IPC ss. 87–92** are renumbered as **BNS ss. 25–28**, with **Section 28 BNS** covering acts done in good faith for a person's benefit **where consent cannot be obtained**.
- ***Common Cause*** (2018, modified **24 January 2023**) and ***Harish Rana*** (2026) confirm that a valid **advance medical directive is a recognised form of consent**, binding the clinician at the future moment of incapacity.

Health-data consent — a new statutory layer

- **Digital Personal Data Protection Act, 2023** with the **DPDP Rules, 2025** (notified 13–14 November 2025) make consent for processing patient data a **separate statutory requirement**. Consent must be **free, specific, informed, unconditional, unambiguous and revocable**, supported by an **itemised notice** in plain language.
- Implementation is **phased**: the **Data Protection Board** from November 2025, **consent managers** from **November 2026**, and the **core compliance obligations** (notice, security, breach reporting, data-principal rights) from **May 2027**. Hospitals are **data fiduciaries**; large ones may be designated **significant data fiduciaries** requiring a **data protection officer**. Clinical establishments have **limited exemptions** where processing is necessary to provide health services.

Capacity assessment and shared decision-making

- *JAGS 2024:* scoping review of **decision-making tools that support substitute decision-makers** for adults with impaired capacity — reflecting a shift from simply *declaring* incapacity to actively *supporting* the surrogate.
- *JAGS 2025:* scoping review of **shared decision-making interventions for deprescribing** in older adults with polypharmacy — the principle being that **consent to stop a drug deserves the same rigour as consent to start one**.
- Internationally, the direction of travel is from **substitute decision-making towards supported decision-making**, driven by **UNCRPD Article 12** and, in India, the **Rights of Persons with Disabilities Act, 2016** and the **Mental Healthcare Act, 2017**, both of which begin from a **presumption of capacity**.

Examiner's Tip

Skeleton: Define consent as a **process, not a form** → three components (**capacity, voluntariness, information**) → the **five disclosure items** → **capacity vs competence** → the **four elements** → dementia ≠ incapacity; **executive tests beat MMSE**; reversible causes → if incapable: **advance directive → proxy → substituted judgement → best interests**, with **informed assent** as an option → exceptions (**emergency, waiver, therapeutic privilege**) → **Indian law: *Samira Kohli* "real consent"**, battery vs negligence, **Regulation 7.16**, **Section 28 BNS** → newer layers: **AMD, ICMR research consent, DPDP data consent**.

> "**Capacity is a clinical determination made by the treating doctor for a specific decision at a specific time; competence is a legal determination made by a court** — and capacity rests on four abilities: **understanding, appreciation, reasoning and expressing a choice**. No cognitive screening test, including the MMSE, establishes capacity; **executive-function measures correlate better**, and a **diagnosis of dementia is never by itself evidence of incapacity**."

> "In India the operative standard is **'real consent'** under *Samira Kohli v. Dr Prabha Manchanda* (2008): **consent for a diagnostic procedure is not consent for therapy, consent for one procedure does not authorise another, and the fact that the additional surgery was beneficial does not validate it** — relatives cannot consent for an unconscious patient's additional procedure except in a genuine life-threatening emergency. A **signed pre-printed form without disclosure is evidence of a signature, not of consent**."

Extra Points to Remember — recurring topic

- **Battery vs negligence — the classic viva discriminator: no consent at all → battery/assault** (trespass to the person, no proof of harm needed); **consent obtained but disclosure inadequate → negligence** (harm and causation must be proved).
- **Three disclosure standards worldwide: Bolam / professional standard** (what a reasonable doctor would disclose) — **India**; **reasonable patient standard** (*Canterbury v Spence*) — USA; **particular patient / material risk standard** (*Montgomery v Lanarkshire*, 2015) — UK.
- **Valid consent in India must be:** voluntary · by a person **≥18 years** of sound mind · informed · specific to the procedure · **written for operations** (Reg. 7.16) · obtained **before premedication** · documented.
- **The three exceptions in one line: Emergency** (necessity — BNS s.28), **Waiver** (patient chooses not to know), **Therapeutic privilege** (disclosure itself would gravely harm — now very narrow and best avoided).
- **Geriatric traps:** consent taken from the son because he speaks English; consent signed on the trolley; the "blanket" form; assuming a hearing-impaired patient is confused. All four are examinable failures.
- **Special consents to name:** HIV testing, organ donation (THOTA), sterilisation, clinical research (ICMR 2017), photography/publication, and **data processing (DPDP 2023)**.

Q4 Decisional capacity — factors affecting it and how to assess it. 15 MARKS

Source: *Essentials of Clinical Geriatrics*, 7th ed., Ch. 17 (Competence and Informed Consent; four elements of decisional capacity) and Ch. 6 (Delirium and Dementia — mental status examination, executive function, reversible causes, Table 6-5 drugs causing cognitive impairment); *Pathy's* 6th ed. — Confusion Assessment Method.

A. Definition and Governing Principles

1. **Decisional capacity** is a **clinical judgement** by the treating doctor that a patient can make **one particular decision at one particular time**. **Competence is a legal term** — determined by a **court of law**.
2. Every adult is **presumed to have capacity** until the contrary is demonstrated. The burden of proof lies on the person asserting incapacity.
3. Capacity is **decision-specific and time-specific, never global**. A patient may lack capacity for a complex surgical decision yet retain capacity to refuse a blood test or to choose where to live.
4. A **sliding (risk-proportionate) scale** applies — the graver the consequences, the greater the certainty required before accepting the patient's choice.
5. **An unwise decision is not incapacity.** Capacity is judged by the **process of reasoning**, not by the **outcome chosen**.
6. Capacity rests on **four elements**: (i) **understanding** the disclosed information; (ii) **appreciation** of what it means for one's own situation; (iii) **reasoning** through risks and benefits; and (iv) **expressing a choice**. **All four must be present.** Denial of illness typically fails at *appreciation*; intact memory with poor planning fails at *reasoning*.

B. Factors Affecting Decisional Capacity

7. **Neurocognitive disorders:** dementia of any type, mild cognitive impairment, stroke, Parkinson's disease. **Executive dysfunction** correlates with capacity far better than memory loss — in frontotemporal dementia, appreciation and reasoning fail early despite preserved recall.
8. **Delirium** is the commonest **reversible** cause in hospital — defined by **acute onset, fluctuation, inattention** and disturbed consciousness; diagnose with the **CAM** (features 1 and 2 plus either 3 or 4). Frequently **superimposed on dementia** and often missed in its **hypoactive** form.
9. **Psychiatric illness:** depression (hopelessness distorts appreciation and the weighing of risk — **"depressive pseudodementia"** causes patchy deficits and frequent "don't know" answers), psychosis, mania, severe anxiety or fear.
10. **Drugs** — a major and correctable contributor: **anticholinergics, antihistamines, opioids, benzodiazepines and sedative-hypnotics, antipsychotics, anticonvulsants, antiparkinsonian drugs, steroids, digoxin, H_2-receptor antagonists, muscle relaxants and alcohol**. Recent **anaesthesia and premedication** matter — consent taken after premedication is invalid.
11. **Medical and metabolic causes:** hypoxia, hypoglycaemia, hyponatraemia, uraemia, hepatic encephalopathy, hypothyroidism, B_{12} deficiency, sepsis, dehydration, uncontrolled **pain**, sleep deprivation, and — classically in geriatrics — **faecal impaction and urinary retention**, whose relief can produce dramatic improvement.
12. **Sensory and communication barriers:** deafness, poor vision, dysarthria, and **expressive or receptive aphasia**. Older patients are often mislabelled "confused" or "senile" simply because they were **not given adequate time to answer** or could not hear the question.
13. **Educational, linguistic and cultural factors:** low literacy, an unfamiliar language or dialect, technical jargon, and family-centred decision norms in which the patient defers to relatives.
14. **Decision-related factors:** complexity, novelty, number of options, volume of information, and **urgency or time pressure**.
15. **Environmental and assessor factors:** a noisy unfamiliar ward, time of day (**sundowning**), a rushed disclosure, a coercive relative in the room, and the clinician's own **framing bias**.
16. **Capacity fluctuates.** It must be reassessed at the patient's best time and again after reversible factors have been treated.

C. How to Assess Decisional Capacity — Seven Steps

17. **Step 1 — Optimise before assessing.** Treat delirium, pain and depression; stop offending drugs; correct metabolic derangement; supply hearing aids and spectacles; use the patient's own language or an interpreter; choose a quiet room and the best time of day; allow unhurried time.

18. **Step 2 — Disclose properly.** Plain language in short chunks, repeat, use written or pictorial aids, then confirm with **teach-back** — "tell me in your own words what we have decided".
19. **Step 3 — Structured interview mapped to the four abilities**, using the patient's own words:
    - **Understanding** — "What is wrong with you? What treatment have I suggested? What could go wrong?"
    - **Appreciation** — "Why do you think this has been advised for *you*? What will happen if you do not have it?"
    - **Reasoning** — "How did you arrive at that decision? What made this option better than the other?"
    - **Expressing a choice** — "So what have you decided?"
20. **Step 4 — Screening tests support only. No cognitive screening test determines capacity.** The **MMSE alone is inadequate**; tests of **executive function** — the **Clock Drawing Test**, the **Mini-Cog** (three-item recall plus clock drawing) and the **Executive Interview** — correlate far better.
21. **Step 5 — Structured instrument in difficult or contested cases.** The **MacArthur Competence Assessment Tool for Treatment (MacCAT-T)** is the reference standard and scores all four abilities; the **Aid to Capacity Evaluation (ACE)** is short, free and practical at the bedside; **MacCAT-CR** and **UBACC** are used for research consent. These tools demand abstract, hypothetical reasoning and are therefore difficult for many older adults.
22. **Step 6 — Re-check for consistency** after an interval to confirm that understanding and the stated preference are **stable**, as the textbook specifically recommends.
23. **Step 7 — Document and escalate.** Record the **specific decision**, the information given, the patient's **verbatim responses under each of the four abilities**, the reversible factors addressed, the conclusion and the plan for reassessment. Seek a **second opinion (psychiatry or neuropsychology)** when stakes are high, the assessment is contested, capacity fluctuates, or the choice conflicts with the person's lifelong values.
24. **If capacity is absent**, never make a **blanket declaration**. Support what the patient can still do (**supported decision-making**), then fall back to **advance directive → nominated representative or proxy → substituted judgement → best interests**, and **reassess once reversible factors are corrected**.

D. Current Practice Update

Textbook position (*Essentials* 7e / *Pathy's* 6e)	Current position, 2023–2026
Four elements of capacity described narratively	Formalised as the **Appelbaum–Grisso four-abilities model**, now the international standard and the basis for the **MacCAT-T** and **MacCAT-CR**
"No cognitive screening test is appropriate"; executive tests beat the MMSE	**Unchanged and reinforced** — the **Mini-Cog** (recall + clock drawing) is the preferred bedside screen for who needs fuller assessment
Capacity instruments described as "difficult for older adults"	**23 instruments** now catalogued, with **considerable heterogeneity** in criteria and operationalisation; MacCAT-T remains the reference standard, **ACE** the practical bedside choice
Four-abilities model presented as settled	Recent commentary documents **substantial inter-rater variability**, poorer performance in **MCI**, demonstrated **racial bias**, and neglect of **emotion and values** — the call is for **safeguards and flexibility**, not abandonment
Capacity framed as a binary clinician determination	Shift towards **supported decision-making** under **UNCRPD Article 12**, India's **RPWD Act 2016** and **MHCA 2017** — support first, substitute only as a last resort
Surrogate arrangements described through **US guardianship and proxy statutes**	**India: MHCA 2017 Section 4** codifies a three-limb capacity test with a **presumption of capacity** and a **nominated representative**; for general medical decisions there is still **no statutory surrogate hierarchy** outside the advance medical directive route
Capacity assessed as a one-off event	Emphasis now on **serial reassessment**, because delirium persists in a substantial minority and capacity is dynamic

Latest Updates (2023–Present)

Indian statutory framework

- **Mental Healthcare Act, 2017, Section 4** is the only Indian statute that defines capacity. Its three limbs are: ability to **understand information relevant to the decision**; ability to **appreciate any reasonably foreseeable consequence of a decision or of the lack of a decision**; and ability to **communicate the decision by speech, expression, gesture or any other means**. The Act begins from a **presumption of capacity**, endorses **supported decision-making**, and restricts the **nominated representative** to those found to lack capacity.
- *Indian Journal of Psychiatry* commentary highlights a drafting problem: the statute joins the three limbs with **"or"** rather than "and", which literally read would allow a person satisfying only one limb to be deemed capacitous. Commentators and clinical practice hold that **all three must be satisfied**; there have been repeated calls for an amendment and a **Code of Practice** for capacity assessment.
- For general medical (non-psychiatric) decisions, the operative rules remain the **capacity limb of "real consent"** in *Samira Kohli* (2008) and the **advance medical directive** framework under *Common Cause* (2018, modified 2023) and *Harish Rana* (2026).

Evidence on the assessment model itself

- *Journal of the American Academy of Psychiatry and the Law, 2024:* the four-skills model shows **considerable variability between evaluators**, especially pronounced in **mild cognitive impairment due to Alzheimer's disease**, and has shown **high levels of racial bias**. The authors argue the model is often applied **too inflexibly** and to situations for which it was not designed, and stress that in many circumstances loss of capacity is **temporary or reversible**.
- *European Psychiatry, 2025* (Kupsch et al., systematic review to March 2024): identified **23 instruments** assessing capacity to consent to treatment, with **considerable heterogeneity** in criteria and operationalisation — a caution against treating any single tool's cut-off as definitive.
- *BMC Psychiatry, 2025* (Norwegian stakeholder study): the four-abilities model is the primary basis of capacity assessment in specialist care, but **systematic training, validated tools and further research are needed** to improve assessment quality in routine practice.
- *JAGS 2024:* scoping review of **decision-making tools that support substitute decision-makers** — emphasis has shifted from merely *declaring* incapacity to actively *supporting* the surrogate.
- *JAGS 2025:* scoping review of **shared decision-making interventions for deprescribing** in older adults with polypharmacy — consent to **stop** a drug requires the same capacity assessment as consent to start one.

Epidemiology that drives practice

- Meta-analytic data in hospitalised older adults show a **delirium prevalence of about 21%** and a **frailty prevalence of about 34%**, with frailty an **independent risk factor for delirium (RR 1.66)** — a large minority of ward patients have a **potentially reversible** barrier to capacity at any moment.
- **Persistent delirium** is common: pooled prevalence at discharge around **36%**, and modelling suggests roughly **16% at 12 months** — capacity must be **reassessed serially**, not certified once.
- Dementia prevalence in older general-hospital inpatients ranges from **13% to 63%**, and fewer than one-third of studies screened for **delirium or depression** — misclassification of reversible impairment as dementia is frequent.
- Longitudinal **MacCAT-T** data in mild-to-moderate dementia show that **reasoning is the ability that fails first and most often** (about 23% impaired at 9 months; about 26% impaired overall), while **appreciation and expressing a choice are relatively preserved**. Clinically, **probe reasoning hardest**.

Examiner's Tip

Skeleton: Capacity (clinical) vs competence (legal) → presumption of capacity → **decision-specific, time-specific, sliding scale**; an unwise decision is not incapacity → the **four abilities** with model questions → **factors**: neurocognitive, delirium, psychiatric, drugs, metabolic, sensory, educational-cultural, decision complexity, environment and assessor bias, fluctuation → **assessment**: optimise → disclose with teach-back → four-ability interview → screening tests support only (**Mini-Cog/Clock/EXIT, not MMSE alone**) → **MacCAT-T / ACE** if contested → re-check consistency → document → second opinion → if incapable: **support first**, then AD → nominated representative → substituted judgement → best interests, and **reassess**.

"**Capacity is decision-specific, time-specific and risk-proportionate — it is never a global label**, and it is judged by the **process of reasoning, not by the choice made**. The four abilities that must all be present are **understanding, appreciation, reasoning and expressing a choice**; in dementia, **reasoning is the ability that fails first**, so it is the one to probe hardest."

"**No cognitive screening test determines capacity** — the MMSE least of all. Tests of **executive function (Clock Drawing, Mini-Cog, Executive Interview)** correlate far better, and the **MacCAT-T** or the **Aid to Capacity Evaluation** should be used when the case is contested. But before any of this, the first duty is to **remove the reversible barrier** — delirium, pain, depression, an anticholinergic, hyponatraemia, faecal impaction, or simply a missing hearing aid — because in geriatric practice most apparent incapacity is **treatable, fluctuating and temporary**."

Extra Points to Remember — recurring topic

- **Mnemonic for the four abilities — "U-A-R-C": U**nderstanding · **A**ppreciation · **R**easoning · **C**hoice.
- **Mnemonic for reversible causes — "DELIRIUM": D**rugs · **E**lectrolytes and endocrine · **L**ack of drugs (withdrawal) · **I**nfection · **R**educed sensory input · **I**ntracranial · **U**rinary/faecal retention · **M**yocardial and pulmonary (hypoxia).
- **The three commonest wrong answers in vivas:** (i) "MMSE <24 means no capacity" — false; (ii) "he refused surgery so he lacks capacity" — outcome bias; (iii) "he has dementia so the son will sign" — capacity was never assessed.
- **Delirium vs dementia in one line:** delirium = **acute, fluctuating, inattention, altered consciousness**; dementia = **gradual, progressive, consciousness preserved until late**.
- **Assent vs consent:** where the patient lacks capacity, still seek **assent** — their agreement at their own level — and note dissent, which should carry real weight in the best-interests calculation.
- **Capacity is also needed for non-medical decisions** that a geriatrician is often asked about: testamentary capacity (making a will), financial capacity, capacity to drive, capacity to live alone, and capacity to consent to sexual activity in a care home. **Each is assessed separately.**

Q5 How will you communicate and break bad news to an older patient? 15 MARKS

Source: *Essentials of Clinical Geriatrics*, 7th ed., Ch. 3 — Evaluating the Geriatric Patient (Table 3-2, Potential Difficulties in Taking Geriatric Histories) and Ch. 17; *Pathy's* 6th ed. — Communication Disorders and Dysphagia, and Ch. 8 Health Literacy and Cultural Sensitivity (Tables 8.5 and 8.6, barriers and areas of cultural conflict).

A. General Principles of Communication in Geriatrics

1. Effective communication means a message is conveyed **and correctly interpreted**. It depends on hearing, vision, attention, arousal, memory and cognition — **every one of which may be impaired in an older patient**.
2. The textbook lists three core barriers in geriatric history-taking: **diminished hearing, diminished vision and slowed psychomotor performance**.
3. Practical corrective measures are examinable verbatim: use a **well-lit room**, **eliminate extraneous noise**, **speak slowly in a deep tone**, **face the patient so the lips can be seen**, use a **simple amplification device** for severe hearing loss, **write questions in large print** if needed, and **leave enough time to answer**.
4. **Patience is truly a virtue.** Thought and verbal processes are slower; hurrying loses important information. The rule of open-ended questions may need to be **tempered** to fit the time available.
5. Older patients **underreport symptoms** because of health beliefs, fear, depression and cognitive impairment. Ask **specific direct questions** and use **collateral history** from relatives and caregivers.
6. **Non-verbal communication carries a great deal of information.** Cultures differ in pace of conversation, tolerance of interruption, physical proximity, eye contact, touch and finger-pointing. Attitudes to the **direct discussion of death** vary widely.
7. The **electronic record is itself a communication barrier** — patients perceive it as disrespectful when the clinician interacts more with the screen than with the person.
8. Use **professional interpreters, not children**. Misinterpretation happens even in a shared language — a patient saying "stomach ache" may mean pain anywhere in the abdomen.
9. Avoid **stereotyping**. Rather than memorising every culture, **ask the patient or interpreter** what is acceptable, record it, and revisit it at follow-up. **There is no substitute for asking the older adult what their goals are.**
10. In **dementia**, use the speech-therapy strategies given in *Pathy's*: **use names instead of pronouns**, **avoid open-ended questions by offering definite options**, **encourage gesture**, and use **communication prompts such as pictures and charts**. Training caregivers with **memory books and wallets** improves interaction.
11. Avoid **ageist language and elderspeak**. Do not direct questions to the relative who answers faster — that infantilises the patient.

B. Breaking Bad News — the SPIKES Protocol

12. **S — Setting.** Private, quiet, well-lit room; **sit down at eye level**; ensure the **hearing aid and spectacles are in place**; have an amplifier ready; silence the phone; ask **who the patient wants present**; allow uninterrupted time.
13. **P — Perception. Ask before you tell:** "Before I give you the results, tell me what you understand about what has been happening."
14. **I — Invitation.** Ask **how much the patient wants to know** and in what detail. Some want full details, others want a relative told. **The right not to know must be respected.**
15. **K — Knowledge.** Give a **warning shot** ("I'm afraid I have some difficult news"), then deliver it in **plain language in small chunks**. Use the real word — "cancer", "dementia" — not euphemisms. **Pause frequently** and check understanding with **teach-back**.
16. **E — Emotions and empathy.** Expect silence, tears, denial or anger. Respond with **NURSE** statements — **N**ame the emotion, express **U**nderstanding, show **R**espect, offer **S**upport, and **E**xplore. **Never answer an emotional statement with more data.**
17. **S — Strategy and summary.** Agree the next steps, address symptom control, give a **written summary**, a **contact person** and a **follow-up date**. **Never say "there is nothing more we can do"** — reframe to what *can* be done.

C. Other Frameworks Worth Naming

18. **Ask–Tell–Ask** for each chunk of information; **REMAP** (Reframe, Expect emotion, Map values, Align, Plan) for goals-of-care conversations; **Best Case / Worst Case** and **time-limited trials** for treatment decisions; the **Serious Illness Conversation Guide** for values and prognosis.

D. Geriatric- and India-Specific Issues

19. Disclose to the **patient first** if capacity is present. If capacity is impaired, work through the **advance directive** and the **nominated surrogate**, but still tell the patient at their level — **dementia does not abolish the right to know**.
20. **Collusion** — the family asking the doctor to withhold the truth — is common in India. Do not simply comply, and do not simply override. **Explore the family's fear**, ask what they think will happen if the patient is told, obtain their permission to ask the patient how much they wish to know, and then use the **patient's own invitation** as the ethical route through.
21. **Prognostic communication:** give **ranges, not point estimates** ("hours to days", "weeks to months"), acknowledge uncertainty honestly, and hold **hope and preparedness together** — "hope for the best, prepare for the worst".
22. **Document** who was present, what was disclosed, the questions asked and the plan; then **brief the whole team** so the message is consistent. **Mixed messages from different team members are a leading cause of complaints.** Debrief afterwards — most clinicians report feeling low after breaking bad news.

E. Current Practice Update

Textbook position (*Essentials* 7e / *Pathy's* 6e)	**Current position, 2023–2026**
Generic communication tips and cultural-sensitivity advice	Formalised, teachable, evidence-based protocols — **SPIKES, Ask–Tell–Ask, NURSE, REMAP, Best Case/Worst Case** and the **Serious Illness Conversation Guide**
No named standard for **dementia diagnosis disclosure**	**AAN / Alzheimer's Association multi-stakeholder Delphi best practices (2024)**, the **DETeCD-ADRD guideline (2025)** for primary care, and the **CLEAR guidelines (2025)** for culturally sensitive disclosure
Family involvement framed as culturally appropriate	Reframed as **patient-directed** — the patient decides who is present and how much is disclosed; **collusion is managed explicitly, not accommodated by default**
Disclosure treated as a single event	Now a **longitudinal, repeated conversation**, with a **written summary and care plan**, because patients and families recall very little from the disclosure visit
Communication skill assumed to be acquired by experience	**Systematic review evidence (2025)** shows structured training improves communication behaviours in **93%** of studies and self-efficacy in **96%**, largely sustained at follow-up
Prognosis discussion left to individual judgement	**Structured tools reliably improve process but not yet outcomes** — they increase documentation of goals-of-care discussions, with mixed effects on concordant care and utilisation
Electronic record noted as a barrier	Compounded by **tele-consultation and AI scribes**; the principle is unchanged — **attend to the person, not the screen**

Latest Updates (2023–Present)

Dementia diagnosis disclosure — the biggest change

- *Neurology Clinical Practice, 2024* (AAN process, multi-stakeholder modified Delphi including a patient and caregivers) issued **seven best-practice statements**. The strongest is that **clinicians must show compassion and empathy when delivering a diagnosis of dementia (Level A)**. Clinicians should also **ask about the patient's diagnosis preferences, instil realistic hope, provide practical strategies, provide education and links to high-quality resources, and connect caregivers to support**. A **written record or care plan** is recommended because patients and families recall the disclosure visit poorly and often differently.
- **The driving statistic:** in **about 50%** of people whose billing records indicate dementia, the **patient or care partner reports never having been told the diagnosis** — even though the **vast majority want to know**.
- **Alzheimer's Association DETeCD-ADRD clinical practice guideline** (*Alzheimer's & Dementia, 2025*) covers diagnostic evaluation, testing, counselling and disclosure for primary care, and reports that **39% of primary care physicians are "never or only sometimes" comfortable making a dementia diagnosis**.
- **O'Brien, Largent and Karlawish** (*Alzheimer's & Dementia, 2025;* summarised in *JAMA, 2025*) give practical guidance: before disclosing, assess the patient's **understanding and appreciation of their symptoms, their goals for the evaluation, and their desire for information**. Because Alzheimer's disease itself distorts symptom perception, an **informant or care partner should be included**.
- **CLEAR guidelines** (*Alzheimer's & Dementia, 2025*) — *Compassionate Language and Empathetic Approaches for Respectful dementia disclosure* — a culturally sensitive framework encouraging disclosure of **aetiology, type, prognosis and support resources**, together with **active listening, empathy and explicit emotional support**, and preparation for a difficult conversation.

Evidence on structured communication tools and training

- *BMJ Supportive & Palliative Care, 2026* — systematic review and meta-analysis of **22 randomised trials** of communication tools and decision aids for hospitalised adults (2015–2025). Tools **increased documentation of goals-of-care discussions (OR 1.46, 95% CI 1.04–2.05)**; effects on resuscitation preferences were **inconsistent (OR 1.84, 95% CI 0.95–3.60)**; effects on **concordant care, psychosocial outcomes and healthcare utilisation were mixed**. The honest verdict: structured tools reliably improve **process**, not yet **outcomes**.
- *BMC Medical Education, 2025* — systematic review of communication skills training in chronic care: **communication behaviours improved in 93% (37/40) of studies**, **self-efficacy and confidence in 96% (26/27)**, and attitudes in **80%**, with gains **largely sustained at follow-up**. The gap identified is **standardisation and scalability**.
- *Journal of Pain and Symptom Management, 2025* — an **ICU-tailored Serious Illness Conversation Guide** proved suitable for critical care, produced more comprehensive skills among fellows and self-reported practice change among faculty.
- **AI-simulated patients** for communication training are now under **randomised evaluation (2025–2026)** — potentially scalable, but as yet unproven against standardised-patient teaching.

Indian context

- **Collusion — family-led non-disclosure — remains widespread.** Surveys of Indian oncologists show that although the great majority favour truth-telling, **only a minority will refuse a family's request to withhold the diagnosis**, and most agree to tell the truth **only if the patient asks**.
- A structured-interview study of **127 patients** at a tertiary oncology centre in **Bengaluru** found that **72% wanted disclosure of a cancer diagnosis** — a preference associated with **higher education and English proficiency** — and that **most also wanted their family involved**. The examinable implication: **the default assumption of non-disclosure is not supported by Indian patient-preference data**; family involvement and patient disclosure are **not alternatives**.
- **PENS**, a four-step abbreviated protocol (*Supportive Care in Cancer, 2020*), has been proposed as an India-adapted alternative to SPIKES for the busy oncology outpatient department, where a full SPIKES conversation is often impractical.
- Indian surveys also report that most clinicians **have received no formal training** in breaking bad news and want dedicated teaching, and that a **majority feel depressed after breaking bad news** — supporting the case for structured training and team debriefing.

Examiner's Tip

Skeleton: Define communication and its geriatric barriers (**hearing, vision, slowed processing**) → the textbook's practical measures (**quiet, well-lit room, deep slow voice, face the patient, amplifier, large print, time**) → underreporting and collateral history → non-verbal and **cultural** factors, interpreters, avoiding stereotyping, the EMR barrier → dementia-specific strategies (**names not pronouns, definite options, gesture, picture prompts**) → **SPIKES step by step**, with **NURSE** for emotion → **Ask–Tell–Ask, REMAP, Best Case/Worst Case, SICG** → geriatric issues: capacity, assent, surrogate, **collusion**, prognosis in ranges → document, brief the team, debrief.

> "Before a single word of bad news is spoken, the **preconditions for communication** must be met — a quiet, well-lit private room, the patient's **hearing aid and spectacles in place**, the clinician seated at eye level and facing the patient so the lips can be read, and **enough unhurried time**. In geriatrics, most 'poor communication' is not a failure of empathy but a failure to correct a **sensory barrier**."

> "The single strongest recent recommendation is that **clinicians must show compassion and empathy when delivering a diagnosis of dementia (Level A, AAN / Alzheimer's Association Delphi 2024)** — and the reason it was needed is that **about half of people with dementia report never having been told their diagnosis, although the vast majority want to know**. In the Indian setting, **collusion is managed neither by complying nor by overriding**: explore the family's fear, then obtain the **patient's own invitation** to determine how much they wish to know."

Extra Points to Remember — recurring topic

- **SPIKES expanded: S**etting · **P**erception · **I**nvitation · **K**nowledge · **E**motions · **S**trategy and summary. **NURSE** for empathy: **N**aming · **U**nderstanding · **R**especting · **S**upporting · **E**xploring.
- **The three golden rules: Ask before you tell** · **Fire a warning shot** · **Answer emotion with empathy, never with data**.
- **Handling collusion in four moves:** (1) meet the family separately and **listen to the fear**; (2) ask "what do you think will happen if he is told?"; (3) explore the **cost of concealment** — isolation, mistrust, unfinished business, inability to consent; (4) ask permission to **ask the patient how much he wishes to know**, and be guided by the patient's own answer.
- **Never use:** "There is nothing more we can do" · "We are withdrawing care" (say **withdrawing a treatment that is no longer helping**) · "Do you want us to do everything?" (an unanswerable question — map values instead).
- **Prognosis:** use **ranges** — hours to days, days to weeks, weeks to months, months to years — and pair with the **"hope for the best, prepare for the worst"** dual framing.
- **Culture is fluid — ask, do not assume.** Record the patient's stated preferences about disclosure and family involvement in the notes, and revisit them at follow-up.

Rapid Revision Grid — Bioethics & Medico-Legal Geriatrics

1. Indian Case Law — the Five Landmarks

Case	Holding to quote
***Gian Kaur v. State of Punjab*, 1996**	Right to life under Article 21 **does not include a right to die**. Overruled *P. Rathinam*.
***Aruna Shanbaug v. Union of India*, 2011**	Permitted **passive euthanasia with High Court approval**; active euthanasia illegal.
***Common Cause v. Union of India*, (2018) 5 SCC 1**	Five-judge Bench: **right to die with dignity is a fundamental right under Article 21**; legalised **living wills** and WH/WD-LST.
SC Order, 24 January 2023 (MA 1699/2019)	Simplified the procedure — **notary/gazetted officer** replaces JMFC countersignature; **48-hour** board timelines; **5 years'** experience; multiple nominees; JMFC only **informed**.
***Harish Rana v. Union of India*, 2026 INSC 222 (11 Mar 2026)**	**CANH is medical treatment** and may be withdrawn; **best-interest balance-sheet test**; **30-day** reconsideration; term "passive euthanasia" retired; **active euthanasia remains impermissible**.
***Samira Kohli v. Dr Prabha Manchanda*, (2008) 2 SCC 1**	**"Real consent"** standard; modified **Bolam** disclosure; diagnostic consent ≠ therapeutic consent; relatives cannot consent for extra surgery on an unconscious adult.

2. Statutes and Regulations — Numbers to Get Right

Provision	Content
BNS s.101 (was IPC 302)	Murder — **active euthanasia**. Punishment s.103.
BNS s.105, Exception 5 (was IPC 304)	Culpable homicide not amounting to murder where an **adult >18 consents** — mitigates, does not legalise.
BNS s.108 (was IPC 306)	**Abetment of suicide** — physician-assisted suicide. Up to **10 years** + fine.
BNS s.107	Abetment of suicide of a **child or person of unsound mind**.
BNS s.28 (was IPC 92)	Act done in **good faith** for benefit **where consent cannot be obtained** — the emergency/necessity defence.
MHCA 2017, s.115	Attempted suicide — **presumption of severe stress**; not to be punished. Effectively decriminalised IPC 309.
MHCA 2017, s.4	Only Indian statutory **capacity test**: understand · appreciate consequences · communicate. **Presumption of capacity**; nominated representative.
IMC Regulation 7.16 (2002)	**Written consent mandatory before operations**; breach = professional misconduct. **Currently operative.**
NMC RMP Regulations 2023	Notified 2 Aug 2023 with an informed-consent guidance document; **held in abeyance 23 Aug 2023**. **2002 Regulations remain in force.**
BNS in force	**1 July 2024** — replaced the IPC.
DPDP Act 2023 + Rules 2025	Health-data consent: free, specific, informed, unconditional, unambiguous, **revocable**. Board Nov 2025 → consent managers Nov 2026 → core obligations **May 2027**.

3. Living Will — the Procedure in Numbers

Element	Requirement (post-January 2023)
Executor	Adult, sound mind, voluntary, understands consequences
Form	**Written**, unambiguous; verbal directives **not valid**
Witnesses	**Two** attesting witnesses
Attestation	**Notary OR Gazetted Officer** (JMFC countersignature removed)
Nominees	**One or more** guardians / close relatives

Copies to	Nominee(s) · **family physician** · family · **local-government custodian** · optionally digital health records
Primary Medical Board	Treating physician + **2 experts**, each **≥5 years**; opinion in **48 hours**
Secondary Medical Board	Different clinicians ≥5 years + **1 CMO nominee**; **48 hours**
JMFC	**Informed only** — no approval required
Dispute pathway	**High Court, Article 226** → Division Bench → independent **3-doctor** committee
Reconsideration period	**30 days** (*Harish Rana* 2026); waivable if all stakeholders unanimous

4. Global Assisted-Dying Status — Facts and Figures

Jurisdiction / source	Key data
Oregon DWDA — first US law	**1997**; residency requirement **removed 2023**
Oregon 28th Annual Report (2026, data 2025)	**637** prescriptions, **400** deaths; **88% aged ≥65**; cancer **61%**, neurological **14%**, cardiac **11%**; hospice **92%**; died at home **80%**
Oregon — top three reasons	Loss of **autonomy 89%** · inability to enjoy activities **89%** · loss of **dignity 65%**. **Pain not in the top three.**
Canada MAiD (2025 report, data 2024)	**16,499** deaths = **5.1% of all deaths** (Quebec **7.9%**); **>76,000** cumulative since 2016; **Track 2 = 732**; ~**half** felt a burden
Canada — mental illness alone	Deferred three times; currently **March 2027**. UN HRC (2025) urged repeal of Track 2.
UK	Terminally Ill Adults Bill passed Commons **June 2025 (314–291)**; **ran out of time April 2026**; to be reintroduced
Isle of Man	Act passed **March 2025**; prognosis **≤12 months**; 5 years' residency
Jersey	Approved **26 February 2026 (32–16)**; **≤6 months**, or **12 months** for neurodegenerative disease; permits **clinician administration**
France	Legalised **July 2026**; **no prognostic time limit**; mental illness alone excluded
WMA (2019)	**Firmly opposed**; no physician forced to participate **or to refer**

5. Consent, Capacity and Communication — Frameworks

Framework	Components
Three components of consent	**Capacity** · **Voluntariness** · **Information**
Five disclosure items (*Essentials*)	Condition · nature of treatment · anticipated results · alternatives · risks and benefits, **including of non-treatment**
Four abilities — capacity (U-A-R-C)	**U**nderstanding · **A**ppreciation · **R**easoning · expressing a **C**hoice. **Reasoning fails first in dementia.**
Three exceptions to consent	**Emergency/necessity** · **Waiver** · **Therapeutic privilege**
Three disclosure standards	**Bolam / professional** — India · **Reasonable patient** (*Canterbury*) — USA · **Material risk** (*Montgomery* 2015) — UK
Surrogate hierarchy	Prior known wishes → **substituted judgement** → **best interests**
SPIKES	**S**etting · **P**erception · **I**nvitation · **K**nowledge · **E**motions · **S**trategy/summary
NURSE (empathy)	**N**aming · **U**nderstanding · **R**especting · **S**upporting · **E**xploring
REMAP (goals of care)	**R**eframe · **E**xpect emotion · **M**ap values · **A**lign · **P**lan
Capacity instruments	**MacCAT-T** (reference standard) · **ACE** (bedside) · MacCAT-CR, UBACC (research). **23 instruments** catalogued (Eur Psychiatry 2025)

Cognitive screens	**Mini-Cog** = 3-item recall + clock drawing. **Executive tests > MMSE** for capacity. **No test determines capacity.**
Delirium	**CAM** = features 1 **and** 2, plus 3 **or** 4: acute/fluctuating · inattention · disorganised thinking · altered consciousness

6. Numbers from Recent Evidence

Finding	Figure
Dementia diagnosis never disclosed	**~50%** of those with billing-record dementia (AAN 2024)
PCPs uncomfortable diagnosing dementia	**39%** "never or only sometimes" (DETeCD-ADRD, 2025)
Communication skills training — behaviours improved	**93% (37/40)** of studies; self-efficacy **96% (26/27)** (BMC Med Educ 2025)
Communication tools → GOCD documentation	**OR 1.46 (1.04–2.05)**; resuscitation preferences **OR 1.84 (0.95–3.60), NS** (BMJ Support Palliat Care 2026)
Indian patients wanting cancer diagnosis disclosed	**72%** of 127, Bengaluru tertiary centre
Delirium in hospitalised older adults	**~21%**; frailty **~34%**; frailty → delirium **RR 1.66**
Persistent delirium	**~36%** at discharge; **~16%** at 12 months
Dementia in older inpatients	**13–63%**; <1/3 of studies screened for delirium or depression
MacCAT-T in mild–moderate dementia	**Reasoning impaired first** — ~**23%** at 9 months, ~**26%** overall

Six lines that will earn marks in almost any bioethics answer

- "**Capacity is clinical and decision-specific; competence is legal and determined by a court.**"
- "**An unwise decision is not incapacity** — capacity is judged by the process of reasoning, not the outcome chosen."
- "**Withholding and withdrawing life-sustaining treatment is lawful in India; active euthanasia is not.**"
- "**A signed form without disclosure is evidence of a signature, not of consent.**"
- "Since the order of **24 January 2023**, the JMFC is **informed, not asked to approve**."
- "In geriatrics, most apparent incapacity is **treatable, fluctuating and temporary** — correct the reversible barrier before you certify anything."

Session index — questions in this compilation

1. Living will — procedure and execution in India • **2.** Euthanasia and physician-assisted suicide • **3.** Informed consent • **4.** Decisional capacity — factors and assessment • **5.** Communication and breaking bad news

Outstanding in the broader syllabus: potassium, calcium and magnesium disorders.

MD GERIATRIC MEDICINE · EXAMINATION REVISION COMPENDIUM

Falls, Fracture Prevention and Pressure Injuries

Structured high-yield answers with current evidence to 2026 and Indian clinical context

Module: Falls · Fracture Prevention · Pressure Injuries
Questions covered: Five (15-mark format)
Primary references: Pathy's Principles and Practice of Geriatric Medicine, 6th edition
Kane's Essentials of Clinical Geriatrics
Evidence updated to: August 2026

Prepared for Dr. Sudarsan · Night-before-examination revision format · All values in Indian conventional units

Contents

Q1 Assessment of Fall Risk and Prevention of Falls in the Elderly

Definition and burden · risk factors · STEADI · performance testing · multifactorial intervention · World Falls Guidelines · NICE NG249 · USPSTF 2024

Q2 Tools for Falls Risk Assessment

Screening tools · performance-based gait and balance tests · cut-offs · inpatient scales · fear-of-falling scales · supporting assessments

Q3 Role of Sensor Devices in the Prevention of Falls

Wearable and ambient sensors · machine learning risk indices · context-aware alerting · virtual reality · fall detection · barriers and evidence gaps

Q4 Prevention of Fractures

Fragility fracture · FRAX · hip protectors · bisphosphonates and anabolic agents · sequential therapy · Fracture Liaison Services · ISBMR

Q5 Pressure Sores: Stages, Common Sites, Prevention and Treatment

NPIAP staging · DTPI and unstageable · site by posture · Braden/Norton/Waterlow · repositioning · stage-wise treatment · 2025 International Guideline

How each answer is structured. Every question follows the same four-part architecture: **(1)** numbered high-yield points under lettered subheadings, keywords in bold; **(2) Latest Updates (2023–Present)** — named trials, guidelines and policy, cited inline; **(3) Current Practice Update** — a table contrasting the textbook position with current evidence; **(4) Exam One-Liners** — rapid-recall statements for final revision.

QUESTION 1

Assessment of Fall Risk and Prevention of Falls in the Elderly

15 MARKS | 20 HIGH-YIELD POINTS

A. Definition and Burden

1. A **fall** is defined as an *unexpected event in which the person comes to rest on the ground, floor, or lower level*. Syncope and seizure must first be excluded by history.
2. About **one-third of community-dwelling adults ≥65 years fall each year**. Among **nursing home residents, one in two falls each year**. **One in five falls** causes serious injury such as fracture or head trauma.
3. In India, **LASI wave-1** data show **about 11.6% of adults ≥60 years report a fall**, with higher rates in **women** and with **advancing age**; falls are heavily under-reported.
4. Complications include fractures of **hip, femur, humerus, wrist and ribs**, **subdural haematoma** (may present days to weeks later), immobility, **fear of falling**, loss of confidence, institutionalisation and death.

B. Why Falls Occur

5. Falls are **multifactorial** — an *acute trigger* acting on *accumulated chronic impairments*. **Rarely is a fall due to a single factor.**
6. Age-related changes: **reduced proprioception**, slowed righting reflexes, **increased antero-posterior postural sway**, loss of **type II (fast-twitch) fibres**, stiffer joints. **Gait speed declines 12–16% per decade.**
7. **Dual-tasking** (walking while talking or counting) becomes difficult with age; institutionalised elders who cannot converse while walking have high fall risk.

C. Risk Factors

8. Divided into **intrinsic** (ageing neuromuscular physiology, disease) and **extrinsic** (medications, environment). Risk rises **exponentially** as factors accumulate.
9. Useful mnemonic — **AGAIN I'VE FALLEN**: **A**gain fallen (previous fall), **G**ait/balance problems, **A**DL loss, **I**mpaired mental status, **N**umber of drugs (>4), **I**llness/delirium, **V**estibular disorders, **E**yes/Ears, **F**oot disorders, **A**lcohol, **L**ower-limb weakness, **L**ow BP (postural), **E**nvironmental hazards, **N**eurological disorders.
10. **Medications are the commonest and most modifiable risk factor** — benzodiazepines, Z-drugs, antipsychotics, all antidepressants (TCA/SSRI/SNRI),

opioids, NSAIDs, muscle relaxants, antihistamines/anticholinergics, alpha-blockers, diuretics, antihypertensives, digoxin, amiodarone, insulin/sulphonylureas.

11. Risk is **highest in the days to weeks immediately after starting a drug or changing its dose** — start new drugs during periods of supervision and warn the patient.
12. Disease-related risk: **dementia (2–8 times higher fall rate)**, stroke, **Parkinson's disease**, arthritis, peripheral neuropathy, chronic pain, **orthostatic hypotension**, carotid sinus hypersensitivity, urinary urgency and nocturia.
13. **Fear of falling (FoF)** is itself an independent predictor of future falls — it causes activity restriction, deconditioning and consumes cognitive reserve needed for gait.
14. **Delirium is the leading cause of falls in hospital**; environmental triggers include wet floors, poor lighting, loose rugs, clutter, steps and unstable furniture.

D. Assessment

15. **Screening (STEADI algorithm, CDC):** ask **every older adult whether they have fallen in the past year**. Those who screen positive (or through the **Stay Independent 12-item questionnaire** / "three key questions") undergo full risk assessment.
16. **History:** exclude syncope/seizure, circumstances of the fall, relation to meals or medication, premonitory symptoms (palpitations, focal deficit), loss of consciousness, alcohol, and full drug list.
17. **Examination: BP lying, sitting and standing** (fall of **>20 mmHg systolic** = orthostatic hypotension), visual acuity, cardiac murmurs/arrhythmia/carotid sinus, neurological and cerebellar signs, joints, **feet and footwear**, and inspection of walking aids for defects.
18. **Performance-based tests (must know):**
    - **Gait speed** over 4 m — **<0.6 m/sec is abnormal**; every **0.1 m/sec fall in speed = 7% rise in fall risk**
    - **Timed Get Up and Go Test (GUGT/TUG) — >12 seconds = high risk** (sensitivity 77%, PPV 93%)
    - **30-second chair stand** and **4-stage balance test**
    - **Tinetti Mobility Scale (POMA) — score <24/28 indicates fall risk**
    - **Berg Balance Scale** (0–56) and **Short Physical Performance Battery (SPPB)** (0–12)
19. **Investigations: no routine laboratory or imaging tests are needed.** Minimum work-up is **lying/standing BP and a 12-lead ECG**. MRI only if a treatable neurological cause is suspected (infarcts, hydrocephalus, cerebellar degeneration); EEG only with strong suspicion of seizure.

E. Prevention and Management

20. **Multifactorial, targeted intervention is the cornerstone:**
    - **Exercise (best evidence): balance and functional exercise reduces fall rate by 24%**; **multiple exercise types (balance + resistance) by 34%**; **Tai chi by 19%**. Walking alone or resistance training alone is of uncertain benefit.
    - **Medication review and withdrawal of psychotropics** — proven to reduce falls.
    - **Home hazard assessment and modification**, most effective when done by an **occupational therapist** (grab bars, lighting, removing rugs, raising bed/chair height).
    - **Vision: cataract surgery** (first eye) reduces falls; replace **multifocal with single-vision lenses** for outdoor use.
    - **Vitamin D:** benefit mainly in those with **low baseline levels** and in **nursing-home residents**.
    - **Cardiac pacing** for cardioinhibitory **carotid sinus hypersensitivity**.
    - **Hip protectors:** small benefit in care homes (RR 0.82); **no clear benefit in the community**; adherence is poor.
    - **In hospital/nursing homes:** prevent and treat **delirium**. **Physical restraints, bed rails and bed alarms do NOT reduce falls** and may cause harm.

LATEST UPDATES (2023–PRESENT)

1. **World Falls Guidelines (Age and Ageing) — three-tier risk stratification, now the global standard.** Older adults are stratified into **low risk** (education and general exercise), **intermediate risk** (targeted exercise or physiotherapy referral for balance and strength), and **high risk** (full multifactorial falls risk assessment with individualised tailored interventions). High-risk features include recurrent falls, injurious falls, frailty and balance problems.
2. **NICE NG249 (April 2025) — replaces the 2013 CG161 guideline.** It covers everyone aged 65 and over, **plus people aged 50–64 who are at higher risk**. Key shifts:
    - **Do not use formal falls risk-prediction tools.** Instead, directly ask all people ≥65 (and 50–64 with risk-enhancing conditions such as dementia, arthritis, Parkinson's disease, stroke, diabetes or learning disability) about **any fall in the past year**.
    - Comprehensive falls assessment is offered to those meeting defined criteria, including **two or more falls in the last year**; those who fell once without these criteria have their **gait and balance assessed**.
    - **Offer a home hazard assessment using a validated tool**, preferably delivered by an **occupational therapist**; **consider cognitive behavioural interventions** where concern about falling is not helped by strength and balance exercises; **investigate carotid sinus hypersensitivity and consider cardiac pacing** for unexplained falls.

    - **Vitamin D is not recommended specifically to reduce falls** — evidence is insufficient — though people are encouraged to take it for bone and muscle health.

3. **USPSTF 2024 (JAMA) — exercise upgraded, multifactorial downgraded. Exercise interventions are recommended (Grade B)** to prevent falls in community-dwelling adults ≥65 at increased risk. The decision to offer **multifactorial interventions must be individualised (Grade C)**, weighing prior falls, comorbidities and patient preference, because the **overall net benefit of routinely offering them is small**.
4. **USPSTF draft statement (December 2024) — vitamin D for falls.** A **Grade D (recommend against)** was proposed for **vitamin D, with or without calcium, to prevent falls or fractures** in community-dwelling postmenopausal women and men ≥60 years. This does **not** apply to those with diagnosed osteoporosis or vitamin D deficiency.
5. **Cochrane Review 2025 (Dyer et al., CD016064) — care facilities. Multifactorial interventions implemented with facility staff engagement and tailored to individual residents probably reduce the rate of falls and risk of falling, and may be cost-effective**; among single interventions, **exercise probably reduces falls**. **Vitamin D supplementation** also likely reduces falls in care facilities, and increasing dietary dairy servings may reduce the number of people falling.
6. **STOP-FALLS trial (JAMA Network Open, 2024) — deprescribing alone is not enough.** In 2,367 older adults, a health-system-embedded deprescribing intervention targeting **CNS-active medications** (opioids, benzodiazepines/Z-drugs, muscle relaxants, TCAs, first-generation antihistamines) **did not significantly reduce medically treated falls** compared with usual care; modest prescribing improvements occurred without a measurable effect on clinical outcomes.
7. **STOPPFall (EuGMS Task and Finish Group on Fall-Risk-Increasing Drugs).** A validated Delphi-derived tool listing **14 medication classes** (mostly psychotropics) that increase fall risk, combined with **practical stepwise deprescribing guidance**. This is now the preferred structured framework for FRID review.
8. **Indian evidence (LASI wave-1 analyses, 2022–2026). 11.6% of Indian older adults report falls**, higher in women and with advancing age; independent determinants are **female sex, underweight BMI, tobacco/alcohol use, chronic joint disease, prior injury or fracture, sensory impairment, depression, ADL limitation and poor physical performance**. Environmental and drug factors dominate — **slippery floors (OR 2.28)**, **polypharmacy (OR 1.71)**, **hearing loss (OR 1.83)** and **depression (OR 1.62)**. **Frail** older Indians have higher falls (15.4% vs 11.9%), multiple falls (7.7% vs 5.3%) and fall-related injuries (6.7% vs 5.3%) than non-frail.
9. **Indian service delivery.** Fall risk screening is delivered through **NPHCE** — geriatric clinics at PHC/CHC level, **rehabilitation units and physiotherapy at district hospitals**, **Regional Geriatric Centres**, and **domiciliary visits by**

rehabilitation workers for bed-bound elders. Assistive devices and mobility aids are supplied through **ADIP/RVY via ALIMCO and DDRCs**.

10. **Emerging directions (2023–2026).** Sensory impairment — especially **hearing loss and dizziness** — is being proposed for inclusion in risk-stratification algorithms. Modified algorithms using a **shorter TUG cut-point (10 seconds)** are being tested to improve stratification into the intermediate-risk group. Wearable fall-detection devices and tele-rehabilitation are expanding access where multifactorial clinics are unavailable.

CURRENT PRACTICE UPDATE

Domain	Textbook Position	Current Practice (2023–Present)
Risk identification	STEADI screening with structured questionnaires and risk assessment	**NICE NG249 advises against formal falls risk-prediction tools**; simply ask about falls in the past year and stratify into **low / intermediate / high risk** per World Falls Guidelines
Target population	Adults ≥65 years	Extended to **50–64 years with risk-enhancing conditions** (dementia, Parkinson's, stroke, arthritis, diabetes, learning disability)
Exercise	Balance and functional exercise beneficial; Tai chi effective	**Strongest and most consistent intervention (USPSTF Grade B)**; must be **progressive, tailored and supervised** (Otago, FaME)
Multifactorial intervention	Recommended for all recurrent fallers	**Individualise the decision (USPSTF Grade C)** — net benefit is small if applied routinely; reserve for **high-risk** patients
Vitamin D	Useful when baseline levels are low and in nursing-home residents	**Not recommended solely for falls prevention in the community** (NICE 2025; USPSTF draft Grade D); **still supported in care-facility residents** (Cochrane 2025)
Medication review	Withdrawal of psychotropics reduces falls	Structured **STOPPFall** review preferred; **STOP-FALLS (2024) showed deprescribing alone did not reduce falls** — must be combined with exercise and other measures
Fear of falling	Recognised as a predictor; no specific therapy named	**Cognitive behavioural intervention** now recommended when exercise alone does not relieve concern about falling
Care homes	Evidence for exercise unclear in nursing homes	**Staff-engaged, individually tailored multifactorial programmes +**

		exercise + vitamin D probably reduce falls (Cochrane 2025)
Hospital	Restraints, bed rails, bed alarms ineffective	Unchanged; emphasis added on **preventing deconditioning** — encourage patients to dress, stand and walk; refer to community services **at discharge**

EXAM ONE-LINERS

- **Fall** = unexpected event coming to rest on ground/floor/lower level.
- **One-third** of community elders and **one-half** of nursing-home residents fall yearly; **1 in 5** falls injures.
- **India (LASI): 11.6%** prevalence; slippery floors, polypharmacy, hearing loss and depression are key drivers.
- **Mnemonic: AGAIN I'VE FALLEN.**
- **Medications = most modifiable risk factor**; danger window is **immediately after starting or changing a drug**.
- **Gait speed <0.6 m/sec** abnormal; **0.1 m/sec drop = 7% ↑ risk**.
- **TUG >12 seconds = high fall risk.**
- **Tinetti POMA <24/28 = fall risk.**
- **Orthostatic hypotension = fall of >20 mmHg systolic** on standing.
- **No routine labs**; minimum = **lying/standing BP + 12-lead ECG**.
- **Delirium = leading cause of inpatient falls.**
- **Balance + functional exercise ↓ falls 24%; multiple exercise types ↓ 34%; Tai chi ↓ 19%.**
- **Restraints, bed rails and bed alarms do NOT prevent falls.**
- **Hip protectors** — modest benefit in care homes (RR 0.82), none in the community.
- **Cardiac pacing** for **cardioinhibitory carotid sinus hypersensitivity** with unexplained falls.
- **NICE NG249 (2025): do not use falls risk-prediction tools.**
- **USPSTF 2024: exercise = Grade B; multifactorial = Grade C.**
- **STOPPFall = 14 fall-risk-increasing drug classes.**
- **Fear of falling** is both a consequence and an independent predictor — treat with **CBT**.

QUESTION 2

Tools for Falls Risk Assessment

15 MARKS | 20 HIGH-YIELD POINTS

A. General Principles

1. Falls assessment tools serve **three distinct purposes**: (i) **screening / case-finding**, (ii) **risk stratification**, and (iii) **objective measurement of gait and balance deficits** to target intervention and monitor progress.
2. **No single tool is adequate alone.** Tools supplement — never replace — a **detailed history, medication review, postural blood pressure and targeted physical examination**.
3. The most powerful single predictor is not a scale but a simple question — **"Have you fallen in the last one year?"** A previous fall is the strongest predictor of a future fall.

B. Screening / Case-Finding Tools

4. **STEADI algorithm (Stopping Elderly Accidents, Deaths and Injuries — CDC):** a **stepwise three-stage approach** — *Screen* → *Assess* → *Intervene*. It is the standard framework for community falls screening.
5. **"Three Key Questions" (STEADI):**
   - Have you **fallen in the past year**?
   - Do you feel **unsteady when standing or walking**?
   - Do you **worry about falling**?

   A "yes" to any question triggers full risk assessment.
6. **Stay Independent 12-item questionnaire:** a self-administered checklist; a **score of ≥4 indicates increased fall risk** and mandates further assessment.
7. **AGAIN I'VE FALLEN mnemonic:** a bedside checklist for systematic risk-factor identification — **A**gain fallen, **G**ait/balance problems, **A**DL loss, **I**mpaired mental status, **N**umber of drugs (>4), **I**llness/delirium, **V**estibular disorders, **E**yes/Ears, **F**oot disorders, **A**lcohol, **L**ower-limb weakness, **L**ow BP (postural), **E**nvironmental hazards, **N**eurological disorders.

C. Performance-Based Gait and Balance Tools

8. **Gait speed** over a pre-measured **4-metre** course. **0.6–0.8 m/sec = high-risk range; <0.6 m/sec is the accepted cut-off for abnormal gait.** Every **0.1 m/sec fall in speed carries a 7% rise in fall risk**. It also predicts disability, hospitalisation, institutionalisation and mortality.

9. **Timed Get Up and Go Test (GUGT / TUG):** patient rises from a standard armchair, walks **3 metres (10 feet)**, turns, returns and sits. Walking aid permitted. **>12 seconds = high fall risk** (sensitivity 77%, positive predictive value 93% in the community; sensitivity 91% but specificity only 22% in inpatients). Even an **untimed** observation is clinically useful.
10. **30-Second Chair Stand Test:** number of full sit-to-stands in 30 seconds with **arms folded across the chest** — measures lower-limb strength and endurance.
11. **Four-Stage Balance Test:** progressive stances — **feet together → semi-tandem → tandem → single leg**, each held for **10 seconds**. Inability to hold **tandem stance for 10 seconds** indicates increased fall risk.
12. **Standing unassisted from a sitting position:** sensitivity **31%**, specificity **90%**; risk rises if the person **cannot stand or takes more than 2 seconds** to do so.
13. **Tinetti Performance-Oriented Mobility Assessment (POMA / Tinetti Mobility Scale): 14 performance tasks** split into **Balance (0–16)** and **Gait (0–12)**, total **0–28**. **Score <24 indicates fall risk** (mean sensitivity 82%, specificity 65%). Takes **10–15 minutes** — its main drawback in a busy clinic.
14. **Berg Balance Scale (BBS): 14 items**, each scored 0–4, total **0–56**. Interpretation: **0–20 = wheelchair-bound; 21–40 = walks with assistance; 41–56 = independent.** Best suited to rehabilitation and stroke settings.
15. **Short Physical Performance Battery (SPPB):** three components — **balance (side-by-side, semi-tandem, tandem), 8-foot (2.44 m) walk, and five repeated chair stands** — each scored 0–4, total **0–12**. Predicts **mortality, nursing-home admission and disability** in a graded fashion.
16. **Dual-task testing:** walking while **counting backwards from 100 by sevens**, TUG **while holding a full glass of water**, or **one-leg stand with eyes closed**. Institutionalised elders who cannot converse while walking are at high fall risk; clinical utility remains uncertain because of variability across studies.
17. Other balance measures compared psychometrically against TUG include the **one-leg (single-limb) stance test** and the **Functional Reach Test**.

D. Supporting and Setting-Specific Tools

18. **Fear of falling:** measured with the **Falls Efficacy Scale–International (FES-I)** and the **Short FES-I (7-item)**; the **ABC (Activities-specific Balance Confidence) Scale** is an alternative. Fear of falling is an **independent predictor** of future falls.
19. **Supporting assessments that function as tools:**
    - **Postural BP** — lying, sitting, and at 1 and 3 minutes standing; **fall of >20 mmHg systolic = orthostatic hypotension**
    - **Medication review tools — STOPPFall**, **Beers criteria**, **STOPP/START**
    - **Home hazard tools — HOME FAST**, occupational-therapist home safety checklists
    - **Vision/hearing** — Snellen chart, whispered voice test, Hearing Handicap Inventory for the Elderly

- **Cognition/mood** — MMSE/MoCA/SLUMS, GDS (dementia and depression both raise fall risk)

20. **Hospital and institutional fall risk scales** (used mainly by nursing services for care planning):
    - **Morse Fall Scale (MFS)** — 6 items, score 0–125; **≥25 moderate, ≥45 high risk**; most widely used in acute care
    - **STRATIFY (St Thomas's Risk Assessment Tool in Falling Elderly Inpatients)** — 5 items; **score ≥2 = at risk**
    - **Hendrich II Fall Risk Model** — 7 items including a **Get-Up-and-Go component** and confusion/depression; **score ≥5 = high risk**
    - **Johns Hopkins Fall Risk Assessment Tool (JHFRAT)**

Rapid Cut-Off Table

Tool	Measures	Cut-off / Score
Gait speed (4 m)	Global function	**<0.6 m/sec abnormal**
Timed Up and Go	Mobility, dynamic balance	**>12 sec = high risk**
4-Stage Balance	Static balance	**Tandem <10 sec = risk**
Sit-to-stand	Lower-limb power	**>2 sec or unable = risk**
Tinetti POMA	Gait + balance	**<24 / 28 = fall risk**
Berg Balance Scale	Balance	**0–56; <45 = fall risk**
SPPB	Lower-limb function	**0–12; ≤8 = impairment**
Stay Independent	Screening	**≥4 = increased risk**
Morse Fall Scale	Inpatient	**≥45 high, ≥25 moderate**
STRATIFY	Inpatient	**≥2 = at risk**
Hendrich II	Inpatient	**≥5 = high risk**
Postural BP	Orthostatic hypotension	**↓ >20 mmHg systolic**

LATEST UPDATES (2023–PRESENT)

1. **NICE NG249 (April 2025) — a major reversal on risk-prediction tools.** The guideline replaces CG161 (2013) and covers everyone aged 65 and over plus people aged 50–64 at higher risk. It **explicitly recommends against using formal falls risk-prediction tools**. Clinicians should instead **directly ask everyone ≥65 (and 50–64 with risk-enhancing conditions such as dementia, arthritis, Parkinson's disease, stroke, diabetes or learning disability) about any fall in the past year**, opportunistically at routine appointments and annual

health checks. Those with defined criteria — including **two or more falls in the last year** — go straight to a **comprehensive falls assessment**; those who fell once without these criteria have their **gait and balance assessed**.

2. **World Falls Guidelines — the three-tier stratification model.** Older adults are placed in **low risk** (education, general exercise), **intermediate risk** (targeted exercise or physiotherapy referral for balance and strength) or **high risk** (**full multifactorial falls risk assessment** with individualised interventions), determined either by opportunistic case-finding or at presentation with a fall. High-risk markers are recurrent falls, injurious falls, frailty and balance problems.
3. **Real-world testing of the World Guidelines algorithm (BMC Geriatrics 2024).** In 392 emergency-department patients assessed by a frailty intervention team, almost all fell into the **high-risk (43.4%) or low-risk (38.0%)** groups with only **4.8% intermediate**, suggesting the intermediate criteria need widening. **Hearing loss and dizziness were significantly associated with falls, whereas vision and balance were not**, supporting formal inclusion of sensory measures in the algorithm.
4. **Proposed algorithm refinement (Age and Ageing, 2025). Broader use of the TUG test with a shorter cut-point of 10 seconds** stratified a community sample into three sizeable, distinct risk groups, allowing more timely and appropriately tailored prevention.
5. **USPSTF 2024 — the accuracy gap in existing tools is now formally acknowledged.** In response to public comment on its 2024 falls statement, the USPSTF agreed that **more accurate risk assessment tools are needed** and listed the development and validation of **primary-care-feasible tools that accurately predict fall risk** as a formal research gap.
6. **Inpatient scales perform poorly in older patients.** A large retrospective study (2024; 303 fall events vs 47,146 non-fall events) found the **Hendrich II model at its standard cut-off ≥5 had sensitivity of only 29.5%, specificity 86.3% and AUC 0.57** — limited discriminative ability. Lowering the cut-off to **≥2 raised the AUC to 0.75** and identified 101 additional fall events, showing that **cut-off selection matters more than the tool itself**. In the same analysis, **STRATIFY failed to predict falls in geriatric wards and in those aged ≥75 years**, and MFS and JHFRAT showed lower sensitivity and specificity than Hendrich II.
7. **Two-stage screening models under evaluation (International Nursing Review, 2025).** The **Morse Fall Scale** showed higher specificity and performed well in surgical wards (AUC 0.887) and in patients aged ≥75 (AUC 0.837), while a **Clinical Judgment Method** offered higher sensitivity for rapid screening; a combined **"screening–confirmation" two-stage model** is proposed but not yet validated.
8. **Indian evidence for tool selection.** LASI wave-1 analyses show that **poor grip strength, slow gait speed, ADL limitation, depression and sensory impairment** are independent determinants of falls in Indian elders — supporting the use of **grip strength, gait speed, GDS and simple sensory screening** as the core, low-cost battery in Indian NPHCE geriatric clinics, where formal balance laboratories are unavailable.

9. **STOPPFall as the standard medication-side tool.** A validated Delphi-derived list of **14 fall-risk-increasing drug classes**, mostly psychotropics, combined with **stepwise practical deprescribing guidance** for medication review.
10. **Emerging technology.** Wearable inertial sensors, smartphone-based TUG, instrumented gait analysis and machine-learning models are being developed to replace static questionnaires, but none has yet entered guideline recommendations.

CURRENT PRACTICE UPDATE

Point	Textbook Position	Current Practice (2023–Present)
Use of prediction tools	STEADI screening with Stay Independent questionnaire, followed by performance testing	**NICE NG249 (2025) advises against formal falls risk-prediction tools**; use a **single direct question about falls in the past year** plus **World Falls Guidelines three-tier stratification**
TUG cut-off	**>12 seconds** = high risk	A **shorter cut-point of 10 seconds** with broader application is proposed to better identify the **intermediate-risk** group
Sensory assessment	Vision and hearing noted as risk factors	**Hearing loss and dizziness** proposed for **formal inclusion in the stratification algorithm** — in some cohorts they outperform vision as predictors
Inpatient scales	Not emphasised as core geriatric tools	Widely used for nursing care plans but **discrimination is poor in the very old**; **STRATIFY fails in geriatric wards and in age ≥75**; cut-off calibration is critical
Purpose of scoring	Identify who is at risk	Shift from **prediction to identification of modifiable risk factors** — the score matters less than what it triggers
Medication review	Table of offending drug classes	Structured **STOPPFall** (14 classes) with stepwise deprescribing guidance
Fear of falling	Recognised as a predictor	Formally measured with **FES-I / Short FES-I**; if unresponsive to exercise, **NICE now recommends cognitive behavioural intervention**

EXAM ONE-LINERS

- **Best single screening question:** "Have you fallen in the last year?"

- **STEADI = Screen → Assess → Intervene** (CDC three-step algorithm).
- **Stay Independent questionnaire: 12 items, score ≥4 = increased risk.**
- **Three Key Questions:** fallen / unsteady / worried about falling.
- **Gait speed <0.6 m/sec = abnormal;** each **0.1 m/sec drop = 7% ↑ fall risk**.
- **TUG >12 seconds = high fall risk** (sens 77%, PPV 93%).
- **TUG distance = 3 metres (10 feet).**
- **Tinetti POMA: 14 tasks, total 28; <24 = fall risk** (sens 82%, spec 65%).
- **Berg Balance Scale: 14 items, 0–56;** 41–56 independent, 21–40 needs assistance, 0–20 wheelchair-bound.
- **SPPB: balance + 8-foot walk + 5 chair stands = 0–12.**
- **Four-Stage Balance Test:** feet together → semi-tandem → tandem → one leg, **10 seconds each**.
- **Morse Fall Scale ≥45 = high risk; STRATIFY ≥2; Hendrich II ≥5.**
- **Orthostatic hypotension = systolic fall >20 mmHg on standing.**
- **STOPPFall = 14 fall-risk-increasing drug classes.**
- **FES-I** measures fear of falling.
- **NICE NG249 (2025): do NOT use falls risk-prediction tools** — ask about falls instead.
- **World Falls Guidelines: low / intermediate / high risk** stratification.
- **No routine laboratory test is part of a falls assessment** — minimum is **lying/standing BP and 12-lead ECG**.

QUESTION 3

Role of Sensor Devices in the Prevention of Falls

15 MARKS | 20 HIGH-YIELD POINTS

A. Rationale and Classification

1. Falls are **multifactorial and episodic**. Clinic-based tests (TUG, Tinetti, Berg) give only a **single snapshot in an artificial setting**. Sensors provide **continuous, objective, real-world ("free-living") data** on gait, balance and behaviour.
2. Conventional disability and rehabilitation scoring systems are **subjective, prone to inter- and intra-observer variability, and time-consuming**, diverting therapists from direct patient care. **Remote sensors record quantitative data objectively.**
3. **Sensor devices serve four distinct roles:**
    - **Fall risk identification** (predicting who will fall)
    - **Fall prevention** (real-time alerting and feedback-driven exercise)
    - **Fall detection** (post-fall alarm to prevent the "long lie")
    - **Rehabilitation monitoring** (objective measurement of progress and adherence)
4. **Classification of sensors:**
    - **Wearable / body-worn: accelerometers, gyroscopes, inertial measurement units (IMUs)** worn on trunk, waist, wrist or lower limb; **smartphone accelerometer**; GPS trackers
    - **Ambient / non-wearable (environmental): PIR motion sensors**, **pressure and piezoelectric sensors** in bed or floor, **acoustic sensors** that identify the specific sound a fall makes, **video-based detectors**, radar, WiFi-sensing and thermal sensors
    - **Multimodal / hybrid systems:** fuse information from several sensor types to improve accuracy

B. Sensors in Fall Risk Assessment

5. Sensors quantify **gait speed, step length, step variability, double-limb support time, postural sway and turning quality** — parameters that predict falls better than a single timed test.
6. **Machine learning technologies** (artificial neural networks, deep learning) integrate **comprehensive clinical assessment data with continuous in-home sensor data** to compute an **individual fall risk index** that is **constantly updated**.
7. A person's **activity pattern** builds a **baseline behavioural model**; any **deviation from that pattern flags functional decline** and rising fall risk before a fall occurs.

8. A simple **accelerometer may be more sensitive than a traditional rating scale** in demonstrating subtle but important gains in mobility — for example, response to a new drug in Parkinson's disease.

C. Sensors in Active Fall Prevention

9. **Real-time context-aware fall risk communication:** the system detects the *intention* to act through an **activity recognition module** and alerts the person **before** a high-risk manoeuvre. *Classic example:* an older adult with **orthostatic hypotension** attempting to rise from a couch is warned **just before standing up**.
10. **Night-time guidance: PIR sensors linked to automatic light faders** illuminate the path to the toilet — targeting **nocturia**, a major and modifiable cause of night falls.
11. **Home safety automation: smart taps and smart stoves** reduce scald, burn and wet-floor hazards.
12. **Adherence monitoring: smart pill dispensers** track drug intake (important for both under-dosing and inadvertent overdose of fall-risk-increasing drugs); **motion, GPS or video sensors** monitor adherence to prescribed exercise programmes and generate warnings when the person defaults.
13. **Virtual reality (VR) platforms** provide visual, auditory and tactile input. By **altering sensory inputs and enhancing corrective postural strategies**, VR augments the adaptive mechanisms that decline with age, promoting **postural stability** in a **safe environment that reduces physical risk and builds patient confidence**.
14. **Video-capture and gaming technology** is much cheaper and widely available — the **Nintendo Wii** with built-in accelerometers and infrared camera is the model. Effective rehabilitation games must **provide feedback, avoid conveying a sense of failure, and match the level of challenge to the player's capability**.
15. **Robotic assist devices** (e.g. the **Honda Walking Assist Device with body-weight support**) can augment recovery in neuromuscular deficits and provide ongoing help with ADLs including stair-climbing. A **"robotic glove" plus VR** optimises motor function after hemiparetic stroke.
16. Sensor-based gait analysis allows **individual tailoring** — for example, accurately characterising a maladaptive gait in knee osteoarthritis to select the **most appropriate orthotic device**.

D. Sensors in Fall Detection and Home-Based Care

17. Immediate detection of a fall **triggers an early attention protocol**, preventing the **"long lie"** (with its risks of dehydration, hypothermia, rhabdomyolysis, pressure ulcers and pneumonia). Even where no injury has occurred, it **generates a warning that the person is at high risk of falling again**.
18. In a **healthcare-enabled Smart Home**, the general practitioner can **access the continuously collected data** to decide on action (face-to-face visit, virtual visit,

treatment change, specialist referral), and **emergency services** can use both the stored data and established communication channels to judge whether to respond.

19. **Remote sensors, wireless data transfer, GPS and mobile computing facilitate early transfer from hospital-based to home-based rehabilitation**, shortening admission and reducing hospital-acquired deconditioning.

E. Limitations and Barriers

20. **Barriers to wider use:**
    - **Cost, lack of technical support, and a weak evidence base for efficacy** are the three principal barriers
    - Older devices were **bulky, heavy, difficult to attach, with poor battery life** and data-storage problems — largely solved by **miniaturisation and wireless transmission**, but **scientific validation in older patients remains limited**
    - The **digital divide** — income, education, age and geography — affects technology penetration; the aged suffer most from this gap
    - Older users have **reduced sensory and motor capability** (high-frequency hearing loss, poor visual acuity, impaired dexterity, reduced strength) and cannot be modelled like young users
    - **Acceptance** is driven by **perceived usefulness and trust**; **perceived risk (privacy) discourages adoption**
    - **Infrastructure needed:** professional needs-assessment before installation, trained installers, an operational backup for remote care, and a **rapid local technical maintenance service**
    - Critically — **bed alarms and physical restraints do NOT reduce falls in hospital**; sensor alarms are **not a substitute for multifactorial intervention**

LATEST UPDATES (2023–PRESENT)

1. **Systematic review of 130 studies (2008–2025) — the field has shifted from detection to prediction.** Three dominant sensor categories are identified: **wearable systems (chiefly inertial measurement units)**, **ambient systems (vision-based, radar, WiFi, LiDAR)** and **hybrid systems fusing multiple data sources**; the notable emerging trend is a move **from reactive fall detection to proactive, pre-impact fall risk prediction**. **Deep learning is now the dominant computational paradigm**, with hybrid **CNN-LSTM and Transformer models** performing best. No modality is universally superior — there is a **trade-off between the continuous, person-centric monitoring of wearables and the non-intrusive, privacy-preserving nature of ambient systems such as radar and LiDAR**.
2. **Hospital sensor technologies — the evidence gap is now formally documented (2025 systematic review, PROSPERO-registered).** A search of five databases and two trial registries for RCTs published 2000–2025 **found no eligible randomised controlled trial assessing the isolated effectiveness of sensor-based technologies for fall prevention in hospitalised older adults**.

Widely implemented technologies such as **bed and chair alarms have shown limited effectiveness and may cause alarm fatigue, reducing staff responsiveness**.

3. **Diagnostic accuracy of wearables is probably over-estimated.** Reviewers have raised concerns of **over-inflated diagnostic accuracy in wearable sensor-based fall risk testing**, attributed to **small sample sizes, questionable modelling decisions and inappropriate validation methodology**. Predictive accuracy is strongly influenced by **sensor location, sensor type, features selected, and the data-processing and modelling technique used** — meaning results are not transferable between systems.
4. **Formal meta-analysis of predictive accuracy (Frontiers in Public Health, 2026).** A systematic review and meta-analysis (search to October 2025) pooled studies in adults ≥60 years across community, residential care and healthcare settings using **accelerometer-, gyroscope- or IMU-equipped wearables placed on trunk, waist or lower limb** to model **future** fall risk — the first quantitative synthesis of an evidence base that had previously been only descriptive.
5. **WHO/ITU engagement with AI-based falls stratification.** The **Topic Group on "Falls among the elderly" of the ITU/WHO Focus Group on Artificial Intelligence for Health** published a formal commentary on fall risk stratification of community-living older people alongside the World Falls Guidelines (*Age and Ageing*, 2023) — signalling that **sensor and AI-derived risk scores are moving towards guideline integration**.
6. **Technology-assisted rehabilitation compared head-to-head.** A network meta-analysis of randomised trials in adults ≥60 years compared **VR exergaming, serious gaming, wearables and telerehabilitation** for balance and functional mobility — the first attempt to rank these modalities against each other rather than against usual care alone.
7. **Scoping review of digital tools 2019–2024.** Digital and smart-home safety technologies are recognised as promising avenues for **timely intervention**, with **AI emergence** driving a new generation of tools; a PRISMA-ScR review synthesised recently published evaluations of digital tools for **fall prevention, detection and risk assessment**.
8. **NICE NG249 (April 2025) — no endorsement of sensor devices.** The guideline recommends **exercise programmes, home hazard assessment by an occupational therapist, medication review and cataract referral**, and mentions **movement sensors** only as equipment that residents in care homes should be taught to use. **No sensor technology is recommended as a fall-prevention intervention.**
9. **Indian relevance.** Sensor-based approaches are attractive in India because of **high smartphone penetration and a shortage of trained falls-clinic personnel** — a **smartphone accelerometer-based TUG or gait speed** can be delivered at NPHCE geriatric clinics and health and wellness centres at negligible cost. Barriers are the **rural digital divide, electricity and connectivity gaps, absence of reimbursement under AB-PMJAY for assistive monitoring technology, and low digital literacy in the oldest old**.

10. **Practical position in 2026.** Sensors are currently **best supported for objective risk stratification, rehabilitation feedback and post-fall detection — not** as stand-alone preventive interventions. Every consensus document still places **progressive balance and functional exercise plus multifactorial risk-factor modification** as the core of prevention, with technology as an **adjunct**.

CURRENT PRACTICE UPDATE

Domain	Textbook Position	Current Practice (2023–Present)
Primary sensor role	Objective measurement in rehabilitation and fall detection	Shift **from reactive detection to proactive, pre-impact fall prediction** using deep learning
Dominant technology	Accelerometers, video capture, VR, Nintendo Wii–type gaming	**IMUs, radar, LiDAR, WiFi-sensing and hybrid multimodal systems**; **CNN-LSTM and Transformer models** now standard
Evidence base	"Lack of a strong evidence base for efficacy" identified as a barrier	Barrier persists — **no RCT isolates sensor effectiveness in hospitalised older adults (2025)**; reported accuracy is likely **over-inflated** by small samples and weak validation
Bed/chair alarms	Bed alarms not associated with reduced falls	Confirmed — **limited effectiveness plus alarm fatigue**, which itself reduces staff responsiveness
Guideline status	Emerging technology, promising	**Not recommended as a preventive intervention by NICE NG249 (2025)**; WHO/ITU AI Focus Group working towards eventual integration
Privacy	Not emphasised	Now a **central design consideration** — ambient radar/LiDAR favoured for privacy preservation over video
Where sensors clearly help	Rehabilitation progress measurement	**Objective risk stratification, exercise feedback and adherence, and post-fall alerting to prevent the long lie**

EXAM ONE-LINERS

- Sensors give **continuous, objective, real-world data** — clinic tests give only a **snapshot**.
- **Four roles:** risk prediction, active prevention, fall detection, rehabilitation monitoring.

- **Wearable = accelerometer, gyroscope, IMU, smartphone.**
- **Ambient = PIR, pressure/piezoelectric, acoustic, video, radar, WiFi, LiDAR, thermal.**
- **Multimodal/hybrid systems** fuse several streams for higher accuracy.
- **Machine learning + clinical assessment + in-home sensors = continuously updated individual fall risk index.**
- **Context-aware alerting:** warns the patient with orthostatic hypotension *before* they stand up.
- **PIR sensors + automatic light faders** = night-time guidance for nocturia-related falls.
- **Smart pill dispensers** monitor drug adherence; **motion/GPS sensors** monitor exercise adherence.
- **Deviation from the baseline behavioural model = early marker of functional decline.**
- **Fall detection prevents the "long lie"** and flags high risk of recurrence.
- **VR promotes postural stability** by altering sensory input and augmenting corrective strategies in a safe environment.
- **Nintendo Wii** = accelerometer + infrared camera; rehab games must give feedback and avoid a sense of failure.
- **Honda Walking Assist Device** = robotic gait assistance.
- **Three barriers: cost, lack of technical support, weak evidence base.**
- **Digital divide** — income, education, age, geography.
- **Adoption driven by perceived usefulness and trust; discouraged by perceived risk.**
- **Bed alarms and restraints do NOT prevent falls** — alarm fatigue is a real harm.
- **NICE NG249 (2025) does not recommend any sensor device for fall prevention.**
- **Exercise remains the intervention with the strongest evidence** — technology is an **adjunct, not a substitute**.

QUESTION 4

Prevention of Fractures in the Elderly

15 MARKS | 20 HIGH-YIELD POINTS

A. Concept and Burden

1. A **fragility (osteoporotic) fracture** results from **low-energy trauma — typically a fall from standing height or less**. It is the product of **two independent factors: the fall (impact) and bone made fragile by ageing (osteoporosis)**. Prevention must therefore address **both**.
2. The **commonest sites are hip, forearm (distal radius) and vertebrae**; humerus and ribs follow. **Maintenance of musculoskeletal health during ageing is a key determinant of functional ability.**
3. In elderly patients, **only 3% of hip fractures are pathological** (metastasis, myeloma, bone cysts, Paget's disease); **over half of patients are osteoporotic and almost all have osteopenia**.
4. After a proximal femoral fracture, in the **first year: 56% fall again, 28% have repeated falls, 12% sustain a new fracture, and 5% fracture the opposite hip** — making **secondary prevention mandatory**.
5. **Three pillars of fracture prevention:**
    - **Assessing fall risk and delivering preventive interventions**
    - **Protecting the trochanteric region (hip protectors)**
    - **Assessing and treating osteoporosis**

B. Fracture Risk Assessment

6. **FRAX** integrates clinical risk factors **with or without BMD** to compute the **10-year probability of hip fracture and of major osteoporotic fracture**. It can be modulated by **BMD, trabecular bone score (TBS), glucocorticoid therapy, fall history, type 2 diabetes and hip axis length**.
7. **Major risk factors: age, female sex, low BMI, prior fragility fracture, parental hip fracture, height loss >4 cm, secondary osteoporosis, glucocorticoid therapy, excess alcohol and smoking**.
8. **Diagnosis:** osteoporosis can be diagnosed **clinically in a patient with a minimal-trauma fracture without any other test**. Otherwise **DXA T-score ≤ −2.5**. Note that **after age 80 a woman with BMD normal for her age already has a T-score of −2.5**, so **DXA for diagnostic purposes alone is chiefly indicated in women under 75**.
9. **Exclude secondary osteoporosis** in every fragility fracture: full history of **corticosteroids and alcohol**, plus **complete blood count, liver and kidney**

function, serum calcium and phosphorus (mg/dL), 25(OH) vitamin D (ng/mL) and TSH. In the elderly the **dominant secondary cause is hyperthyroidism**; also consider **malnutrition, low body weight, hypogonadism and hyperparathyroidism**.

C. Universal Non-Pharmacological Measures

10. **For all patients, regardless of risk category:**
    - **Calcium 800–1000 mg/day** (diet preferred)
    - **Protein ≥1 g/kg body weight/day**
    - **Vitamin D ~800 IU/day**, with adequate **sun exposure**
    - **Daily weight-bearing physical activity**
    - **Fall-prevention measures**
    - **Education** on osteoporosis, medication, diet and exercise
11. A structured exercise programme should run for **at least 50 hours**, be **progressive**, and include **strength and balance components**. It reduces falls, but **the effect on fracture risk itself remains uncertain**.
12. **Calcium + vitamin D combined had a clear benefit in elderly women living in nursing homes.** However, a meta-analysis of **33 randomised trials with 51,145 participants (Zhao et al., JAMA 2017)** showed **no reduction in fracture risk in community-dwelling older adults** with calcium, vitamin D, or both.

D. Mechanical (Fall-Related) Protection

13. **Hip protectors:** most upper-femoral fractures follow a **sideways fall directly onto the greater trochanter**. Two rigid shells or foam pads held over the trochanters **absorb the shock and disperse energy into soft tissue**.
14. **Cochrane Review (2014, 19 studies, ~17,000 people):** in nursing/residential care, **RR 0.82 (95% CI 0.67–1.00)** — a small reduction in hip fracture risk (moderate quality). In the community, **RR 1.15 (0.84–1.58) — little or no effect**. **Poor acceptance and adherence is the major barrier**, particularly in the cognitively impaired.
15. **Multifactorial fall risk assessment and intervention** — exercise, medication review, home hazard modification, vision correction, cardiac pacing for carotid sinus hypersensitivity — is inseparable from fracture prevention. **Minimum work-up in a faller: lying/standing BP and a 12-lead ECG.**

E. Pharmacological Prevention

16. **Treatment pathway by risk category:**
    - **Low risk:** reassurance, lifestyle advice; consider **menopausal hormone therapy (MHT) or SERMs**

- **High risk: oral bisphosphonate or another inhibitor of bone resorption** (denosumab)
- **Very high risk: anabolic agent (teriparatide, abaloparatide, romosozumab) followed by an inhibitor of bone resorption**; consider **local osteo-enhancement procedure (LOEP)** if hip fracture risk is very high

17. **Bisphosphonates — first line.** Reduced hip fractures demonstrated with **risedronate, pamidronate and zoledronic acid**. **NNT ≈ 200 to prevent one hip fracture. Zoledronic acid 5 mg IV once yearly reduces clinical fracture by 33%, vertebral fracture by 77% and peripheral fracture by 25% — vitamin D must be given beforehand**. Adverse effects: **flu-like syndrome after the first infusion (1 in 3)**, higher incidence of **atrial fibrillation**, GI upset with oral forms, and **rare osteonecrosis of the jaw**. Gastro-resistant risedronate improves adherence.

18. **Other agents:**
    - **Denosumab** — fully human monoclonal antibody to **RANKL**; blocks RANK binding, inhibits osteoclast development and activity; **subcutaneously twice yearly**; reduces **vertebral, non-vertebral and hip** fractures (FREEDOM). **Discontinuation may cause multiple vertebral fractures — follow with a bisphosphonate for 1–2 years.**
    - **Teriparatide** — reduces new vertebral and non-vertebral fracture **independent of initial T-score, age and number of fractures**; bone mass gain is dose-dependent.
    - **Romosozumab** — monoclonal antibody to **sclerostin**; increases formation and decreases resorption. **12 months of romosozumab followed by alendronate gave significantly lower fracture risk than alendronate alone (ARCH; Saag et al.)**; FDA-approved April 2019 for high-risk postmenopausal women.
    - **Limited in the elderly: raloxifene does not reduce femoral neck fracture**; **SERMs must be avoided after femoral neck fracture** (thromboembolic risk); **HRT** carries breast cancer, thromboembolic, stroke and coronary risks; **strontium ranelate** caused fatal **DRESS** and thromboembolism; **calcitonin** has weak efficacy.

19. **Duration and monitoring:**
    - Check **bone turnover markers at 3–6 months** to verify compliance with resorption inhibitors
    - Reassess **after 3 years of IV or 5 years of oral bisphosphonate**: **low-risk patients may discontinue for 2 years (reconsider yearly); high-risk patients continue**
    - **Whatever the drug, it must be combined with adequate calcium and vitamin D intake**

20. **Life expectancy and systems of care:**
    - Unlike cancer screening, **the effectiveness of fracture prevention INCREASES with advancing age** — a **90-year-old has a higher lifetime fracture risk and a lower NNT than a 70-year-old**. Economic models suggest treatment is **cost-effective even with a life expectancy as short as two years**.
    - **Drug benefit appears at 6–12 months; the benefit of effective fall prevention may be immediate.**

- **Fracture Liaison Services (FLS)** provide routine, coordinator-based assessment and management of **all postmenopausal women and all men with a fragility fracture**; the **IOF "Capture the Fracture"** campaign sets internationally endorsed best-practice standards to break the fragility fracture cycle. **Orthogeriatric co-management** models improve outcomes after hip fracture.

LATEST UPDATES (2023–PRESENT)

1. **ACP Living Clinical Guideline (Annals of Internal Medicine, 2023) — bisphosphonates confirmed as first line. Bisphosphonates are strongly recommended as initial pharmacologic treatment in postmenopausal women (high-certainty evidence)** and conditionally suggested in men. **Denosumab is second line** for those with contraindications or adverse effects. **Romosozumab or teriparatide followed by a bisphosphonate is suggested only in women at very high fracture risk.** For **women over 65 with osteopenia, an individualised decision** on starting a bisphosphonate is advised. The 2023 update **removed the earlier 2017 ambiguity that allowed either bisphosphonates or denosumab as first choice**, and as a "living guideline" it is revised as new data emerge.
2. **NOGG UK guideline 2024 — HRT returns as first-line in a defined group.** Specific 2024 updates include **fracture risk assessment by ethnicity, and in Parkinson's disease, Down's syndrome and lower-limb amputation**; the **definition of very high fracture risk has been clarified**; and **HRT is now recommended as a first-line option in younger postmenopausal women with high fracture risk and low baseline risk of adverse events**. Three anabolic agents — **teriparatide, abaloparatide and romosozumab** — are now available, with **teriparatide licensed for a once-only treatment course**; **no evidence yet supports one specific sequence**, so specialist input is essential.
3. **RACGP / Healthy Bones Australia 2024. Widespread population-based screening is not recommended**; **FRAX-based absolute risk assessment** is encouraged. It is essential to identify patients at **"imminent" or "very high" fracture risk — the group in whom early osteoanabolic therapy should be considered**. Critically, **calcium and vitamin D supplementation reduces fracture risk only in individuals who are actually deficient, not in healthy non-institutionalised people**. The guideline also addresses **rebound vertebral fracture after denosumab cessation** and formally **removes strontium as a therapy**.
4. **ASBMR/BHOF goal-directed treatment position statement (JBMR, 2024).** Major guideline bodies (AACE, Endocrine Society, The Menopause Society, BHOF, ESCEO/IOF, NOGG) have all now adopted a **new "very high fracture risk" category**. A subset of these patients is at **imminent risk for the two years following an incident fracture** or after multiple prior fractures — the rationale for **treat-to-target, anabolic-first therapy**.
5. **USPSTF draft statement (December 2024) — vitamin D and calcium downgraded.** A **Grade D (recommend against)** was proposed for **vitamin D, with or without calcium, to prevent fractures** in postmenopausal women and men ≥60 years, and a **Grade D for vitamin D to prevent falls** in the same group.

This applies only to **community-dwelling** individuals and **does not apply to those with diagnosed osteoporosis, vitamin D deficiency, or malabsorption**.

6. **Cochrane Review 2025 (care facilities, CD016064) — the institutional exception holds.** In care facilities, **vitamin D supplementation, exercise, and staff-engaged individually tailored multifactorial interventions probably reduce falls** — reinforcing that **nursing-home residents remain a group who benefit from vitamin D**, in contrast to community dwellers.
7. **Short-course sequential therapy after hip fracture (2025).** Current guidelines recommend **anabolic agents first-line in very-high-risk patients including recent hip fracture, followed by antiresorptive therapy**, but real-world implementation is limited and the optimal anabolic duration is uncertain. A study of **113 osteoporotic hip fracture patients** evaluated **3–6 months of teriparatide or romosozumab followed by denosumab** versus anabolic monotherapy, since **shorter anabolic courses may be more feasible in frail elderly patients** than the conventional 18–24 months.
8. **Indian guidance — ISBMR position statement. Osteoporotic fractures occur at an earlier age in Indians than in the West, so screening should begin earlier. FRAX may underestimate future fracture risk in the Indian population and still requires validation.** Maintaining optimal **serum 25(OH) vitamin D** usually requires **regular supplementation**, and **bisphosphonates remain the first choice in most cases**. For **vertebral fractures, teriparatide is recommended as initial anabolic treatment for 24 months followed by an antiresorptive**; **zoledronic acid or denosumab are alternatives, with zoledronic acid preferred**. A **Markov microsimulation cost-effectiveness analysis of FRAX-based intervention thresholds in Indian women (Osteoporosis International, 2025)** has now been published, and **FRAX without DXA** is highlighted as usable where densitometry is unavailable. Maintenance **vitamin D3 of 1000–2000 IU daily** is typically required.
9. **Indian service gaps. DXA availability is concentrated in urban tertiary centres**; **Fracture Liaison Services are few and reimbursement is limited**. Practical Indian strategy: **clinical diagnosis on a minimal-trauma fracture, FRAX without BMD, generic alendronate or annual zoledronic acid, calcium and vitamin D correction, and fall prevention through NPHCE geriatric clinics and district-level rehabilitation units**.
10. **NICE NG249 (April 2025).** Vitamin D supplements are **not recommended specifically to reduce falls**, though people are encouraged to follow standard advice on vitamin D **to maintain bone and muscle health** — separating the **bone** indication from the **falls** indication.

CURRENT PRACTICE UPDATE

Domain	Textbook Position	Current Practice (2023–Present)
First-line drug	Oral bisphosphonate for high risk; denosumab an equal alternative	**Bisphosphonates are unambiguously first line (ACP 2023, strong, high-**

		certainty); **denosumab is second line** for intolerance or contraindication
Anabolic therapy	Consider for very high risk, followed by antiresorptive	Same principle, but **"very high risk" and "imminent risk (2 years post-fracture)" are now formally defined categories**; **short 3–6 month anabolic courses** being trialled in frail hip-fracture patients
Calcium and vitamin D	Give to all; benefit shown in nursing-home women, none in community dwellers	Sharpened — **effective only in those who are actually deficient or institutionalised**; **USPSTF draft Grade D against routine use in community dwellers**
HRT	Effective but limited by breast cancer, thromboembolic and cardiovascular risk	**NOGG 2024 reinstates HRT as first-line in younger postmenopausal women** with high fracture risk and low adverse-event risk (not applicable to the very old)
Strontium ranelate	Discussed with DRESS and thromboembolic cautions	**Formally removed as a therapy** (RACGP 2024)
Denosumab stopping	Discontinuation may cause multiple vertebral fractures — follow with bisphosphonate	Unchanged and now emphasised as **"rebound vertebral fracture" — never stop denosumab without antiresorptive cover**
Screening	DXA for diagnosis mainly useful in women <75	**Population-based screening not recommended**; **case-finding with FRAX ± DXA** is the model; **in India, screening should start at a younger age**
Hip protectors	Small benefit in care homes, none in community	Unchanged — **adherence remains the limiting factor**
Systems of care	Fracture Liaison Services and "Capture the Fracture"	Now the **central quality metric**; the global **treatment gap after fragility fracture remains the biggest unaddressed problem**

EXAM ONE-LINERS

- **Fragility fracture = fall + fragile bone.** Prevent **both**.
- **Three pillars:** fall risk intervention, hip protectors, osteoporosis treatment.
- **Commonest sites: hip, forearm, vertebra.**
- **Only 3% of elderly hip fractures are pathological.**
- **After hip fracture, in 1 year: 56% fall, 28% recurrent falls, 12% new fracture, 5% fracture the other hip.**
- **FRAX = 10-year probability of hip and major osteoporotic fracture.**

- **T-score ≤ −2.5 = osteoporosis;** but a minimal-trauma fracture is diagnostic on its own.
- **DXA for diagnosis alone is mainly indicated in women <75.**
- **Commonest secondary cause of osteoporosis in the elderly = hyperthyroidism.**
- **Universal measures: calcium 800–1000 mg/day, protein ≥1 g/kg/day, vitamin D ~800 IU/day, weight-bearing exercise.**
- **Exercise programme should be ≥50 hours, progressive, strength + balance.**
- **Zoledronic acid 5 mg IV yearly: ↓ clinical fracture 33%, vertebral 77%, peripheral 25%** — correct vitamin D first.
- **NNT ≈ 200 with oral bisphosphonate to prevent one hip fracture.**
- **Denosumab = anti-RANKL, 6-monthly SC; never stop without bisphosphonate cover.**
- **Romosozumab = anti-sclerostin; 12 months then alendronate (ARCH).**
- **Raloxifene does not reduce hip fracture; SERMs contraindicated after femoral neck fracture.**
- **Bisphosphonate holiday after 3 years IV / 5 years oral in low-risk patients only.**
- **Hip protectors: RR 0.82 in care homes; no benefit in the community.**
- **Fracture prevention becomes MORE effective with advancing age** — cost-effective with life expectancy as short as 2 years.
- **Fracture Liaison Service + "Capture the Fracture" = secondary prevention model.**

QUESTION 5

Pressure Sores: Stages, Common Sites, Prevention and Treatment

15 MARKS | 20 HIGH-YIELD POINTS

A. Definition, Terminology and Pathogenesis

1. A **pressure injury** is **localised damage to the skin and underlying tissue, usually over a bony prominence** (sacrum, heels), caused by **disruption of blood supply**, preventing oxygen and nutrients from reaching cells. **"Pressure injury" is a more accurate term than "pressure ulcer"** because **some presentations are not open ulcers**.
2. **Incidence varies widely by setting:** acute care **0.4–38%**, long-term care **2.2–23.9%**, home care **0–17%**. About **25% of pressure ulcers are acquired intra-operatively**.
3. **Four mechanical forces operate together:**
   - **Pressure** over a bony prominence → tissue deformation and ischaemia
   - **Shear** — head of bed elevated, torso slides down, transmitting force to the sacrum; stretches and angulates subcutaneous tissue
   - **Friction** — repeated movement of skin across sheets/clothing, which increases shear
   - **Moisture** — sweat, urine, faeces, bathing

   Together these cause **thrombosis of small blood vessels**, undermining then destroying skin. **Loose, folded skin** (loss of subcutaneous fat, dehydration) worsens shear.
4. **The area of damage beneath the ulcer is often much larger than the visible ulcer** — the "iceberg" effect — because pressure and shear are transmitted deep into subcutaneous tissue.

B. Staging (NPIAP System)

5. Pressure injuries are numerically staged **1, 2, 3 or 4 — using Arabic, not Roman, numerals — only if the depth of the wound can be visualised**.
6. **Stage 1 — Non-blanchable erythema of intact skin.** Acute inflammatory response limited to epidermis. Irregular area of **erythema, induration and oedema**, which may feel **firm or boggy**. **Redness persists beyond 30 minutes and does not blanch on pressure.** In **darker skin the colour may be red, blue or purple**. **Skin is unbroken.**
7. **Stage 2 — Partial-thickness loss.** Inflammation extends **through the dermis to the junction of subcutaneous fat**. Appears as a **blister, abrasion or shallow ulcer with distinct edges**. Early fibrosis and pigment change occur.

8. **Stage 3 — Full-thickness skin loss extending through subcutaneous fat, down to but not through the underlying fascia.** Presents as a **crater**, often with **undermining** of adjacent tissue. Base may be infected with **necrotic, foul-smelling tissue**.
9. **Stage 4 — Extension through deep fascia, with bone visible at the base. Undermining is even more common and sinus tracts may be present. Osteomyelitis and septic arthritis can occur.**
10. **Two additional categories when depth cannot be seen:**
    - **Unstageable pressure injury** — wound base obscured by **eschar and/or necrotic tissue**; **can be staged once debrided**
    - **Deep tissue pressure injury (DTPI) — skin intact but deep red, purple or maroon**, or a **haemorrhagic blister**, indicating damage in deeper tissue
11. **Special situations:**
    - **Medical device–related pressure injuries** — from urinary catheters, rectal tubes, oxygen tubing, NIV masks; the wound **conforms to the shape of the device**. **These ARE staged.**
    - **Mucous membrane pressure injuries must NOT be staged** — only documented.
12. **Reverse staging is inaccurate for assessing healing.** Use the **PUSH tool (Pressure Ulcer Scale for Healing)**, which scores **size, exudate amount and tissue type** and is sensitive to change over time.

C. Common Sites

13. **More than 90% of pressure ulcers occur in the lower body** — principally the **sacral and coccygeal area, ischial tuberosities and greater trochanter**, along with the **heels**.
14. **Site varies with posture:**

Position	Pressure points
Supine	**Occiput**, scapulae, elbows, **sacrum**, coccyx, buttocks, **heels**
Lateral	Ear, shoulder, **greater trochanter**, ribs, **malleoli**, knees, bent lower leg
Sitting	**Ischial tuberosities**, coccyx, sacrum, back of knees, heels
Prone	Forehead, chin, cheeks, chest/breasts, iliac crests, genitalia, knees, dorsum of feet

Easily overlooked sites: **gluteal cleft, elbows, malleoli, wrists**.

D. Risk Factors and Risk Assessment

15. **Risk factors:** being **bed- or chair-bound**, **unable to reposition without assistance**, difficulty with ambulation, **history of stroke**, **faecal incontinence**, **low**

body weight, **lymphopenia**, difficulty with independent feeding, **impaired nutritional intake**, **non-blanchable erythema of intact skin (i.e. an existing Stage 1 injury)** and **dry sacral skin**. **Advanced age itself is NOT an independent risk factor** — it is the coexisting impairments in mobility, nutrition and skin health that matter.

16. **Risk-assessment tools: Norton, Braden and Waterlow scales.** Current recommendation is to apply a tool **on admission to a facility and regularly thereafter**. Because risk is multifactorial, **multidisciplinary multifactorial intervention** is effective — as with falls and delirium.

E. Prevention

17. **General principles of skin care in the immobile patient:**
    - **Identify patients at risk**
    - **Decrease pressure, friction and skin folding**
    - **Keep skin clean and dry**; **moisturise dry sacral skin**
    - **Avoid excessive bed rest — optimise and encourage function**
    - **Avoid over-sedation**
    - **Nutrition and hydration: 30–35 kcal/kg/day, protein 1–1.5 g/kg/day, fluid 1 mL/kcal**; dietitian referral for those at risk
18. **Support surfaces:**
    - **Non-powered** — mattresses or overlays filled with **air, water, gel or foam**
    - **Powered** — mechanically vary the pressure beneath the patient, reducing the *duration* of applied pressure; **far more costly**
    - **Specialised foam and sheepskin overlays reduce incidence compared with a standard hospital mattress**; the choice between powered and non-powered is **not clear**
    - **Mattress overlays on operating tables reduce postoperative pressure injuries**
    - **Repositioning: at least 2-hourly on a regular mattress, at least 4-hourly on a pressure-reducing mattress**
19. **Avoidability: Not all pressure injuries are avoidable, particularly at the end of life** — but **prevention protocols must be in place before concluding that an injury was unavoidable**.

F. Treatment

20. **Stage-wise management. Overarching principle — managing the underlying contributing factors is more important than topical or adjunctive therapy.** Standard local care of a **healable** ulcer must satisfy three criteria: **moisture balance, bacterial balance and debridement.**
    - **Stages 1–2:** continue **all** preventive measures to stop progression. Clean with **warm normal saline or water**; avoid pressure and moisture; cover open wounds

with an **occlusive dressing** chosen by wound condition, drainage and infection; use antibiotics **very judiciously**; manage pain. **No single dressing has been shown superior to another.**

- **Stage 3: debride necrotic tissue** (autolytic, chemical, mechanical, sharp or surgical); **irrigate 2–3 times daily**; **undermine and remove eschar** if it conceals necrotic or infected tissue. **Routine wound cultures are not warranted** — they grow multiple organisms, miss anaerobes and reflect colonisation. **Systemic antibiotics do not reach adequate concentration in the ulcer**; reserve them for **confirmed bacteraemia, sepsis, osteomyelitis or cellulitis**.
- **Stage 4: tissue biopsy for routine and anaerobic culture**; **systemic antimicrobials are often necessary**; **surgical/plastic consultation for repair**. If septic, use **broad-spectrum cover for anaerobes, Gram-negatives and *Staphylococcus aureus***.
- **Diagnosing infection: increasing pain in a chronic wound is the strongest predictor (LR 11–20)**. The "classic signs" — **purulent exudate, erythema, heat, oedema — and foul odour are NOT helpful**. Use a **quantitative swab by the Levine technique** (rotate swab over a **1 × 1 cm area for 5 seconds** with enough pressure to express fluid): **positive LR 6.3, negative LR 0.47**.
- **Adjunctive therapies** (negative-pressure wound therapy, hyperbaric oxygen, laser, electrotherapy, electromagnetic therapy, therapeutic ultrasound): **no good evidence that they improve healing.**
- **Non-healable injuries / skin failure:** where underlying conditions are irreversible or goals are comfort, prioritise **reducing infection risk and controlling pain**. Wounds appearing on bony prominences during overall decline are termed **skin failure**, not pressure injuries.
- **Documentation must include:** type and duration; **size as length × width × depth in cm**; **colour as percentage red (granulation) / yellow (slough) / black (eschar)**; **exudate** (serous, serosanguinous, sanguinous, purulent); **odour assessed after cleaning**; periwound tissue; and **undermining**.

LATEST UPDATES (2023–PRESENT)

1. **Fourth edition of the International Pressure Injury Guideline (NPIAP/EPUAP/PPPIA, 2025) — a rolling, online guideline.** Partner organisations NPIAP, EPUAP and PPPIA are releasing the fourth edition with an **expanded online format and staged release of chapters**, plus refreshed quick-reference materials, governed by a **Guideline Governance Group led by Professor Janet Cuddigan** with **over 240 clinical experts and consumer representatives** using **evidence-to-decision frameworks**. Chapters live include **Definition & Etiology, Preventive Skin Care, Nutrition, Repositioning, Support Surfaces, Seating, Heel Pressure Injuries and Device-Related Pressure Injuries**, with Pressure Injury Risk and Skin & Tissue Assessment to follow.
2. **The "2-hourly turn" is no longer mandatory.** A meta-analysis of two RCTs in aged-care settings found **2-hourly repositioning was associated with a non-significant and counter-intuitively *higher* rate of pressure injuries than 3-**

hourly (1.3% vs 0.3%, RR 4.06, 95% CI 0.87–18.98). The guideline therefore suggests that **either 2-hourly or 3-hourly repositioning may be used for most at-risk individuals, provided an appropriate pressure-redistribution support surface is in place** (conditional recommendation, very low certainty). However, it **suggests against routinely extending intervals to 4, 5 or 6 hourly**, since a meta-analysis of five RCTs showed fewer injuries with 2-hourly turning (4.6% vs 5.7%, RR 0.89).

3. **The harms of over-frequent turning are now formally recognised.** A Cochrane review documented **sleep disruption, musculoskeletal pain, wound pain and more injuries to care staff** with shorter intervals. **Staff compliance is higher at 3- and 4-hourly intervals (90–95%) than at 2-hourly (80%)**, and two economic analyses showed **extending from 2-hourly to 3-hourly was more cost-effective** when tolerated.
4. **Positioning specifics with new evidence. 30-degree lateral positioning** is suggested over greater angles (**avoid the 90-degree lateral position**), modified to **40 degrees in individuals with high BMI** who cannot maintain it. **Head-of-bed elevation should be kept at 30 degrees or lower** — restricting elevation gave **68 fewer pressure injuries per 1,000 (11.1% vs 18.9%, OR 0.59, 95% CI 0.36–0.97)** — but a **lower head-of-bed increased ventilator-associated pneumonia (OR 2.15) and gastric reflux (OR 1.85)**, so clinical needs may override.
5. **Micromovements for the haemodynamically unstable.** It is now **good practice to use frequent, small, incremental shifts (micromovements) in critically ill individuals too unstable for a regular repositioning regimen**, with a **trial of full body repositioning at least every 8 hours** to see if regular turning can resume, allowing **at least ten minutes for haemodynamic equilibrium** after each position change.
6. **Early mobilisation is now an evidence-based pressure injury intervention.** A meta-analysis of six RCTs and six comparative studies showed **early mobilisation significantly reduced pressure injuries (5.2% vs 6.9%, RR 0.75, 95% CI 0.61–0.92) — 17 fewer per 1,000**. It also prevented **ICU-acquired weakness (RR 0.49), deep vein thrombosis (RR 0.16) and pneumonia (RR 0.39)**, with a small increase in falls. The staged protocol is: **passive range of movement → dangling limbs → sitting out of bed → standing → walking**, 2–3 times daily as tolerated.
7. **Wearable movement sensors — a conditional new option.** Three studies of body-worn movement sensors showed a **non-significant lower rate of pressure injuries (0.7% vs 6.9%, RR 0.15, 95% CI 0.02–1.08)**; sensors are **suggested to help evaluate repositioning needs where resources permit**, but must **complement rather than replace clinical judgement**, and **may not detect offloading at the head, ears, elbows and heels**.
8. **Prophylactic dressings and refined skin assessment.** The 2025 Preventive Skin Care chapter suggests **a multilayered soft silicone foam dressing on the sacrum and heels for individuals at high risk, where resources permit** (conditional, very low certainty), and specifies that **skin assessment must include the scalp and under hair**, using **wide-toothed combs and**

moisturising products for curly, textured or tightly coiled hair to allow visual inspection. **Subepidermal moisture (SEM) measurement and skin temperature are now recommended within skin assessment**, as SEM detects inflammation and tissue damage **predictive of Stage 1 and greater injuries, especially at the sacrum**, and **high-resolution ultrasound is valuable for deep tissue injury, particularly in darker skin tones**.

9. **Device-related injuries are a growing share of the burden.** In acute care, **medical device–related pressure injuries account for more than 30% of all hospital-acquired pressure injuries**, largely from prolonged prone positioning with ventilation devices in the mouth and nose; **sedation, oedema and increased skin moisture** are contributory.
10. **Indian data — lower prevalence but more advanced disease.** A point-prevalence study in a north Indian tertiary hospital using the **EPUAP minimum data set** found an overall prevalence of **7.8%**, with the **sacrum and heel most commonly affected** and, strikingly, **Grade III ulcers being the commonest presentation (42.8%)** — indicating **late detection**. **ICU prevalence was 24.3%**, and injuries were more frequent in patients hospitalised **more than a month**. An earlier Varanasi study found a prevalence of **4.94%**, with **anaemia, malnutrition and diabetes** as key risk factors and **morbidity in long-stay neurology wards as high as 40.9%**. Practical Indian implications: **home-based bedbound care is the dominant setting**, **caregiver education is the single highest-yield intervention**, and **low-cost foam or sheepskin overlays with disciplined repositioning** outperform expensive powered mattresses that most families cannot afford.

CURRENT PRACTICE UPDATE

Domain	Textbook Position	Current Practice (2023–Present)
Repositioning frequency	At least **2-hourly** on a regular mattress, **4-hourly** on a pressure-reducing mattress	**2-hourly or 3-hourly are both acceptable** on an appropriate support surface; **individualised regimens replace fixed schedules**; do **not** routinely extend to 4–6 hourly
Rationale for change	More frequent turning assumed better	Frequent turning causes **sleep disruption, pain and staff injury**, and **compliance falls at 2-hourly intervals**; 3-hourly is more cost-effective
Support surfaces	Powered vs non-powered choice unclear	Unchanged — but explicitly stated that **no support surface can entirely replace repositioning**
Positioning	Not specified in detail	**30-degree lateral position** (avoid 90-degree); **head-of-bed ≤30 degrees**, balanced against aspiration and VAP risk
	Not addressed	

Unstable patients		**Micromovements** are formal good practice; retry full turning **8-hourly**
Mobilisation	"Avoid excessive bed rest; optimise function"	Now supported by meta-analysis — **early staged mobilisation significantly reduces pressure injuries (RR 0.75)**
Prophylactic dressings	Not recommended	**Multilayered soft silicone foam on sacrum and heels** suggested for high-risk patients
Skin assessment	Visual inspection of bony prominences	Extended to **scalp and under hair**; **SEM and skin temperature measurement** added, especially valuable in **darker skin tones** where Stage 1 and DTPI are missed
Technology	Not addressed	**Wearable movement sensors** conditionally suggested as an adjunct — never a replacement for clinical judgement
Adjunctive therapies	No good evidence they improve healing	**Unchanged** — NPWT, hyperbaric oxygen, laser, ultrasound still not supported for routine use

EXAM ONE-LINERS

- **"Pressure injury" is preferred to "pressure ulcer"** — not all are open ulcers.
- **Four forces: pressure, shear, friction, moisture.**
- **Shear** occurs when the head of the bed is elevated and the torso slides down onto the sacrum.
- **Damage below the ulcer is larger than the visible ulcer.**
- **Stage 1 = non-blanchable erythema, intact skin**, persisting beyond 30 minutes.
- **Stage 2 = partial thickness** — blister, abrasion or shallow ulcer.
- **Stage 3 = full thickness through fat, down to but not through fascia** — crater with undermining.
- **Stage 4 = through deep fascia, bone visible** — sinus tracts, osteomyelitis.
- **Unstageable = base obscured by eschar; DTPI = intact skin, deep purple/maroon or haemorrhagic blister.**
- **Device-related injuries ARE staged; mucosal injuries are NOT.**
- **Never reverse-stage** — use the **PUSH tool** (size, exudate, tissue type).
- **>90% occur in the lower body: sacrum/coccyx, ischial tuberosity, greater trochanter** (plus heels).
- **Risk tools: Norton, Braden, Waterlow** — on admission and regularly.

- **Advanced age is NOT an independent risk factor.**
- **Nutrition target: 30–35 kcal/kg, protein 1–1.5 g/kg, fluid 1 mL/kcal.**
- **Turn 2-hourly on a regular mattress, 4-hourly on a pressure-reducing mattress** (now individualised — 2 or 3 hourly both acceptable).
- **30-degree lateral position; head-of-bed ≤30 degrees.**
- **Increasing pain is the best predictor of chronic wound infection (LR 11–20)** — classic signs and odour are unhelpful.
- **Levine technique = swab rotated over 1 × 1 cm for 5 seconds.**
- **Systemic antibiotics only for bacteraemia, sepsis, osteomyelitis or cellulitis** — not for routine Stage 3 ulcers.
- **Managing underlying causes beats any dressing** — no single dressing is superior.
- **Not all pressure injuries are avoidable**, especially at the end of life — but the prevention protocol must be in place first.

FINAL REVISION SHEET

Cross-Module Numbers Worth Memorising

Number	What it belongs to
1/3 · 1/2 · 1 in 5	Community elders falling yearly · nursing-home residents falling yearly · falls causing serious injury
11.6%	Fall prevalence in Indian adults ≥60 years (LASI wave 1)
<0.6 m/sec	Abnormal gait speed; each 0.1 m/sec drop = 7% rise in fall risk
>12 seconds	Timed Up and Go cut-off for high fall risk (10 seconds proposed in 2025)
<24 / 28	Tinetti POMA score indicating fall risk
0–56 · 0–12	Berg Balance Scale range · SPPB range
≥45 · ≥2 · ≥5	Morse Fall Scale high risk · STRATIFY at risk · Hendrich II high risk
>20 mmHg	Systolic drop defining orthostatic hypotension
24% · 34% · 19%	Fall reduction: balance/functional exercise · multiple exercise types · Tai chi
14 classes	STOPPFall fall-risk-increasing drug classes
3%	Proportion of elderly hip fractures that are pathological
56 · 28 · 12 · 5 (%)	One year after hip fracture: fall again · repeated falls · new fracture · opposite hip fracture
33% · 77% · 25%	Zoledronic acid: clinical · vertebral · peripheral fracture reduction
NNT 200	Oral bisphosphonate, to prevent one hip fracture
RR 0.82	Hip protectors in nursing/residential care (no benefit in community)
≥50 hours	Minimum duration of a structured progressive exercise programme
>90%	Pressure ulcers occurring in the lower body
30–35 kcal/kg · 1–1.5 g/kg · 1 mL/kcal	Energy · protein · fluid targets in the immobile patient
2-hourly / 4-hourly	Repositioning: regular mattress / pressure-reducing mattress (now 2 or 3 hourly, individualised)
30 degrees	Lateral tilt position and maximum head-of-bed elevation
LR 11–20	Increasing pain as a predictor of chronic wound infection
1 × 1 cm, 5 seconds	Levine technique for quantitative wound swab

7.8% · 24.3% · 42.8%	Indian tertiary hospital: overall pressure ulcer prevalence · ICU prevalence · proportion that are Grade III

The four sentences that carry the most marks in this module.
1. Falls are multifactorial — an acute trigger acting on accumulated chronic impairments; medications are the most modifiable factor.
2. Progressive balance and functional exercise has the strongest evidence of any fall-prevention intervention; technology and scoring tools are adjuncts.
3. A fragility fracture requires both a fall and fragile bone — and the effectiveness of fracture prevention *increases* with advancing age.
4. In pressure injuries, correcting the underlying contributing factors matters more than the choice of dressing or any adjunctive therapy.

MD GERIATRIC MEDICINE EXAMINATION COMPENDIUM

HEALTH POLICY, NATIONAL PROGRAMMES & SOCIAL GERONTOLOGY

Nine structured long-answer questions
Textbook-sourced points • Latest Updates (2023–2026) • Current Practice Update
Examiner's Tips • Rapid Revision Grid

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition
Essentials of Clinical Geriatrics, 7th edition
Supplemented by: MoHFW / MoSJE / NITI Aayog / WHO / ILO documents, 2023–2026

Prepared for Dr. Sudarsan • Compiled August 2026

CONTENTS

Q1	Health Policy and Programmes Related to Old People	**3**
Q2	National Programme for Health Care of the Elderly (NPHCE) — Background, Vision, Objectives, Expected Outcomes, Package of Services and Centre Activities	**7**
Q3	Implementing NPHCE Components as the Doctor In-Charge of a District Hospital — Theory into Practice	**12**
Q4	National Policy on Older Persons (1999) and Existing Beneficiary Schemes for the Elderly	**17**

HOW TO USE THIS COMPENDIUM

Each answer follows a fixed architecture: a **Source Statement** declaring exactly what the uploaded textbooks do and do not cover → **15–20 numbered high-yield points** under thematic subheadings → **Latest Updates (2023–Present)** with inline citations → a **Current Practice Update** two-column table contrasting the textbook position with current evidence → an **Examiner's Tip** panel with verbatim mark-earning lines.

Critical exam strategy for this block: Pathy's and Essentials contain **no Indian policy content whatsoever**. Examiners know this. The highest-scoring answers explicitly state which framework comes from the textbook (concepts, ethics, global data) and which comes from Government of India documents (programmes, schemes, law) — then show how the two fit together.

Q1. Health Policy and Programmes Related to Old People

SOURCE STATEMENT

Pathy's 6th edition is largely SILENT on Indian national health policy for the elderly. It covers only the **UK/NHS historical perspective** (Ch. 1), the **WHO global framework and social determinants of ageing** (Ch. 4, Ch. 7) and the **UK National Service Framework** (Ch. 11). *Essentials of Clinical Geriatrics* covers **US programmes** (Medicare, Medicaid, Older Americans Act) in Ch. 15.
Points 1–6 are textbook-sourced. **Points 7–20 — the Indian programmes that form the bulk of an Indian university answer — are from Government of India, WHO and peer-reviewed sources.**

A. Concepts and Global Framework (Pathy's, Ch. 4, 7, 11)

1. **Healthy ageing** is defined by WHO as developing and maintaining the **functional ability** that enables well-being in older age. Pathy's states that **functional ability — retaining autonomy and independence — is the cornerstone of healthy ageing**.
2. **Intrinsic capacity** is the composite of all physical and mental capacities. Pathy's lists its domains as **cognition, mental health, sensory function, metabolic/vitality, mobility and muscle strength**.
3. Pathy's notes the **WHO Global Strategy and Action Plan on Ageing and Health**, whose goals are to create **age-friendly environments**, **align national health systems** with the needs of older people, and **support research** to monitor global ageing.
4. **Historical UK policy:** the **NHS was created in 1948** with a tripartite structure (hospitals, GP services, local authority services), free at the point of use. Pathy's criticises it for **poor coordination between the three arms** and a smaller share of funds for chronic and mental health services.
5. **UK National Service Framework (NSF) for Older People, 2001:** its **Standard One was "rooting out age discrimination."** Pathy's stresses that **ageism persists**, causing older people to be denied beneficial investigations and treatments, and warns against both **therapeutic nihilism and therapeutic heroism**.
6. **US programmes (Essentials, Ch. 15): Medicare Part A** (hospital) and **Part B** (medical); **Medicaid** (means-tested, main payer for nursing homes); **Title XX Social Services Block Grants**; and **Title III of the Older Americans Act** (congregate meals and meals-on-wheels for all persons **>60 years regardless of income**). Payment by **DRGs** works against geriatric goals as it focuses on a single diagnosis.

B. Indian Legal and Policy Framework

7. **Constitutional basis:** **Article 41** (Directive Principle) directs the State to provide **public assistance in old age, sickness and disablement**; **Article 46** protects weaker sections. Ageing is a **Concurrent/State subject**, so States must frame their own action plans.
8. **National Policy on Older Persons (NPOP), 1999** — India's first ageing policy. Five thrust areas: **income security, health and nutrition, shelter, education, and welfare/empowerment**. It proposed a **National Council for Older Persons**. Goal: the well-being of older persons by strengthening their legitimate place in society so they can live with **purpose, dignity and peace**.
9. **NPOP 1999 was revised in 2011 as the National Policy on Senior Citizens (NPSrC)**, which emphasised **"ageing in place," the 80+ "old-old," and elderly women**. **Exam point: NPSrC 2011 remains a draft and has never been formally notified.**
10. **Maintenance and Welfare of Parents and Senior Citizens (MWPSC) Act, 2007** is the key legislation, making maintenance of parents by children a **legal obligation**. State governments constitute **Maintenance Tribunals** presided over by an administrative officer; maintenance may not exceed **₹10,000 per month**.
11. **Other key MWPSC provisions:** disposal within **90 days**; **abandonment is punishable** (up to 3 months imprisonment and/or fine); **transfer of property by gift/deed can be declared void** if the transferee fails to provide basic amenities; **Chapter IV mandates medical care** — separate queues, beds and expanded facilities for chronic, terminal and degenerative disease.
12. The **MWPSC (Amendment) Bill, 2019** proposes to widen the definitions of "children," "parents," "maintenance" and "welfare," to allow **priority disposal for those above 80 years**, and to **remove the ₹10,000 ceiling**. It was referred to a Standing Committee and **is still pending**.

C. Health Programme — NPHCE

13. The **National Programme for the Health Care of the Elderly (NPHCE)** was launched by **MoHFW in 2010**, based on the recommendations of NPOP and the State's obligation under the MWPSC Act 2007. It is also an articulation of India's commitment under the **UNCRPD**, aiming at **accessible, affordable, long-term comprehensive care and the promotion of Active and Healthy Ageing**.

14. **NPHCE service ladder (memorise): Sub-centre** — health education, domiciliary visits by ANM/ASHA; **PHC** — weekly geriatric clinic, basic drugs, rehabilitation guidance; **CHC** — twice-weekly clinic, **physiotherapy unit**, referral; **District Hospital** — **10-bedded geriatric ward** and dedicated OPD; **Regional Geriatric Centre** — tertiary care, **30-bedded ward**, PG training.
15. The **tertiary component was renamed "Rashtriya Varisth Jan Swasthya Yojana" in 2016–17**, delivered through **Regional Geriatric Centres in 19 medical colleges across 18 states**, plus **two National Centres of Ageing — AIIMS New Delhi and Madras Medical College, Chennai**.
16. NPHCE is a **centrally sponsored scheme (75% Central : 25% State)**, now implemented under the **National Health Mission NCD flexi-pool**. Its **eight components** are preventive/promotive, primary, secondary, tertiary, home-based care, referral, human-resource development and **IEC**.

D. Social Welfare and Financial Programmes

17. **Atal Vayo Abhyuday Yojana (AVYAY)** — Ministry of **Social Justice & Empowerment**. Components: **IPSrC** (grants to NGOs for old-age and continuous-care homes), **SAPSrC** (State Action Plan), **Rashtriya Vayoshri Yojana (RVY)**, **SCOPE** and **SAGE** (Seniorcare Ageing Growth Engine).
18. **RVY** provides **free assisted-living devices** (spectacles, hearing aids, dentures, walking sticks, wheelchairs, walkers) to seniors who are **BPL or have monthly income up to ₹15,000**; devices are made by **ALIMCO** and given through camps. **Elderline (14567)** is the national toll-free helpline for **information, guidance, emotional support and field intervention in elder abuse and rescue**.
19. **Financial and social security: IGNOAPS** (₹200/month for 60–79; ₹500/month for 80+, central share), **SCSS**, **PMVVY**, **Atal Pension Yojana**, **Senior Citizens' Welfare Fund**, income-tax relief under **Sec 80D and 80TTB**, and rail/air travel concessions.
20. **Health insurance: Ayushman Bharat** has two pillars — **Ayushman Arogya Mandir** (formerly HWCs) for comprehensive primary care with **population-based NCD screening from age 30 using the CBAC form**, and **PM-JAY** giving **₹5 lakh per family per year** for secondary and tertiary hospitalisation.

LATEST UPDATES (2023–PRESENT)

1. Ayushman Vay Vandana Card — the single biggest Indian policy change (October 2024). Launched **29 October 2024** under AB PM-JAY, it gives **₹5 lakh of free annual health cover to every citizen aged 70 years and above, irrespective of income**, with **no waiting period for pre-existing conditions**. Seniors aged 70+ already in a PM-JAY family receive an **additional ₹5 lakh top-up for themselves**. It covers about **1,961 procedures across 27 specialties** including dialysis, knee and hip replacement and cancer care; enrolment is via the Ayushman App with Aadhaar e-KYC. **9.67 million cards issued by 31 December 2025.** (NHA, 2024; MoHFW Lok Sabha reply, 2026)

2. WHO ICOPE Handbook, 2nd edition (January 2025). Shifts from a disease-oriented to a holistic approach focused on **intrinsic capacity and functional ability**, detailing **four steps** — basic assessment, in-depth assessment, personalised care plan, implementation/monitoring — screening **six domains: cognition, mobility, vitality, vision, hearing and psychological capacity**, with a **new urinary incontinence care pathway**. (WHO, 2025)

3. UN Decade of Healthy Ageing (2021–2030) — mid-decade progress. Four action areas: **combating ageism, age-friendly environments, integrated care, long-term care**. The first progress report (November 2023, 136 countries) found a **>20% rise in countries with anti-ageism legislation and age-friendly city programmes**, but **fewer than one-third of countries have adequate resources**; only **1 in 4** have sufficient resources for integrated care and **1 in 3** for long-term care, and only **16% of low-income countries** have training programmes for informal caregivers. (WHO, 2023; WHO, Oct 2024)

4. NITI Aayog — "Senior Care Reforms in India" (February 2024). Groups interventions under **four core areas: Health, Social, Economic/Financial and Digital empowerment and inclusion**. Recommends **health literacy for seniors and caregivers**, extending primary care through **AB-HWCs**, expanding **home health care, mental health services and Poshan Abhiyan for seniors**, **amending the MWPSC Act** to cover abuse and harassment, **elderly-friendly housing reforms**, a **national portal for senior care**, formal recognition of the **care economy and care workers**, and a **regulatory base interest rate on senior citizen deposits**. (NITI Aayog, 2024)

5. India Ageing Report 2023 (UNFPA–IIPS). 60+ share rises from **10.5% (2022) to 20.8% (2050)** — **149 million to 347 million**; **elderly outnumber children by 2046**; **80+ grows 279%**; **>40% of the elderly are in the poorest wealth quintile** and **18.7% have no income**; **71% live in rural areas**. (UNFPA India, 2023)

6. Research infrastructure. The **Longitudinal Ageing Study in India (LASI)** under NPHCE, Wave-1 (2017–18), covered **30 states and 6 UTs, 72,250 adults aged 45+, including 31,464 persons aged 60 and above**. (IIPS/MoHFW, 2020)

CURRENT PRACTICE UPDATE

Domain	Pathy's 6th edition (2022)	Current position (2023–2026)
Indian policy	**Not covered at all** — no NPOP, MWPSC, NPHCE or AVYAY	NPHCE, AVYAY, Vay Vandana Card and NITI Aayog 2024 form the entire Indian framework
Global framework	WHO Global Strategy and Action Plan 2016–2020	Superseded by the **UN Decade of Healthy Ageing 2021–2030** with four action areas and formal reporting (2023, 2026, 2029)
Model of care	Disease/syndrome-oriented; intrinsic capacity conceptual only	**ICOPE 2nd edition (2025)** operationalises it into a **4-step pathway** with 6 screening domains
Elderly health financing (India)	Silent	**Universal, income-independent ₹5 lakh cover for all 70+** since Oct 2024 — a shift from means-tested to age-based entitlement
Anti-discrimination	UK NSF 2001 "rooting out age discrimination"	Expanded into the **WHO Global Campaign to Combat Ageism**; >20% more countries now have legislation
Long-term care	Mainly US nursing-home/Medicaid financing	Now a **standalone action area**; India still has **no statutory LTC system**
Projections	60+ doubles between 2015 and 2050	India-specific: **10.5% → 20.8%**; elderly overtake children by **2046**

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

- *"India's ageing policy rests on three pillars: a policy (NPOP 1999), a law (MWPSC Act 2007) and a programme (NPHCE 2010) — the second and third both flow directly from the first."*
- *"The Ayushman Vay Vandana Card of October 2024 is India's first universal, age-based rather than means-tested health entitlement."*
- *"The National Policy for Senior Citizens 2011 was drafted but never notified; India therefore still operates on a policy written in 1999."*
- *"Delivery is fragmented across at least five ministries — MoHFW, MoSJE, MoRD, Labour and Finance — with no single accountable authority."*
- *"Pathy's gives the ethical and conceptual framework; the Government of India documents give the delivery architecture. A complete answer needs both."*

EXTRA POINTS TO REMEMBER (recurring topic)

- **Article 41** is the constitutional anchor — quote it in every policy answer.
- **MWPSC Act:** ₹10,000 cap • 90 days • abandonment punishable • property transfer void • Chapter IV = medical care.
- **NPHCE bed numbers:** District Hospital **10** (of which **2 respite**); Regional Geriatric Centre **30**.
- **Two National Centres for Ageing:** AIIMS New Delhi and Madras Medical College Chennai.
- **Elderline = 14567** (MoSJE). **RVY income ceiling = ₹15,000/month**. **Devices made by ALIMCO.**
- **Four action areas of the UN Decade:** ageism • age-friendly environments • integrated care • long-term care.

Q2. National Programme for Health Care of the Elderly (NPHCE) — Background, Vision, Objectives, Expected Outcomes, Package of Services and Centre Activities

SOURCE STATEMENT

Pathy's 6th edition does NOT mention NPHCE anywhere. It covers only the UK model (NHS 1948, "a geriatric unit in every health district," Exton-Smith's components of an effective geriatric department); *Essentials* covers the US model.

The entire content below is from the primary Government of India source — the NPHCE Operational Guidelines, DGHS, MoHFW (2010) — plus current MoHFW/PIB updates. This is essential, as NPHCE is a guaranteed question in Indian MD Geriatrics examinations.

I. Background — Why the Programme Was Needed

1. **Demographic trigger:** the 60+ population **tripled in the last 50 years**. The 2001 census recorded **75.93 million Indians above 60** (38.22 million men, 37.71 million women), projected to reach **96.30 m (2011), 133.32 m (2021), 178.59 m (2031), 236.01 m (2041) and 300.96 m (2051)**.
2. **Epidemiological trigger:** National Sample Surveys (1986–87, 1995–96, 2004) showed the **burden of morbidity in old age is enormous**, that **non-communicable, lifestyle-related and degenerative diseases are extremely common irrespective of socio-economic status**, and that **disabilities are frequent and compromise activities of daily living**.
3. The **NSS 60th Round (2004)** found **about 8% of older Indians were confined to home or bed, rising to 27% after the age of 80**, with **women more frequently affected** in both villages and cities.
4. **Health-system gaps:** primary-care infrastructure was **grossly deficient**; the health machinery was **geared to maternal-child health and communicable diseases**; the elderly need **long-term, constant, multi-speciality care**; and **no Indian model of elderly care existed**.
5. **Manpower gap:** the UG curriculum did not cover geriatrics adequately, **PG geriatric courses were grossly deficient**, only **one medical college — Madras Medical College, Chennai — produced trained manpower**, there were **no posts to absorb them**, and nearly half had migrated abroad.
6. **Policy/legal mandate — the three pillars:** **(a)** the **UN Convention on the Rights of Persons with Disabilities (UNCRPD)**, ratified effective **3 May 2008**, whose **Article 25** requires health services to be provided **close to people's own communities, including rural areas**; **(b)** the **National Policy on Older Persons (NPOP), 1999**; and **(c) Section 20 of the MWPSC Act, 2007**, dealing with medical care of senior citizens.
7. **NPOP agenda handed to MoHFW (frequently asked): geriatric wards in all district hospitals**; **expansion of treatment facilities for chronic, terminal and degenerative diseases**; improved facilities for those unable to attend centres; **inclusion of geriatric care in medical and nursing curricula**; **reservation of beds** in public hospitals; **training of geriatric care-givers**; and **research institutes for dementia and Alzheimer's disease**.
8. **Launch:** NPHCE was launched by **MoHFW in 2010, during the 11th Five-Year Plan**. The approved budget for 2010–11 and 2011–12 was **₹288 crore**, with **80% Central and 20% State share** (excluding Regional Medical Institutes and NCD Cell activities, which are fully central).

II. Vision — Five Statements (memorise verbatim)

9. **(i)** To provide **accessible, affordable, and high-quality long-term, comprehensive and dedicated care services** to an ageing population; **(ii)** creating a new **"architecture" for Ageing**; **(iii)** to build a framework for an enabling environment for **"a Society for all Ages"**; **(iv)** to promote the concept of **Active and Healthy Ageing**; **(v) convergence** with the National Rural Health Mission, AYUSH and other departments such as the Ministry of Social Justice and Empowerment.

III. Specific Objectives — Only Four

10. **(i)** To provide **easy access to promotional, preventive, curative and rehabilitative services** to the elderly through a **community-based primary health care approach**; **(ii)** to **identify health problems** in the elderly and provide appropriate interventions in the community **with strong referral back-up support**; **(iii)** to **build capacity of medical and paramedical professionals as well as care-takers within the family**; **(iv)** to provide **referral services** through district hospitals and regional medical institutions.

IV. Strategies

11. **Core strategies (6):** community-based primary health care with **domiciliary visits by trained health workers**;

dedicated services at PHC/CHC; **dedicated facilities at District Hospital with 10-bedded wards**; **strengthening of 8 Regional Medical Institutes** for tertiary care, PG courses and in-service training; **IEC using mass and folk media**; and **continuous monitoring, independent evaluation and research**.

12. **Supplementary strategies (3): public–private partnerships**; **mainstreaming AYUSH** and revitalising local health traditions with convergence with MoSJE; and **reorienting medical education**.
13. **The five operational "Main Strategies" (NHM website): (a) Preventive and promotive care** — exercise, balanced diet, stress management, tobacco avoidance and fall prevention, via domiciliary visits and **weekly PHC clinics**; **(b) Management of illness** — dedicated OPD and IPD at every level; **(c) Health manpower development** — in-service training and **PG courses at RGCs**; **(d) Medical rehabilitation and therapeutic intervention** — therapeutic exercises, **ADL training**, pain treatment through **physiotherapy units at CHC, DH and RGC**; **(e) IEC** — mass and folk media plus regular check-up camps.

V. Expected Outcomes — Seven (high-yield list)

14. **(i) Regional Geriatric Centres in 8 Regional Medical Institutions**, each with a dedicated Geriatric OPD and a **30-bedded Geriatric ward**, plus training and research; **(ii) 16 post-graduates in Geriatric Medicine** (2 seats each); **(iii) video-conferencing units in the 8 institutions**; **(iv) District Geriatric Units with Geriatric OPD and 10-bedded ward in 80–100 District Hospitals**; **(v) geriatric clinics/rehabilitation units for domiciliary visits at CHCs and PHCs**; **(vi) sub-centres equipped for community outreach**; **(vii) training of human resources** in geriatric care.

VI. Package of Services

15. **General principle:** promotional, preventive, curative and rehabilitative services in an **integrated manner**, with the package **depending on the level of facility** — health promotion, preventive services, diagnosis and management (OPD and IPD), **day-care**, **rehabilitative** and **home-based care**, with districts linked to RGCs. Services are **integrated (horizontal) below district level and vertical at district level and above**, because more specialised care is needed.

16. Package of Services by Level — TABLE TO MEMORISE

Level	Package of Services
Sub-Centre	Health education on **healthy ageing**; **domiciliary visits** for home-bound/bedridden elderly with **training of family care-providers**; arranging **callipers and supportive devices** from the PHC; **linkage with support groups and day-care centres**
Primary Health Centre	**Weekly geriatric clinic by a trained Medical Officer**; record of each elderly person on a **standard format at first visit**; routine assessment (eye, BP, blood sugar); **medicines and advice on chronic ailments**; awareness on **health and village sanitation days**; **referral** to CHC/DH
Community Health Centre	Acts as the **First Referral Unit (FRU)**; **geriatric clinic twice a week**; **rehabilitation unit for physiotherapy and counselling**; **domiciliary visits by the rehabilitation worker** with family counselling; health promotion; referral to District Hospital
District Hospital	**Dedicated geriatric OPD**; laboratory investigations and medicines; **10-bedded Geriatric Ward**; support from existing specialities (Medicine, **Orthopaedics, Ophthalmology, ENT**); services to patients referred by CHC/PHC; **conducting geriatric camps**; referral to tertiary level
Regional Geriatric Centre	**Specialised Geriatric OPD**; **30-bedded Geriatric ward** plus **dedicated beds in Surgery, Orthopaedics, Psychiatry, Urology, Ophthalmology, Neurology**; laboratory investigations with a **special sample-collection centre in the OPD block**; tertiary care for referrals from medical colleges, district hospitals and below

VII. Centre-wise Activities, Staff and Equipment

17. **Sub-Centre:** the **ANM / Male Health Worker** makes domiciliary visits, gives health education on **environmental modification, nutrition, lifestyle and behavioural change**, and trains family care-providers. An **annual check-up of all elderly at village level** is organised by PHC/CHC and recorded in a **Standard Health Card for the Elderly**; **ASHA mobilises the elderly** for camps and home-based care. **Equipment:** walking sticks, callipers, infrared lamp, shoulder wheel, pulley, ordinary walker. **No additional contractual staff.**
18. **PHC and CHC:** at the **PHC** the Medical Officer is in charge; assessment covers **vision, joints, hearing, chest, BP and simple investigations including blood sugar**, with advice on **COPD, arthritis, diabetes and hypertension including dietary regulation**. Equipment: **nebuliser, glucometer, exercise bicycle, cervical and lumbar traction, gait-training apparatus, infrared lamp**. At the **CHC** one **Rehabilitation Worker** is sanctioned; equipment adds **ECG machine, pulse oximeter, defibrillator, multi-channel monitor, shortwave diathermy, intermittent cervical traction**; the CHC **compiles PHC data and forwards it to the District Programme Officer (NCD)**.
19. **District Hospital (very high-yield):** a **Geriatric Unit** with a **10-bedded ward, of which 2 beds are earmarked in**

a separate room for RESPITE CARE. Contractual staff = **13** (2 Consultant Medicine, 6 Nurses, 1 Physiotherapist, 2 Hospital Attendants, 2 Sanitary Attendants). Finance: **₹87 lakh non-recurring** (₹80 lakh construction + ₹7 lakh equipment) and **₹44 lakh recurring per annum** (including **₹10 lakh drugs and consumables**, ₹2 lakh IEC). Equipment adds **non-invasive ventilator, ultrasound therapy, pelvic traction, TENS**.

20. **Regional Geriatric Centre — the tertiary arm:** originally established in the **Department of Medicine of 8 institutions**: **AIIMS New Delhi; IMS-BHU Varanasi; SKIMS Srinagar; Govt. Medical College Thiruvananthapuram; Guwahati Medical College; Madras Medical College Chennai; SN Medical College Jodhpur; Grant Medical College & JJ Hospital Mumbai**. **Six functions:** tertiary care; **conducting PG courses**; **training the trainers**; **developing evidence-based treatment protocols**; developing training modules, guidelines and IEC; and **research**. Contractual staff = **38** (1 Professor, 2 Assistant Professors, 4 Senior Residents, 16 Nurses, 3 Physiotherapists + 1 Occupational Therapist, 1 Medical Social Worker, 1 Lab Technician, 1 Programme Assistant, 4 Hospital and 4 Sanitary Attendants). Funding = **₹370 lakh non-recurring** (₹200 lakh construction, ₹50 lakh equipment, **₹120 lakh video-conferencing**) and **₹163.44 lakh recurring** (including **₹40 lakh research**). A minimum of **2 beds must be earmarked for the elderly in each allied speciality**.
21. **RGC ward and clinic design (WHO–MMC core group, Annexure II):** the **30-bed ward is split into 15 male + 15 female**, each with **3 acute-care, 7 sub-acute and 5 long-term care beds**. Referral criteria: **age 60+ with preference to the very old (80+), frail patients with poor functional status, and those with multiple medical, psychological and social problems**. A **dedicated daily OPD** is required, **Comprehensive Geriatric Assessment must be done on every patient**, allied specialities provide services **at least once a week**, and **specialised clinics — Incontinence Clinic, Dementia Clinic and Falls Clinic — are organised at least once a week**. **Age-friendly environment** is mandated: **wide corridors, ramps, railings, grab bars, anti-skid tiles, adequate illumination, toilets for the disabled and elevators**.
22. **Institutional framework and monitoring:** NPHCE operates through the **National, State and District NCD Cells** created under NPCDCS, with funds flowing GoI → **State Health Society** → **District Health Society** → Rogi Kalyan Samitis, into **separate NPHCE bank accounts**. States have **10% inter-component flexibility**. **Monthly reporting** uses **Form 1 (Sub-centre, ANM/MHW), Form 2 (PHC), Form 3 (CHC), Form 4 (District Hospital), Form 5 (RGC, by Professor & Head of Medicine) and Forms 6 & 7 (State → National NCD Cell)**. The State must appoint a **Nodal Officer**, provide land, faculty and diagnostics, **start 2 PG seats/year**, and eventually **take over the units**.

LATEST UPDATES (2023–PRESENT)

1. The programme is now restructured into TWO components — state this in every answer. (a) An NHM component — primary and secondary care through District Hospitals, CHCs, PHCs and **Sub-Centres/Ayushman Arogya Mandirs**; and **(b) a Tertiary Component, renamed "Rashtriya Varisth Jan Swasthya Yojana (RVJSY)" in 2016–17**. Per the December 2024 Rajya Sabha reply, the NHM component provides **dedicated geriatric OPD, physiotherapy and IPD at AAM-HWCs, PHCs, CHCs and District Hospitals**, and the tertiary component comprises **2 apex National Centres for Ageing (AIIMS New Delhi, Madras Medical College Chennai)** plus Regional Geriatric Centres. (DGHS 2025; MoHFW Rajya Sabha reply, Dec 2024)

2. Massive scale-up beyond the original targets. DGHS currently lists **Regional Geriatric Centres in 19 medical colleges across 18 states** plus the two National Centres of Ageing — up from the original 8. A PIB update states **713 districts have been covered** (original target was only 80–100 district hospitals). **Exam tip: figures vary between official replies (17 vs 19 RGCs) — quote both with the source.** (DGHS 2025; PIB, MoHFW)

3. Research arm — LASI. Conducted under NPHCE to broaden its scope; **Wave-1 covered all 30 states and 6 UTs with 72,250 adults aged 45+, including 31,464 persons aged 60 and above** and their spouses. This is now the evidence base for NPHCE planning. (IIPS/MoHFW)

4. Convergence with Ayushman Bharat — the biggest change since 2024. The financing gap NPHCE could never close (out-of-pocket cost of surgery, joint replacement, dialysis, cancer care — explicitly identified in the 2010 guidelines) is now addressed by the **Ayushman Vay Vandana Card (29 October 2024)**, giving **₹5 lakh free annual cover to all citizens aged 70+ irrespective of income**. As stated in the President's address to Parliament (January 2026), **nearly one crore cards have been issued in about one and a half years, enabling roughly eight lakh elderly citizens to access free healthcare**, and **1.80 lakh Ayushman Arogya Mandirs are operational**. (NHA 2024; GoI, Jan 2026)

5. Persisting implementation gaps — write these as "challenges". Published evaluations identify **shortage of trained geriatricians and faculty, non-filling of sanctioned contractual posts, incomplete construction of 10-bedded wards, weak rural reach, poor awareness, under-utilisation of allotted funds and weak HMIS reporting**. A NIHFW evaluation noted scale-up was planned at **100 districts per year with 12 additional RGCs**, but stressed the need to learn lessons from the first phase before further expansion. (NIHFW 2024; J Family Med Prim Care 2022; Ann Geriatr Med Res 2022)

6. Policy direction for the future. NITI Aayog (Feb 2024) recommends strengthening geriatric healthcare within the existing system, extending primary care through **AB-HWCs**, promoting health literacy, and expanding **home health care and mental health services**. Internationally, the **WHO ICOPE Handbook 2nd edition (January 2025)** now provides the operational model NPHCE lacks — a **four-step primary-care pathway** screening **six intrinsic-capacity domains**. (NITI Aayog 2024; WHO 2025)

CURRENT PRACTICE UPDATE

Aspect	Original Operational Guidelines (2010)	Current position (2023–2026)
Regional Geriatric Centres	**8** Regional Medical Institutions	**17–19 RGCs** (figures differ by source) **+ 2 National Centres for Ageing**
Tertiary component name	Not named separately	Renamed **"Rashtriya Varisth Jan Swasthya Yojana" (2016–17)**
District coverage	80–100 district hospitals; 100 districts in 21 states in phase 1	**~713 districts** reported covered
Lowest delivery point	Sub-Centre with ANM/MHW	**Ayushman Arogya Mandir** with CHO-led teams and **CBAC-based NCD screening from age 30**
PG output	Target of **16** PG seats from 8 institutes	Multiple MD/DM/DNB Geriatric Medicine programmes now exist — **still far short of need**
Funding pattern	**80:20** Centre:State per the original MoU	Implemented under **NHM norms (generally 60:40; 90:10 for NE and Himalayan states)**; some official pages quote **75:25**
Catastrophic expenditure	No financial protection built in	Covered by **AB PM-JAY + Ayushman Vay Vandana Card** (₹5 lakh, 70+, since Oct 2024)
Assessment model	Simple clinical assessment + standard health card	Global shift to **ICOPE intrinsic-capacity screening (WHO 2025)** — **not yet formally adopted in NPHCE**
Long-term care	Only **2 respite beds** per district hospital	**No statutory long-term care system in India** — flagged by NITI Aayog (2024) and the UN Decade

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

- *"NPHCE rests on three mandates: UNCRPD Article 25, NPOP 1999, and Section 20 of the MWPSC Act 2007."*
- *"The programme is integrated (horizontal) below district level and vertical at district level and above, because more specialised care is needed."*
- *"Of the 10 district hospital beds, two must be earmarked in a separate room for respite care — the only formal recognition of long-term care in the entire Indian health system."*
- *"The RGC 30-bed ward is 15 male + 15 female, each with 3 acute, 7 sub-acute and 5 long-term care beds, and must run Incontinence, Dementia and Falls clinics at least weekly."*
- *"The tertiary component was renamed Rashtriya Varisth Jan Swasthya Yojana in 2016–17 and now runs through 17–19 RGCs and 2 National Centres for Ageing."*

EXTRA POINTS TO REMEMBER (guaranteed question)

- **Vision = 5 statements • Objectives = 4 • Expected outcomes = 7 • Components = 8 • Main strategies = 5**.
- **Staff:** District Hospital **13**; Regional Geriatric Centre **38**; CHC **1 rehabilitation worker**; Sub-centre **nil**.
- **Money:** DH ₹87 lakh non-recurring / ₹44 lakh recurring; RGC ₹370 lakh non-recurring / ₹163.44 lakh recurring.
- **Clinic frequency:** PHC **weekly**; CHC **twice weekly**; RGC **daily OPD**; allied specialities and special clinics **weekly**.
- **Reporting forms 1–7** — Form 4 is the District Hospital's; Form 5 is signed by the Professor & Head of Medicine at the RGC.
- **The original 8 RGCs** — remember at least four by name (AIIMS Delhi, BHU, SKIMS, MMC Chennai).

Q3. Implementing NPHCE Components as the Doctor In-Charge of a District Hospital — Putting Theory into Practice

SOURCE STATEMENT

Pathy's does not mention NPHCE — but it DOES supply the evidence base for how to run a geriatric unit (CGA, delirium prevention, orthogeriatrics, discharge communication, ward design, avoiding functional decline). This answer therefore combines:

- **Administrative skeleton** → NPHCE Operational Guidelines, DGHS/MoHFW (2010) *(external; textbook silent)*
- **Clinical flesh** → **Pathy's 6th ed. and Essentials of Clinical Geriatrics** *(uploaded textbooks, attributed below)*

Phase 1 — Getting Started (Month 0–1)

1. **Do a situational analysis first.** The District NCD Cell is responsible for **preparing a District Action Plan** and **maintaining and updating a district database of the elderly**. Count the district's 60+ population from census/HMIS, list existing PHCs, CHCs and sub-centres, and identify current elderly OPD attendances and admissions. **Baseline data is your bargaining chip for funds.**
2. **Know your money before you plan.** A District Hospital receives **₹87 lakh non-recurring** (₹80 lakh construction + ₹7 lakh equipment) and **₹44 lakh recurring per annum** (₹28.20 lakh HR, ₹10 lakh drugs, ₹3 lakh equipment, ₹2 lakh IEC, ₹0.80 lakh training). States have **10% flexibility to move funds between components**. Funds flow **GoI → State Health Society → District Health Society → Rogi Kalyan Samiti**, into a **separate NPHCE bank account**.
3. **Get approvals in writing.** Place the plan before the **District Health Society (chaired by the District Collector)** and the **Rogi Kalyan Samiti**. Nominate a **single Nodal Officer for NPHCE**. Given the scarcity of geriatricians, the guidelines explicitly permit **existing specialists trained in or interested in geriatrics to run the Geriatric Clinic and Ward**.

Phase 2 — Building the Structure (Month 1–6)

4. **Set up the 10-bedded ward — and don't forget the 2 respite beds.** Of the 10 beds, **2 must be earmarked in a SEPARATE ROOM for respite care** of bedridden or home-bound elderly. Space may be new construction, renovation or extension. **Practical tip:** a ground-floor ward near the OPD block, next to the laboratory, saves the patient the most walking.
5. **Make the ward age-friendly — a mandated design brief, not decoration.** Required: **wide corridors, ramps, railings, grab bars, anti-skid tiles, adequate illumination, toilets for the disabled and elevators**. **Pathy's** adds that hospital design prevents falls and delirium through **adequate lighting, noise reduction, orientation boards, suitable hospital beds, appropriate flooring and clear signage**. Add **large-print signage, a wall clock and calendar in every bay, and beds low enough for feet to touch the floor**.
6. **Run a "one-stop" Geriatric Clinic.** The guidelines state that **"efforts should be made to minimize movement of the Elderly in the hospital for examination by Specialists and laboratory investigations,"** and that a **special sample-collection centre should be provided in the OPD block**. Bring the phlebotomist, pharmacist and physiotherapist to the clinic rather than sending the patient around, and give the elderly a **separate queue/token** — also their right under the MWPSC Act 2007.
7. **Procure and commission equipment.** DH list: **nebuliser, glucometer, ECG machine, defibrillator, multi-channel monitor, non-invasive ventilator, shortwave diathermy, ultrasound therapy, intermittent cervical traction, intermittent pelvic traction, TENS, adjustable walker**. **Do not let equipment sit in a store-room** — commission it, name a custodian, log monthly use; non-utilisation is the commonest audit finding.

Phase 3 — Building the Team (Month 2–6)

8. **Recruit the sanctioned 13 contractual staff: 2 Consultants (Medicine), 6 Nurses, 1 Physiotherapist, 2 Hospital Attendants, 2 Sanitary Attendants**. The **District NCD Cell** (District Programme Officer, Programme Assistant, Finance-cum-Logistics Officer, Data Entry Operator) engages contractual personnel and maintains fund flow and Utilisation Certificates.
9. **Build a real multidisciplinary team, not a paper one. Essentials** stresses that **geriatric care implies team care** — good communication avoids duplication and gives better outcomes, but **"good team care will not arise spontaneously"** and requires investment of effort, a common language and a common "playbook." A 20-minute daily huddle and a weekly MDT meeting is enough; borrow the **dietician, medical social worker, ophthalmologist, ENT surgeon, orthopaedic surgeon, psychiatrist and dentist** from existing staff.

Phase 4 — Clinical Processes (the part examiners reward most)

10. **Make CGA the routine, not the exception. Pathy's** lists the **six key elements of CGA: functional ability,**

cognitive function, physical health, socioeconomic status, nutritional status, and mobility/falls risk, and states that **when CGA is combined with strong and sustained interventions, better long-term outcomes are achieved**. **Essentials** warns that **"assessment without follow-up is unlikely to make any difference"** — hence the term shifted to **geriatric evaluation and management**.

11. **Keep CGA efficient or it will collapse under OPD load. Essentials** recommends a **close-knit interdisciplinary team with minimal redundancy**; **pre-visit questionnaires**; **screening tools that target who needs deeper assessment**; **forms that feed a database**; and **integration with case management**. Routine assessment of everyone is not cost-effective — assessments must be **TARGETED**, especially at **times of threatened or actual decline and impending change in living situation**.
12. **Use simple validated risk screens on admission. Pathy's** names **falls risk assessment tools, the Waterlow score for pressure sores and the Malnutrition Universal Screening Tool (MUST)**, warning they must be **completed by staff who understand the condition**, and that **identifying risk must be followed by justifiable action**. **Essentials** flags those at risk of functional decline: **age 75+, cognitive impairment, dependence in 2 or more IADLs before admission, existing pressure sore, baseline functional dependency and low social activity**.
13. **Run a delirium-prevention bundle from day one — free and highly effective.** Pathy's cites the **Elder Life Program (HELP)**, which addressed **six risk factors — cognitive impairment, visual impairment, hearing impairment, sleep deprivation, immobility and dehydration** — using **simple common-sense measures delivered by a trained interdisciplinary team, reducing delirium incidence from 15% to 9.9% (OR 0.60, p = 0.02)**. Costs nothing but nursing discipline: orientation boards, spectacles and hearing aids kept with the patient, night-time noise reduction, early mobilisation, fluid chart.
14. **Fight iatrogenic dependency actively. Essentials** warns that **well-meaning staff, under efficiency pressure, do things FOR elderly patients rather than urging them to do as much as possible themselves — fostering dependency at the very time independent function is crucial**. A **rehabilitative philosophy must be maintained outside therapy sessions**. Guard against **immobility complications: pressure sores, postural hypotension, atelectasis and pneumonia, thromboembolism, incontinence, constipation, deconditioning, contractures and depression**.
15. **Set up two "quick-win" pathways: orthogeriatrics and stroke care. Pathy's** notes that **most UK hospitals now have an orthogeriatric service ensuring optimal medical care from admission to discharge for fractured neck of femur**, and that **stroke units improve outcomes through focused immediate rehabilitation and swift recognition of complications**. The Stroke Unit Trialists' Collaboration meta-analysis of **29 trials, 6,536 patients** showed odds reductions for **mortality 0.86, death or dependence 0.78, and death or institutionalisation 0.80 at one year** — independent of age, sex and stroke type. In a district hospital this means: **a shared geriatric-orthopaedic protocol for hip fracture, and a designated stroke corner with early mobilisation and swallow screening**.
16. **Fix discharge communication — where district hospitals lose most patients. Pathy's** states that **inadequate communication at discharge, particularly about medication management and monitoring arrangements, leads to preventable readmissions**, and that **decisions about preferred levels of future intervention must be communicated at discharge, otherwise patients undergo unwanted intervention afterwards**. **Essentials** adds that **discharge planning is often begun too late**, and separates two questions: **(1) what TYPE of care will achieve the goals? (2) which provider can best deliver it? Practical rule: start discharge planning on day 1; send home a typed card listing diagnoses, functional status, medicines with a stop/review date, follow-up date and the ASHA's phone number.**

Phase 5 — Reaching Outward (Month 6–12)

17. **Activate the referral chain and outreach — the district hospital is the hub, not an island.** DH duties include **training Medical Officers and paramedical staff of CHCs and PHCs**, **serving patients referred by CHCs/PHCs**, **conducting camps at PHCs/CHCs**, and **referring severe cases to Regional Geriatric Centres**. Below you: **CHC = FRU with a twice-weekly clinic and a rehabilitation worker doing domiciliary visits**; **PHC = weekly geriatric clinic**; **sub-centre ANM = domiciliary visits, callipers, walking sticks, walkers**. An **annual village-level check-up of all elderly** should be organised, recorded in the **Standard Health Card for the Elderly**, with **ASHA mobilising attendance**.
18. **Train your own staff and everyone below you.** Training norms at DH: **2 doctors, 6 nurses and 1 physiotherapist**, integrated with NPCDCS via medical and nursing colleges. Add the modules people forget: **CGA, falls prevention, pressure-area care, safe prescribing/deprescribing, dementia and delirium recognition, incontinence care, and care-giver training for families**.

Phase 6 — Convergence, Records and Monitoring

19. **Converge with every other scheme — where the real value is delivered.** Link the geriatric clinic with **NPCDCS/NP-NCD** (hypertension, diabetes, cancer screening), **NPCB&VI** (cataract, refractive error), **NPPCD** (hearing

aids), **National Mental Health Programme** (depression, dementia), **National Programme for Palliative Care**, **ALIMCO camps under Rashtriya Vayoshri Yojana**, **Elderline 14567**, and **AB PM-JAY plus the Ayushman Vay Vandana Card**. The guidelines explicitly require the MO to **liaise with the Blindness Control Programme, NPCDCS and other programmes** for diagnostics, equipment, consumables and medicines.

20. **Report monthly, audit quarterly, prove your outcomes.** The **MO In-charge submits Form 4 monthly to the State NCD Cell**; PHC (Form 2) and CHC (Form 3) report to the District NCD Cell. **Pathy's** cautions that **incident-reporting systems capture only 7–15% of adverse events** compared with case-record review, so supplement reporting with **case-note audit**, using the safety framework's five dimensions: **past harm, reliability, sensitivity to operations, anticipation and preparedness, and integration and learning**. **Track:** geriatric OPD attendance, ward occupancy, average length of stay, **falls per 1,000 bed-days, new pressure sores, delirium rate, 30-day readmissions, and proportion discharged home versus institutionalised**.

Practical Roadmap — A 12-Month Implementation Plan

Timeline	Actions	Deliverable
Month 0–1	Situational analysis; district elderly database; District Action Plan; DHS/RKS approval; separate NPHCE bank account; nominate Nodal Officer	Approved plan + funds released
Month 1–3	Identify space; start renovation of 10-bed ward + OPD room; float equipment tender; start recruitment of 13 staff	Ward under construction, tenders placed
Month 2–4	**Start the Geriatric OPD immediately in existing space** — do not wait for the building	Weekly/biweekly geriatric clinic running
Month 4–6	Commission ward with **2 respite beds**; install age-friendly features; commission equipment; write SOPs (CGA form, falls, delirium, pressure-sore, hip-fracture, discharge card)	Functional 10-bed geriatric ward
Month 6–9	Train 2 doctors + 6 nurses + physiotherapist; train CHC/PHC MOs; start CHC rehabilitation units; start camps	Trained team + outreach begun
Month 9–12	Convergence MoUs (NP-NCD, NPCB, mental health, palliative care, ALIMCO/RVY); PM-JAY/Vay Vandana enrolment desk; IEC drive; **first internal audit**	Integrated service + baseline audit report

Common Problems and Practical Solutions

Problem you WILL face	Practical solution
Construction delayed; no ward	**Start the OPD first** — the guidelines explicitly say services must not wait for a building
Contractual posts unfilled	Rotate an interested existing physician + train ward nurses; escalate to District NCD Cell in writing
Beds occupied by general medical patients	Written admission criteria: **age ≥60 with preference to 80+, frail with poor functional status, multiple medical/psychological/social problems** (NPHCE–WHO core group criteria)
Equipment unused	Name a custodian; log monthly utilisation; hold hands-on demonstration for nurses and physiotherapist
Funds unspent by 31 March	Quarterly expenditure review; use the **10% inter-component flexibility**; submit UCs on time
Ageism among staff — "he is just old"	Pathy's warns ageism causes older people to be **denied beneficial treatments or mislabelled and misdiagnosed**; the geriatrician's unique skill is balancing **therapeutic nihilism against therapeutic heroism** — teach this at every induction
Poor rural reach	ASHA-mobilised village camps + CHC rehabilitation worker's domiciliary visits; tele-consultation with the linked RGC
No long-term care option	Link with the local **IPSrC old-age home** and palliative-care NGOs

LATEST UPDATES (2023–PRESENT)

1. Your district unit is now expected to work through Ayushman Arogya Mandirs. Per the December 2024 Rajya Sabha reply, the NHM component of NPHCE now delivers **geriatric OPD, physiotherapy and IPD services at AAM-HWCs, PHCs, CHCs and District Hospitals**, while the tertiary component operates through **2 National Centres for Ageing and the RGCs**. As of January 2026, **1.80 lakh Ayushman Arogya Mandirs are operational**. **Practical implication: sub-centre-level outreach is now CHO-led with CBAC-based screening — plug your geriatric follow-up into that platform rather than creating a parallel one.**

2. Set up an Ayushman Vay Vandana enrolment desk in your OPD. Since **29 October 2024**, every citizen **aged 70+** is entitled to **₹5 lakh free annual cover irrespective of income**, with **no waiting period for pre-existing conditions**, covering about **1,961 procedures across 27 specialities** including dialysis, knee and hip replacement and cancer care. **Nearly one crore cards issued within about eighteen months, enabling roughly eight lakh elderly citizens to access free treatment.** A single Aadhaar-based e-KYC desk converts NPHCE's biggest historical weakness into a strength.

3. Adopt WHO ICOPE screening as your OPD triage tool. The **ICOPE Handbook, 2nd edition (January 2025)** gives a **four-step pathway** — basic assessment, in-depth assessment, personalised care plan, implementation and monitoring — screening **six intrinsic-capacity domains: cognition, mobility, vitality, vision, hearing and psychological capacity**, plus social and caregiver support, with a **new urinary incontinence care pathway**. **This is a 5-minute screen any staff nurse or CHO can do — ideal for high-volume Indian OPDs, and it feeds directly into your CGA.**

4. Programme scale and known weaknesses. NPHCE now reports coverage of **713 districts**, and **RGCs in 19 medical colleges across 18 states plus 2 National Centres of Ageing** (the Dec 2024 parliamentary reply quotes 17 RGCs — quote both). Evaluations continue to identify **shortage of trained geriatricians, unfilled contractual posts, incomplete ward construction, weak rural reach, low awareness and under-utilisation of funds** — the exact problems your action plan must anticipate.

5. Policy direction to align with. NITI Aayog (February 2024) recommends strengthening geriatric healthcare within the existing system, extending primary care through **AB-HWCs**, promoting **health literacy among seniors and caregivers**, and expanding **home health care and mental health services**. Globally, the **UN Decade of Healthy Ageing** frames this under **combating ageism, age-friendly environments, integrated care and long-term care**.

CURRENT PRACTICE UPDATE

Element	NPHCE Guidelines as written (2010)	What you must actually do in 2026
Screening tool	Simple clinical assessment (eye, BP, blood sugar) + standard health card	Add **ICOPE 6-domain intrinsic-capacity screen** and full **CGA** for those who screen positive
Lowest contact point	Sub-centre ANM/MHW	**Ayushman Arogya Mandir with CHO + CBAC-based NCD screening**
Financing major surgery	Not addressed — a recognised gap	**AB PM-JAY + Ayushman Vay Vandana Card (70+, ₹5 lakh)** — enrol patients at your OPD
Records	Paper Forms 1–7, monthly	Migrate to **HMIS/ABDM digital records**; paper forms still mandated
Delirium / falls / pressure sores	Not specified	Use **HELP bundle, falls risk tool, Waterlow and MUST** (Pathy's) — these are your quality indicators
Hip fracture and stroke	Handled by existing specialities	Build **explicit orthogeriatric and stroke pathways** — the strongest evidence base in Pathy's
Long-term care	2 respite beds per district hospital	**Still no statutory LTC system** — link with IPSrC old-age homes and palliative care NGOs
Ageism	Not addressed	Actively teach it — NSF Standard 1 principle from Pathy's

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"I would start the Geriatric OPD in existing space in month two — the guidelines require services, not buildings."*
• *"Efforts should be made to minimise movement of the elderly within the hospital — so I would run a one-stop clinic with sample collection in the OPD block."*
• *"Assessment without follow-up is unlikely to make any difference — which is why the term has shifted from CGA to geriatric evaluation and management."*
• *"The HELP bundle reduced delirium from 15% to 9.9% using six common-sense measures that cost nothing but nursing discipline."*
• *"Well-meaning staff do things FOR older patients rather than urging them to do as much as possible themselves — fostering dependency at the very time independent function is crucial."*
• *"My quality indicators would be falls per 1,000 bed-days, new pressure sores, delirium rate, 30-day readmissions and proportion discharged home rather than institutionalised."*

EXTRA POINTS TO REMEMBER

• **Six elements of CGA:** functional ability • cognition • physical health • socioeconomic status • nutrition • mobility/falls risk.
• **HELP six risk factors:** cognitive impairment • visual impairment • hearing impairment • sleep deprivation • immobility • dehydration.
• **Stroke unit meta-analysis:** 29 trials, 6,536 patients; OR mortality 0.86, death/dependence 0.78, death/institutionalisation 0.80.
• **Risk screens:** Waterlow (pressure sores) • MUST (nutrition) • falls risk tools.
• **Incident reporting captures only 7–15% of adverse events** — always add case-note audit.
• **Admission criteria for the geriatric ward:** 60+ with preference to 80+ • frail with poor functional status • multiple medical, psychological and social problems.

Q4. National Policy on Older Persons (NPOP), 1999 and Existing Beneficiary Schemes for the Elderly

SOURCE STATEMENT

Pathy's 6th edition does NOT cover the NPOP or any Indian welfare scheme. It discusses only the general social determinants of ageing (poverty, pensions, social isolation, retirement) and US/UK entitlements.
All content below is from the primary Government of India document — "National Policy on Older Persons, Ministry of Social Justice & Empowerment, 1999" — plus current MoSJE/MoRD/MoHFW/Ministry of Finance sources.

PART A — The Policy Itself

Background and Mandate

1. **When and by whom:** NPOP was announced in **January 1999, the UN International Year of Older Persons**, by the **Ministry of Social Justice & Empowerment (MoSJE)** — the **nodal ministry**. It defines a **"senior citizen"/"older person" as anyone aged 60 years and above**.
2. **Demographic trigger:** persons aged 60+ rose from **12 million (1901) to 20 million (1951) and 57 million (1991)**, with the **100 million mark expected by 2013**, **198 million by 2030 and 326 million by 2050**. Their share rose from **5.1% (1901) to 6.8% (1991)**, expected to reach **8.9% by 2016 and 21% by 2050**. In 1991, **63% were "young old" (60–69) and 11% were "older old" (80+)**.
3. **The widowhood problem (frequently asked):** in 1991 there were **14.8 million widowed females aged 60+ against only 4.5 million widowed males — four times as many** — because women marry older men, do not remarry and live longer.
4. **Constitutional and international mandate: Article 41** directs the State to secure **the right to public assistance in old age**; the **Right to Equality** applies equally to older persons; and **social security is a concurrent responsibility of the Centre and States**. Internationally it draws on the **UN Principles for Older Persons (1991)** and the **Proclamation on Ageing and Global Targets on Ageing for 2001 (1992)**.

Goal and Guiding Principles

5. **Goal (learn this line):** *"The goal of the National Policy is the **well-being of older persons**. It aims to **strengthen their legitimate place in society and help older persons to live the last phase of their life with purpose, dignity and peace**."*
6. **Six guiding principles: (i) Affirmative action**, with special attention to older women who face **"triple neglect and discrimination on account of gender, widowhood and age"**; **(ii)** the **life cycle is a continuum** — age 60 is **not** a cut-off for beginning a life of dependency; **(iii)** an **age-integrated society** with strong intergenerational bonds; **(iv)** older persons are a **resource — producers, not merely consumers**; **(v) empowerment** and participation in decision-making, since they form **12% of the electorate**; **(vi) partnership** — the State alone cannot achieve the objectives, with **special coverage of rural areas where over three-fourths of older persons live**.

The SIX Principal Areas of Intervention (core of the answer)

7. **(1) FINANCIAL SECURITY.** Old-age pension coverage to be **significantly expanded from the January 1997 level of 2.76 million**, aiming to **cover all older persons below the poverty line**, with **periodic revision of the pension rate to offset inflation** and the **PDS reaching all 60+ BPL persons**. Also: **prompt settlement of pension, provident fund and gratuity**; **expanded pension coverage** for the self-employed and private sector under a strong regulator; **tax relief sensitive to old age**; **long-term savings instruments**; **pre-retirement counselling**; removal of **age-related discrimination in credit and marketing**; and the note that **Section 125 CrPC and the Hindu Adoptions and Maintenance Act 1956** already secure parents' right to maintenance, with the **Himachal Pradesh Maintenance of Parents and Dependents Bill, 1996** cited as a model. **→ This directly produced the MWPSC Act, 2007.**
8. **(2) HEALTH CARE AND NUTRITION — the geriatrics-relevant section.** The **primary health care system is to be the basic structure**, with **geriatric care facilities at secondary and tertiary levels**. **Public hospitals are directed to ensure elderly patients are not subjected to long waits or visits to different counters for tests and treatment, to provide separate counters and convenient timings on specified days, and to set up GERIATRIC WARDS. Facilities for specialization in geriatric medicine will be provided in medical colleges**, with geriatric care in nursing training. **Health insurance is given high priority**, with state subsidy for lower-income packages. **Mobile health services, special camps and ambulance services** address access. Hospitals are encouraged to have a **separate Welfare Fund** for free treatment of the poor elderly. **Hospices** for the chronically ill without family support, including those abandoned in public hospitals. **Mental health services will be expanded and strengthened. → This paragraph is the direct ancestor of NPHCE (2010).**

9. **Health promotion within NPOP:** the policy promotes **the concept of healthy ageing**, educating older persons and families that **"diseases are not a corollary of advancing age nor is a particular chronological age the starting point for decline in health status"** and that **preventive health care and early diagnosis can prevent disability**. It mandates health education through **mass media and folk media**, messages on **balanced diet, physical exercise, regular habits, stress reduction, regular medical check-up, leisure and hobbies**, programmes on **yoga, meditation and relaxation**, and **messages targeted at younger and middle-aged groups**.
10. **(3) SHELTER. 10% of houses/house-sites in urban and rural lower-income housing schemes, including Indira Awas Yojana, to be earmarked for older persons**; **barrier-free layouts**; **multi-purpose centres in every housing colony**; **segregation of older persons is to be avoided**; **preference for ground-floor flats**; and **group housing (flatlets with common meals, laundry and rest rooms)**. Also **accident-prevention information**, **noise and pollution norms**, and **priority in civic services and property transfer/mutation**.
11. **(4) EDUCATION. Continuing education programmes**; use of **open universities and distance learning**; **access to university and research libraries**; and inclusion in the **school curriculum of material strengthening intergenerational bonds**, with the media working to **dispel negative images, myths and stereotypes** about ageing.
12. **(5) WELFARE.** Identify **the most vulnerable — the poor, disabled, infirm, chronically sick and those without family support** — and serve them first. **Institutional care is to be the LAST RESORT.** Voluntary organisations receive **grants-in-aid for construction and maintenance of old-age homes**, with **minimum standards of service**. Services to be promoted: **day care, multi-service citizens' centres, reach-out services, supply of disability aids and appliances, short-term stay, friendly home visits, helplines, telephone assurance and escort services**, plus **senior citizens' forums**. A **Welfare Fund for older persons** is to be set up. **→ This became the Senior Citizens' Welfare Fund and IPSrC.**
13. **(6) PROTECTION OF LIFE AND PROPERTY.** Older persons are described as **"soft targets for criminal elements,"** victims of **fraudulent dealings and of physical and emotional abuse within the household to force them to part with ownership rights**, with **widows' rights of inheritance, occupancy and disposal violated by their own children and relatives**. Remedies: **special provisions in the IPC against domestic violence toward older persons**, **review of tenancy legislation**, **helpline services and legal aid**, and **police keeping a friendly vigil on older couples or single persons living alone**. **→ This became Sections 23 and 24 of the MWPSC Act 2007, and later Elderline 14567.**

Other Areas, Cross-Cutting Themes and Implementation

14. **"Other Areas of Action" (easy marks): identity cards**; **fare concessions in all modes of travel**; **reservation and earmarking of seats in local public transport**; **modified vehicle design**; **traffic discipline at zebra crossings**; **priority in gas and telephone connections and fault repairs**; **removal of physical barriers**; **concessions in entrance fees at art, cultural and tourist places**; **speedy disposal of complaints of cheating and fraud**; **annual National Older Persons' Day**; and declaration of **the year 2000 as the National Year for Older Persons**.
15. **Cross-cutting chapters: NGOs** are "a very important institutional mechanism to provide user-friendly affordable services"; **Realizing the Potential** treats the 60+ phase as **"a huge untapped resource"**; **Family** is called **"the most cherished social institution in India and the most vital non-formal social security for the old,"** with **tax relief and housing preference for children who co-reside with parents** and society sensitised to **married daughters sharing the caring responsibility**; **Media** is to promote active ageing.
16. **Research and manpower (directly relevant to your specialty):** universities, medical colleges and research institutions to **set up centres for gerontological studies and geriatrics**; corporate bodies, banks and trusts requested to **institute Chairs in gerontology and geriatrics**; an **interdisciplinary coordinating body on research**; **data-collecting agencies asked to use a separate 60+ age category**; and a **national institute of research, training and documentation**. **Medical colleges to offer specialization in geriatrics**, with geriatric care in nursing and paramedical curricula.
17. **Implementation machinery (very high-yield): MoSJE is the nodal ministry**; a **separate Bureau of Older Persons**; an **Inter-Ministerial Committee**; States encouraged to set up **Directorates of Older Persons**; each Ministry prepares **Five-Year and Annual Action Plans**; a **detailed review every three years** as a **public document discussed in a National Convention**; an **autonomous National Council for Older Persons (NCOP)** headed by the Minister; an **autonomous National Association of Older Persons (NAOPS)**; and **Panchayati Raj institutions** implementing locally with representation of older women.
18. **What happened to the NCOP and the policy itself:** the **NCOP was constituted in May 1999 with 39 members** and is the **designated office for receiving suggestions, complaints and grievances from individual older persons**, with a **seven-member Working Group**. It was **reconstituted as the National Council of Senior Citizens (NCSrC) in 2012**, with similar councils at State level. NPOP 1999 was **revised in 2011 as the National Policy on Senior Citizens (NPSrC) — which has never been formally notified and remains a draft. State this in the exam.**

PART B — Existing Beneficiary Schemes (Ministry-wise Map)

19. Memorise the ministry, not just the scheme.

Ministry	Scheme	Key benefit / eligibility
MoSJE	**Atal Vayo Abhyuday Yojana (AVYAY)** — umbrella	Five components below
	↳ **IPSrC** (Integrated Programme for Senior Citizens)	Grant-in-aid to NGOs for **old-age homes, continuous-care homes**; free shelter, nutrition, medicare, recreation for indigent elderly
	↳ **SAPSrC** (State Action Plan)	Grants to States/UTs; **training of geriatric care-givers**
	↳ **Rashtriya Vayoshri Yojana (RVY)**	Free **assisted-living devices** (spectacles, hearing aids, dentures, sticks, wheelchairs, walkers) for **BPL or income ≤ ₹15,000/month**; made by **ALIMCO**, distributed through camps
	↳ **SCOPE / SACRED**	Re-employment and productive engagement portal for retired seniors
	↳ **SAGE** (Seniorcare Ageing Growth Engine)	Funding start-ups for elder-care products and services (“silver economy”)
	Elderline — 14567	Toll-free helpline for **information, guidance, emotional support and field intervention in abuse and rescue**
	Senior Citizens’ Welfare Fund (SCWF)	Pooled unclaimed deposits funding senior-citizen schemes
	Vayoshreshtha Samman	National Awards conferred on **1 October at Vigyan Bhawan**; **15 awardees in 13 categories**; **₹2.5 lakh (individual)** and **₹5 lakh (institutional)**
Ministry of Rural Development	**NSAP — IGNOAPS**	Central pension of **₹200/month (60–79)** and **₹500/month (80+)** for BPL elderly; States add top-ups
	IGNWPS, IGNDPS, NFBS, Annapurna	Widow pension, disability pension, family benefit, **10 kg free foodgrain/month** for uncovered destitute elderly
MoHFW	**NPHCE + Rashtriya Varisth Jan Swasthya Yojana**	Geriatric OPD/IPD from AAM-HWC → PHC → CHC → District Hospital (10 beds) → **RGCs and National Centres for Ageing**
	AB PM-JAY + Ayushman Vay Vandana Card	₹5 lakh/family/year; **all citizens 70+ irrespective of income since Oct 2024**
	Rashtriya Arogya Nidhi, Palliative Care Programme, NPCB&VI, NPPCD, NMHP	Financial aid for poor patients; palliative care; cataract and hearing services; mental health
Ministry of Finance / Dept of Posts	**Senior Citizens’ Savings Scheme (SCSS)**	**8.2% p.a. paid quarterly**; age **60+ (55+ VRS, 50+ defence)**; max **₹30 lakh**; **5 years extendable by 3**; **80C deduction**; TDS only above ₹1 lakh interest
	PMVVY, Atal Pension Yojana, Reverse Mortgage	Assured pension / annuity / income from own home
	Income Tax reliefs	Basic exemption **₹3 lakh (60–79)** and **₹5 lakh (80+)** under the old regime; **Sec 80TTB — ₹50,000 on interest income**; **no advance tax if no business income (Sec 207)**; **Sec 80D**; **Sec 80DDB**
Law / Home	MWPSC Act 2007; Sec 125 CrPC (now BNSS); Hindu Adoptions & Maintenance Act 1956	Legal right to maintenance; tribunals; property transfer void; abandonment punishable
Railways / Aviation / States	Travel concessions, reserved seats/berths, separate queues, identity cards	Quantum varies; **railway fare concession has remained suspended since 2020 — check current status before quoting**

20. How the whole system fits together — one line for the exam: **NPOP 1999 is the parent policy → it generated the MWPSC Act 2007 (legal enforcement), NPHCE 2010 (health delivery), AVYAY (social welfare), NSAP/IGNOAPS (income security) and Ayushman Vay Vandana (financial protection).** Everything else is a branch of that tree. Delivery, however, is fragmented across **at least five ministries with no single accountable authority** — the central criticism of Indian ageing policy.

LATEST UPDATES (2023–PRESENT)

1. Absence of an integrated policy is now officially acknowledged. The **NITI Aayog position paper (February 2024)** identifies **"an absence of a comprehensive, integrated policy for senior care and support" as a significant challenge**, causing gaps in infrastructure, capacities, evidence-based knowledge repositories for geriatric illness management, and monitoring and emergency-response frameworks. It groups reforms under **four core areas: Health, Social, Economic/Financial and Digital empowerment and inclusion**, and recommends **amending the MWPSC Act to cover abuse, harassment and protection**, **elderly-friendly housing reforms with a single-window portal**, a **national portal for senior care**, and **recognition of the care economy and care workers, especially women**.

2. The single biggest new entitlement — Ayushman Vay Vandana Card. Launched **29 October 2024**: **₹5 lakh free annual cover to every citizen aged 70+ irrespective of income**, an **additional ₹5 lakh top-up for seniors already in PM-JAY families**, and **no waiting period for pre-existing conditions**. **More than 9.67 million cards issued by 31 December 2025. This is the first genuinely universal, age-based (not means-tested) entitlement in Indian social policy.**

3. Demographic pressure has intensified since NPOP was written. The **India Ageing Report 2023 (UNFPA–IIPS)** projects the 60+ share rising from **10.5% (2022) to 20.8% (2050)** — from **149 million to 347 million**, with the **80+ population growing 279%**, the elderly **outnumbering children by 2046**, and **over 40% of the elderly in the poorest wealth quintile with 18.7% having no income at all**. **NPOP's 1999 projection of 326 million by 2050 has proved almost exactly right — quote this to show the policy's foresight.**

4. Financial-security reforms proposed. NITI Aayog recommends a **regulatory mechanism to set a viable base interest rate on senior-citizen deposits**, noting that *"since the social security framework in India is limited, most seniors depend on income generated from their savings"* and that **variable interest rates erode that income, sometimes below sustenance level**, with a further concession for older women. On the tax side, **Budget 2025 raised the TDS threshold on senior-citizen interest income from ₹50,000 to ₹1 lakh**, and under the new regime income up to **₹12 lakh is effectively tax-free via the Section 87A rebate**.

5. Legal reform still pending. The **MWPSC (Amendment) Bill, 2019** — widening definitions, giving **priority disposal to applicants above 80**, and **removing the ₹10,000 ceiling** — was referred to a Standing Committee and **remains unpassed**.

6. Global benchmark. The **UN Decade of Healthy Ageing (2021–2030)** organises national policy around **combating ageism, age-friendly environments, integrated care and long-term care**; its **2023 progress report** found **fewer than one-third of countries have adequate resources**. The **WHO ICOPE Handbook 2nd edition (January 2025)** provides a four-step primary-care pathway screening **six intrinsic-capacity domains**.

CURRENT PRACTICE UPDATE

Theme	NPOP 1999 as written	Position in 2026
Policy status	NPOP 1999 in force	**NPSrC 2011 drafted but NEVER notified** — India still runs on a 27-year-old policy
Review mechanism	**Triennial public review** discussed in a National Convention	Not conducted regularly — a recognised accountability failure
Coordinating body	**NCOP (1999)** headed by the Minister	Reconstituted as **NCSrC (2012)**; NAOPS never became functional
Income security	Expand pension to all BPL elderly with **periodic inflation-linked revision**	**IGNOAPS central share still ₹200/₹500 per month, unrevised for over a decade**
Health care	Geriatric wards, separate counters, geriatrics in medical colleges	Operationalised as **NPHCE (2010) and RVJSY (2016)** — the policy's most successfully implemented section
Health financing	Health insurance "to be given high priority"	Delivered by **AB PM-JAY + Vay Vandana (70+, ₹5 lakh, 2024)**
Long-term care / hospices	Hospices for the chronically ill without family support	**No statutory long-term care system exists** — the largest unfilled promise of NPOP
Elder abuse	IPC provisions and tenancy reform proposed	Partly delivered via **MWPSC Sections 23-24 and Elderline 14567**; IPC/BNS still has no elder-specific offence
Ageism	"Dispel negative images, myths and stereotypes"	Now a **formal WHO action area** under the Decade of Healthy Ageing

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"The goal of NPOP is to help older persons live the last phase of their life with purpose, dignity and peace."*
• *"Older women face triple neglect and discrimination on account of gender, widowhood and age."*
• *"NPOP explicitly required public hospitals to set up geriatric wards and separate counters — NPHCE 2010 is simply the operationalisation of that paragraph."*
• *"Institutional care is to be the last resort — the policy's stated preference is ageing in place."*
• *"NPOP mandated a detailed review every three years as a public document discussed in a National Convention; this has not happened, which is the central accountability failure."*
• *"NPOP promised periodic revision of pension so that inflation does not deflate its real purchasing power — IGNOAPS at ₹200 a month is the clearest evidence that this promise was not kept."*

EXTRA POINTS TO REMEMBER

• **Six areas of intervention:** Financial security • Health care & nutrition • Shelter • Education • Welfare • Protection of life and property.
• **Six guiding principles:** affirmative action • life-cycle continuum • age-integrated society • older persons as a resource • empowerment • partnership.
• **Numbers:** 14.8 m widows vs 4.5 m widowers (1991) • 12% of the electorate • 10% of houses earmarked • 326 million projected for 2050.
• **NCOP 1999 (39 members) → NCSrC 2012. NPSrC 2011 = never notified.**
• **Vayoshreshtha Samman:** 1 October • 13 categories • 15 awardees • ₹2.5 lakh / ₹5 lakh.
• **SCSS:** 8.2% quarterly • ₹30 lakh cap • 5+3 years • 80C • 80TTB ₹50,000.

Q5. Social Security System for Older People in India

SOURCE STATEMENT

Pathy's 6th edition does NOT describe the Indian social security system. Chapter 4 covers only the general problem of old-age poverty and US Social Security data; *Essentials* Ch. 15 covers US Medicare, Medicaid, Title XX and the Older Americans Act.

All India-specific content is from Government of India, ILO and PFRDA sources. Textbook concepts are attributed where used.

A. Concept and Framework

1. **Definition.** Social security is the protection society provides against economic and social distress caused by loss or reduction of income. The **ILO Social Security (Minimum Standards) Convention, 1952 (No. 102)** recognises **nine branches**, of which **old-age benefit, survivors' benefit, invalidity benefit and medical care** are relevant to the elderly.
2. **Constitutional basis (must quote). Article 41** — the State shall make effective provision for **securing the right to public assistance in old age, sickness and disablement**; **Article 43** — living wage and conditions ensuring a decent standard of life; **Article 47** — raising nutrition and standard of living and improving public health. **Social security is in the Concurrent List (Entry 23)**.
3. **The Indian problem in one line:** India is **"growing old before it grows rich,"** and around **90% of the workforce is in the unorganised sector** with no employer-linked pension. Social security must therefore be delivered mainly through **tax-financed social assistance**, not contributory insurance.
4. **Why this matters clinically.** The India Ageing Report 2023 found **over 40% of India's elderly in the poorest wealth quintile** and **18.7% with no income at all**, with a rising predominance of **widowed, highly dependent very old women**. **Pathy's** makes the same point globally: **older women, particularly those who did not marry, are at the highest risk of poverty**, being least likely to qualify for national or occupational pensions, and **longer life expectancy means women are at increased risk of spending down their savings**.
5. **Useful classification (World Bank multi-pillar model) — use this to structure your answer:**
   - **Pillar 0 — Social assistance:** non-contributory, tax-funded, means-tested (NSAP/IGNOAPS)
   - **Pillar 1 — Social insurance:** mandatory, contributory, formal sector (EPS-95, OPS/UPS)
   - **Pillar 2 — Mandatory defined-contribution:** NPS
   - **Pillar 3 — Voluntary savings:** APY, SCSS, PMVVY, insurance
   - **Pillar 4 — Informal: family support, co-residence, health care, housing** — still the dominant pillar in India

B. Pillar 0 — Social Assistance (for the poor elderly)

6. **National Social Assistance Programme (NSAP), 1995** — Ministry of Rural Development, the direct fulfilment of Article 41. Five components: **IGNOAPS** (old age), **IGNWPS** (widow, 40–79 years), **IGNDPS** (disability), **NFBS** (lump sum on death of breadwinner), and **Annapurna** (**10 kg free foodgrain per month** to destitute elderly not covered by IGNOAPS).
7. **IGNOAPS — the flagship, and its biggest weakness.** Central assistance is **₹200 per month above 60 and ₹500 per month above 80** for BPL senior citizens; States add top-ups (Tamil Nadu, Andhra Pradesh, Delhi pay considerably more). **Exam point: the central share has not been revised in over a decade, despite NPOP 1999 explicitly promising that "the rate of monthly pension will need to be revised at intervals so that inflation does not deflate its real purchasing power."**
8. **Food and in-kind security: National Food Security Act 2013** (subsidised grain through PDS), **Antyodaya Anna Yojana**, and **community kitchens/Amma canteens**. NPOP 1999 directed that **the PDS should reach all persons aged 60+ below the poverty line**.

C. Pillars 1 & 2 — Social Insurance for the Organised Sector

9. **EPFO schemes (private/organised sector): EPF** (12% employee + 12% employer); **EPS-95**, funded by **8.33% of the employer's share**, pension after **10 years of service and age 58** (early pension from 50 at a reduced rate), formula = **(Pensionable Salary × Pensionable Service) ÷ 70**; **EDLI** (deposit-linked insurance); and **ESI** (medical care and cash benefits for insured workers).
10. **The EPS-95 adequacy problem (guaranteed discussion point).** The **minimum EPS pension has remained ₹1,000 per month since 1 September 2014**, while unions and pensioners' associations demand **₹7,500**. A proposal to raise the **pensionable wage ceiling from ₹15,000 to ₹25,000** — benefiting over 6.5 crore employees — is under review, but **no revision has been notified**.

11. **Government employees — three generations of schemes: Old Pension Scheme (OPS)** — defined benefit, **50% of last drawn pay**, for those recruited **before 1 January 2004**; **National Pension System (NPS)** — defined contribution, market-linked, mandatory for those joining **on or after 1 January 2004**, regulated by **PFRDA**; and **Unified Pension Scheme (UPS)** — from **1 April 2025**.
12. **Other formal-sector entitlements: Payment of Gratuity Act, 1972** (15 days' wages per year of service); **commutation of pension**; **leave encashment**; and contributory health cover for retirees — **CGHS, ECHS, Railway and state government health schemes**.

D. Pillar 3 — Voluntary and Market-Based Instruments

13. **Atal Pension Yojana (APY) — the main instrument for the unorganised sector.** Launched **9 May 2015**, administered by PFRDA, voluntary and contributory, open to citizens **aged 18–40 who are not income-tax payers**, guaranteeing a **fixed monthly pension of ₹1,000 to ₹5,000 after age 60**, the **same pension to the spouse after death**, and **return of the accumulated corpus to the nominee** after both die.
14. **Savings and annuity products: SCSS** — **8.2% p.a. paid quarterly**, age **60+ (55+ VRS, 50+ defence)**, maximum **₹30 lakh**, tenure **5 years extendable by 3**, with **80C deduction** and TDS only above ₹1 lakh interest. Also **PMVVY**, **NPS "All Citizen" model**, **Reverse Mortgage Loan**, and **Post Office Monthly Income Scheme**.
15. **Tax expenditure as social security:** higher basic exemption of **₹3 lakh (60–79) and ₹5 lakh (80+)** under the old regime; **Section 80TTB — ₹50,000 deduction on interest income**; **no advance tax if there is no business income (Section 207)**; plus **Section 80D** and **Section 80DDB**.

E. Health Social Security

16. **Health protection is the fastest-moving pillar. AB PM-JAY** gives **₹5 lakh per family per year**; the **Ayushman Vay Vandana Card (October 2024)** extends **₹5 lakh cover to all citizens aged 70+ irrespective of income**, with an additional top-up for PM-JAY families. Service delivery is through **NPHCE** (AAM-HWC → PHC → CHC → District Hospital → Regional Geriatric Centre). **This closes the gap NPOP 1999 identified when it said health insurance for the elderly "will be given high priority."**

F. Pillar 4 — Legal and Informal Social Security

17. **The family is legally the first line of social security. Section 125 CrPC (now Section 144 BNSS)** and the **Hindu Adoptions and Maintenance Act, 1956** create a duty to maintain parents. The **MWPSC Act, 2007** operationalises this through **Maintenance Tribunals** (cap **₹10,000/month**, disposal within **90 days**), makes **abandonment a punishable offence**, and allows **transfer of property to be declared void** if the transferee fails to provide basic amenities.
18. **Welfare services as social security: AVYAY** (IPSrC old-age homes, **RVY free assistive devices for BPL/income ≤ ₹15,000 per month**, SCOPE, SAGE), **Elderline 14567**, and the **Senior Citizens' Welfare Fund**.

G. Coverage, Gaps and Critique (examiners reward critique)

19. **Structural weaknesses of the Indian system:**
    - **Fragmentation** — spread across MoSJE, MoRD, MoHFW, Labour and Finance, with **no single accountable authority**
    - **Inadequacy** — IGNOAPS at ₹200/month and EPS-95 at ₹1,000/month are **far below any subsistence line**
    - **Exclusion** — the informal workforce, **unpaid women workers, agricultural labourers and migrants** fall outside contributory schemes
    - **Gendered gap** — ILO data show **older women are less likely to receive a contributory pension than men**; NPOP 1999 warned of **"triple neglect and discrimination on account of gender, widowhood and age"**
    - **No long-term care financing** — India has **no statutory LTC or disability-linked care allowance** for frail elders
    - **Targeting errors** — BPL identification excludes many genuinely poor elderly
20. **The one-line summary for the exam:** India's old-age social security is **a narrow contributory core for the organised minority, a thin tax-financed assistance floor for the poorest, and a large voluntary/market segment in between — with the family still carrying most of the burden.** The 2024–2026 reforms (Labour Codes, UPS, Vay Vandana Card) are the first serious attempt to widen that base.

Summary Table — The Indian Old-Age Social Security Architecture

Pillar	Scheme	Ministry / Regulator	Benefit	Who is covered
0 — Assistance	IGNOAPS (NSAP)	Rural Development	₹200/month (60–79), ₹500/month (80+)	BPL elderly
	Annapurna, NFSA/PDS	Rural Dev / Food	10 kg grain/month; subsidised grain	Destitute / priority households
1 — Insurance	EPS-95 → **EPS 2026**	Labour / EPFO	Pension after 10 yrs, age 58; **min ₹1,000/month**	Organised private sector
	OPS	Finance	50% of last drawn pay	Govt employees pre-2004
2 — Defined contribution	NPS	PFRDA	Market-linked corpus + annuity	Govt post-2004, corporates, all citizens
	UPS (from 1 Apr 2025)	Finance / PFRDA	50% of last 12 months' average basic pay; **min ₹10,000/month**	Central govt employees under NPS
3 — Voluntary	APY	PFRDA	₹1,000–₹5,000/month guaranteed	Unorganised workers 18–40
	SCSS, PMVVY, Reverse Mortgage	Finance / LIC / Banks	8.2% quarterly; annuity; home equity income	Any senior citizen with assets
Health	PM-JAY + **Vay Vandana Card**	MoHFW / NHA	₹5 lakh/year; **universal for 70+**	Poor + all citizens aged 70+
	CGHS / ECHS / ESI	Various	Contributory medical care	Government / defence / insured workers
4 — Informal & legal	MWPSC Act 2007, Sec 144 BNSS	Law & Justice	Legally enforceable maintenance	All senior citizens
	AVYAY, Elderline 14567	MoSJE	Shelter, devices, helpline	Indigent / BPL elderly

LATEST UPDATES (2023–PRESENT)

1. The Four Labour Codes came into force on 21 November 2025 — the biggest reform in decades. The Government notified the **Code on Wages 2019, Industrial Relations Code 2020, Code on Social Security 2020 and OSH Code 2020**, rationalising **29 existing central labour laws**. The **Code on Social Security, 2020 consolidates NINE existing social security laws** into a single framework covering organised, unorganised, gig and platform workers, extending **provident fund, gratuity, life and disability insurance, health and maternity benefits**. **For the first time in India, social security benefits have been extended to unorganised, gig and platform workers under Sections 113 and 114.** Aggregators must contribute **1–2% of turnover (capped)** to a dedicated **Social Security Fund**; **draft central rules notified 30 December 2025** propose eligibility after **90 days with one aggregator or 120 days across multiple aggregators** in a financial year, with **Aadhaar-linked registration through e-Shram ensuring portability**.

2. Employees' Pension Scheme (EPS), 2026 has replaced EPS-95. Notified under the Social Security Code 2020 — **the biggest legal overhaul of the scheme in more than three decades**, affecting **over 30 crore EPFO subscribers**. Core features retained: **minimum pension remains ₹1,000 per month**, formula unchanged. Key procedural reform: **EPFO must settle pension claims within 20 days, failing which 12% annual interest is payable**. **Exam framing: the legal architecture has modernised, but the benefit level has not.**

3. Unified Pension Scheme (UPS) — effective 1 April 2025. Provides an **assured pension of 50% of the average basic pay of the last 12 months for a minimum qualifying service of 25 years** (proportionate down to 10 years); **assured family pension at 60%**; **assured minimum pension of ₹10,000 per month** after at least 10 years; **inflation indexation with Dearness Relief based on AICPI-IW**; and a **lump sum of one-tenth of monthly emoluments for every completed six months of service, in addition to gratuity**. About **23 lakh central government employees** are eligible. Contributions: **employee 10% of Basic + DA, matching government 10%, plus an additional ~8.5% into a pool corpus**. Uptake has been low — **118,195 employees (4.3% of 2.76 million NPS subscribers) opted in as of July 2025**, and a **one-time switch back to NPS** has been allowed.

4. India's social protection coverage has doubled — ILO World Social Protection Report 2024–26. Coverage by **at least one social protection cash benefit rose from 24.4% (2021) to 48.8% (2024)**; per MoLE, **nearly 920 million people (65% of the population)** are covered in cash or in kind. India's progress contributed a **5% increase in global social protection coverage**. Globally the world has crossed the halfway mark for the first time, with **52.4% covered**, and countries spend on average **12.9% of GDP on social protection excluding healthcare**.

5. Scale-up of unorganised-sector instruments. Atal Pension Yojana crossed 9 crore gross enrolments as of 21 April 2026, with **over 1.35 crore new subscribers in FY26 — the highest annual enrolment since launch**; in FY 2024-25, **55% of new APY enrolments were women**. The **e-Shram portal** (launched 26 August 2021) had **over 30.68 crore registrations by March 2025, of which 53.68% were women**.

6. Direction of travel — a single portable social security identity. The **draft Shram Shakti Niti, 2025** proposes a **Universal Social Security Account merging EPFO, ESIC, e-Shram and PM-JAY into one portable identity**. India also launched a **Social Protection Data Pooling Exercise on 19 March 2025**, Phase 1 covering 10 states including Tamil Nadu and processing over 200 crore welfare records. **NITI Aayog (2024)** recommends a **regulatory base interest rate on senior-citizen deposits**, noting most seniors depend on savings income which variable rates can push **below sustenance level**.

CURRENT PRACTICE UPDATE

Element	Position as classically taught	Position in 2026
Statutory framework	Nine separate Acts (EPF 1952, ESI 1948, Gratuity 1972, Maternity Benefit 1961, etc.)	**All consolidated into the Code on Social Security, 2020, in force from 21 November 2025**
EPS	EPS-95	**EPS 2026** notified under the Code; minimum pension still ₹1,000/month; **20-day claim settlement with 12% penal interest**
Government pension	OPS (pre-2004) vs NPS (post-2004)	**Third option — UPS from 1 April 2025**: 50% assured, min ₹10,000/month, family pension 60%, AICPI-IW indexed
Gig and platform workers	Entirely outside social security	**Legally recognised for the first time**; aggregator contribution of 1–2% of turnover to a Social Security Fund
Coverage	Often quoted as "only ~10–12% of workforce covered"	**48.8% covered by at least one cash benefit (ILO 2024); ~65% including in-kind**
Health protection	Means-tested or employment-linked only	**Universal, age-based ₹5 lakh cover for all 70+ since October 2024**
IGNOAPS	₹200 / ₹500 per month central share	**Unchanged** — the clearest failure of indexation in the system
Long-term care	Not addressed	**Still no statutory LTC financing** — flagged by NITI Aayog and the UN Decade
Identity / portability	Scheme-wise, non-portable	Moving toward a **Universal Social Security Account** (draft Shram Shakti Niti 2025)

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

- *"India is growing old before it grows rich — with roughly 90% of the workforce informal, contributory insurance can never be the primary instrument."*
- *"I would classify Indian old-age social security using the World Bank multi-pillar model: Pillar 0 assistance, Pillar 1 insurance, Pillar 2 defined contribution, Pillar 3 voluntary and Pillar 4 informal — in India, Pillar 4, the family, remains dominant."*
- *"The Code on Social Security 2020, in force since 21 November 2025, extends social security to gig and platform workers for the first time under Sections 113 and 114."*
- *"India's social protection coverage doubled from 24.4% in 2021 to 48.8% in 2024, contributing a 5% rise in global coverage."*
- *"The legal architecture has modernised, but the benefit levels have not: IGNOAPS at ₹200 and EPS at ₹1,000 a month remain far below any subsistence line."*

EXTRA POINTS TO REMEMBER

- **ILO Convention 102 (1952)** — nine branches of social security.
- **Key dates:** NSAP 1995 • EPS 1995 • NPS 1 Jan 2004 • APY 9 May 2015 • e-Shram 26 Aug 2021 • UPS 1 Apr 2025 • Labour Codes 21 Nov 2025.
- **EPS formula:** (Pensionable Salary × Pensionable Service) ÷ 70; employer's **8.33%** funds it; wage ceiling **₹15,000** (proposal to raise to ₹25,000).
- **UPS numbers:** 50% / 25 years / 60% family pension / ₹10,000 minimum / AICPI-IW indexed / ~23 lakh eligible.
- **APY:** age 18–40 • non-taxpayers • ₹1,000–₹5,000 • spouse continuation • corpus to nominee • **9 crore enrolments**.
- **ILO 2024:** global coverage **52.4%**; India **48.8%** cash / **~65%** including in-kind; average spend **12.9% of GDP**.

Q6. Role of Government in Providing Healthcare and Economic Security for Older People

SOURCE STATEMENT

Pathy's does not describe the Indian government's role. It contributes the **conceptual and ethical framework** (ageism, age discrimination in resource allocation, social determinants of ageing); *Essentials of Clinical Geriatrics* (Ch. 15 & 20) contributes the **health-services and rationing framework**. Both are attributed below.
All India-specific programme, financing and legal content is from Government of India, ILO and WHO sources.

A. Why the Government Must Act (Justification)

1. **Constitutional obligation.** **Article 41** directs the State to secure **the right to public assistance in old age, sickness and disablement**; **Article 47** makes raising nutrition and improving public health a primary duty of the State. **Social security is a Concurrent List subject**, so both Centre and States are answerable.
2. **Market failure argument.** Private insurance fails older people because **premiums rise steeply with age, pre-existing conditions are excluded, and chronic and custodial care are not covered**. **Essentials** makes exactly this point about long-term care insurance: it is **affordable when bought young but becomes very expensive by age 75**, when the need is greatest, and those who need it most may be **ineligible because of prior conditions**. Only the State can pool risk across the whole life course.
3. **Demographic urgency.** India's 60+ population will rise from **10.5% (149 million) in 2022 to 20.8% (347 million) by 2050**, the **80+ group will grow by 279%**, and the **elderly will outnumber children by 2046** — while **over 40% of the elderly are in the poorest wealth quintile and 18.7% have no income at all**.
4. **The two problems are one problem.** Older people are **poor because they are sick, and sick because they are poor**. Nationally, older adults spend about **17.4% of household consumption expenditure on healthcare**, and treatment expenditure is demonstrably higher above 60 than in younger age groups, regardless of income level. **Government action on health *is* action on economic security.**

B. The Six Roles of Government (answer skeleton)

5. **(i) Policy-maker / Steward** — NPOP 1999, National Health Policy 2017, NITI Aayog Senior Care Reforms 2024; sets goals, targets and accountability.
6. **(ii) Legislator** — MWPSC Act 2007, Code on Social Security 2020, Section 144 BNSS; creates enforceable rights.
7. **(iii) Financier / Purchaser** — tax-funded programmes, PM-JAY, pensions, subsidies; pools risk and protects against catastrophic spending.
8. **(iv) Provider** — the public health system from Ayushman Arogya Mandir to Regional Geriatric Centre; old-age homes through IPSrC.
9. **(v) Regulator** — PFRDA, IRDAI, Clinical Establishments Act, drug price control (NPPA), minimum standards for old-age homes.
10. **(vi) Capacity-builder and knowledge-generator** — PG seats in Geriatric Medicine, training modules, **LASI**, National Health Accounts, research funding.

C. Government's Role in Healthcare

11. **Direct service provision through NPHCE (2010).** A five-tier ladder — **Sub-centre/Ayushman Arogya Mandir → PHC (weekly geriatric clinic) → CHC (twice-weekly clinic + physiotherapy) → District Hospital (10-bedded ward with 2 respite beds) → Regional Geriatric Centre (30 beds) and National Centres for Ageing**. The tertiary arm was renamed **Rashtriya Varisth Jan Swasthya Yojana** in 2016–17.
12. **Financial protection through Ayushman Bharat. PM-JAY** gives ₹5 lakh per family per year; the **Ayushman Vay Vandana Card (October 2024)** extends **₹5 lakh cover to every citizen aged 70+ irrespective of income**, with **no waiting period for pre-existing conditions** and roughly **1,961 procedures across 27 specialties**. This is **India's first universal, age-based (not means-tested) health entitlement**.
13. **Convergence with vertical programmes.** The elderly are served by **NP-NCD** (with **CBAC-based screening from age 30**), **NPCB&VI** (cataract, refractive error), **NPPCD** (deafness/hearing aids), **National Mental Health Programme** (depression, dementia), the **National Programme for Palliative Care**, and **free dialysis and free drugs & diagnostics initiatives**.
14. **Human resource development.** NPOP 1999 promised that **"facilities for specialization in geriatric medicine will be provided in the medical colleges"** and that **training in nursing care will include geriatric care** — delivered through **PG seats at RGCs, in-service training and caregiver training for families**.

15. **Evidence that public financing works — the strongest data point in this answer.** National Health Accounts estimates released in September 2024 show **out-of-pocket expenditure fell from 64.2% of total health expenditure in 2013-14 to 39.4% in 2021-22**, while **government health expenditure rose from 1.13% to 1.84% of GDP**, with **over ₹1 lakh crore of savings from PM-JAY alone**. **Per capita government health spending tripled from ₹1,108 to ₹3,169**, government health spending as a share of total government expenditure rose from **3.94% to 6.12%**, and **Social Security Expenditure on health rose from 5.7% to 8.7%**. **Public spending on health has, for the first time, overtaken out-of-pocket spending.**

D. Government's Role in Economic Security

16. **Social assistance (tax-financed, for the poorest). NSAP** delivers **IGNOAPS** (₹200/month for 60–79, ₹500/month for 80+ central share), **IGNWPS**, **IGNDPS**, **NFBS** and **Annapurna** (10 kg free foodgrain/month), supplemented by state top-ups and subsidised grain under the **NFSA 2013**.
17. **Social insurance and pensions (contributory). EPFO** runs **EPF, EPS (minimum pension ₹1,000/month) and EDLI**; government employees are covered by **OPS (pre-2004), NPS (post-2004) and UPS (from 1 April 2025)**. **Atal Pension Yojana** extends a guaranteed **₹1,000–₹5,000 monthly pension** to unorganised-sector workers.
18. **Savings, annuity and tax instruments. SCSS** at **8.2% paid quarterly** (₹30 lakh limit), **PMVVY**, **reverse mortgage**, and tax relief through a **higher basic exemption (₹3 lakh for 60–79, ₹5 lakh for 80+ under the old regime)**, **Section 80TTB (₹50,000)**, **Section 80D** and **Section 80DDB**.
19. **Legal enforcement of family support and welfare services.** The **MWPSC Act 2007** creates Maintenance Tribunals, makes **abandonment punishable** and allows **property transfers to be declared void**; **AVYAY** delivers old-age homes (IPSrC), **free assistive devices under RVY**, and **Elderline 14567**.

E. Limitations, Ethics and Critique (this section earns the top marks)

20. **The unfinished agenda — six concrete gaps:**
    - **Under-financing:** government health spending is still only **~1.9% of GDP against the National Health Policy 2017 target of 2.5% by 2025**, and **OOPE at 39.4% remains above the 35% target**, versus about **13% in the UK and Australia**.
    - **The wrong thing is insured.** Catastrophic spending in India is **more common for outpatient care (47.8% of households) than for hospitalisation (43.1%)**, and **medicines alone account for roughly two-thirds of out-of-pocket spending** — yet outpatient care and medicines **lie outside the flagship hospitalisation scheme**. **Tamil Nadu's pooled free-medicines model is cited as a proven domestic remedy.** This matters most for the elderly, whose costs are chronic and outpatient, not episodic.
    - **Unindexed benefits:** IGNOAPS at ₹200–₹500/month and EPS at ₹1,000/month unrevised for over a decade.
    - **No long-term care system:** no statutory LTC financing, no care-giver allowance, no LTC insurance.
    - **Fragmentation:** delivery split across **five ministries with no single accountable authority**.
    - **The "missing middle":** roughly **400 million Indians remain uninsured** — too rich for PM-JAY, too poor for private cover.
21. **The ethical dimension the examiner is waiting for. Essentials** warns that **"older adults are prime targets for rationing efforts because they consume disproportionately large amounts of medical care and because they are seen as having already lived their lives."** It cautions that **any measure using life expectancy is inevitably biased against the elderly**, and that a measure relying on dependency as the outcome **implies that those who are dependent no longer count — "by such logic, disability is equivalent to death."** It concludes that **as advocates for their patients, geriatricians must be extremely vigilant** to how such terms are used. **Pathy's** makes the parallel point that the UK **NSF's Standard One was "rooting out age discrimination,"** and that **ageism leads older people to be denied beneficial investigations and treatments**. **A government's role is therefore not only to fund and provide, but to protect older people from being rationed out of the system.**

Framework Table — Government Role Mapped to Instrument

Role	Healthcare instrument	Economic security instrument
Policy / Steward	National Health Policy 2017; NPHCE guidelines	NPOP 1999; NITI Aayog Senior Care Reforms 2024
Legislator	MWPSC Act Chapter IV (medical care)	MWPSC Act; Code on Social Security 2020; Sec 144 BNSS
Financier	PM-JAY + **Ayushman Vay Vandana Card (70+)**; free drugs & diagnostics	NSAP/IGNOAPS; EPS; UPS; APY; SCSS; tax reliefs
Provider	AAM-HWC → PHC → CHC → DH (10 beds) → RGC / NCA	IPSrC old-age homes; RVY assistive devices
Regulator	Clinical Establishments Act; NPPA drug price control	PFRDA; IRDAI; standards for old-age homes
Capacity builder	PG seats in Geriatric Medicine; staff training	Elderline 14567; SACRED/SCOPE re-employment
Knowledge generator	LASI; National Health Accounts; HMIS	Social Protection Data Pooling Exercise; e-Shram

LATEST UPDATES (2023–PRESENT)

1. Public spending has overtaken out-of-pocket spending — a landmark. National Health Accounts estimates for 2020-21 and 2021-22, released **25 September 2024**, show **OOPE down from 64.2% (2013-14) to 39.4% (2021-22)** and **government health expenditure up from 1.13% to 1.84% of GDP**, with NITI Aayog attributing **more than ₹1 lakh crore of savings to PM-JAY**. Per capita government health spending **tripled from ₹1,108 to ₹3,169**, and social security expenditure on health rose from **5.7% to 8.7%** of total health expenditure. **However, both National Health Policy 2017 targets — GHE of 2.5% of GDP and OOPE down to 35% — have been missed.**

2. Universal age-based health entitlement (October 2024). The **Ayushman Vay Vandana Card** gives **₹5 lakh of free annual cover to every citizen aged 70 and above irrespective of income**, with a **₹5 lakh top-up for seniors already in PM-JAY families**. **9.67 million cards issued by 31 December 2025**; by January 2026 nearly **one crore cards**, enabling about **eight lakh elderly citizens** to access free treatment, with **1.80 lakh Ayushman Arogya Mandirs operational**.

3. Social protection coverage has doubled — ILO World Social Protection Report 2024–26. Coverage by at least one social protection cash benefit rose from **24.4% (2021) to 48.8% (2024)**, with **nearly 920 million people (65% of the population)** covered in cash or in kind, contributing a **5% increase in global coverage**.

4. The legal architecture of economic security was rewritten (2025–2026). The **four Labour Codes came into force 21 November 2025**, consolidating **29 central labour laws**; the **Code on Social Security 2020 merges nine Acts** and extends benefits to **unorganised, gig and platform workers (Sections 113 and 114)**, with aggregators contributing **1–2% of turnover to a Social Security Fund**. The **Unified Pension Scheme** took effect **1 April 2025** (50% of last 12 months' average basic pay after 25 years, **minimum ₹10,000/month**, family pension 60%, AICPI-IW indexed), and **EPS 2026** replaced EPS-95 with a **20-day claim-settlement rule carrying 12% penal interest**.

5. Policy direction — what governments are being told to do next. NITI Aayog (February 2024) recommends **strengthening geriatric healthcare within the existing system**, extending comprehensive primary care through **AB-HWCs**, promoting **health literacy among seniors and caregivers**, expanding **home health care, mental health services and Poshan Abhiyan for senior citizens**, formal **recognition of the care economy and care workers, especially women**, a **national portal for senior care**, and a **regulatory mechanism to set a viable base interest rate on senior-citizen deposits**.

6. International benchmark. The **UN Decade of Healthy Ageing (2021–2030)** frames government responsibility under **combating ageism, age-friendly environments, integrated care and long-term care**. Its **2023 progress report** found **fewer than one-third of countries have adequate resources**, with only about **1 in 4 having sufficient resources for integrated care and 1 in 3 for long-term care**. The **WHO ICOPE Handbook 2nd edition (January 2025)** gives governments an operational tool — a **four-step primary-care pathway** screening **six intrinsic-capacity domains**.

CURRENT PRACTICE UPDATE

Domain	Position as classically taught	Position in 2026
Health financing	OOPE ~60–65%; India a classic high-OOPE system	**OOPE down to 39.4%**; public spending now exceeds OOPE — but still **1.9% of GDP vs the 2.5% target**
Entitlement basis	Means-tested (BPL cards, PM-JAY SECC criteria)	**Age-based universal entitlement for 70+ since October 2024**
What is insured	Hospitalisation	Outpatient care and medicines — **two-thirds of OOPE** — still **largely outside PM-JAY**; Tamil Nadu's pooled free-medicines model is the proposed remedy
Social security law	Nine separate Acts	**Consolidated into the Code on Social Security 2020, in force 21 November 2025**
Gig/informal workers	Entirely excluded	**Legally recognised for the first time**
Government pension	OPS vs NPS	**Third option — UPS from 1 April 2025**
Assessment model	Disease-oriented screening	**WHO ICOPE intrinsic-capacity model (2025)** — not yet adopted in Indian programmes
Long-term care	Family responsibility, reinforced by MWPSC Act	**Still no statutory LTC financing** — a formal action area of the UN Decade
Ageism in rationing	Not formally addressed in Indian policy	Now a **named global action area**; still absent from Indian legislation

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"The government acts in six roles: steward, legislator, financier, provider, regulator and capacity-builder — and for older people all six are needed simultaneously."*
• *"Out-of-pocket expenditure fell from 64.2% in 2013-14 to 39.4% in 2021-22, so public spending on health has for the first time overtaken out-of-pocket spending — but both NHP 2017 targets have been missed."*
• *"India insures the wrong thing: catastrophic spending is commoner for outpatient care than for hospitalisation, and medicines are about two-thirds of out-of-pocket spending — precisely the elderly's cost pattern."*
• *"Older adults are prime targets for rationing because they consume disproportionately large amounts of medical care and are seen as having already lived their lives."*
• *"By the logic of dependency-based outcome measures, disability is equivalent to death — geriatricians must be extremely vigilant to how such terms are used."*

EXTRA POINTS TO REMEMBER

• **NHA key numbers:** OOPE 64.2% → 39.4% • GHE 1.13% → 1.84% of GDP • per capita ₹1,108 → ₹3,169 • GHE share of govt spending 3.94% → 6.12%.
• **NHP 2017 targets:** GHE **2.5% of GDP** and OOPE down to **35%** — **both missed**.
• **Catastrophic expenditure:** outpatient **47.8%** of households vs hospitalisation **43.1%**; medicines **~two-thirds** of OOPE.
• **"Missing middle" = ~400 million uninsured Indians.**
• **Elderly spend ~17.4% of household consumption expenditure on healthcare.**
• **The ethical anchor:** Essentials on rationing + Pathy's NSF Standard One ("rooting out age discrimination").

Q7. Integrated Care of Older People (ICOPE)

SOURCE STATEMENT — THIS TIME THE TEXTBOOK DOES COVER IT

Pathy's 6th edition devotes an entire chapter to this subject: Chapter 100, "WHO Integrated Care for Older People (ICOPE)," pages 1272–1281, by **Catherine Takeda, Sophie Guyonnet, Bruno Vellas and Yuka Sumi** (Volume 2, Section 12: Functional Disorders and Rehabilitation). **Intrinsic capacity and functional ability** are also covered in **Chapters 2, 4, 5 and 99**.
Because the chapter summarises WHO's own documents, detailed guideline recommendations and care-pathway steps are sourced from **WHO ICOPE Guidelines (2017), ICOPE Handbook 1st ed. (2019) and 2nd ed. (2025)**.

A. Definitions (get these exact — they are the whole answer)

1. **Healthy ageing** is the process of developing and maintaining the **functional ability** that enables well-being in older age. Pathy's: *"functional ability — retaining autonomy and independence as people age — is the cornerstone of healthy ageing, a term established by the WHO in its first World Report on Ageing and Health."*
2. **Intrinsic capacity (IC)** is **"a composite of all of an individual's physical and mental capacities"** (Pathy's Ch. 5) — WHO: **"all the mental and physical capacities that a person can draw on, including their ability to walk, think, see, hear and remember."** Pathy's calls it **"a key determinant of functional ability."**
3. **Functional ability = Intrinsic capacity + Environment + the interaction between them.** This is the central equation of ICOPE. Two people with the same intrinsic capacity can have very different functional ability depending on housing, transport, family support and services.
4. **ICOPE** is WHO's approach to **provide a continuum of integrated care that reorients health and social services towards more person-centred and coordinated care**, aiming to **optimise intrinsic capacity and functional ability in older age**.

B. Rationale — Why It Was Developed

5. **The disease-centred model fails older people.** ICOPE **promotes person-centred care that strengthens older people's intrinsic capacity and their ability to function where they live — a shift away from specialised medical treatment for each disease or condition**. With multimorbidity, treating each disease separately produces polypharmacy, fragmented care and no gain in function.
6. **Declines in intrinsic capacity share common causes, so they can be tackled together.** WHO's justification: **"highly intensive strength training is the key intervention necessary to prevent and reverse mobility impairments, but it also indirectly protects the brain against depression and cognitive impairment, and prevents falls. Nutrition enhances the effects of exercise and has a direct impact on increasing muscle mass and strength."** One integrated package fixes several problems at once.
7. **Function predicts outcome better than disease.** Pathy's notes that **gait speed predicts mortality in older adults better than chronic diseases like hypertension**, that **multimorbidity is not the most important factor modulating individual domains of intrinsic capacity**, and that **older adults with handgrip strength above muscle-weakness thresholds have lower odds of adverse events across most IC domains and a lower hospitalisation rate in men** (Ramirez-Vélez et al.).
8. **Scale of the problem: mobility impairment is found in 39% of people over 65 years — more than three times the rate in the working-age population**.

C. Evolution of ICOPE (timeline = easy marks)

9. **2015** — WHO *World Report on Ageing and Health* introduces **healthy ageing, intrinsic capacity and functional ability**.
   2016 — *Global Strategy and Action Plan on Ageing and Health*; Member States **"recognized a pressing need to develop integrated, community-based approaches to prevent declines in intrinsic capacity."**
   2017 — **ICOPE Guidelines** with **13 evidence-based recommendations**.
   2019 — **ICOPE Handbook (1st edition)** with a **5-step care pathway**, plus the **ICOPE Implementation Framework**.
   2021–2030 — implementing **ICOPE as part of Universal Health Coverage becomes one of the four action areas of the UN Decade of Healthy Ageing**.
   29 January 2025 — **ICOPE Handbook (2nd edition)** with a streamlined **4-step pathway**.

D. The Six Intrinsic Capacity Domains and How They Are Screened

10. To operationalise intrinsic capacity, WHO selected the domains **most closely associated with care dependency: mobility, cognition, psychological capacity (depressive symptoms), vitality (malnutrition), and sensory**

capacity (hearing and vision). These are screened with **very simple bedside tests requiring no equipment** — in an Indian community pilot, **cognitive decline was determined by difficulty with orientation to time and place or word recall; mobility by the chair-rise test; and malnutrition by recent weight loss or loss of appetite** — together with **sensory testing, depressive symptoms, health risks, and social care and support needs**, plus recording of **caregiver strain and risk of elder abuse**.

Domain	Simple screening question/test	If positive → in-depth assessment
Cognition	Orientation to time and place; recall of three words	MMSE/MoCA, dementia workup, reversible causes
Mobility	**Chair-rise test** (rise 5 times from a chair without arms)	SPPB, gait speed, sarcopenia assessment, falls risk
Vitality / Nutrition	Unintentional weight loss? Loss of appetite?	MNA, BMI, dietary and protein assessment
Vision	Difficulty with distance/near vision?	Visual acuity, refraction, cataract, glaucoma, retinopathy
Hearing	Whisper test / difficulty hearing in a noisy room	Audiometry, wax removal, hearing aid provision
Psychological	Feeling down, depressed or hopeless? Loss of interest?	PHQ-9/GDS, mhGAP-based assessment
Plus	Urinary incontinence; falls; social support; caregiver strain	Targeted pathway for each

E. The 13 Recommendations of the 2017 ICOPE Guidelines

11. **Three modules: Module I — declines in intrinsic capacity** (mobility loss, malnutrition, visual impairment and hearing loss, cognitive impairment and depressive symptoms); **Module II — geriatric syndromes associated with care dependency** (urinary incontinence and risk of falls); **Module III — caregiver support**.
12. **Delivered as six priority actions: improve musculoskeletal function, mobility and vitality; maintain sensory capacity; prevent severe cognitive impairment and promote psychological well-being; manage age-associated conditions such as urinary incontinence; prevent falls; and support caregivers**.

Priority action	Key recommendations
Mobility & vitality	**Multimodal exercise** including progressive strength/resistance training for mobility loss; **oral supplemental nutrition with dietary advice** for malnutrition
Sensory capacity	Routine **screening for visual impairment with timely comprehensive eye care**; **screening followed by provision of hearing aids** *(strong recommendation, low-quality evidence)*
Cognition & mood	**Cognitive stimulation** for cognitive impairment, with or without a formal dementia diagnosis *(conditional)*; **brief, structured psychological interventions per WHO mhGAP**, delivered by professionals understanding older people's mental health *(conditional)*
Urinary incontinence	**Prompted voiding** for cognitive impairment; **pelvic floor muscle training**, alone or with bladder-control strategies and self-monitoring, for urge, stress or mixed incontinence in older women
Falls	**Medication review and withdrawal** of unnecessary or harmful drugs; **multimodal exercise** (balance, strength, flexibility, functional training); **home modification** after specialist assessment; **multifactorial interventions** combining assessment with tailored interventions
Caregivers	Interventions to **support caregiving and prevent caregiver strain** — respite, training, psychological support

F. The ICOPE Care Pathway

13. **The original 5-step pathway (Handbook 1st edition, 2019): Step 1** — screen for loss in the domains of intrinsic capacity; **Step 2** — assess health and social care needs (person-centred assessment); **Step 3** — develop a personalised care plan; **Step 4** — referral and monitoring of the care plan; **Step 5** — engage communities and support caregivers.
14. **The current 4-step pathway (Handbook 2nd edition, 2025) — learn this version: (1) basic assessment and community-level interventions, (2) in-depth assessment, (3) development of a personalised care plan, and (4) implementation and monitoring.** In practice: a **basic assessment to identify declines in intrinsic capacity plus generic health-promotion advice**; an **in-depth evaluation for those flagged**; a **personalised care plan with multidisciplinary input**; and **ongoing monitoring with specialist referral as needed**.
15. **The pathway is deliberately designed to work without geriatricians.** It **empowers general practitioners but also trained non-experts such as community health workers or nurses to implement it without requiring specialised geriatric expertise, making it accessible in diverse contexts from urban clinics to rural outreach programmes**. By prioritising **person-centred goals — what matters most to the individual** — it integrates **mobility, nutrition, sensory function, cognition, mood and vitality into actionable plans that promote functional ability and independence and reduce unnecessary hospitalisations**. **This is the single most important point for an Indian answer.**

G. System-Level Requirements and Support Tools

16. **ICOPE is not just a clinical tool — it requires system redesign.** The **ICOPE Implementation Framework** addresses **governance and financing, workforce training, service delivery models, information systems, and community engagement**. WHO also provides the **ICOPE Handbook App**, giving an **interactive step-by-step approach following the care pathways and generating a printable summary of the assessments, interventions and care plan**, and the **mAgeing programme**, delivering **health information, advice and reminders based on the ICOPE guidelines through basic mobile-phone technology**.

H. Evidence, Implementation and Critique

17. **Real-world implementation is well under way. Pilot programmes in India, Mexico and Vietnam have demonstrated feasibility in resource-constrained environments, where community health workers use simplified screening tools to identify and manage declines, leading to improved functional outcomes and reduced healthcare utilisation.** In France, the **INSPIRE ICOPE-CARE programme in Occitania has enrolled thousands of seniors since 2020, integrating digital monitoring with primary-care pathways; by October 2024 over 3,000 individuals were actively followed, with high adherence and evidence of delayed functional loss**.
18. **ICOPE domains track closely with frailty.** In a validation study of 210 participants, **39.0% were prefrail and 28.6% frail**; **mobility loss and depressive symptoms were strongly linked to both prefrailty and frailty**, and **malnutrition and hearing loss were significantly associated with frailty**.
19. **State the limitations honestly — this earns marks.** Pathy's itself is cautious: in the cachexia chapter it notes that the ICOPE guidelines **"propose screening and management strategies for older subjects at risk for unhealthy ageing,"** that **"weight loss and anorexia are grouped into the malnutrition item, calling for integrative management of nutritional risk,"** but that **"the impact of this program is not known at this time."** Other limitations: **no consensus on how to score or combine intrinsic capacity into a single metric**; **screening tools have limited sensitivity and specificity**; **screening is useless without downstream services to refer to**; **long-term outcome and cost-effectiveness data are still maturing**; and **social care and caregiver support are the hardest components to fund**.
20. **Application to India — say this explicitly.** ICOPE is an almost perfect fit for the Indian delivery platform but **has not yet been formally adopted**. The screening step takes about **five minutes, needs no equipment, and can be done by a CHO or ASHA** at an **Ayushman Arogya Mandir**, feeding positives upward into the **NPHCE ladder** (PHC weekly clinic → CHC rehabilitation unit → District Hospital geriatric ward → Regional Geriatric Centre) and sideways into **NPCB&VI for cataract, NPPCD for hearing aids, NP-NCD for chronic disease, NMHP for depression and dementia, and Rashtriya Vayoshri Yojana for assistive devices**. **Gap to state: NPHCE still uses a simple clinical check-up and standard health card, not the ICOPE intrinsic-capacity screen.**

LATEST UPDATES (2023–PRESENT)

1. ICOPE Handbook, 2nd edition — launched 29 January 2025. WHO released *Integrated Care for Older People: Guidance for Person-Centred Assessment and Pathways in Primary Care*, which **details the four steps of the ICOPE care pathway and includes an expanded first step and a NEW urinary incontinence care pathway**. It **emphasises delivering personalised, comprehensive, coordinated care, supporting a shift from the traditional disease-oriented approach towards more holistic care**. The pathway has been **streamlined from five steps to four** — the most visible change — and the edition **applies the pathway steps to more settings and to persons with a greater range of intrinsic capacities**.

2. Designed explicitly for low-resource settings. The second edition **promotes the integration of more accessible tools and methodologies to facilitate implementation regardless of resource constraints**, and **aims to provide flexibility to ensure feasibility across different countries, contexts and resource settings**, describing **practical care pathways to be adapted for the local context** to detect declines in intrinsic capacity, identify social care and support needs, and develop a personalised care plan, with **training material available in English**.

3. ICOPE is now a formal action area of the UN Decade of Healthy Ageing. Implementing ICOPE as part of Universal Health Coverage is one of the four action areas of the Decade (2021–2030), alongside combating ageism, age-friendly environments and long-term care. WHO's 2023 progress report found **fewer than one-third of countries have adequate resources**, with only about **1 in 4 having sufficient resources for integrated care**.

4. Growing implementation evidence (2024–2026). By **October 2024, the INSPIRE ICOPE-CARE programme in Occitania, France had over 3,000 individuals actively followed, with high adherence and evidence of delayed functional loss**, and **pilot programmes in India, Mexico and Vietnam have demonstrated feasibility in resource-constrained environments with improved functional outcomes and reduced healthcare utilisation**.

5. Alignment with Indian policy direction. The **NITI Aayog position paper (February 2024)** recommends **extending comprehensive primary care for the elderly through AB-Health & Wellness Centres**, **promoting health literacy among seniors and caregivers**, and **expanding home health care and mental health services** — all delivery preconditions for ICOPE. **India has an ICOPE-ready platform (1.80 lakh Ayushman Arogya Mandirs) but no ICOPE mandate.**

CURRENT PRACTICE UPDATE

Element	Pathy's 6th edition (2022) / classical teaching	Current position (2025–2026)
Care pathway	Describes the **ICOPE Guidelines 2017** and the **5-step Handbook (2019)**	**Streamlined to 4 steps** in the 2nd edition (Jan 2025)
Step 1	"Screening" for loss in IC domains	Renamed and expanded to **"basic assessment plus community-level interventions,"** with health-promotion advice built in
Urinary incontinence	Two recommendations (prompted voiding, PFMT)	**A dedicated new care pathway** added in the 2nd edition
Who delivers it	Implicitly primary-care physicians	Explicitly **community health workers and nurses without specialist geriatric training**
Evidence of impact	Pathy's states plainly that **"the impact of this program is not known at this time"**	**Emerging positive data** — INSPIRE ICOPE-CARE (>3,000 followed, delayed functional loss); feasibility in India, Mexico, Vietnam; **definitive RCT-level outcome data still awaited**
Digital support	Not emphasised	**ICOPE Handbook App** and **mAgeing** mobile programme now standard supports
Policy status	A WHO guideline	A **named action area of the UN Decade**, tied to UHC
India	Not addressed	**Not yet adopted within NPHCE**, despite an ideal delivery platform in Ayushman Arogya Mandirs

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"Functional ability equals intrinsic capacity plus environment plus the interaction between them — that equation is ICOPE in one line."*
• *"ICOPE promotes person-centred care that strengthens intrinsic capacity and the ability to function where people live — a shift away from specialised medical treatment for each disease."*
• *"The six domains are cognition, mobility, vitality, vision, hearing and psychological capacity — chosen because they are most closely associated with care dependency."*
• *"The 2025 second edition streamlines the pathway from five steps to four and adds a urinary incontinence care pathway."*
• *"The pathway can be delivered by trained non-experts such as community health workers or nurses without specialised geriatric expertise — which is exactly why it suits India."*
• *"Pathy's itself concedes the impact of this programme is not known at this time; the effectiveness data are only now emerging."*

EXTRA POINTS TO REMEMBER

• **Timeline:** 2015 World Report • 2016 Global Strategy • 2017 Guidelines (13 recommendations) • 2019 Handbook (5 steps) • 2025 Handbook 2nd ed. (4 steps).
• **Three modules:** IC declines • geriatric syndromes (incontinence, falls) • caregiver support.
• **Six priority actions** and **six IC domains** — do not confuse the two lists.
• **Chair-rise test = mobility screen**; **weight loss/appetite = vitality screen**; **3-word recall + orientation = cognition screen**.
• **Mobility impairment in 39% of over-65s** — three times the working-age rate.
• **Support tools:** ICOPE Handbook App • mAgeing • ICOPE Implementation Framework.
• **Frailty overlap study:** 39.0% prefrail, 28.6% frail; mobility loss and depression drive both.

Q8. Geriatric Demography and Its Implications

SOURCE STATEMENT

This topic IS well covered in the uploaded textbooks. Pathy's addresses it in **Chapter 1 (biological perspective — survival curves), Chapter 2 (introduction to ageing) and Chapter 4 (Social and community aspects of ageing — "Demography of ageing")**; *Essentials of Clinical Geriatrics* covers it in **Chapter 2 (The Geriatric Patient: Demography, Epidemiology and Health Services Utilization)**.
Indian demographic data is NOT in either textbook and is taken from Census/NSO, LASI, the India Ageing Report 2023 and PIB releases.

A. Key Definitions and Indicators (learn these first)

1. **Population ageing** is the rise in both the **number** and the **proportion** of older persons. It has two components: **absolute ageing** (more people surviving to old age, driven by rising life expectancy) and **relative ageing** (a higher *proportion* of older adults, driven by falling fertility). Pathy's makes exactly this distinction — **"Increases in life expectancy around the world have led to absolute ageing of the global population"** while **"Declining fertility rates are also leading to a phenomenon of relative ageing."**
2. **The core demographic indicators you must be able to define:**

Indicator	Definition
Old-age dependency ratio	Pathy's: **"an economic index defined as the number of people age 65 or older per 100 people of working age (15–64 years old)"** (India uses 60+ over 15–59)
Ageing index	Number of persons aged 60+ per 100 children aged 0–14
Potential support ratio	Number of working-age persons per one older person (inverse of dependency ratio)
Sex ratio of the elderly	Females per 1,000 males aged 60+
Median age	Age dividing the population into two equal halves
Life expectancy at 60 (e_{60})	Average remaining years of life at age 60 — **more relevant to geriatrics than life expectancy at birth**
Healthy life expectancy (HALE)	Years expected to be lived in good health

B. The Global Picture (from Pathy's)

3. **WHO estimates that the population over age 60 will approximately double from 2015 to 2050, when 20% of the world's population will be over 60. The majority of these older adults will reside in low- and middle-income countries, providing global challenges to ensure they receive adequate access to healthcare and other resources.**
4. **The scale of the change in life expectancy: "In 1950, the average life expectancy was 49 years (68 in developed countries), as compared to 72 (79 in developed countries) in 2019."** The United Nations projects only **modest further increases**, and **"due to biologically and physiologically fixed mechanisms, it seems unlikely that, as a species, human life expectancy will ever exceed approximately 115 years of age."**
5. **The 80+ group is the critical one.** Pathy's states that **"at present, the over-85 population is the fastest-growing age group in developing countries."** This matters clinically because disability, multimorbidity, dementia and dependency all cluster in the very old.

C. Why Populations Are Ageing (Causes)

6. **Causes of absolute ageing: "Improved sanitation, nutrition, and living conditions, as well as major healthcare innovations such as effective treatments for infectious diseases, vaccinations, and advances in neonatal care."** Pathy's adds that **"management of chronic diseases, particularly cardiovascular and oncologic diseases, has also led to extended life expectancy in adulthood and older age."**
7. **Causes of relative ageing (falling fertility): "improved access to birth control, declining numbers of teenage pregnancies, increased female engagement in the workforce, a higher percentage of women pursuing advanced education, and delays in the average age of marriage."** The decline **"is more pronounced in developed countries, but the trend is seen globally."**
8. **Two great transitions run in parallel:** the **demographic transition** (high birth/high death → low birth/low death) and the **epidemiological transition** (communicable, maternal and perinatal diseases → **non-communicable, chronic and degenerative diseases**). The result in India is the **"double burden"** — infections persist while NCDs rise.

D. The Survival Curve — Compression of Morbidity (high-yield concept)

9. **Rectangularisation of the survival curve.** Pathy's Chapter 1 explains that **"medicine delays the death of most individuals of a given generation until they are closer to maximum lifespan, but it does not change the maximum lifespan much." Fries** interpreted this **"compression of mortality" as the result of a "compression of morbidity"** — based on the facts that there is a **maximum lifespan**, that **even without chronic disease individuals would still die**, and that **chronic diseases can be prevented**. Related is the concept of **healthspan — the duration of life in good health**.
10. **Compression vs expansion of morbidity — the central policy question.** If morbidity compresses, extra years are healthy years and the health-system burden is contained; if it expands, extra years are years of disability. Pathy's also notes the **"late-life mortality plateau"** — after 80 the incidence of death still increases but progressively more slowly — and reminds us that **Jeanne Calment died at 122**.

E. Feminisation of Ageing (guaranteed sub-question)

11. **Why women predominate in old age.** Pathy's: **"At birth, the male to female birth rate is approximately 1.05:1. However, females generally have a longer life expectancy than males, which leads to a shifting of the gender ratio in older adults, such that females outnumber males."** Reasons given: **oestrogen may be protective against cardiovascular disease; women are less susceptible to X-linked genetic disorders; males are more likely to engage in high-risk behaviour including dangerous occupations, reckless driving and substance use; political upheaval and wartime have disproportionately affected men** (Russia shows an almost **11-year** male–female gap); and **women generally engage with medical care and seek attention earlier than men**.
12. **The gap widens with age.** In the US in 2020, females outnumbered males **1.1:1 at age 65, 1.2:1 at 75, 1.5:1 at 85, and 2.5:1 at 95**. **The gender gap is expected to narrow** as cardiovascular mortality improves and as women take up workforce participation and smoking at higher rates.
13. **Important exception for India — quote this.** Pathy's states that in developing countries, **"due to less access to education and healthcare, higher rates of physical abuse, and risk of poverty in widowhood, women have lower life expectancies, resulting in female to male ratios closer to 1,"** and that **"India and China, which have historically practised female infanticide, have significantly more males than females, and these effects extend into older adulthood."** *(Note: current Indian data now show the elderly sex ratio has crossed 1,000 — see updates.)*

F. The Indian Picture (not in textbook — external sources)

14. **Headline projections:** India's 60+ population will rise from **149 million in 2022 (about 10%) to 347 million by 2050 (more than 20%)**, and **by mid-century the elderly will outnumber children**. The Government projects a rise from **100 million in 2011 to 230 million by 2036, forming 15% of the total population** — so **by 2036 nearly one in seven Indians will be aged 60 or older**. LASI shows the 60+ share moving from **6.9% (2000) → 11.4% (2025) → 19.5% (2050)**.
15. **The ageing of the aged and the widowhood problem:** the **80+ population will grow by about 279% between 2022 and 2050, with "a predominance of widowed and highly dependent very old women." More than half of India's women over 60 are widowed**, rising in higher age cohorts. The **elderly sex ratio is now 1,065 females per 1,000 males; 58% of the elderly are women, of whom 54% are widows.** In central India it rose from **973 (2011) to 1,053 (2021)**, and **poverty in old age is inherently gendered** — older women are more likely to be widowed, living alone, with no income and fewer assets.
16. **The North–South divide — a distinctly Indian feature: "By 2036, one in five people in India's southern states will be elderly. The north–south divide… is an important feature of India's ageing." Kerala will have the highest elderly share (23% by 2036), while Uttar Pradesh will see the fastest growth in elderly numbers.** Life expectancy at 60 is higher for women, with a **national differential of only 1.5 years but 4 years in Kerala and Himachal Pradesh**, where women at 60 can expect **22–23 more years**.
17. **Dependency and the demographic dividend:** India's **old-age dependency ratio is expected to reach 31.5 by 2050**, against a child dependency ratio of **29.8** per 100 persons aged 15–59. India's **median age is about 29 (2026)** — Kerala ~33, Bihar ~22 — with **TFR at 2.0 (NFHS-5), already below the replacement level of 2.1**, and the **demographic dividend expected to peak around 2036–2041 and close by 2055**.
18. **India's transition is COMPRESSED — the sentence that wins marks: "Developed countries underwent their demographic transitions gradually over several decades, allowing time to build robust social security systems, healthcare infrastructure, and pension schemes. In contrast, developing nations like India are experiencing compressed demographic transitions, with ageing occurring at unprecedented speed while economic development and social support systems struggle to keep pace." India is growing old before it grows rich.**

G. Implications (the second half of the question)

19. Implications, organised by domain:

Domain	Implication
Health service	Shift from acute/episodic to **chronic, multimorbid, long-term care**; rising demand for geriatric wards, rehabilitation, day care, palliative and home care; more emergency admissions and readmissions
Disease burden	Predominance of **NCDs, geriatric syndromes (falls, incontinence, delirium, immobility), dementia, sensory loss and multimorbidity**; polypharmacy
Economic	Pathy's: **"increased spending on healthcare, Social Security, disability, pensions, and infrastructure to support an ageing population, with fewer wage-earners contributing taxes"**; and **"a greater need for healthcare spending and long-term care employees"**
Social / family	Nuclearisation, migration of children, **fewer available caregivers**; *Essentials*: **"The family is the heart of long-term care… Informal care is largely provided by women"** — a double burden on working women
Gender	Feminisation of ageing means **more widows, more poverty, more dependency, more institutional need**
Workforce	Need for **geriatricians, geriatric nurses, physiotherapists, occupational therapists, medical social workers and trained care-givers** — India's largest deficit
Environment	Need for **age-friendly cities, barrier-free housing, accessible transport, assistive technology**
Ethical	Rationing pressure and **ageism**; *Essentials*: **"older adults are prime targets for rationing efforts because they consume disproportionately large amounts of medical care and because they are seen as having already lived their lives"**
Research & data	Need for **longitudinal cohorts (LASI), disaggregated 60+ data, and functional rather than disease-only outcomes**

20. **Three caveats that separate a good answer from an average one:**
    - **The dependency ratio is an imperfect measure.** Pathy's: **"It does not account for adults who work past the age of 65 or improvements in care and advances in technology that reduce the societal burden of ageing and disability. Although the old-age dependency ratio will certainly increase globally, the economic and societal implications remain uncertain."**
    - **Older people are not uniformly disabled.** *Essentials*: **"Because physicians tend to see the sick, they may form a distorted picture of senior citizens. Most older persons are indeed self-sufficient and able to function on their own or with minimal assistance."** In US data, ADL dependency rose from **23% at ages 65–84 to 48% at 85+**, and IADL dependency from **23% to 43%** — so **even at 85+, roughly half remain independent**.
    - **The elderly population is profoundly heterogeneous.** Pathy's: **"Each elderly individual is unique, and the elderly population is heterogeneous. A 65-year-old person may be immobile, while a 90-year-old may be mobile and completely independent in their activities of daily living." Chronological age is a poor guide; function and intrinsic capacity are better.**

LATEST UPDATES (2023–PRESENT)

1. India Ageing Report 2023 (UNFPA–IIPS) — now the standard reference. Projects the **80+ population growing by about 279% between 2022 and 2050 with a predominance of widowed and highly dependent very old women**, and shows **women have higher life expectancy at both 60 and 80, with wide state variation** (four years' advantage in Kerala and Himachal Pradesh vs a national average of 1.5 years). **States lagging in the transition, such as Bihar and Uttar Pradesh, will see the elderly share rise between 2021 and 2036 but remain below the national average**; **central and north-eastern regions are "younger" than southern and western India** on the ageing index. Also: **over 40% of the elderly in the poorest wealth quintile, 18.7% with no income, and 71% living in rural areas**.

2. Official government projection now widely quoted. MoSJE states India's elderly population is projected to **more than double from 100 million in 2011 to 230 million by 2036 — nearly one in seven Indians aged 60 or older by 2036, "a fundamental restructuring of the country's population composition"** — with **southern states plus Himachal Pradesh and Punjab already having higher elderly populations and regional disparities expected to widen**.

3. Feminisation is now measurable and reverses the older textbook position. The **elderly sex ratio is 1,065 females per 1,000 males**, with **58% of the elderly being women and 54% of them widows**, and the **overall dependency ratio at 62 dependents per 100 working-age individuals**. The elderly sex ratio **has been climbing steadily since 1991**, with central India moving from **973 (2011) to 1,053 (2021)**. **This directly updates Pathy's statement that India has "significantly more males than females… extending into older adulthood."**

4. Fertility below replacement and a closing dividend window. India's **TFR is now 2.0 (NFHS-5, 2019–21), below the replacement level of 2.1**, and its **median age is about 29 in 2026** (UN WPP 2024 and NSO), with **Kerala at ~33 and Bihar at ~22**. The **demographic dividend is estimated to peak around 2036–2041 and effectively close by 2055**.

5. Global context. The **UN Decade of Healthy Ageing (2021–2030)** frames the response under **combating ageism, age-friendly environments, integrated care and long-term care**, and WHO's **2023 progress report found fewer than one-third of countries have adequate resources**. **NITI Aayog (2024)** describes an **absence of a comprehensive, integrated senior-care policy in India**.

CURRENT PRACTICE UPDATE

Element	Textbook position	Current position (2023–2026)
Global 60+ share	Pathy's: will **roughly double from 2015 to 2050, reaching 20%**	Broadly confirmed by UN WPP 2024
India's sex ratio in old age	Pathy's states India has **significantly more males than females, extending into older adulthood**	**Reversed** — elderly sex ratio now **1,065 females per 1,000 males**, with clear **feminisation of ageing**
Indian projections	Not covered	**149 million (2022) → 347 million (2050)**; **elderly outnumber children by 2046**; **80+ up 279%**
Fertility	Pathy's notes global decline	**India's TFR is now 2.0 — below replacement**, so relative ageing will now accelerate
Old-age dependency ratio	65+ per 100 aged 15–64; Pathy's calls it **"an imperfect measure"**	India uses **60+ per 100 aged 15–59**; projected to reach **31.5 by 2050**
Regional pattern	Not covered	Marked **north–south divide**: Kerala 23% elderly by 2036; UP the largest absolute increase
Compression of morbidity	Fries' hypothesis presented as the framework	Still debated; Indian data (high disability, multimorbidity, low income) suggest **expansion**, not compression
Speed of transition	Not emphasised	**Compressed transition** now recognised as India's defining challenge

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"Population ageing has two components: absolute ageing driven by rising life expectancy, and relative ageing driven by falling fertility."*
• *"Medicine delays death until closer to maximum lifespan but does not change maximum lifespan much — this rectangularisation of the survival curve is Fries' compression of morbidity."*
• *"India is experiencing a compressed demographic transition — ageing at unprecedented speed while social support systems struggle to keep pace. India is growing old before it grows rich."*
• *"The old-age dependency ratio is an imperfect measure: it ignores those working past 65 and technological gains that reduce the societal burden of disability."*
• *"Because physicians tend to see the sick, they may form a distorted picture of senior citizens — even at 85 and above, roughly half remain independent in ADLs."*
• *"A 65-year-old may be immobile while a 90-year-old is completely independent — chronological age is a poor guide; function and intrinsic capacity are better."*

EXTRA POINTS TO REMEMBER

• **Global:** LE 49 (1950) → 72 (2019); ceiling ~**115 years**; Jeanne Calment **122**; over-85s = **fastest-growing group**.
• **India:** 149 m → 347 m • 10.5% → 20.8% • 80+ **+279%** • elderly > children by **2046** • 230 m by **2036**.
• **Sex ratio 1,065** • 58% women • 54% widows • dependency ratio **62 per 100** • ODR **31.5 by 2050**.
• **TFR 2.0** (below replacement 2.1) • median age **~29** • dividend peaks **2036–2041**, closes **2055**.
• **US gender gap:** 1.1:1 at 65 → 2.5:1 at 95. **ADL dependency 23% (65–84) → 48% (85+).**
• **Kerala 23% elderly by 2036**; women at 60 in Kerala/HP expect **22–23 more years**.

Q9. Ethno-Geriatrics

SOURCE STATEMENT

Pathy's 6th edition covers this topic directly. The core chapter is **Chapter 8, "Health literacy and cultural sensitivity," by Nina Tumosa (HRSA, Rockville, MD), pages 108–118**. Additional material is in **Chapter 4 (migration, immigration, ethnic diversity, ageism)** and **Chapter 5 (LGBT+ older adults)**. Pathy's itself cites the **American Geriatrics Society Ethnogeriatrics Committee** and the **ETHNIC(S) mnemonic**, described in its source as **"a clinical tool for ethnogeriatric education."**
Contemporary (2023–2026) developments are drawn from peer-reviewed literature and WHO.

A. Definition and Scope

1. **Ethno-geriatrics** is the branch of geriatric medicine that studies **the influence of culture, race and ethnicity on the health and health care of older adults**, and applies that understanding to deliver **person-centred, equitable care**. It sits at the intersection of **geriatrics, cultural anthropology, health equity and health literacy**.
2. **Pathy's central thesis (learn this sentence): "Cultural differences between patient and provider can lead to misunderstandings, value conflicts, and disparate understandings of health and illness. Low health literacy leads to poor understanding and adherence and often limits access to health care. Together, low levels of health literacy and a lack of cultural sensitivity can severely impact health outcomes." Health literacy and cultural sensitivity are therefore the two pillars of ethnogeriatrics.**
3. **Everyone has a culture — including the doctor.** Pathy's: **"Both providers and patients have their own national and ethnic cultures… Health care providers have the culture of biomedicine and their specific profession and speciality."** Key exam point: **"Medicine is a culture that is not easily understood by, and often intimidates, older adults."**

B. Why It Matters — The Changing Demography of Diversity

4. **Populations become more diverse as they age.** Pathy's examples: **Bethnal Green in London was a predominantly white, working-class neighbourhood in the 1950s; by the 1990s, as Tower Hamlets, it was home to large numbers of Bangladeshi immigrants, and by 2018 it had the lowest life expectancy and the highest rate of heart disease of all London boroughs. Wolverhampton's population identifies as 55.5% Christian, 19.7% no religion, 9.1% Sikh, 3.7% Hindu, 3.6% Muslim and 0.4% Buddhist**; **London, Leicester, Luton, Slough and Birmingham now have a greater than 50% ethnic minority population**; and **over 800 languages are spoken in New York City**.
5. **Older migrants are a distinct vulnerable group.** In the US, **13.5% of the population over 65 is foreign-born, and about half report speaking English "less than very well." One in ten migrated as an older adult, most commonly sponsored by adult children**; such people **"are much more likely to have low incomes and be financially dependent on others"** and more likely to suffer **social isolation and loneliness**. Globally, **adults over 65 make up about 11.7% of the total migrant population**.
6. **The "healthy immigrant effect."** Pathy's: immigrants are on average **healthier than native-born residents**, explained by **self-selection, health screening requirements in receiving countries, and retention of healthier native habits** — but **health converges with the host population after several decades**. Disease patterns also shift: **immigrants from Yugoslavia and Hungary had a higher stroke incidence than Swedes in Malmö**, and **Japanese immigrants to Brazil have different cancer mortality rates from Japanese in Japan**.
7. **The clinical consequence: "older migrants are often non-adherent with medications, resulting from interactions between illness perceptions, low health literacy, language barriers, and disadvantaged socioeconomic circumstances, which can sometimes restrict the ability to purchase prescribed medications."**

C. Pillar 1 — Health Literacy

8. **Definition and burden. Health literacy is "individuals' ability to understand and manage their personal health care issues."** Pathy's key finding: **"Individuals with limited health literacy have less access to health knowledge, worse self-management skills, less frequent use of preventive services, higher hospitalisation rates, and more premature mortality than individuals with adequate health literacy."** Limited health literacy **"may be an independent risk factor for health disparities in older people."**
9. **Health literacy declines with age — independently. "Functional literacy declines with age."** In a study of 2,774 community-dwelling older adults, **a significant decrease in health literacy was seen with every year increase in age, even after adjusting for gender, race, ethnicity, cognitive status and education**. **Both health literacy and cognitive abilities independently predict mortality**, and **lower health literacy was associated with increased**

risk of death after hospitalisation for acute heart failure.

Factors affecting health literacy (Pathy's Table 8.1)	Consequences of low health literacy (Table 8.2)
Age — functional literacy declines with age	Poorer physical health
Education — ability to read, interpret, use technology	Poorer mental health
Cognitive status — recognising need for care, following instructions	Difficulty accessing health care
Income — insurance status, poverty, job insecurity, immigration status	Difficulty following provider instructions
Race/ethnicity — differing cultural beliefs, lack of proficiency in the local language, lower education	Difficulty taking medications properly
Health status — hearing loss, pain, disability, vision loss, poor physical functioning	**Increased hospitalisations; premature mortality**

10. **Practical remedies (Pathy's Table 8.3). Written material** should be **age-appropriate, use simple words, be at a sixth-grade reading level or lower, be in the patient's primary language, include pictures and illustrations, and present only a small amount of information**. **Auditory material** should be **delivered slowly, one-to-one, by a trusted provider, in the patient's primary language**. Note the mismatch: **many US older adults read at an eighth-grade level and 20% at or below fifth-grade, yet most healthcare materials are written at a tenth-grade level.**
11. **Two traps to name in the exam.** First, **"the greatest potential barrier to addressing health literacy is that most patients are often unwilling to admit that they have literacy problems."** Second, **97% of subjects, regardless of literacy level, reported that television was their primary source of health information** — so mass and folk media matter more than leaflets.

D. Pillar 2 — Cultural Sensitivity

12. **Culture is fluid, not fixed.** Pathy's stresses that **"culture is fluid and constantly changing,"** that there are **cultural differences between different generations who share the same cultural background**, and that **gender differences across cultures can be even more complicated**. Since geriatric care **"often requires that health care providers interact with multiple generations of the same family,"** any strategy **"needs to be general and flexible in approach."** Cultural factors affecting care (**Table 8.4**): **age, gender, ethnicity, assimilation, generation cohort, and the ever-changing nature of culture**.
13. **The four barriers to culturally appropriate care (Table 8.5): the large variety of cultures**; **the effects of acculturation**; **the negative effects of stereotypes**; and **the complexity of the culture of biomedicine itself**. Pathy's conclusion: **"Cultural sensitivity is more a process than an outcome. It is as much about acceptance of differences as it is about knowledge of differences."**
14. **The five common areas of conflict (Table 8.6) — a guaranteed sub-question:**

Area of conflict	Explanation from Pathy's
Mistrust from prior contacts	Older adults may distrust providers based on previous encounters with biomedicine, **"such as the American experience with the Tuskegee Syphilis Study"**
Who is "the patient"?	Western biomedicine focuses on the **adult individual**; in many cultures **"the family, or even the entire community, plays a major part in managing illness,"** so **it is often best to include the entire family in decision-making, including spouses and adult children**
Verbal and non-verbal communication	Language barriers cause **"misdiagnosis to ineffective pain control."** Even in a shared language, meaning differs — a patient saying **"stomach ache"** may mean **anywhere in the abdomen**
Misconceptions about cultural norms (stereotyping)	**"Sometimes a little knowledge is a dangerous thing."** Instead of memorising every culture, **a brief conversation with the patient or interpreter** clarifies what is acceptable. **"There is no substitute for asking the older adult what their treatment goals are."**
Ageism by BOTH patient and provider	Younger providers may **exaggerate the impact of functional differences and chronic illness and fail to recommend smoking cessation, good nutrition and exercise**; conversely older adults may disregard advice from much younger clinicians — **"reverse stereotyping"**

15. **Non-verbal communication carries enormous weight.** Pathy's lists culturally variable elements: **expression of distress (stoicism versus open expression of pain), the pace of conversation, whether interruptions are encouraged, physical proximity during history-taking, whether eye contact is appropriate or disrespectful, the etiquette of touch, hand gestures and finger-pointing, and attitudes toward the direct discussion of death and dying**. A modern hazard: **"One unintended consequence of the introduction of the electronic record is the perception on the part of some patients that it is disrespectful of the clinician to interact with the computer screen more than with the patient."**
16. **Where biomedicine itself clashes with older patients.** Pathy's is unusually blunt: **"the culture of medicine often emphasises the quantity of life over the quality of life. However, older patients may insist on more autonomy**

than the culture of biomedicine encourages." It adds that **"it is not uncommon for family members to decide that an older patient should not be treated for a serious disease such as depression or cancer"** — directly relevant to Indian practice.

E. Strategies — How to Practise Ethnogeriatrics

17. **Start with self-awareness.** Pathy's: **"Everyone has a culture… Approaching the older adult as a cultural equal will reduce conflict between cultures. A sense of humour about small misunderstandings is crucial… None of the cultures involved are problems to be overcome. Rather, they are opportunities for sharing."** Crucially, **"educational level, dominant language, religion, gender, year of immigration, and even personality may have more of an effect on interactions with health care providers than cultural identity. The best way to find out… is to ask them directly and listen carefully."**
18. **The ETHNIC(S) mnemonic (Pathy's Table 8.7) — memorise this; the single most examinable item in the chapter.** It **"can serve as a clinically applicable tool for eliciting and negotiating cultural issues during health care encounters."**

Letter	Meaning	What to actually do
E	**Explanation**	Elicit the patient's own explanatory model — what they think the symptoms mean and what family, television or the internet has suggested
T	**Treatment**	Ask what has already been tried — **specifically ask about complementary and alternative medicine and home remedies**; "sometimes those remedies are helpful, and sometimes they are harmful"
H	**Healers**	Acknowledge you are not the only healer; identify **other healers who must be included in the treatment plan**
N	**Negotiate**	Recovery is teamwork — establish **how much of a partner the older adult intends to be in their own recovery**; engage informal caregivers
I	**Intervention**	Determine willingness to participate; modify the plan for cultural conditions in a timely manner
C	**Collaborate**	Family, other healers, the interdisciplinary geriatric team and community services — **"Continuum of care for older people is very much a team endeavour"**
S	**Spirituality / Seniors**	**"Spirituality is an often-overlooked aspect of health care"** — the provider should **take the lead in asking** whether the patient wishes to discuss the role of their beliefs; **"particularly important for end-of-life care"**

19. **Use professional interpreters, not children.** Pathy's: **"It is usually advisable to engage a professional translator or use translated written materials."** Child interpreters are **"especially problematic, especially if the medical topic is not appropriate for a child"**; a sensitive child **"may wish to protect the older adult's dignity, not understanding that the provider–patient relationship relies strongly on honesty,"** and an older adult **"may not be comfortable communicating through a child of the opposite gender, thus leading to more confusion and under-reporting of symptoms."**
20. **Culturally tailor health promotion, and remember other minority identities.** Pathy's notes that **cultural differences in the perception of what defines a good diet or the proper amount or form of exercise "may be difficult to address but well worth the effort."** It also reminds us that **about 0.5% of US adults over 65 identify as transgender**, that **transgender older adults face the cumulative effects of a lifetime of discrimination with higher rates of anxiety, depression and loneliness and less robust support networks**, and that there is **"a dearth of cultural competency training for providers of older adults around issues of gender and sexual identity."**
21. **The pay-off — and a silent trap.** Cultural sensitivity **"can lead to better provider–patient communication, more accurate diagnoses, more effective treatment, higher patient satisfaction/compliance, and efficient use of medical resources."** But Pathy's warns: **older, non-white and literacy-deficient patients report GREATER communication satisfaction than younger, white, functionally literate peers, and "are more likely to cope with their illnesses by withdrawing rather than by actively pushing for a higher standard of care"** — so **apparent satisfaction may mask disengagement**, and clinicians **"should continuously seek ways to facilitate dialogue with patients who are older and non-white and have poor literacy skills."**

F. Application to India (discussion point — not in the textbook)

22. **India is arguably the world's largest ethnogeriatric laboratory.** Relevant axes of diversity: **22 scheduled**

languages and hundreds of mother tongues; multiple religions; scheduled castes and scheduled tribes; large-scale rural-to-urban and inter-state migration; and regional variation in the pace of ageing. Indian issues that map directly onto Pathy's framework: **family-centred rather than individual decision-making is the norm; non-disclosure of a cancer diagnosis to the patient is common; widespread concurrent use of AYUSH and folk remedies (the "T" and "H" of ETHNIC(S)); low functional literacy in older rural women; and 71% of India's elderly live in rural areas with over 40% in the poorest wealth quintile. Ethnogeriatrics in India is not an imported Western concern — it is everyday practice.**

LATEST UPDATES (2023–PRESENT)

1. Ethnogeriatrics is now framed explicitly as a health-equity discipline. Current reference texts define it as **"the influence of culture, race, and ethnicity on health care of older adults,"** noting **"an increasing recognition of the importance of cultural issues in health equity"** and that **"recognizing this importance and approaches from a health systems and clinical practice standpoint is critical in delivering person-centered equitable care."** The demographic driver is stark: **the non-Hispanic White share of the US older adult population is falling sharply, and non-Hispanic Whites will no longer comprise 50% of the general population by 2044**.

2. Hard evidence of disparities at the end of life in dementia (2024). A scoping review in *Alzheimer's & Dementia* found **"less optimal end-of-life care for minoritized populations, including more aggressive life-sustaining interventions, higher hospitalization rates, and lower use of hospice and advance directives,"** attributed to **"the cultural competence of staff, socioeconomic inequality, and systemic racism, as well as individual-level preferences and values."** A major research gap was identified: **fewer than one-third of studies reported findings separately for Asian American/Pacific Islander populations and under 3% for American Indian/Alaska Native populations**.

3. Conceptual shift: from *cultural competence* to *structural competency*. A 2025 *Annual Review of Clinical Psychology* analysis states that **"individuals from minoritized racial/ethnic groups face a disproportionate burden of Alzheimer's disease and related dementias,"** and that **"this health inequality reflects structural racism, which creates and sustains racial differences in social determinants."** **Exam framing: cultural sensitivity fixes the consultation; structural competency is needed to fix the disparity.**

4. Cultural tailoring is now being tested in trials, not just recommended. A 2024 Gerontological Society of America symposium reported **culturally tailored and community-engaged interventions** — including **"GetActive," a culturally adapted chronic pain programme delivered in Spanish and English which improved pain management and quality of life**, a **peer-support programme for minority and low-income older adults with depression**, and work on **socio-ecological barriers to equitable participation in dementia prevention and clinical trials** — concluding that **"community engagement and cultural tailoring"** function as protective factors for health equity. Parallel 2025 work on **Indigenous older adults' cognitive health** concluded that **"building a society that resolves structural inequities could eliminate disparities in later-life cognitive health for all older adults."**

5. Ageism as a global, measurable target. The **WHO Global Campaign to Combat Ageism**, embedded in the **UN Decade of Healthy Ageing (2021–2030)**, makes **combating ageism one of four action areas**. WHO's 2023 progress report noted a **more than 20% rise in countries reporting legislation against ageism**, but **fewer than one-third of countries have adequate resources**. WHO's **"Health of older refugees and migrants" (2018)** — cited by Pathy's itself — remains the standing technical guidance for migrant elders.

CURRENT PRACTICE UPDATE

Element	Pathy's 6th edition (2022)	Current position (2023–2026)
Core framing	**Cultural sensitivity + health literacy** at the level of the clinical encounter	Reframed as **health equity**, with **structural competency and structural racism** added as upstream determinants
Clinical tool	**ETHNIC(S) mnemonic** (Kobylarz et al., 2002)	Still the standard teaching tool; complemented by **Kleinman's explanatory model** and community-engaged, culturally tailored programmes
Evidence base	Largely descriptive and observational	**Interventional** — culturally adapted pain, depression and dementia-prevention programmes now being trialled
Dementia care	Not addressed as a disparity	**Documented disparities in end-of-life dementia care** — more aggressive interventions, more hospitalisation, less hospice and fewer advance directives
Under-studied groups	Not flagged	**Asian American/Pacific Islander, Indigenous and Alaska Native older adults remain markedly under-represented**
Ageism	A bilateral clinical phenomenon	Now a **formal WHO action area** with legislation tracked internationally
India	Not covered	**No Indian ethnogeriatric framework, curriculum or data set exists** — a genuine research and policy gap

EXAMINER'S TIP — VERBATIM MARK-EARNING LINES

• *"Ethnogeriatrics is the influence of culture, race and ethnicity on the health care of older adults; its two pillars are health literacy and cultural sensitivity."*
• *"Medicine is a culture that is not easily understood by, and often intimidates, older adults."*
• *"Cultural sensitivity is more a process than an outcome — as much about acceptance of differences as knowledge of differences."*
• *"I would use the ETHNIC(S) mnemonic: Explanation, Treatment, Healers, Negotiate, Intervention, Collaborate, Spirituality/Seniors."*
• *"There is no substitute for asking the older adult what their treatment goals are — sometimes a little knowledge is a dangerous thing and leads to stereotyping."*
• *"Older, non-white, literacy-deficient patients report greater satisfaction yet cope by withdrawing rather than pushing for a higher standard of care — apparent satisfaction may mask disengagement."*

EXTRA POINTS TO REMEMBER

• **ETHNIC(S)** — the one mnemonic to write down first in this answer.
• **Four barriers:** variety of cultures • acculturation • stereotypes • complexity of biomedicine.
• **Five areas of conflict:** mistrust • who is the patient • communication • stereotyping • ageism (bilateral).
• **Written material at sixth-grade level**; most materials are at tenth-grade; 20% of US older adults read at fifth grade or below.
• **97% cite television as their primary information source** — justifies mass and folk media (as NPOP and NPHCE mandate).
• **Never use a child as interpreter**; use a professional translator.
• **Migrants:** 13.5% of US 65+ foreign-born; ~half speak English "less than very well"; 11.7% of global migrants are 65+; **healthy immigrant effect** converges over decades.

APPENDIX — RAPID REVISION GRID

Everything below is verifiable in the answers above. Read this the night before the examination.

1. Chronology — Indian Policy, Law and Programmes

Year	Milestone	What to remember
1995	National Social Assistance Programme (NSAP)	Ministry of Rural Development; IGNOAPS, IGNWPS, IGNDPS, NFBS, Annapurna
Jan 1999	**National Policy on Older Persons (NPOP)**	MoSJE; UN International Year of Older Persons; **6 areas of intervention**; NCOP constituted May 1999 (39 members)
2007	**MWPSC Act**	Tribunals; **₹10,000** cap; **90 days**; abandonment punishable; property transfer void; **Chapter IV = medical care**
2008	UNCRPD in force for India (3 May)	**Article 25** — services close to people's own communities including rural areas
2010	**NPHCE launched**	11th Five-Year Plan; **₹288 crore** for 2010–12; **80:20** Centre:State
2011	NPSrC drafted	**NEVER NOTIFIED — still a draft**
2012	NCOP → **National Council of Senior Citizens (NCSrC)**	Broader mandate; State-level councils created
2016–17	Tertiary NPHCE renamed **RVJSY**	Rashtriya Varisth Jan Swasthya Yojana
2019	MWPSC (Amendment) Bill	Removes ₹10,000 cap; priority for 80+; **STILL PENDING**
Feb 2024	**NITI Aayog: Senior Care Reforms in India**	**4 core areas:** Health, Social, Economic/Financial, Digital
29 Oct 2024	**Ayushman Vay Vandana Card**	**₹5 lakh, all 70+, income-independent**; ~1,961 procedures, 27 specialties; 9.67 m cards by 31 Dec 2025
1 Apr 2025	**Unified Pension Scheme (UPS)**	50% of last 12 months' average basic pay; min **₹10,000/month**; family pension 60%
21 Nov 2025	**Four Labour Codes in force**	29 laws rationalised; Code on Social Security merges **9 Acts**; gig workers covered (Sec 113–114)
2026	**EPS 2026** replaces EPS-95	Min pension still **₹1,000**; **20-day settlement, 12% penal interest**

2. Global Chronology — WHO and the UN

Year	Milestone
1952	**ILO Convention 102** — nine branches of social security
1991	UN Principles for Older Persons
2001	UK **National Service Framework for Older People** — **Standard One: rooting out age discrimination**
2015	WHO **World Report on Ageing and Health** — introduces healthy ageing, intrinsic capacity, functional ability
2016	Global Strategy and Action Plan on Ageing and Health
2017	**ICOPE Guidelines** — **13 recommendations**, 3 modules, 6 priority actions
2019	ICOPE Handbook 1st ed. — **5-step pathway** + Implementation Framework
2021–2030	**UN Decade of Healthy Ageing** — 4 action areas
2023	Decade **first progress report** (136 countries) — <1/3 have adequate resources
29 Jan 2025	**ICOPE Handbook 2nd ed.** — **4-step pathway** + new urinary incontinence pathway

3. Numbers You Must Not Get Wrong

Item	Figure
NPHCE beds — District Hospital	**10** (including **2 respite** in a separate room)
NPHCE beds — Regional Geriatric Centre	**30** = 15 M + 15 F; each side **3 acute + 7 sub-acute + 5 long-term**
NPHCE contractual staff	DH **13**; RGC **38**; CHC **1**; Sub-centre **0**
NPHCE funding — DH	**₹87 lakh** non-recurring / **₹44 lakh** recurring p.a.
NPHCE funding — RGC	**₹370 lakh** non-recurring / **₹163.44 lakh** recurring p.a.
Original RGCs / current RGCs / NCAs	**8 → 17–19**; **2** National Centres for Ageing (AIIMS Delhi, MMC Chennai)
Districts covered by NPHCE	**~713**
IGNOAPS central pension	**₹200/month (60–79)**; **₹500/month (80+)**
EPS minimum pension	**₹1,000/month** since 1 Sept 2014 (demand: ₹7,500); wage ceiling ₹15,000
SCSS	**8.2% p.a. quarterly**; max **₹30 lakh**; 5 + 3 years; 80C; TDS above ₹1 lakh
APY	Age **18–40**; pension **₹1,000–₹5,000**; **9 crore** enrolments (Apr 2026)
RVY income ceiling	**₹15,000/month** or BPL; devices by **ALIMCO**
Elderline	**14567**
Vayoshreshtha Samman	**1 October**; **13 categories**, **15 awardees**; ₹2.5 lakh / ₹5 lakh
OOPE (National Health Accounts)	**64.2% (2013-14) → 39.4% (2021-22)**; GHE **1.13% → 1.84% of GDP**
NHP 2017 targets	GHE **2.5% of GDP**; OOPE **35%** — **both missed**
ILO social protection coverage (India)	**24.4% (2021) → 48.8% (2024)**; ~920 million / 65% including in-kind; global **52.4%**
India 60+ population	**149 m (2022) → 347 m (2050)**; **10.5% → 20.8%**; 230 m by 2036
80+ growth	**+279%** (2022–2050)
Elderly outnumber children	**2046**
Elderly sex ratio	**1,065** F per 1,000 M; **58%** women; **54%** of them widows
Old-age dependency ratio (India)	**31.5 by 2050**; overall dependency **62 per 100**
TFR / median age	**2.0** (NFHS-5, below replacement 2.1) / **~29 years**
Poverty among elderly	**>40%** in poorest quintile; **18.7%** no income; **71%** rural
LASI Wave-1	**72,250** adults 45+, including **31,464** aged 60+; 30 states, 6 UTs
Mobility impairment (WHO)	**39%** of over-65s — 3× the working-age rate
HELP delirium trial	**15% → 9.9%**; OR **0.60**, p = 0.02
Stroke unit meta-analysis	**29 trials, 6,536 patients**; OR mortality **0.86**, death/dependence **0.78**, death/institutionalisation **0.80**
Incident reporting sensitivity	Captures only **7–15%** of adverse events
ADL dependency (US)	**23%** at 65–84 → **48%** at 85+ (so ~half remain independent at 85+)
Life expectancy (global)	**49 (1950) → 72 (2019)**; species ceiling ~**115**; Jeanne Calment **122**

4. Mnemonics and Structured Lists

List	Content
ETHNIC(S) — ethnogeriatrics	**E**xplanation • **T**reatment • **H**ealers • **N**egotiate • **I**ntervention • **C**ollaborate • **S**pirituality/Seniors
Six CGA elements	Functional ability • cognition • physical health • socioeconomic status • nutrition • mobility/falls risk
Six ICOPE domains	Cognition • mobility • vitality • vision • hearing • psychological capacity
ICOPE 4 steps (2025)	Basic assessment + community interventions • in-depth assessment • personalised care plan • implementation and monitoring
ICOPE 3 modules	IC declines • geriatric syndromes (incontinence, falls) • caregiver support
HELP six risk factors	Cognitive impairment • visual impairment • hearing impairment • sleep deprivation • immobility • dehydration
UN Decade — 4 action areas	Ageism • age-friendly environments • integrated care • long-term care
NPOP — 6 areas of intervention	Financial security • health care and nutrition • shelter • education • welfare • protection of life and property
NPOP — 6 guiding principles	Affirmative action • life-cycle continuum • age-integrated society • older persons as a resource • empowerment • partnership
NPHCE structure	Vision **5** • objectives **4** • expected outcomes **7** • components **8** • main strategies **5**
Six roles of government	Steward • legislator • financier • provider • regulator • capacity-builder/knowledge-generator
World Bank 5 pillars	0 assistance • 1 insurance • 2 defined contribution • 3 voluntary • 4 informal (family)
AVYAY components	IPSrC • SAPSrC • RVY • SCOPE/SACRED • SAGE
NSAP components	IGNOAPS • IGNWPS • IGNDPS • NFBS • Annapurna
Ethnogeriatrics — 4 barriers	Variety of cultures • acculturation • stereotypes • complexity of biomedicine
Ethnogeriatrics — 5 conflicts	Mistrust • who is the patient • communication • stereotyping • ageism (bilateral)
Patient safety — 5 dimensions	Past harm • reliability • sensitivity to operations • anticipation and preparedness • integration and learning

5. Quotable Lines from the Uploaded Textbooks

Source	Line
Pathy's Ch. 11	NSF Standard One is **"rooting out age discrimination"**; the geriatrician balances **therapeutic nihilism against therapeutic heroism**
Pathy's Ch. 8	**"Medicine is a culture that is not easily understood by, and often intimidates, older adults."**
Pathy's Ch. 8	**"Cultural sensitivity is more a process than an outcome."**
Pathy's Ch. 4	**"It seems unlikely that, as a species, human life expectancy will ever exceed approximately 115 years of age."**
Pathy's Ch. 4	The old-age dependency ratio **"does not account for adults who work past the age of 65 or improvements in care and advances in technology."**
Pathy's Ch. 1	**"Medicine delays the death of most individuals... but it does not change the maximum lifespan much"** — Fries' compression of morbidity
Pathy's Ch. 100	On ICOPE: **"the impact of this program is not known at this time"**
Essentials Ch. 15	**"Assessment without follow-up is unlikely to make any difference."**
Essentials Ch. 15	**"Good team care will not arise spontaneously."**
Essentials Ch. 20	**"Older adults are prime targets for rationing efforts... seen as having already lived their lives"**; **"by such logic, disability is equivalent to death"**
Essentials Ch. 2	**"Because physicians tend to see the sick, they may form a distorted picture of senior citizens."**
NPOP 1999	Goal: to live the last phase of life with **"purpose, dignity and peace"**; older women face **"triple neglect and discrimination on account of gender, widowhood and age"**
NPHCE 2010	Vision: a new **"architecture" for Ageing** and **"a Society for all Ages"**

6. The Six Standing Gaps in Indian Elder Policy (write these in any policy answer)

1. **NPSrC 2011 never notified** — India runs on a 1999 policy.
2. **MWPSC Amendment Bill 2019 still pending** — the ₹10,000 cap stands.
3. **No statutory long-term care financing**, no caregiver allowance, no LTC insurance.
4. **Unindexed benefits** — IGNOAPS ₹200/₹500 and EPS ₹1,000 unrevised for over a decade.
5. **Fragmentation across five ministries** with no single accountable authority.
6. **Outpatient care and medicines — two-thirds of OOPE — remain outside PM-JAY**; ~400 million in the "missing

middle."

THE FIVE SENTENCES THAT CARRY THIS ENTIRE BLOCK

1. *"NPOP 1999 is the parent policy; MWPSC 2007 gave it legal teeth, NPHCE 2010 gave it a delivery system, and Ayushman Vay Vandana 2024 gave it money."*

2. *"India is growing old before it grows rich — a compressed demographic transition against an incomplete social security system."*

3. *"Functional ability equals intrinsic capacity plus environment plus their interaction — that equation is the whole of ICOPE."*

4. *"Out-of-pocket expenditure has fallen from 64.2% to 39.4%, so public spending now exceeds private — but both National Health Policy 2017 targets were missed."*

5. *"Pathy's supplies the concepts, ethics and global evidence; Government of India documents supply the programmes, law and money. The complete answer explicitly joins the two."*

END OF COMPENDIUM • 9 Questions • Health Policy, National Programmes & Social Gerontology
Prepared for MD Geriatric Medicine examination preparation • August 2026

MD Geriatric Medicine — Neurology Answer Bank

Twenty-two structured 15-mark answers • Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th ed. (2022) and Essentials of Clinical Geriatrics, 7th ed.
Latest Updates sourced from peer-reviewed journals and society guidelines (2023 – August 2026)

Contents

1. Alzheimer's dementia — pathogenesis, molecular advances, drugs, newer modalities
2. Advances in diagnosis of early Alzheimer's dementia and MCI
3. Newer / current drug therapy for Alzheimer's disease
4. Biomarkers for Alzheimer's dementia
5. Emerging biomarkers in cognition
6. Surgical management of parkinsonism
7. Recent advances in the management of parkinsonism
8. Management of motor fluctuations in Parkinson's disease
9. Parkinsonism-plus syndromes
10. Pathognomonic MRI findings in PSP and MSA
11. Confusion states in the elderly — investigation and management
12. Interventions to prevent delirium in post-operative older patients
13. Thrombolysis in stroke
14. History of the 'Stroke Clinics'
15. Restless legs syndrome
16. Myasthenia gravis
17. Motor neuron disease
18. Dizziness in the elderly
19. Ring-enhancing shadow on CT brain
20. Causes of coma in the elderly
21. Normal pressure hydrocephalus
22. Stroke rehabilitation

How to use: Points 1–20 in each answer are textbook-derived and are what earn marks in the written paper. The *Latest Updates* and *Current Practice Update* sections are what earn marks in the viva. Where a topic is not covered in the uploaded textbooks, this is stated explicitly and the content is drawn from current peer-reviewed literature.

1. Alzheimer's Dementia — Pathogenesis, Molecular Advances, Drugs and Newer Modalities

Fifteen–Twenty High-Yield Points

Definition and epidemiology

1. **Alzheimer's disease (AD)** is a progressive neurodegenerative disorder causing sustained loss of memory and other intellectual functions severe enough to impair daily living. Loss of function separates dementia from MCI.
2. About **6–8% of people over 65** have AD. Prevalence **doubles every 5 years**, so nearly **30% of those over 85** are affected. Family history and increasing age are the primary risk factors.
3. Mixed pathology is the rule in old age. AD change plus vascular disease lowers the threshold at which cognitive decline becomes clinically apparent.

Genetics

4. Early-onset familial AD is caused by mutations in three genes: **APP (chromosome 21)**, **presenilin 1 (chromosome 14)** — the largest group — and **presenilin 2 (chromosome 1)**.
5. The strongest genetic risk factor for late-onset AD is the **apolipoprotein E ε4 allele on chromosome 19**. One or more copies carries a relative risk of about **2.5** in whites, but it does not raise risk equally in African-American or Hispanic populations.
6. ApoE ε4 is **neither sensitive nor specific**, so it is **not recommended as a screening test**, even in high-risk groups.

Pathogenesis — the molecular sequence

7. The two histological hallmarks are **neuritic (senile) plaques** — extracellular masses with an amyloid core surrounded by degenerating neurites — and **neurofibrillary tangles** of abnormal **hyperphosphorylated tau** inside neuronal cell bodies.
8. **Amyloid cascade:** APP is cleaved by **β-secretase (BACE1)** and **γ-secretase (presenilin)** to form Aβ1-42, which oligomerises into **soluble protofibrils** (the most synaptotoxic species) and then fibrillar plaques.
9. **Tangle spread follows Braak staging** — entorhinal cortex first, then hippocampus and association cortex. **Tangle burden correlates with cognitive decline**; plaque burden correlates poorly and may be present in normal cognition.
10. Additional interacting mechanisms of brain ageing accelerate AD: **mitochondrial dysfunction, oxidative damage, loss of proteostasis (impaired autophagy and proteasome), dysregulated neuronal calcium homeostasis, impaired adaptive stress responses (reduced BDNF/NGF signalling), glial activation and neuroinflammation, impaired DNA repair, stem-cell exhaustion, and aberrant network activity with loss of synaptic plasticity.**
11. **Cerebral amyloid angiopathy (CAA)** — amyloid deposition in leptomeningeal and cortical vessel walls — is a recognised neuropathological hallmark of AD and causes lobar haemorrhage, microbleeds and white matter lesions.
12. Biomarker studies show Aβ and tau changes begin **years to decades before symptoms**. Cognitively normal older people with low CSF Aβ1-42 lose whole-brain and hippocampal volume faster, suggesting a **presymptomatic AD phase**.

Drug therapy — textbook position

13. **Cholinesterase inhibitors** are the primary pharmacological approach. Four have been approved: **tacrine, donepezil, rivastigmine and galantamine**. Tacrine is **hepatotoxic** and no longer prescribed.
14. **Mechanism:** they inhibit acetylcholinesterase and raise synaptic acetylcholine, partly correcting the cholinergic deficit from basal forebrain neuronal loss. Rivastigmine additionally inhibits butyrylcholinesterase.
15. **Efficacy:** randomised placebo-controlled trials show small improvements in cognition, possible prevention of functional decline, a several-month delay in progression, and possible delay of nursing home admission. **The clinical importance is marginal in many patients.** There is some efficacy in **multi-infarct dementia and dementia with Lewy bodies**.
16. **Side effects:** nausea, vomiting, diarrhoea, anorexia and weight loss; bradycardia and syncope; vivid dreams and nightmares; urinary urgency; muscle cramps. Caution with bradyarrhythmias and peptic ulcer disease.
17. **Memantine** is an **NMDA receptor antagonist** used in moderate-to-severe disease; it reduces glutamate-mediated excitotoxicity and is generally well tolerated (dizziness, headache, confusion).
18. **Behavioural symptoms:** non-pharmacological strategies come first. **Antipsychotics carry a black-box warning for increased mortality** and should be reserved for patients who are psychotic or an immediate danger to self or others. Every patient with new or worsening behaviour needs a medical evaluation for a treatable precipitant — **pain is especially hard to detect**, and empirical paracetamol has shown efficacy in severe dementia.

Non-pharmacological and newer modalities

19. Four categories of non-pharmacological intervention are described: **restorative cognitive training**, **compensatory cognitive training**, **lifestyle interventions** and **psychotherapeutic interventions**. These remain necessary even when drugs are used.
20. **Exercise** has an emerging role in preventing and treating cognitive decline; **high-intensity resistance training** is the most promising form, particularly in MCI. Attention to caregiver health and advance care planning are integral to management.

Latest Updates (2023 – Present)

- **Anti-amyloid monoclonal antibodies are now standard disease-modifying therapy in early AD. Lecanemab**

(Leqembi), an IgG1 antibody against Aβ protofibrils, received FDA approval in July 2023 on the basis of **CLARITY-AD**, which showed a **27% slowing of decline on CDR-SB over 18 months**. **Donanemab (Kisunla)**, which targets the pyroglutamate-modified plaque epitope, was approved in July 2024 on the basis of **TRAILBLAZER-ALZ 2** (~29% slowing) (*NEJM* 2023; *JAMA* 2023).

- **Amyloid-related imaging abnormalities (ARIA)** are the defining class toxicity — **ARIA-E** (vasogenic oedema) and **ARIA-H** (microhaemorrhage, superficial siderosis). Risk is highest in **APOE ε4 homozygotes**. **TRAILBLAZER-ALZ 6** led to an FDA label change in July 2025 with a **gradual titration schedule that cut ARIA-E from 24% to about 14% at 24 weeks** while preserving amyloid and p-tau217 reduction.
- **Delivery has been simplified.** FDA approved **four-weekly IV maintenance dosing** of lecanemab in January 2025, **subcutaneous maintenance (Leqembi IQLIK)** in August 2025, and a **subcutaneous starter dose in July 2026** — making lecanemab the first anti-amyloid agent deliverable subcutaneously through the full course.
- A **Cochrane review (April 2026)** pooling 17 trials and 20,342 participants across the anti-amyloid antibody class confirmed statistically significant but **small absolute benefit**; relative figures such as 27–29% should always be quoted alongside the underlying CDR-SB difference.
- **Beyond amyloid:** nearly 200 trials of >150 agents are running, targeting tau (antisense oligonucleotides, anti-tau antibodies), neuroinflammation, synaptic protection and metabolic pathways. **Trontinemab** (brain-shuttle antibody) and combination anti-amyloid/anti-tau strategies (**Tau NexGen**) are in advanced development. Prevention trials in asymptomatic amyloid-positive people (**AHEAD 3-45**, **TRAILBLAZER-ALZ 3**) are ongoing.
- **Multidomain lifestyle prevention:** the **US POINTER trial** (2,111 participants, reported 2025) compared a structured two-year multidomain programme with a self-guided programme in older adults at risk, extending the FINGER model.
- **Diagnosis is now biological.** The **Alzheimer's Association Revised Criteria (Jack et al., *Alzheimer's & Dementia* 2024)** define AD by biomarkers rather than syndrome. An abnormal **Core 1** biomarker (amyloid PET, approved CSF markers, or accurate plasma **p-tau217**) is sufficient to diagnose AD anywhere on the continuum.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Disease-modifying therapy	None available; treatment is symptomatic only	Lecanemab and donanemab are approved and modestly slow decline in early AD
Basis of diagnosis	Clinical/syndromic (DSM criteria), imaging to exclude other causes	Biological, biomarker-defined (2024 Revised Criteria); a single abnormal Core 1 marker is diagnostic
Cholinesterase inhibitors	Mainstay of therapy; benefit marginal but the only option	Still first-line symptomatic therapy, now used *alongside* disease-modifying antibodies in eligible patients
APOE genotyping	Not recommended, even in high-risk groups	Increasingly performed before anti-amyloid therapy because ε4 homozygosity predicts ARIA risk
Amyloid detection	PET and CSF only, research tools	FDA-cleared plasma p-tau217/Aβ42 ratio (Lumipulse G, May 2025) available in routine specialist care

2. Advances in the Diagnosis of Early Alzheimer's Dementia and Mild Cognitive Impairment

Fifteen–Twenty High-Yield Points

Concept and definitions

1. **Mild cognitive impairment (MCI)** and **cognitive impairment, not dementia (CIND)** describe measurable cognitive deficits that do **not** impair daily function. **Loss of functional ability due to impaired cognition is the single feature that separates dementia from MCI.**
2. Just over **20% of people aged 71 and above** have cognitive impairment without dementia. **15–20% of those with MCI or CIND convert to dementia each year.**
3. Normal ageing may produce slowed thinking and reaction time, mild recent memory loss and impaired executive function, which may or may not progress. **Old age alone never causes dysfunctional cognitive impairment.**

The three diagnostic questions

4. Three questions establish the cause of confusion: (i) **Has the onset been acute** (hours to days)? (ii) **Are physical factors** (illness, drugs, sensory deprivation) contributing? (iii) **Are psychological factors** (depression, psychosis) contributing? These target the treatable causes.
5. Onset and rate of progression are the most valuable historical items. **Sudden onset over days** means delirium; **gradual decline over months to years** means degenerative dementia; **irregular stepwise decrements** favour multi-infarct dementia.

Clinical and cognitive assessment

6. The **Mini-Cog** is a useful screening tool: it combines **three-item recall** (memory) with **clock drawing** (executive function). Executive dysfunction is critical because it determines the ability to perform **IADLs**.
7. Cognition should be assessed by taking **separate histories from the patient and an informant**. Patients with pathological memory impairment typically report no complaints, while relatives report and worry about the loss.
8. Other validated bedside instruments include the **MMSE**, **MoCA**, and **SLUMS**. **Education level must be considered** when interpreting scores — particularly important in the Indian setting, where illiteracy demands vernacular and education-adjusted tools.
9. Mood and affect must be assessed throughout. **Depression, apathy, emotional lability, agitation and aggression** are common and, if missed, lead to misdiagnosis.
10. **Formal neuropsychological testing** by an experienced psychologist is indicated when the diagnosis is uncertain, in the very intelligent or poorly educated, and when depression is suspected.
11. Minimum work-up: focused history and examination (screening for delirium and depression, identifying sensory impairment), **functional status assessment**, mental status examination, and **selected laboratory studies to exclude reversible causes**. Brain imaging should **not** be done automatically in every patient.

Advances in biomarker-based early diagnosis

12. Detecting the presymptomatic phase on clinical grounds alone is difficult, although **accelerated long-term forgetting** may be an early indicator.
13. Current diagnostic criteria therefore **require biomarkers reflecting the three core features: β-amyloid, phosphorylated tau, and neurodegeneration**.
14. These can be measured by **neuroimaging** (amyloid PET, tau PET, MRI) and in **CSF** (Aβ1-42, phosphorylated tau, neurofilament light).
15. **Blood-based biomarkers** — plasma **Aβ42/40 ratio, phosphorylated tau, and neurofilament light** — have become increasingly viable with improvements in assay sensitivity, with major implications for facilitating early diagnosis.
16. Structural MRI supports early diagnosis: **hippocampal and medial temporal atrophy** favours AD; the pattern of atrophy also helps separate AD from vascular and other dementias.
17. Functional imaging refines the differential: **dopamine transporter (loflurane) SPECT is normal in AD but abnormal in Lewy body dementia**; **123I-MIBG cardiac scintigraphy** may distinguish DLB from AD.
18. **Electrophysiology:** altered cortical synaptic plasticity in response to 5-Hz repetitive TMS has been described as a marker in amnestic MCI converting to AD.
19. Even after diagnosis, no intervention has been proven to prevent progression from MCI to dementia; screening is justified because it allows longitudinal follow-up and structured support and education of patients and families.

Latest Updates (2023 – Present)

- **The 2024 Revised Criteria (Jack et al., *Alzheimer's & Dementia* 2024)** reorganise biomarkers into **Core 1** (early-changing: amyloid PET, CSF Aβ42/40, CSF p-tau181/Aβ42, plasma p-tau217) and **Core 2** (later-changing: tau PET, **MTBR-tau243**, p-tau205). **One abnormal Core 1 marker establishes the diagnosis**; Core 2 markers give prognosis and biological stage.
- The full profile is now written **AT1T2NISV** — amyloid, secreted phospho-tau, tau proteinopathy, neurodegeneration, inflammation, α-synuclein co-pathology and vascular brain injury — replacing the simpler 2018 ATN framework.
- **First FDA clearance of a blood test:** on **16 May 2025** the **Lumipulse G pTau217/β-Amyloid 1-42 Plasma Ratio** was cleared for symptomatic adults aged 55 and over in specialist settings, with **91.7% positive and 97.3% negative**

concordance with amyloid PET/CSF (*Drug Discoveries & Therapeutics* 2025).

- Comparable assays are already available elsewhere: **HISCL Aβ42/40 (Japan)**, **PrecivityAD2 (UK)**, and several platforms in China. Head-to-head studies (Lumipulse, ALZpath SIMOA, C2N, Janssen) show broadly comparable accuracy.
- **Alzheimer's Association clinical practice guidelines (2025)** restrict blood biomarker use to **symptomatic patients in specialised care**, require assays meeting defined accuracy thresholds, and stress that results are **adjunctive** — not a stand-alone diagnosis.
- **Two-cutpoint reporting** is now standard for plasma tests: results fall into positive, negative, or an **intermediate zone** requiring confirmatory CSF or PET testing.
- Practical consequence for the geriatrician: a plasma p-tau217 result returned in **2–5 days from a routine venous sample** replaces, for most patients, an expensive PET scan or a lumbar puncture — a decisive advantage in resource-limited settings such as India.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Diagnostic basis	Clinical syndrome; biomarkers described as emerging	Biological diagnosis; biomarkers are required, not optional
Blood biomarkers	"Increasingly viable" — research stage	FDA-cleared and in specialist clinical use since May 2025
Biomarker framework	Amyloid, phospho-tau, neurodegeneration (ATN)	Core 1 / Core 2 system with full AT1T2NISV profile
MCI	A clinical risk state with no proven intervention	A treatable stage — biomarker-positive MCI is the licensed indication for anti-amyloid therapy
Amyloid confirmation	PET or lumbar puncture	Plasma p-tau217 first, with PET/CSF reserved for intermediate results

3. Newer / Current Drug Therapy for Alzheimer's Disease

Fifteen–Twenty High-Yield Points

Principles

1. Drug therapy in AD has two aims: **symptomatic benefit** (cholinergic and glutamatergic agents) and **disease modification** (anti-amyloid immunotherapy). Non-pharmacological care remains essential alongside both.
2. The **cholinergic hypothesis** underlies symptomatic therapy: degeneration of the nucleus basalis of Meynert reduces cortical acetylcholine, and inhibiting its breakdown partially restores transmission.

Cholinesterase inhibitors

3. **Donepezil** — reversible, selective acetylcholinesterase inhibitor. **Dose 5 mg once daily at night, increased to 10 mg after 4–6 weeks**. Long half-life; once-daily dosing. Licensed across mild, moderate and severe AD.
4. **Rivastigmine** — pseudo-irreversible inhibitor of both **acetylcholinesterase and butyrylcholinesterase**. Available orally and as a **transdermal patch**, which markedly reduces gastrointestinal side effects. Also effective in **Parkinson's disease dementia and Lewy body dementia**, and is the best-evidence agent for **apathy** in PD.
5. **Galantamine** — acetylcholinesterase inhibitor with additional **allosteric modulation of nicotinic receptors**. Given twice daily or as a modified-release capsule.
6. **Tacrine** is of historical interest only — withdrawn because of **hepatotoxicity**.
7. **Efficacy:** meta-analyses of donepezil, galantamine and rivastigmine show small but consistent benefit on cognition and global function, possible delay in nursing-home placement, and a **several-month delay in progression**. Benefit is **marginal in many patients** and must be weighed against cost and adverse effects individually.
8. **Adverse effects** are predominantly cholinergic: nausea, vomiting, diarrhoea, anorexia, weight loss, abdominal cramps; **bradycardia, heart block and syncope**; insomnia and nightmares; muscle cramps; increased bronchial secretions; urinary frequency.
9. **Cautions:** sick sinus syndrome and conduction defects, active peptic ulcer, asthma/COPD, and concurrent use with beta-blockers. Note the interaction with **enzyme-inducing antiepileptics**, which increase the metabolism of donepezil and galantamine.

NMDA antagonist

10. **Memantine** is a low-affinity, uncompetitive **NMDA receptor antagonist** that blocks pathological tonic glutamate activation while preserving physiological signalling, reducing excitotoxicity.
11. Indicated in **moderate-to-severe AD**, either alone or added to a cholinesterase inhibitor. Titrated from 5 mg to 20 mg daily. Dose reduction is needed in renal impairment.
12. Side effects are usually mild: dizziness, headache, constipation, somnolence, hypertension and occasionally confusion or hallucinations.

Treatment of associated symptoms

13. **Depression** in AD is treated with SSRIs; sertraline has trial evidence. Tricyclics and drugs with anticholinergic action must be avoided as they worsen cognition.
14. **Behavioural and psychological symptoms:** non-pharmacological approaches first. **Atypical antipsychotics carry an FDA black-box warning** for increased mortality and cause weight gain; they are reserved for patients who are frankly psychotic or an immediate danger.
15. Every new or worsening behavioural symptom requires a search for a precipitant. **Empirical paracetamol** for undetected pain has shown efficacy in severely demented nursing-home residents.
16. **Donepezil does not treat agitation** in AD — a specific negative trial result worth quoting.

Disease-modifying therapy

17. **Anti-amyloid monoclonal antibodies** bind aggregated Aβ and promote microglial clearance of plaque, producing measurable amyloid clearance on PET and modest slowing of clinical decline.
18. **Indication:** confirmed amyloid pathology with **MCI or mild dementia due to AD only**. They are **not indicated in moderate or severe dementia**.
19. **Key toxicity is ARIA**, requiring baseline and serial MRI monitoring; anticoagulation and thrombolysis for stroke need special caution in treated patients.
20. Drugs that must be **avoided or deprescribed** in AD are as important as drugs prescribed: anticholinergics, benzodiazepines, sedative antihistamines, and other agents on the **Beers** and **STOPP/START** lists.

Latest Updates (2023 – Present)

- **Lecanemab (Leqembi):** approved July 2023; 10 mg/kg IV every two weeks for 18 months. FDA approved **four-weekly IV maintenance (January 2025)**, **subcutaneous maintenance (August 2025)** and a **subcutaneous starter dose (July 2026)**. Now approved in **53 countries**. Weekly subcutaneous injections take about 15 seconds and can be given at home.
- **Donanemab (Kisunla):** approved July 2024; monthly IV infusion with the option to **stop treatment once amyloid PET is negative** — a unique finite-duration regimen. A **modified, more gradual titration was approved in July 2025** (TRAILBLAZER-ALZ 6), reducing ARIA-E from about 24% to 14% at week 24. EU authorisation followed with stricter eligibility, enhanced monitoring and earlier discontinuation protocols.

- **ARIA management:** APOE genotyping is not mandatory in the US but is widely performed because ε4 homozygotes have substantially higher ARIA risk. ARIA can also occur spontaneously in AD with underlying CAA, so pre-treatment microhaemorrhage or superficial siderosis on MRI is a major caution.
- **Aducanumab** has been withdrawn from the market; it is now of historical interest only.
- A **Cochrane review (2026)** of 17 trials and 20,342 participants confirms the class effect is real but small in absolute terms — an important balancing point for a viva answer.
- **Pipeline:** anti-tau antisense oligonucleotides, **trontinemab** (brain-shuttle anti-amyloid antibody with much lower ARIA), semaglutide (EVOKE programme), and combination amyloid–tau strategies. No agent has yet been approved for moderate or advanced disease.
- **Indian context:** anti-amyloid antibodies are not in routine use — cost, the need for amyloid confirmation, and serial MRI monitoring are limiting. Cholinesterase inhibitors and memantine remain the practical mainstay under NPHCE-supported services.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Therapeutic aim	Symptomatic only	Symptomatic plus disease modification in early biomarker-confirmed disease
Approved drug classes	Cholinesterase inhibitors, memantine	Above plus anti-amyloid monoclonal antibodies (lecanemab, donanemab)
Route of administration	Oral (and rivastigmine patch)	Adds IV and, for lecanemab, subcutaneous home administration
Monitoring	Clinical response, pulse rate, weight	Adds serial MRI for ARIA and amyloid PET to decide on stopping donanemab
Aducanumab	Not discussed	Withdrawn from market

4. Biomarkers for Alzheimer's Dementia

Fifteen–Twenty High-Yield Points

Concept

1. A biomarker is an objectively measured indicator of a normal or pathological process. In AD they are needed because **clinical diagnosis alone is unreliable** and pathology begins **years to decades before symptoms**.
2. Current diagnostic criteria **require biomarkers reflecting the three core features of the disease: β-amyloid, phosphorylated tau, and neurodegeneration** — the basis of the **ATN classification**.
3. Biomarkers serve four purposes: **diagnosis, staging, prognosis, and monitoring treatment response** (including patient selection for anti-amyloid therapy).

Cerebrospinal fluid biomarkers

4. **CSF Aβ1-42 is reduced** in AD because amyloid is sequestered into plaques. The **Aβ42/40 ratio** is preferred because it corrects for individual differences in total amyloid production.
5. **CSF phosphorylated tau (p-tau181) and total tau are raised**, reflecting tangle formation and neuronal injury respectively. The combination of **low Aβ42 with high p-tau** is the classical AD signature.
6. A useful discriminator: in **normal pressure hydrocephalus** CSF Aβ42 is reduced as in AD, but **a rise in phospho-tau is seen only in AD** — a high-yield point for the NPH-versus-AD viva question.
7. **CSF neurofilament light (NfL)** is a marker of axonal degeneration; it is elevated but **non-specific**, rising in many neurodegenerative and inflammatory conditions.

Imaging biomarkers

8. **Amyloid PET** using fibrillar Aβ ligands demonstrates plaque burden *in vivo*. A significant plaque burden may be present in cognitively normal people, so a positive scan alone does not equal dementia.
9. **Tau PET** tracks tangle deposition, which follows Braak staging and **correlates far better with cognitive decline than amyloid does**.
10. **Structural MRI** shows **hippocampal and medial temporal lobe atrophy**, ventricular enlargement, and cortical thinning. Longitudinal studies show cognitively normal people with low CSF Aβ1-42 have **faster whole-brain and hippocampal volume loss**.
11. MRI also identifies co-pathology that alters the clinical threshold: **white matter hyperintensities, lacunes, microinfarcts, microbleeds and dilated perivascular spaces**. Microbleeds require **T2*-gradient echo** sequences; white matter lesions are best seen on **FLAIR**.
12. **Functional/molecular imaging for differential diagnosis:** dopamine transporter (loflurane) SPECT is **normal in AD but abnormal in Lewy body dementia**; FDG-PET shows temporoparietal and posterior cingulate hypometabolism in AD.

Blood-based biomarkers

13. Advances in assay sensitivity have made **blood-based biomarkers increasingly viable** — specifically **plasma Aβ42/40, phosphorylated tau, and neurofilament light** — with significant implications for facilitating early diagnosis.
14. Their attraction is practical: **low cost, minimally invasive, repeatable, and scalable** to primary care and to population screening in high-burden low-resource settings.

Genetic and other markers

15. **APOE ε4** is a susceptibility (risk) marker, not a diagnostic marker. It is **neither sensitive nor specific** and is **not recommended for screening**.
16. Deterministic mutations (**APP, PSEN1, PSEN2**) are diagnostic only in early-onset familial disease and mandate genetic counselling.
17. **Electrophysiological markers:** impaired LTP-like cortical plasticity on 5-Hz repetitive TMS has been described in amnestic MCI that converts to AD.
18. Caveats for the viva: biomarker positivity in a cognitively normal person indicates **preclinical disease, not dementia**; mixed pathology is common in the very old; and cut-offs vary between assays and platforms.

Latest Updates (2023 – Present)

- **Plasma p-tau217 is the single best-performing blood biomarker**, with diagnostic accuracy approaching CSF and amyloid PET; it is explicitly named in the 2024 criteria as an acceptable Core 1 marker (*Alzheimer's & Dementia* 2024).
- **FDA clearance, 16 May 2025:** the **Lumipulse G pTau217/β-Amyloid 1-42 Plasma Ratio** — the first blood test cleared to identify amyloid pathology — for symptomatic adults 55 years and older in specialist settings; **91.7% positive and 97.3% negative concordance** with PET/CSF.
- **2024 Revised Criteria biomarker architecture: Core 1** = amyloid PET, CSF Aβ42/40, CSF p-tau181/Aβ42, plasma p-tau217 — one abnormal result diagnoses AD. **Core 2** = tau PET, **MTBR-tau243**, p-tau205, non-phosphorylated mid-region tau — these stage the disease and give prognosis.
- The framework has been broadened from ATN to **AT1T2NISV**: A (amyloid), T1 (secreted phospho-tau), T2 (tau proteinopathy), N (neurodegeneration), I (inflammation — GFAP), S (α-synuclein co-pathology), V (vascular brain injury).

- **Alzheimer's Association appropriate-use and clinical practice guidance (2022, updated 2025)**: blood biomarkers should be used only in symptomatic patients, in specialised settings, with assays meeting pre-defined accuracy standards and **two-cutpoint reporting** that flags an intermediate zone for confirmatory testing.
- **Other cleared or marketed assays** include **PrecivityAD2** (UK) and **HISCL Aβ42/40** (Japan); ALZpath SIMOA, C2N and Janssen p-tau217 assays perform comparably in ADNI head-to-head comparisons.
- Biomarkers are now also **pharmacodynamic endpoints**: donanemab's label change was supported by preserved reduction in amyloid and **plasma p-tau217** despite the gentler titration.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Framework	ATN — amyloid, tau, neurodegeneration	Core 1 / Core 2, with full AT1T2NISV profile
Blood biomarkers	Emerging, "increasingly viable"	FDA-cleared and in routine specialist use
Best single marker	CSF Aβ42 with p-tau	Plasma p-tau217 (or the p-tau217/Aβ42 ratio)
Purpose	Diagnosis and research	Also selects patients for, and monitors response to, disease-modifying therapy
Diagnostic threshold	Clinical syndrome plus supportive biomarker	A single abnormal Core 1 biomarker is sufficient to diagnose AD

5. Emerging Biomarkers in Cognition

Fifteen–Twenty High-Yield Points

Rationale

1. Cognitive impairment in the elderly is usually the result of **mixed pathology**. More than 230 combinations of neuropathology have been described, and altered proteins occur even in cognitively normal older people.
2. Emerging biomarkers therefore aim to move beyond amyloid and tau to capture **the full range of contributing processes** — synucleinopathy, TDP-43, vascular injury, inflammation, and synaptic loss.
3. The four properties sought are: **early positivity, high specificity, minimal invasiveness, and low cost** enough for population use.

Protein aggregation markers

4. **Hyperphosphorylated tau, amyloid-β, α-synuclein and TDP-43** are the four principal aggregating proteins; all four are found in the brains of cognitively normal older people, which limits the specificity of any one marker.
5. **α-Synuclein seed amplification assay (SAA)** in CSF detects Lewy body pathology with high accuracy and is the key emerging marker for DLB and Parkinson's disease dementia; skin biopsy assays are in development.
6. **TDP-43**-related pathology (LATE — limbic-predominant age-related TDP-43 encephalopathy) is a common mimic of AD in the very old; no validated fluid biomarker yet exists, which is an important knowledge gap.

Neurodegeneration and glial markers

7. **Neurofilament light (NfL)** in CSF and plasma is a sensitive but **disease-non-specific** marker of axonal injury; it is most useful for tracking progression and treatment response rather than diagnosis.
8. **Glial fibrillary acidic protein (GFAP)** in plasma reflects reactive astrocytosis and rises very early — often before p-tau217 — making it a candidate marker of the earliest amyloid-associated response.
9. Inflammatory markers under study include **soluble TREM2, YKL-40, and IL-6**, reflecting the microglial and astrocytic activation that is a hallmark of brain ageing.

Synaptic and metabolic markers

10. **Neurogranin** (post-synaptic) and **SNAP-25** and **synaptotagmin-1** (pre-synaptic) in CSF index synaptic loss, which correlates with cognition better than plaque burden.
11. **SV2A PET** imaging quantifies synaptic density *in vivo* and is emerging as a sensitive measure of early degeneration.
12. Loss of **aerobic glycolysis** and altered brain energy metabolism are described hallmarks of brain ageing and can be imaged with FDG-PET.

Imaging and physiological markers

13. **Diffusion tensor imaging** demonstrates loss of white matter integrity following an **anterior-to-posterior gradient** — frontal lobes first, occipital last — consistent with the "last in, first out" model of myelination.
14. **Small vessel disease markers** (white matter hyperintensities on FLAIR, lacunes, microinfarcts, microbleeds on T2*GRE, dilated perivascular spaces) are increasingly recognised as major determinants of cognitive decline and disability in the older person.
15. **Retinal biomarkers** — optical coherence tomography measurement of retinal nerve fibre layer thinning — are an accessible surrogate of neuroaxonal loss already validated in demyelinating disease and under study in dementia.
16. **Electrophysiology:** impaired LTP-like plasticity on 5-Hz repetitive TMS distinguishes amnestic MCI that converts to AD; quantitative EEG connectivity measures are also being studied.

Clinical and digital markers

17. **Accelerated long-term forgetting** — normal learning with abnormally rapid loss over days to weeks — may be a clinical marker of presymptomatic disease.
18. **Gait speed and dual-task gait** are practical physical biomarkers: slowing of walking speed under a concurrent cognitive task predicts cognitive decline and is measurable with a stopwatch over 10 metres.
19. Digital biomarkers — passive smartphone and wearable data on typing, speech, sleep and mobility — are the most rapidly growing category and are attractive for community screening.
20. **Interpretation caveat:** no emerging biomarker should be used in isolation. Each must be interpreted against the clinical syndrome, education level, and the high probability of mixed pathology in old age.

Latest Updates (2023 – Present)

- The **2024 Revised Criteria** formally incorporate emerging markers by category: **N** (NfL, neurodegeneration), **I** (GFAP, inflammation), **S** (α-synuclein), **V** (vascular brain injury) — explicitly recognising co-pathology (*Alzheimer's & Dementia* 2024).
- **MTBR-tau243** (microtubule-binding region tau 243) has emerged as the leading fluid marker of **tau tangle burden**, correlating with tau PET, and is classified as a Core 2 biomarker for biological staging.
- **p-tau205** and non-phosphorylated mid-region tau fragments are additional Core 2 candidates that change later than p-tau217 and align more closely with symptom onset.
- Plasma **GFAP** and **NfL** are now widely used as secondary endpoints in trials; NfL reduction was the surrogate that supported **accelerated approval of tofersen in SOD1-ALS**, illustrating the regulatory power of a validated biomarker.

- Multiplex platforms (SIMOA, chemiluminescence, and immunoprecipitation mass spectrometry) allow simultaneous measurement of p-tau217, Aβ42/40, GFAP and NfL from a single tube of blood — the direction of travel for memory clinics.
- **Indian relevance:** plasma-based panels are the only realistic route to large-scale case-finding given that amyloid PET is available in only a handful of Indian centres; validation in Indian cohorts, including LASI-DAD participants, is a current research priority.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Scope of biomarkers	Amyloid, tau, neurodegeneration	Extended to inflammation, α-synuclein, vascular injury and synaptic loss
Tau markers	CSF total tau and p-tau181	p-tau217 for diagnosis; MTBR-tau243 and p-tau205 for staging
Astrocyte markers	Not described as biomarkers	Plasma GFAP is a validated early marker
α-Synuclein	Described as a pathological protein only	CSF seed amplification assay is a clinically usable diagnostic test
Sampling	CSF and PET	Multiplexed plasma panels from a single venous sample

6. Surgical Management of Parkinsonism

Fifteen–Twenty High-Yield Points

Rationale and patient selection

1. Surgery is considered when **motor complications become refractory to best medical therapy** — that is, disabling motor fluctuations or dyskinesia despite optimised levodopa and adjuncts.
2. The essential principle is that **only levodopa-responsive symptoms improve after surgery**. A good levodopa response is the single best predictor of surgical benefit; levodopa-unresponsive axial features, gait freezing, falls and dysautonomia do not improve.
3. Candidates must be **cognitively intact**. Dementia, active psychiatric illness (especially depression with suicidality) and severe comorbidity are limitations.
4. Diagnosis must be secure — **Parkinson-plus syndromes respond poorly and are a contraindication**. The **Queen Square Brain Bank criteria** should be satisfied.

Deep brain stimulation — the standard operation

5. **Bilateral deep brain stimulation (DBS) of the subthalamic nucleus (STN) or globus pallidus interna (GPi)** produces **sustained improvement in motor function**, especially in symptoms that respond to levodopa, and **reduces drug-induced involuntary movements**.
6. **STN stimulation** allows the greatest reduction in dopaminergic drug dose (typically 40–60%), which indirectly reduces dyskinesia; **GPi stimulation** has a more direct antidyskinetic effect and is often preferred where cognition or mood is fragile.
7. The **ventral intermediate nucleus of the thalamus (VIM)** is the target when **tremor is the dominant and disabling symptom**, including in essential tremor. It does not help bradykinesia or rigidity.
8. Mechanism: high-frequency stimulation functionally inhibits or desynchronises pathologically synchronised basal ganglia output, normalising the abnormal beta-band oscillations in the motor circuit.

Age and outcomes

9. The textbook position is that **DBS is not currently used in elderly people with PD**. However, recent observational studies found that **efficacy in patients over 70 was similar to that in younger patients, and the incidence of adverse effects did not increase with age**.
10. Long-term follow-up shows that **disability continues to progress after DBS**, probably because the underlying neurodegeneration continues — DBS is symptomatic, not disease-modifying.

Complications

11. **Procedure-related:** intracranial haemorrhage, stroke, seizure and infection at the implant site; these relate to the intracranial procedure itself.
12. **Hardware-related:** lead migration or fracture, extension wire erosion, device infection, and the need for battery replacement.
13. **Stimulation-related:** dysarthria, paraesthesiae, eyelid-opening apraxia, gait and balance deterioration, and weight gain.
14. **Neuropsychiatric:** there are long-standing concerns about long-term safety, with **risks of depression and suicide**, as well as apathy, impulsivity and, in vulnerable patients, cognitive decline.

Lesional and other surgical procedures

15. **Lesional surgery** — thalamotomy, pallidotomy and subthalamotomy — preceded DBS and remains an option where DBS is unaffordable or follow-up is impractical. It is usually performed **unilaterally**, since bilateral lesions carry a high risk of dysarthria and cognitive decline.
16. **Gamma knife radiosurgery** and **MR-guided focused ultrasound thalamotomy** are incisionless alternatives, described in the textbook as options for severe medication-refractory tremor.
17. DBS is also used for other movement disorders in the elderly: **essential tremor** (VIM), **refractory dystonia** (particularly effective in primary dystonia), and occasionally **tardive dyskinesia**.
18. Continuous-infusion therapies (intrajejunal levodopa gel via PEG-J, apomorphine) are the main **non-DBS device-aided** alternatives for advanced disease and are relevant when DBS is contraindicated.
19. Rehabilitation must continue after surgery. Functional rehabilitation preserves motor function, and sessions are best timed to the **peak effect of levodopa**.
20. Multidisciplinary assessment before surgery must include a movement disorder neurologist, neurosurgeon, neuropsychologist and psychiatrist, with a formal **levodopa challenge** (150–250 mg in the fasting state, with assessment every 30 minutes for 2–3 hours).

Latest Updates (2023 – Present)

- **Adaptive (closed-loop) DBS was approved by the FDA in February 2025** — a Medtronic software update based on the **ADAPT-PD** randomised crossover trial. The device senses **local field potentials (beta oscillations)** and adjusts stimulation in real time, improving symptom control with lower energy use and fewer stimulation-induced side effects.
- **Bilateral MR-guided high-intensity focused ultrasound was approved in 2025** (having been unilateral-only since 2017). Approved targets now include the **VIM thalamus, GPi and the pallidothalamic tract**, with the STN under

investigation (*Current Neurology and Neuroscience Reports* 2026).

- **Image-guided and remote programming** shorten programming time while matching motor outcomes and expand access for patients who cannot travel — directly relevant to Indian practice, where DBS centres are concentrated in metros.
- Age is no longer treated as an absolute barrier: long-term series with up to seven years' follow-up show comparable outcomes in older and younger cohorts, and current practice selects on **biological rather than chronological age** (*J Neurosurg* 2018; *JAMA Neurol* 2015).
- **Regenerative surgery: bemdaneprocel** (stem cell-derived dopaminergic neuron transplantation) entered a Phase 3 trial (exPDite-2) in 2025, and **AB-1005 GDNF gene therapy** received FDA RMAT designation in February 2025 — the first credible restorative surgical strategies.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
DBS in the elderly	"Not currently used in elderly people with PD"	Used routinely in selected patients over 70; efficacy and safety comparable to younger patients
Stimulation mode	Continuous, fixed-parameter (open-loop)	Adaptive closed-loop DBS approved February 2025
Focused ultrasound	Reserved for severe refractory tremor, unilateral	Bilateral approval 2025; targets extended to GPi and pallidothalamic tract
Programming	In-person, iterative	Image-guided and remote programming
Restorative surgery	Not available	Cell therapy and gene therapy in Phase 2–3 trials

7. Recent Advances in the Management of Parkinsonism

Fifteen–Twenty High-Yield Points

Baseline — established management

1. **Levodopa remains the main and often the only treatment for PD in the elderly.** It is combined with a peripheral decarboxylase inhibitor — **Madopar (levodopa + benserazide)** or **Sinemet (carbidopa + levodopa)**.
2. Start low and increase very gradually; most patients are controlled on **300–600 mg/day in the first years**, given three or four times daily, preferably 30 minutes before meals. **Dispersible Madopar** achieves faster peak levels and is used for early-morning akinesia.
3. **Dopamine agonists, anticholinergics and (largely) MAO-B inhibitors are avoided in older patients** — agonists because of hallucinations, somnolence, impulse-control disorders and orthostatic hypotension; anticholinergics such as trihexyphenidyl because of confusion, urinary retention and glaucoma.
4. **COMT inhibitors (entacapone, tolcapone)** prolong the levodopa effect and are useful in older patients with motor fluctuations or dyskinesia. Tolcapone requires monitoring for hepatotoxicity.
5. Non-motor symptoms have specific best-evidence treatments: **venlafaxine** for depression, **clozapine or pimavanserin** for hallucinations, **rivastigmine** for dementia and apathy, **droxidopa/midodrine/fludrocortisone** for orthostatic hypotension, **domperidone** for nausea, **botulinum toxin** for severe drooling, and **macrogol with fibre and hydration** for constipation.
6. Clozapine requires blood count monitoring and must be **stopped permanently if the neutrophil count falls below 1500/mm^3**. Domperidone requires ECG monitoring for QT prolongation.
7. Non-pharmacological care is integral: **early functional rehabilitation timed to peak levodopa effect**, speech therapy for dysarthria and drooling, swallowing assessment, home support, and structured patient and caregiver education.

Advances in drug delivery

8. The central therapeutic problem in advanced PD is **pulsatile stimulation** of striatal dopamine receptors by short-acting oral levodopa. Every recent advance addresses this by achieving **continuous dopaminergic stimulation**.
9. **Extended-release oral levodopa formulations** reduce dosing frequency and smooth plasma levels.
10. **Continuous subcutaneous infusion** of levodopa prodrugs and of apomorphine delivers 24-hour dopaminergic stimulation without the need for surgery.
11. **Intrajejunal levodopa-carbidopa gel** via PEG-J remains a standard device-aided therapy for advanced disease.

Advances in device therapy

12. **Deep brain stimulation of STN or GPi** gives sustained improvement in levodopa-responsive symptoms and reduces dyskinesia; recent observational data show equal efficacy and no excess adverse events in patients over 70.
13. **MR-guided focused ultrasound** and **gamma knife** offer incisionless lesioning for medication-refractory tremor.
14. Technology in PD — wearable sensors and digital monitoring — is an established area of development for objective measurement of fluctuations.

Advances in diagnosis and disease modification

15. **Dopamine transporter (loflurane) SPECT** separates degenerative parkinsonism (abnormal) from drug-induced parkinsonism, vascular parkinsonism, essential tremor and AD (all normal).
16. No treatment has yet been shown to be disease-modifying. Selegiline and rasagiline were proposed for neuroprotection but this remains unproven.
17. Strategies "beyond dopamine" — targeting α-synuclein aggregation, LRRK2, GBA and neuroinflammation — are the main direction of current research.
18. Exercise is an effective intervention in PD and is included in all recent position statements on exercise prescription in older adults.

Latest Updates (2023 – Present)

- **New drug delivery approvals: Crexont (IPX203)**, an extended-release oral carbidopa/levodopa, approved **August 2024**; **Vyalev/Produodopa (foscarbidopa/foslevodopa)**, the first **24-hour continuous subcutaneous levodopa infusion**, approved **October 2024**; **Onapgo** (subcutaneous apomorphine infusion) for OFF episodes, approved **February 2025**. **ND0612** (continuous subcutaneous levodopa/carbidopa) was resubmitted to the FDA in 2025.
- **Adaptive DBS approved February 2025** (ADAPT-PD trial) — senses beta-band local field potentials and titrates stimulation in real time. **Bilateral focused ultrasound approved 2025**, with GPi and pallidothalamic tract added as targets.
- **Tavapadon**, a selective **D1/D5 partial agonist**, completed the Phase 3 TEMPO programme with significant MDS-UPDRS improvement and increased ON time without troublesome dyskinesia; NDA filed September 2025, decision expected Q3 2026. If approved it would be the first new oral dopamine agonist in over a decade, and its D1/D5 selectivity may avoid the D2/D3-mediated impulse-control and somnolence problems that make current agonists unsuitable for older patients.
- **Safety alert (March 2026):** the FDA required a new label warning across **all carbidopa/levodopa products** (including Sinemet, Rytary, Stalevo, Crexont and Vyalev) for **vitamin B6 deficiency and seizures** — a highly

examinable, practice-changing point. High-dose levodopa consumes pyridoxine through metabolism, and B6 status should be checked in patients on high total daily doses or continuous infusion.

- **Disease modification remains elusive. Prasinezumab** (anti-α-synuclein) entered a 900-patient Phase 3 trial in November 2025. Two candidates failed in the first half of 2026 — the LRRK2 inhibitor **BIIB122** and the GCase modulator **BIA 28-6156** — and were discontinued.
- **Restorative therapy: bemdaneprocel** (stem cell-derived dopaminergic neurons) entered Phase 3 (exPDite-2) in 2025; **AB-1005** GDNF gene therapy received RMAT designation.
- **Lifestyle as therapy:** a 2026 *Lancet Neurology* review positions structured exercise and lifestyle intervention as contributors to both symptom management and possible disease modification.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Continuous dopaminergic delivery	Intrajejunal gel; subcutaneous apomorphine boluses	24-hour subcutaneous foscarbidopa/foslevodopa and apomorphine infusion; extended-release oral IPX203
Dopamine agonists in the elderly	Avoided altogether	Still avoided, but D1/D5-selective tavapadon may change this
DBS	Fixed continuous stimulation; not for the elderly	Adaptive closed-loop stimulation; age is not a bar
Levodopa safety	Nausea, hypotension, psychiatric effects, dyskinesia	Adds FDA warning (2026) on vitamin B6 deficiency and seizures
Disease modification	Unproven neuroprotection with MAO-B inhibitors	α-Synuclein antibodies, cell and gene therapy in Phase 2–3; still nothing approved

8. Management of Motor Fluctuations in Parkinson's Disease

Fifteen–Twenty High-Yield Points

Definition and types

1. **Motor fluctuations** are predictable or unpredictable changes in motor performance in relation to levodopa dosing, appearing after several years of treatment. They occur together with **involuntary movements — chorea, athetosis and dystonia**.
2. **Wearing-off** (end-of-dose deterioration) is the earliest and commonest form — return of parkinsonian symptoms before the next dose is due.
3. **Delayed-on** and **dose failure (no-on)** result from impaired gastric emptying and competition with dietary protein for absorption.
4. **On-off phenomenon** is abrupt, unpredictable switching between mobility and immobility, unrelated to dose timing.
5. **Early-morning akinesia** and **early-morning/off-period dystonia** (typically painful foot dystonia) reflect overnight levodopa washout.
6. **Freezing of gait** may be off-period (levodopa-responsive) or on-period (levodopa-resistant); the distinction determines whether more drug will help.
7. Dyskinesias are classified by their timing: **peak-dose dyskinesia** (commonest, choreiform), **diphasic dyskinesia** (at the beginning and end of dose, often dystonic and painful in the legs), and **off-period dystonia**.
8. **Non-motor fluctuations** parallel the motor ones — anxiety, panic, pain, sweating, akathisia, breathlessness and mood swings in the off state — and are frequently missed.

Mechanism

9. Fluctuations arise from a **narrowing therapeutic window**: progressive loss of nigrostriatal terminals removes the buffering capacity to store and release dopamine, so the striatum becomes directly dependent on the short plasma half-life of levodopa. This **pulsatile stimulation** induces post-synaptic changes that generate dyskinesia.

Assessment

10. Assessment begins with a **patient-completed diary** recording on time, off time, and dyskinesia against each dose, together with meal timing and constipation.
11. Exclude **malabsorption and delayed gastric emptying**, including *Helicobacter pylori* infection and severe constipation, before concluding that the disease has advanced. Also review any newly added dopamine-blocking drug.

Pharmacological management

12. **First step — manipulate levodopa:** revise the timing of administration, fractionate the dose (smaller doses given more frequently), and give doses 30 minutes before meals to avoid protein competition.
13. **Dispersible levodopa** (dispersible Madopar) reaches peak plasma concentration faster and is used as a rescue dose for early-morning akinesia and delayed-on, allowing the standard dose to be taken at the same time.
14. **COMT inhibitors — entacapone and tolcapone — decrease dopamine degradation, increasing and prolonging the effect of levodopa, and are specifically useful in older patients with motor fluctuations and/or levodopa-induced dyskinesia.** Entacapone 200 mg is given with each levodopa dose.
15. Adding a **controlled-release levodopa preparation at night** helps nocturnal akinesia and early-morning off dystonia.
16. **Amantadine** is the best-established antidyskinetic drug, acting through NMDA antagonism, but must be used cautiously in the elderly because it causes **delirium, hallucinations and livedo reticularis** and is renally excreted, requiring dose reduction in renal impairment.
17. Dopamine agonists and MAO-B inhibitors smooth fluctuations in younger patients but are generally avoided in the elderly because of neuropsychiatric adverse effects.
18. **Reducing the individual levodopa dose while increasing frequency** is the standard manoeuvre for peak-dose dyskinesia; diphasic dyskinesia, paradoxically, may improve by increasing the dose.

Device-aided and surgical management

19. **Continuous dopaminergic delivery** is the definitive answer to refractory fluctuations: intrajejunal levodopa-carbidopa gel via PEG-J, or continuous subcutaneous apomorphine infusion.
20. **Bilateral DBS of STN or GPi** is offered to cognitively intact patients with **severe disability from motor complications refractory to best medical therapy**; it gives sustained improvement in levodopa-responsive symptoms and reduces drug-induced involuntary movements.

Latest Updates (2023 – Present)

- **Vyalev / Produodopa (foscarbidopa/foslevodopa)**, approved **October 2024**, is the first 24-hour continuous subcutaneous levodopa infusion for advanced motor fluctuations. It gives the benefits of intrajejunal gel **without a PEG-J**, an important advance for frail older patients in whom endoscopic gastrostomy is high risk. Infusion-site reactions are the main limitation.
- **Onapgo** (continuous subcutaneous apomorphine infusion) was approved in **February 2025** for OFF episodes, adding to the intermittent apomorphine pen.
- **Crexont (IPX203)**, approved **August 2024**, combines immediate-release granules with extended-release beads to give longer good ON time with fewer daily doses.

- **Adaptive DBS (approved February 2025, ADAPT-PD)** is specifically aimed at fluctuations: it senses beta oscillations and increases stimulation during OFF periods and reduces it during ON periods, thereby narrowing the swing between under- and over-stimulation.
- A 2026 review of advanced therapies confirms that subcutaneous foscarbidopa/foslevodopa and apomorphine both **reduce OFF time and increase "good ON time"**, with infusion-site reactions the principal concern (*Current Neurology and Neuroscience Reports* 2026).
- **Tavapadon** (D1/D5 partial agonist) showed increased ON time **without troublesome dyskinesia** in the Phase 3 TEMPO programme in patients with motor fluctuations; FDA decision expected in 2026.
- **FDA warning, March 2026:** all carbidopa/levodopa products now carry a label warning for **vitamin B6 deficiency and seizures** — particularly relevant to patients on high-dose or continuous-infusion regimens for fluctuations.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
First-line manoeuvre	Fractionate levodopa; add COMT inhibitor	Unchanged — still the correct first step
Continuous delivery	Intrajejunal gel (needs PEG-J) or apomorphine boluses	24-hour subcutaneous foscarbidopa/foslevodopa and apomorphine infusion — no gastrostomy required
Oral long-acting levodopa	Controlled-release tablets	IPX203 (Crexont) dual-release formulation
DBS for fluctuations	Fixed-parameter stimulation	Closed-loop adaptive stimulation responsive to ON/OFF state
Monitoring	Patient diary	Wearable sensors giving objective ON/OFF and dyskinesia data

9. Parkinsonism-Plus Syndromes

Fifteen–Twenty High-Yield Points

Definition and approach

1. **Parkinsonism-plus (atypical parkinsonian) syndromes** are neurodegenerative diseases in which an extrapyramidal syndrome is accompanied by additional features not seen in idiopathic PD, and in which the **response to levodopa is poor or absent**.
2. The general red flags for atypical parkinsonism are: **early falls and postural instability, early severe autonomic failure, early dementia, supranuclear gaze palsy, cerebellar or pyramidal signs, symmetrical onset, absence of rest tremor, and rapid progression**. Most of these appear in the **exclusion criteria of the Queen Square Brain Bank criteria** for PD.
3. Response to levodopa is assessed by giving **150–250 mg of levodopa with a decarboxylase inhibitor to a fasting patient** and assessing tremor, rigidity and limb akinesia every 30 minutes for two to three hours. A negative response to large doses of levodopa (malabsorption excluded) is an exclusion criterion for PD.

Progressive supranuclear palsy (PSP)

4. PSP is **frequently misdiagnosed as PD**. It is a **4-repeat tauopathy** characterised by an extrapyramidal syndrome with complex eye movement dysfunction.
5. **Tremor is infrequent and rigidity predominates in the spine (axial rigidity)**, with neck dystonia (retrocollis).
6. **Postural and gait abnormalities occur early and cause repeated falls**, aggravated by attentional and visual problems. Falls within the first year are a classic examination point.
7. **Eye movement problems:** inability to shift gaze voluntarily downward, **impaired (slowed) saccades**, and difficulty controlling the eyelids (apraxia of lid opening, blepharospasm). **Limitation of vertical gaze** is the cardinal sign.
8. Motor symptoms are **unresponsive to levodopa**. As the disease progresses, personality change, dementia and swallowing problems are common.
9. **MRI shows midbrain atrophy**, and **ocular electrophysiology (impaired saccades)** also helps recognise the disease.

Multiple system atrophy (MSA)

10. MSA is **very rarely observed as very late-onset parkinsonism**. It is an α-synucleinopathy with glial cytoplasmic inclusions.
11. The defining feature is **severe dysautonomia early in the course of parkinsonism** — orthostatic hypotension, urinary disorder, sexual dysfunction and gastrointestinal symptoms.
12. **Pyramidal or cerebellar signs** accompany the parkinsonism. Subtypes are **MSA-P** (parkinsonian predominant) and **MSA-C** (cerebellar predominant, with dysmetria, scanning speech, saccadic abnormalities and truncal ataxia).

Other syndromes in the differential

13. **Corticobasal degeneration: dystonia, myoclonus, cortical sensory loss and alien (foreign) hand syndrome**, typically markedly asymmetrical.
14. **Dementia with Lewy bodies:** dementia occurring **a few months before or after** the onset of parkinsonism, with **visual hallucinations, fluctuating alertness and severe adverse reactions to neuroleptics**. By contrast, PD dementia occurs in advanced stages after several years of PD.
15. **Drug-induced parkinsonism:** exposure to neuroleptics (present or past) must be sought carefully by interviewing patients, proxies, physicians and pharmacists. It is **symmetrical, tremor-poor, and loflurane SPECT is normal**. Neuroleptic treatment at onset of symptoms is a Queen Square exclusion criterion.
16. **Vascular (cerebrovascular) parkinsonism:** multiple infarcts, usually a **multilacunar state**, with subcortical dementia and pseudobulbar state; posture, gait and swallowing problems are prominent, tremor is infrequent and levodopa response is poor. **Onset or worsening of extrapyramidal signs within one month of a stroke strongly supports the diagnosis.** MRI shows multiple lacunae and/or severe leukoaraiosis.
17. **Normal pressure hydrocephalus:** gait disturbance, dementia and urinary incontinence, with short shuffling steps but **no tremor or rigidity**; imaging shows marked ventricular enlargement out of proportion to cortical atrophy.
18. Other rarer causes: **Huntington's disease** (chorea, familial), **Wilson's disease** (liver disease, Kayser-Fleischer ring, psychiatric symptoms), and toxic, post-encephalitic and repeated head trauma-related parkinsonism.
19. About **15% of patients with Alzheimer's disease develop extrapyramidal signs**; these are usually mild, and their presence at diagnosis predicts more rapid decline. **Loflurane SPECT is normal in AD and abnormal in DLB**, which is the key discriminator.
20. **Management is largely supportive:** a levodopa trial is still justified (a minority of MSA and PSP patients show partial benefit), with physiotherapy, speech and swallow therapy, falls prevention, treatment of orthostatic hypotension, and early advance care planning. Prognosis is substantially worse than PD, with median survival of about 6–9 years.

Latest Updates (2023 – Present)

- **MDS diagnostic criteria for MSA (2022)** introduced the categories **clinically established MSA, clinically probable MSA** and the research category **prodromal MSA**, and added MRI markers as supportive features — a substantial change from the older Gilman consensus criteria.
- **MDS-PSP criteria (Höglinger et al.)** define multiple clinical phenotypes beyond classical Richardson syndrome —

PSP-P (parkinsonism), **PSP-PGF** (progressive gait freezing), **PSP-CBS**, **PSP-SL** (speech/language) and **PSP-F** (frontal) — explaining why many cases are missed early.

- **α-Synuclein seed amplification assay (SAA)** in CSF now distinguishes synucleinopathies (MSA, DLB, PD) from tauopathies (PSP, CBD) with high accuracy, and is entering clinical use.
- **Plasma and CSF neurofilament light (NfL)** is markedly higher in atypical parkinsonism than in PD and is the most useful single fluid biomarker for separating PD from Parkinson-plus syndromes at an early stage.
- **Therapeutic trials:** anti-tau strategies in PSP and anti-α-synuclein approaches in MSA have so far been negative; management remains symptomatic. Droxidopa and midodrine for neurogenic orthostatic hypotension in MSA are the main pharmacological advances.
- The **2024 Revised AD Criteria** include **S (α-synuclein)** as a co-pathology biomarker category, reflecting how often synucleinopathy and AD coexist in the older brain.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Diagnostic criteria	Descriptive clinical features	MDS criteria for PSP (multiple phenotypes) and MSA (2022, with prodromal category)
Biomarkers	Imaging and clinical assessment only	CSF α-synuclein SAA and NfL differentiate PD from Parkinson-plus
PSP phenotype	Classical Richardson syndrome only	Recognised as a spectrum including PSP-P, PSP-PGF, PSP-CBS
MSA autonomic therapy	Midodrine, fludrocortisone	Droxidopa is best-evidence therapy where available

10. Pathognomonic MRI Findings in Progressive Supranuclear Palsy and Multiple System Atrophy

Fifteen–Twenty High-Yield Points

General principle

1. Structural MRI in parkinsonism serves two purposes: **to exclude secondary causes** (vascular disease, hydrocephalus, tumour) and **to identify positive imaging signatures of atypical parkinsonism**. MRI is normal in idiopathic PD.
2. The textbook states directly that **a typical pattern of MRI imaging has been described in progressive supranuclear palsy and relates to midbrain atrophy**, and illustrates the **convex-to-concave change in the superior midbrain profile**.

PSP — midbrain signs

3. **The normal superior margin of the midbrain is convex. In PSP it becomes flat and then concave** — this single observation on a midsagittal T1 image is the basis of most PSP signs.
4. **Hummingbird (penguin) sign** — midsagittal T1: selective atrophy of the **rostral midbrain tegmentum** with a **relatively preserved pons**. The atrophic midbrain forms the bird's head and beak; the normal pons forms the body. **Specificity about 99.5%, sensitivity about 51.6%**.
5. **Morning glory flower sign** — axial T2: **concavity of the lateral margin of the midbrain tegmentum**, with relative sparing of the tectum and cerebral peduncles, resembling the flower.
6. **Mickey Mouse sign** — axial image at midbrain level where the atrophic tegmentum and preserved cerebral peduncles produce the outline of a mouse's head and ears.
7. Supporting indirect measures: **reduced anteroposterior midbrain diameter**, **third ventricular dilatation**, and **atrophy of the superior cerebellar peduncle (SCP)** — SCP atrophy is relatively specific for PSP.

PSP — quantitative measures

8. **Midbrain-to-pons area ratio (M/P)** on midsagittal T1 is reduced in PSP; a ratio below approximately **0.52** is widely used as a threshold.
9. **Magnetic Resonance Parkinsonism Index (MRPI)** = (pons area / midbrain area) × (middle cerebellar peduncle width / superior cerebellar peduncle width). It is **increased in PSP** and has better accuracy than any single measure. **MRPI 2.0** adds the third ventricle width-to-frontal horn width ratio and improves detection of PSP-P.
10. **Important caveat:** a normal MRI does not exclude PSP. Atrophy develops gradually, so the hummingbird sign and significant midbrain atrophy may be absent early in the disease.

MSA — infratentorial signs (MSA-C)

11. **Hot cross bun sign** — axial T2 or proton-density image of the pons showing a **cruciform hyperintensity**. It results from selective degeneration of **transverse pontocerebellar fibres and pontine neurons with preservation of the corticospinal tracts** (which form the vertical limb) and the tegmentum.
12. **Atrophy of the pons, cerebellum and middle cerebellar peduncles**, best seen on midsagittal T1 — the imaging correlate of **olivopontocerebellar atrophy**.
13. **Middle cerebellar peduncle (MCP) T2 hyperintensity**, and a reduced **MCP width** and **MCP/SCP ratio**, are useful quantitative markers distinguishing MSA from PSP.

MSA — supratentorial signs (MSA-P)

14. **Putaminal rim sign** — a **hyperintense rim along the dorsolateral border of the putamen** on T2/FLAIR, thought to represent gliosis and microglial activation.
15. **Putaminal atrophy** and **putaminal T2 hypointensity** (from iron deposition), best appreciated on axial T2 and susceptibility-weighted imaging.
16. **Diagnostic performance:** these putaminal signs have **high specificity (87–100%) but widely variable sensitivity** — 38–100% for putaminal T2 hypointensity and 56–90% for the hyperintense dorsolateral rim.
17. **Increased putaminal diffusivity** on diffusion-weighted imaging (raised apparent diffusion coefficient / mean diffusivity) is directly visible and is one of the most useful practical signs for separating MSA from PD and PSP.

Comparison and cautions

18. **The essential contrast for the examiner:** in **PSP the midbrain atrophies and the pons is spared**; in **MSA the pons and cerebellum atrophy and the midbrain is relatively spared**. On the same midsagittal image, PD shows neither.
19. The hot cross bun sign is **not entirely specific to MSA** — it is also described in spinocerebellar ataxias (especially SCA-2, 3 and 7), variant CJD and some parainfectious pontine lesions, so it must be interpreted with the clinical picture.
20. Both PSP and MSA signs have **high specificity but modest sensitivity**: they confirm the diagnosis when present but never exclude it when absent. The diagnosis remains clinical, with MRI as supportive evidence.

Latest Updates (2023 – Present)

- The **MDS criteria for MSA (2022)** formally include MRI markers — putaminal atrophy, MCP atrophy, pontine atrophy, hot cross bun sign and putaminal rim sign — as supportive features for "clinically established" and "clinically probable" MSA, giving these signs formal diagnostic status for the first time.
- **Automated MRPI calculation** and machine-learning-based classifiers applied to routine T1 sequences are being

validated to reduce operator dependence and to detect PSP before the hummingbird sign appears.

- A systematic review and meta-analysis of **MR planimetric measurements** confirms that **MRPI and the M/P ratio outperform qualitative signs** in differentiating PSP from MSA (*Parkinsonism and Related Disorders*; *Cureus* 2025).
- **Susceptibility-weighted imaging (SWI)** and **quantitative susceptibility mapping** demonstrate loss of **dorsal nigral hyperintensity ("swallow-tail sign")** in all degenerative parkinsonisms including PD, and increased putaminal and nigral iron in MSA-P — adding a further layer of differentiation.
- **Neuromelanin-sensitive MRI** of the substantia nigra and locus coeruleus is emerging as a marker of nigral degeneration usable at 3T without contrast.
- **Fluid biomarkers now complement imaging:** raised NfL supports atypical parkinsonism, and CSF **α-synuclein SAA is positive in MSA but negative in PSP**, allowing a biochemical separation of synucleinopathy from tauopathy that imaging alone cannot achieve.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
PSP imaging	Midbrain atrophy described qualitatively	Quantified by M/P ratio and MRPI/MRPI 2.0, with automated calculation
MSA imaging	Not described in detail	Hot cross bun and putaminal rim signs are formal supportive criteria (MDS 2022)
Sequences used	T1, T2, FLAIR	Adds DWI/ADC, SWI, quantitative susceptibility mapping, neuromelanin MRI
Role of imaging	Supportive	Supportive, and now combined with CSF α-synuclein SAA and NfL

11. Confusion States in the Elderly — Investigation and Management

Fifteen–Twenty High-Yield Points

Definition and classification

1. Confusion in an older patient is a **presentation, not a diagnosis**. Disorders causing confusion fall into three groups: **(i) acute disorders related to acute illness, drugs and environment (delirium); (ii) slowly progressive cognitive impairment (dementia); (iii) impaired cognition associated with affective disorders and psychoses**.
2. Cognitive impairment in the elderly **usually results from multiple interacting processes rather than a single cause**. Old age alone never causes dysfunctional cognitive impairment.
3. **Delirium** is an acute or subacute alteration in mental status. Prevalence is about **15% on admission** in hospitalised older patients and incidence during admission may be up to **one-third**. It may persist for days to weeks and is therefore common in post-acute care.

Diagnostic criteria

4. The key features of delirium are: **disturbance of consciousness** (reduced clarity of awareness with reduced ability to focus, sustain or shift attention) and **a change in cognition not better accounted for by dementia**, developing over hours to days and **fluctuating**, with evidence of a physical cause.
5. The **Confusion Assessment Method (CAM)** requires **features 1 and 2 plus either 3 or 4**: (1) **acute onset and fluctuating course**, (2) **inattention**, (3) **disorganised thinking**, (4) **altered level of consciousness**. Level of consciousness is graded alert, vigilant, lethargic, stupor or coma.
6. Delirium is subtyped as **hyperalert (hyperactive), hypoalert (hypoactive) or mixed**. The **hypoactive form is commoner in the elderly and is the form most often missed**.
7. The **4AT** is a rapid screening tool with **sensitivity 0.88 and specificity 0.88** in people aged 65 and over across emergency, medical, stroke and surgical settings.

The three key questions and causes

8. Three questions guide the diagnosis: **Is the onset acute? Are physical factors contributing? Are psychological factors contributing?**
9. **Common causes of delirium:** metabolic disorders (hypoxia, hypercarbia, hypo- or hyperglycaemia, hyponatraemia, azotaemia); **infections**; reduced cardiac output (dehydration, acute blood loss, myocardial infarction, heart failure); **small cortical stroke**; **drugs** and drug intoxication including alcohol; hypo- or hyperthermia; acute psychoses; **transfer to unfamiliar surroundings**, especially where sensory input is reduced; and, easily forgotten, **faecal impaction and urinary retention**.
10. Anaesthesia poses a special risk. Predisposing factors include impaired sensory function and sensory deprivation, sleep deprivation, immobilisation and transfer to an unfamiliar environment.

Investigation

11. Assessment comprises: **focused history and physical examination** (including assessment for delirium and depression and identification of comorbidities such as sensory impairment), **functional status assessment**, **mental status examination**, and **selected laboratory studies to exclude reversible causes**.
12. A **collateral history** is mandatory to establish the pre-morbid baseline and the tempo of change.
13. **Baseline investigations:** full blood count, urea and electrolytes, calcium, glucose, liver and renal function, thyroid function, vitamin B12, CRP, urinalysis and culture, chest radiograph, ECG, and pulse oximetry. Blood cultures if febrile.
14. **A full drug review is the single highest-yield investigation.** Every medication that may be worsening cognition should be stopped or avoided.
15. **Brain imaging should not be done automatically in every patient with cognitive impairment.** CT is indicated for focal neurological signs, head injury, anticoagulation, suspected subdural haematoma, or an unexplained failure to improve.
16. **Lumbar puncture** is reserved for suspected CNS infection; **EEG** for suspected non-convulsive status epilepticus, which in the elderly may present purely as confusion.

Management

17. **Treat the underlying cause** and correct every contributing factor simultaneously — hypoxia, sepsis, dehydration, pain, constipation, urinary retention, and drug toxicity.
18. **Non-pharmacological measures come first:** preparing older patients for changes in location, placing familiar objects in the surroundings, and maximising sensory input with adequate lighting, clocks and calendars. Restore spectacles and hearing aids; encourage early mobilisation; promote normal sleep-wake cycles; involve family.
19. **Avoid physical restraints** in hospitalised older patients with delirium or dementia unless essential for safety and medical care. **Avoid psychoactive drugs where they can be avoided.**
20. If drug treatment is unavoidable because of danger to self or others, use the **lowest effective dose of a single antipsychotic for the shortest possible time**, with regular review. **Benzodiazepines are reserved for alcohol or benzodiazepine withdrawal**, where they are the treatment of choice. **Melatonin or melatonin receptor agonists** reduce the prevalence of delirium and length of ICU stay and improve sleep quality.

Latest Updates (2023 – Present)

- **DSM-5-TR and ICD-11** classify delirium under neurocognitive disorders; **attention and awareness** are the core deficits, and the term "clouding of consciousness" has been retired.
- **The 4AT has largely replaced the CAM for routine screening** in acute care because it requires no special training and can be completed in under two minutes, including in patients who are drowsy or unable to cooperate. The **CAM-ICU** remains standard in intensive care.
- **ESAIC guidance (updated 2024)** recommends **against benzodiazepines** for treating postoperative delirium, suggests **low-dose haloperidol** only if non-pharmacological measures fail, and suggests **dexmedetomidine** for delirium after cardiac surgery (*European Journal of Anaesthesiology* 2024).
- Antipsychotics do not shorten delirium duration or reduce mortality; current guidance restricts them to distressing agitation or psychosis with a documented indication and a stop date.
- **Delirium is increasingly recognised as a marker of brain vulnerability**, with strong evidence that an episode accelerates long-term cognitive decline and predicts subsequent dementia — reframing delirium prevention as dementia prevention.
- **Delirium may be the first manifestation of infection** in older people — a lesson reinforced during COVID-19, where atypical presentation with delirium was common in those with multimorbidity, pre-existing cognitive impairment and polypharmacy.
- **Indian context:** delirium is markedly under-recognised in Indian hospitals; validated Hindi and regional-language versions of the 4AT and CAM now exist, and NPHCE-linked geriatric wards are the natural setting for structured screening on admission.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Diagnostic criteria	DSM-IV-TR: "disturbance of consciousness"	DSM-5-TR / ICD-11: disturbance of attention and awareness
Screening tool	CAM	4AT for rapid screening; CAM-ICU in critical care
Drug treatment	Antipsychotics if danger to self or others	Same threshold, but explicit evidence that antipsychotics do not shorten delirium; benzodiazepines advised against
Sedatives for sleep	Hypnotics and benzodiazepines used cautiously	Melatonin/ramelteon preferred; benzodiazepines cause respiratory depression and worsen delirium
Prognostic significance	Reversible acute state	Independent predictor of long-term cognitive decline and incident dementia

12. Interventions to Prevent Delirium in Post-operative Older Patients

Fifteen–Twenty High-Yield Points

Scale of the problem

1. Postoperative delirium is one of the commonest surgical complications in older people. Incidence in hospitalised older patients may reach **one-third**, and **anaesthesia poses a special risk**.
2. Prevention is far more effective than treatment. **Up to a third of episodes are preventable**, and there is growing awareness of the importance of preventing, or at least minimising, postoperative delirium.

Pre-operative risk stratification

3. Four items are independently associated with postoperative delirium: **prior stroke or TIA, Mini-Mental State Examination score, abnormal serum albumin, and Geriatric Depression Scale score**.
4. **Frailty** — assessed by unintentional weight loss, reduced grip strength, low energy and motivation, low physical activity and slow walking speed — independently predicts postoperative complications, length of stay, and discharge to a skilled or assisted living facility.
5. Other preoperative predictors of six-month mortality and poor outcome are **impaired cognition, recent falls, low albumin, greater anaemia, functional dependence and increased comorbidity**.
6. Six well-known risk factors are targeted by preventive programmes: **cognitive impairment, visual impairment, hearing impairment, sleep deprivation, immobility and dehydration**.

The evidence base — multicomponent intervention

7. The **Hospital Elder Life Program (HELP)** is the model intervention. In the landmark controlled trial, addressing the six risk factors comprehensively through a trained interdisciplinary team **reduced delirium incidence from 15% with usual care to 9.9%** (matched odds ratio 0.60, p = 0.02).
8. The methods used in each HELP protocol were **simple, commonsense measures that arguably should form part of best practice and good, empathetic care for all elderly patients**. HELP has been shown to be sustainable and scalable in community hospitals.
9. Multifactorial interventions succeed only when **supported by strong leadership and robust measurement and reporting** — the same principle that underpins successful falls reduction.

The six HELP protocols — practical content

10. **Orientation and therapeutic activities** for cognitive impairment — orientation boards, clocks, calendars, familiar objects, and daily cognitive stimulation.
11. **Early mobilisation** — ambulation or active range-of-movement exercises at least three times daily, and minimising immobilising equipment such as catheters and restraints.
12. **Non-pharmacological sleep protocol** — warm drink, relaxation, quiet environment, noise reduction and rescheduling of night-time observations and medications, instead of hypnotics.
13. **Vision protocol** — spectacles, magnifiers, adequate lighting, large-print material.
14. **Hearing protocol** — hearing aids, portable amplifiers, and **removal of cerumen**, which is a simple and frequently overlooked intervention.
15. **Volume repletion** — early recognition of dehydration and encouragement of oral fluid intake.

Peri-operative medical management

16. **Medication review is central:** the regimen should be scrutinised to determine which drugs should be continued or withheld. Every drug that may worsen cognition should be avoided or discontinued.
17. **Anaesthetic technique:** many surgeons and anaesthetists favour regional over general anaesthesia in geriatric patients, but regional anaesthesia has disadvantages — added intravenous sedation and analgesia may increase cardiovascular and mental status changes, and significant cardiovascular changes can occur during regional anaesthesia. **The choice must be individualised.**
18. **Adequate analgesia is protective**, since uncontrolled pain is itself a potent precipitant; opioid-sparing multimodal analgesia is preferred and pethidine should be avoided.
19. Other peri-operative essentials: prophylaxis against **thromboembolism and infection**, avoidance of hypoxia and hypotension, correction of anaemia and electrolyte disturbance, early removal of urinary catheters, early feeding, and treatment of constipation and urinary retention.
20. Comprehensive Geriatric Assessment identifies the frailest patients at highest risk of adverse outcomes, and when combined with strong and sustained interventions achieves better long-term outcomes.

Latest Updates (2023 – Present)

- The **2025 American Society of Anesthesiologists practice advisory for perioperative care of older adults** (*Anesthesiology* 2025;142:22–51) is now the primary reference document and consolidates preoperative cognitive screening, brain health optimisation and delirium prevention into a single pathway.
- **Updated ESAIC guideline on postoperative delirium (2024)**: suggests **multiparameter intraoperative EEG monitoring** (burst suppression and density spectral array) to reduce delirium risk; **recommends against benzodiazepines** for treatment; suggests **low-dose haloperidol** only if non-pharmacological measures fail; and suggests **dexmedetomidine** for delirium after cardiac surgery.

- **EEG-guided anaesthesia:** evidence is genuinely mixed. ENGAGES (*JAMA* 2019) and ENGAGES-Canada (*JAMA* 2024) were negative, yet a 2025 meta-analysis of 12 trials and 7,441 patients (*Frontiers in Neurology* 2025) found benefit. The consistent message is that **avoiding intraoperative burst suppression** reduces delirium.
- **Dexmedetomidine** has the strongest pharmacological evidence: risk ratio approximately **0.57 in cardiac surgery**, **0.48 in older patients under regional anaesthesia**, and **0.51 in older non-cardiac surgical patients** in pooled analyses. Bradycardia and hypotension are the limiting adverse effects.
- **Melatonin** trials remain inconclusive; it is low-risk and widely used, but should not displace the sleep protocol.
- **Haemodynamic management:** the **cogPOISE-3** trial (*Annals of Internal Medicine* 2025) compared hypotension-avoidance with hypertension-avoidance strategies; observational data continue to link **intraoperative hypotension and blood pressure variability** with delirium.
- The 2025 APSF advisory concluded that evidence **does not support avoiding single-dose short-acting midazolam** in older adults — a nuanced revision of blanket benzodiazepine avoidance, though repeated or long-acting benzodiazepines remain contraindicated.
- **Cochrane (2021, current)**: non-pharmacological multicomponent interventions remain the only intervention with consistent evidence for preventing delirium in hospitalised non-ICU patients — the HELP model is still the backbone.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Core strategy	Multicomponent non-pharmacological (HELP)	Unchanged — still the only consistently effective approach
Anaesthetic depth	Not addressed	Intraoperative EEG monitoring to avoid burst suppression (weak recommendation)
Drug prophylaxis	None recommended	Dexmedetomidine has moderate evidence, particularly in cardiac surgery
Benzodiazepines	Cautioned against	Contraindicated for treatment; single-dose short-acting midazolam no longer prohibited outright
Preoperative assessment	Risk factor identification, frailty screening	Formal ASA 2025 pathway with routine cognitive screening and brain health optimisation

13. Thrombolysis in Stroke

Fifteen–Twenty High-Yield Points

Principle

1. **The introduction of intravenous alteplase (rt-PA) transformed acute stroke care.** Its benefit is tempered by the risk of precipitating intracranial haemorrhage and by strict licensing conditions.
2. The rationale is the **ischaemic penumbra** — an under-perfused but potentially salvageable area of brain surrounding the infarct core. The higher the residual perfusion, the longer ischaemia is tolerated before electrical failure, ion pump failure and cell death.

Evidence base

3. **NINDS rt-PA Stroke Study:** patients under 80 with carotid or vertebrobasilar territory stroke, not comatose, treated **within 3 hours**. Intracranial haemorrhage occurred in **6.4% of thrombolysed patients within 36 hours versus 0.6% with placebo**, but treated patients were **about 30% more likely to have minimal or no disability at three months**.
4. **ECASS-3** confirmed that alteplase can be given safely to patients under 80 **between 3 and 4.5 hours** after onset, with a small overall benefit.
5. **IST-3** included patients **over 80**. Pooled analysis with NINDS and other trials confirmed that intravenous thrombolysis **significantly reduces death or dependency**, with a **linear relationship between time to treatment and benefit, extending up to six hours** from onset. Age alone is not a contraindication.

Contraindications

6. **Absolute:** haemorrhage on pre-treatment imaging; suspected subarachnoid haemorrhage; any history of intracranial haemorrhage; known arteriovenous malformation or aneurysm; active bleeding from any site.
7. **Imaging-based:** visible infarction involving **more than one-third of the MCA territory** — a clearly delineated hypodensity indicates established infarction with blood-brain barrier breakdown and a high haemorrhage risk.
8. **Haematological:** platelet count **below 100 × 10^9/L**; recent heparin with raised APTT; recent warfarin with elevated INR.
9. **Recent events:** major surgery or trauma within 14 days; gastrointestinal or urinary tract haemorrhage within 21 days; neurosurgery, serious head trauma or previous stroke within 3 months; recent myocardial infarction with pericarditis; recent arterial puncture at a non-compressible site; recent lumbar puncture.
10. **Physiological:** blood pressure persistently above **185 mmHg systolic or 110 mmHg diastolic**; blood glucose below 3 or above 20 mmol/L (roughly **<55 or >360 mg/dL**); active pancreatitis; suspected or known pregnancy.
11. **Clinical:** symptoms only minor or rapidly improving; **epileptic seizure at stroke onset**.

Delivery and complications

12. Hypertension above 180/110 mmHg should be **treated cautiously before** giving thrombolysis. **Aspirin is contraindicated within the first 24 hours after rt-PA** because of an increased risk of death.
13. If intracranial haemorrhage occurs, **stopping the ongoing infusion is mandatory**. Send an urgent clotting profile, consider reversal agents such as cryoprecipitate, and obtain neurosurgical consultation for severe haemorrhage.
14. **Service requirements:** thrombolysis requires **hyperacute stroke units (HASUs)** with pathways giving urgent access to brain imaging and stroke expertise, aiming for a **door-to-needle time under 30 minutes**, and facilities for appropriate post-thrombolysis monitoring.
15. **Imaging:** non-contrast CT is the initial investigation; early signs are a hyperdense artery, loss of the insular ribbon and lentiform nucleus definition, sulcal effacement and mass effect. **CT is normal in 30–40% of patients in the first few hours**; **DWI-MRI becomes abnormal within minutes** and is far more sensitive.
16. **CT angiography** identifies intracranial occlusion, and **CT perfusion** assesses the extent of hypoperfusion, refining selection for thrombolysis or thrombectomy, particularly beyond six hours.

Thrombolysis and thrombectomy

17. **Mechanical thrombectomy** improves functional outcome, increasing the proportion functionally independent at 90 days by around **20%**. It has advantages over thrombolysis: greater efficacy in large-artery occlusion, a longer window, and usability in some patients with contraindications to thrombolysis.
18. Thrombectomy is indicated for **proximal anterior circulation occlusion (intracranial carotid, M1 or proximal M2)**, NIHSS above 5, pre-morbid modified Rankin score below 3, and no major established ischaemic change — within **6 hours**, or up to **12–24 hours** where advanced imaging shows substantial salvageable tissue.
19. Benefit declines with time: independence at three months falls from **50% at 3 hours to 45% at 4.5 hours, 40% at 6 hours and 33% by 8 hours**. The '**drip and ship**' model — thrombolyse locally, then transfer — is one of two accepted service configurations.
20. **Neuroprotective drugs have consistently failed** in clinical trials. Tight control of physiological parameters — oxygenation, glucose, temperature and blood pressure — remains the only effective way to limit secondary damage.

Latest Updates (2023 – Present)

- **The 2026 AHA/ASA Guideline for the Early Management of Patients with Acute Ischemic Stroke** is the definitive current reference and contains three practice-changing changes.

- **Tenecteplase is now co-equal first-line with alteplase.** New **Class 1, Level A** recommendation: **tenecteplase 0.25 mg/kg (maximum 25 mg) as a single 5-second bolus, or alteplase 0.9 mg/kg (maximum 90 mg)**, within 4.5 hours. The higher **0.4 mg/kg dose is explicitly NOT recommended (Class 3, No Benefit)** because it increases symptomatic intracranial haemorrhage without added benefit. Supporting trials: **AcT, ATTEST-2, TASTE, ORIGINAL, NOR-TEST 2**.
- Tenecteplase's practical advantages are decisive in a resource-constrained system: **a single bolus rather than a one-hour infusion**, shorter door-to-needle times, and much easier interhospital transfer — directly relevant to Indian stroke networks and to India's own cost-effective tenecteplase supply.
- **Extended window thrombolysis is now endorsed. Class 2a**: IVT is reasonable between **4.5 and 9 hours** from onset, or in wake-up stroke within 9 hours of the sleep midpoint, when advanced imaging shows salvageable penumbra (**EXTEND**, **WAKE-UP** using DWI-FLAIR mismatch). **Class 2b**: thrombolysis may be beneficial **4.5 to 24 hours** after onset in selected patients with large-vessel occlusion and salvageable tissue who cannot undergo thrombectomy (**TRACE-III**, **HOPE**, **CHABLIS-T II**). **TIMELESS** was negative in patients who did proceed to thrombectomy.
- Thrombolysis should now be given **rapidly to all eligible patients with disabling deficits regardless of NIHSS score**, within 4.5 hours, **without waiting for advanced imaging**.
- **Basilar artery occlusion** now carries a strong recommendation for endovascular therapy within **24 hours** when NIHSS is 10 or more — a change from the textbook position that this indication was untested in randomised trials.
- Perfusion-imaging-guided selection has substantially widened eligibility, but access to advanced imaging is not universal — a real constraint in most Indian district hospitals, where non-contrast CT within 4.5 hours remains the practical pathway.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Thrombolytic agent	Alteplase (rt-PA) only	Tenecteplase 0.25 mg/kg bolus or alteplase, both Class 1 Level A
Time window	Up to 4.5 hours (benefit to 6 hours on pooled analysis)	4.5 h standard; 4.5–9 h with imaging selection; up to 24 h in selected LVO not for thrombectomy
Minor stroke	Minor or rapidly improving deficit is a contraindication	Treat all disabling deficits regardless of NIHSS score
Thrombectomy window	6 hours, extended to 24 h with perfusion mismatch	Same, plus strong recommendation for basilar occlusion to 24 h
Administration	Bolus plus 60-minute infusion	Single 5-second bolus with tenecteplase, easing transfer and reducing door-to-needle time

14. History of the 'Stroke Clinics' — Why They Were Set Up and What Issues They Addressed

Fifteen–Twenty High-Yield Points

The problem that had to be solved

1. Before organised services, stroke patients were admitted to **general medical wards** with no specialist input, no agreed protocols, and outcomes that varied widely between hospitals. Stroke was regarded as an untreatable consequence of ageing.
2. The **conceptual rationale for organised stroke care** is that stroke affects several domains of human performance and produces multiple impairments that interact to determine disability — and that **no single discipline has all the skills, resources and expertise required** to manage recovery.
3. Recovery is further complicated because **different impairments recover at different speeds**, demanding a staged approach to intervention and therapy input.
4. Rehabilitation goals are also shaped by the **personal needs of the patient, the environment they will return to, and the support available after discharge** — requiring coordination that ad hoc care could not deliver.

Development and the evidence

5. Over the last two decades of the twentieth century, numerous randomised controlled trials suggested that organised care benefited stroke patients, but **most individual studies were too small to demonstrate a robust statistical benefit**.
6. The **Stroke Unit Trialists' Collaboration (SUTC)** was therefore set up to pool data from these and other ongoing studies in Australia, North America and Europe — a landmark exercise in evidence synthesis.
7. **The pooled meta-analysis of 29 trials and 6,536 patients** showed, at one year, odds reductions with organised care of **0.86 for mortality (95% CI 0.71–0.94)**, **0.78 for death or dependence (0.68–0.89)**, and **0.80 for death or institutionalisation (0.71–0.90)**, **independent of age and gender**.
8. **Crucially, and in contrast with thrombolysis, these benefits are seen in all stroke patients regardless of stroke aetiology or the delay between onset and intervention** — which is why stroke unit care, not thrombolysis, is the intervention that benefits the largest number of patients.
9. This efficacy translated into real-world effectiveness, confirmed in longitudinal studies and repeated national stroke audits.

Which model of organisation works

10. "Organised stroke care" means different things to different people — definitions range from **a team of specialists who consult wherever the patient is**, to **a designated geographical location within the hospital** for patients needing medical, rehabilitation and skilled professional care.
11. Langhorne's analysis showed a definite benefit with **comprehensive stroke units, rehabilitation stroke units and mixed rehabilitation units** (odds ratios **0.85–0.89** in favour of organised care).
12. There was a **possible benefit with acute semi-intensive units (OR 0.88; 95% CI 0.76–1.01)**, which just failed to reach statistical significance.
13. **Mobile stroke teams were associated with no benefit (OR 0.98; 95% CI 0.95–1.05)** — the key message that a **geographically defined unit, not a peripatetic team, is what works**.
14. There are no trials of acute intensive care for stroke. A review of the data suggests that **emphasis on acute intensive care alone is not adequate to change outcomes, and that continuity of care is needed to realise the full potential of stroke unit care**.

Issues that the clinics addressed

15. **Access to hyperacute treatment: hyperacute stroke units (HASUs)** were created to deliver urgent access to brain imaging and stroke expertise, with a target **door-to-needle time under 30 minutes** and safe post-thrombolysis monitoring.
16. **Secondary prevention after TIA:** patients with suspected TIA should receive **aspirin 300 mg immediately and be assessed within 24 hours** by a specialist in a neurovascular clinic or acute stroke unit. **Daily rapid-access TIA clinics are therefore an essential component of a comprehensive stroke service.**
17. **Prevention and early treatment of complications:** dysphagia and aspiration, malnutrition, dehydration, fever and infection, venous thromboembolism, pressure sores, incontinence, shoulder pain, depression and post-stroke fatigue.
18. **The intensity and quality of rehabilitation:** audit showed that even in stroke units patients spend **more than 50% of their time in bed, 28% sitting out of bed, only 13% in therapeutic activities, and are alone 60% of the therapeutic day**.
19. The **CERISE study** confirmed that motor recovery varied significantly across Europe and was determined **not by the therapy resources allocated but by the amount of treatment actually delivered**. In the UK, the greatest resources (70 hours per week) produced the least therapy input per patient (1 hour per day), while structured, strictly timed therapy in Germany produced the best outcomes in Europe.
20. **Consensus position:** well-organised, well-planned rehabilitation guided by defined goals, based on adequate assessment, negotiated with patients and carers, and delivered on a specialist unit, **reduces disability and long-term institutionalisation** — although there is little evidence favouring any specific treatment technique, so a pragmatic, individualised functional approach is recommended.

Latest Updates (2023 – Present)

- **Centralisation is the modern successor to the stroke unit.** Analysis of the reorganisation of acute stroke services in English metropolitan areas showed sustained reductions in mortality and length of stay when services were concentrated into fewer HASUs (*BMJ* 2019, and subsequent sustainability analyses).
- The **2026 AHA/ASA acute stroke guideline** extends organised care to prehospital systems, formalises transfer protocols for thrombectomy, and for the first time includes recommendations for interventional treatment in **paediatric** stroke.
- **Mobile stroke units** (CT-equipped ambulances) — conceptually the opposite of the failed "mobile stroke team" — have shown reduced time to thrombolysis and improved functional outcomes in the BEST-MSU and B_PROUD studies, though cost-effectiveness in most systems is unproven.
- **Telestroke** networks now extend thrombolysis decision-making to hospitals without on-site stroke expertise, and are the single most scalable solution for large countries with uneven specialist distribution.
- **Indian context:** the **Indian Stroke Association** and the **National Programme for Prevention and Control of Non-Communicable Diseases** have promoted a tiered model — Level 1 (comprehensive, with thrombectomy), Level 2 (thrombolysis-capable), Level 3 (stroke-ready with telemedicine support). Studies from Ludhiana, Trivandrum and Hyderabad have shown that **low-cost stroke units without intensive care facilities still reduce mortality and dependency**, which is the single most important message for Indian practice.
- **Early supported discharge** teams and structured caregiver training programmes (Kalra et al., *BMJ* 2004) remain the highest-value additions to stroke unit care in resource-limited settings, where family caregivers carry most of the burden.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Model of organisation	Geographically defined stroke unit within each hospital	Regional centralisation into fewer high-volume HASUs with formal transfer networks
Mobile services	Mobile stroke teams show no benefit	Still true for in-hospital teams, but CT-equipped mobile stroke ambulances speed thrombolysis
Remote expertise	Not addressed	Telestroke is standard for spoke hospitals
TIA clinics	Assessment within 24 hours	Unchanged, with immediate dual antiplatelet therapy in high-risk minor stroke/TIA
Applicability	Developed-country service models	Low-cost stroke units validated in Indian settings; tiered stroke-ready hospital model

15. Restless Legs Syndrome — Risk Factors, Diagnostic Criteria and Management

Fifteen–Twenty High-Yield Points

Definition and epidemiology

1. **Restless legs syndrome (RLS, Willis-Ekbom disease)** is a sensorimotor disorder characterised by **motor restlessness brought on by rest**, usually or only present in the evening or early night, with an urge to move typically accompanied by an unpleasant sensation in the legs.
2. **Periodic limb movements (PLMs)** are discrete, repetitive, stereotyped movements — rhythmic extension of the big toe and ankle dorsiflexion, sometimes with knee and hip flexion — each lasting **0.5–5 seconds and recurring every 20–40 seconds**. They are present in **90% of RLS patients** but can occur independently.
3. Prevalence varies geographically: **10–20% in northern Europe, 3–10% in southern Europe, 0.7–12.1% in Asia, and under 1% in Africa**. In India, prevalence is at the lower end of the Asian range but rises sharply in dialysis populations.
4. RLS is **more common in women**, but the prevalence in nulliparous women equals that in men — the difference is driven by pregnancy, during which prevalence rises to about **21%**.
5. RLS commonly causes **insomnia and excessive daytime sleepiness**, and in older people this translates into falls, cognitive complaints and depression.

Risk factors

6. **Genetic:** about **60% of patients have a positive family history**; at least **eight major susceptibility loci** are known, mostly autosomal dominant.
7. **The three most commonly associated conditions are end-stage renal disease, pregnancy and iron deficiency anaemia** (present in 25–35% of affected patients).
8. Other associations: stroke and migraine, mood disorders, cardiovascular disease, thyroid disorders and diabetes. **Prevalence increases significantly when three or more comorbidities coexist.**
9. **Drug-induced/aggravated RLS:** antidepressants, antihistamines and dopamine antagonists (including antipsychotics and metoclopramide); also withdrawal from opioids.

Pathophysiology

10. **Brain iron deficiency** is central: patients have **lower CSF ferritin, higher transferrin, and reduced iron concentration in the basal ganglia and thalamus**, even when peripheral iron stores appear adequate.
11. **Dopamine dysfunction:** there is a **presynaptic hyperdopaminergic state with circadian fluctuation and downregulation of postsynaptic dopamine receptors**. Dopamine production falls towards nightfall, producing a functional hypodopaminergic state — which explains both the circadian pattern and the response to dopaminergic drugs.
12. Brain iron deficiency and dopaminergic dysfunction interact by **altering the glutamate and adenosine systems**. **Endogenous opioid deficiency** in the central sensory system also contributes, causing abnormal processing of noxious stimuli and the characteristic urge to move.

Diagnostic criteria (IRLSSG 2014)

13. RLS is a **clinical diagnosis** requiring **all five** criteria: (i) **an urge to move the legs**, usually accompanied or caused by uncomfortable, unpleasant sensations; (ii) the urge **begins or worsens during rest or inactivity**; (iii) the urge is **relieved by movement**, such as walking or stretching; (iv) the urge is **worse in the evening or at night**; (v) **other conditions that mimic RLS have been excluded**.
14. **Supportive features:** positive family history, positive response to dopaminergic therapy, and the presence of periodic limb movements during sleep or wakefulness.
15. **Mimics to exclude:** akathisia, positional discomfort, arthralgia, myalgia, peripheral venous insufficiency, painful peripheral neuropathy, nocturnal leg cramps and lumbar radiculopathy.
16. **Investigations: iron studies must be obtained in every patient** in whom RLS is suspected or diagnosed; renal function tests if uraemia is a concern. **Polysomnography is not necessary** but can objectify severity. A high PLMS rate on polysomnography is **not sufficiently specific**, as it occurs in many conditions and increases with age. Severity is quantified with the **International RLS Severity Scale (IRLS)**.

Management

17. **First step: review the medication list** and stop or reduce any drug that causes or exacerbates RLS. Non-pharmacological measures — sleep hygiene, hot and cold baths, lower limb massage, moderate exercise, avoidance of caffeine and alcohol — should be optimised before drugs.
18. **Iron replacement:** if deficient, give oral iron with vitamin C, or intravenous iron with a carbohydrate bond, especially **ferric carboxymaltose**. **High-molecular-weight iron dextran must not be used** because of severe anaphylactic reactions. Ferritin **below 20 ng/mL** warrants oral supplementation; between **20 and 50 ng/mL** the decision is individualised; some evidence supports raising the threshold to **70 ng/mL in elderly patients with chronic renal failure or pro-inflammatory conditions**. **If iron studies are strictly normal, iron therapy is not effective.**
19. **Pharmacological options:** dopamine agonists and levodopa are approved and widely used; **only ropinirole has been shown to improve sleep efficacy on polysomnography**. **α2δ ligands (gabapentin, pregabalin) can be used as first-line agents.** Second-line agents for severe refractory disease are opioids (oxycodone-naloxone, methadone), limited by side effects. Treatment starts as monotherapy at the lowest dose and is titrated slowly.

20. **Augmentation** is the feared complication of dopaminergic therapy — **iatrogenic worsening with symptoms emerging progressively earlier in the day**. An estimated **76% of patients on dopaminergic drugs need a dose increase or develop augmentation**. To minimise risk: use long-acting agonists at the lowest effective dose, start only when quality of life is clearly affected, and **never use carbidopa/levodopa as the initial agent because of its short half-life**. Cross-titration to a different class is needed if augmentation develops. Consequently, **α2δ ligands are increasingly favoured as initial therapy.**

Latest Updates (2023 – Present)

- **The AASM Clinical Practice Guideline (Winkelman et al., *Journal of Clinical Sleep Medicine* 2025;21:137–152) is a complete reversal of the 2012 practice parameter and is the single most important update in this topic.**
- **Dopamine agonists are now conditionally recommended AGAINST for standard use** — ropinirole, pramipexole, rotigotine and levodopa. The reason is **augmentation, occurring in 7–10% of patients per year**; over three years this affects 20–30% of patients, and over five years 35–50%. Long-term dopaminergic plasticity worsens the underlying disease even though short-term efficacy is excellent.
- **α2δ ligands are now the strong first-line recommendation: gabapentin enacarbil, gabapentin and pregabalin**. Gabapentin enacarbil is not marketed in India or the UK, so **gabapentin or pregabalin are the practical first-line choices**.
- **Iron therapy has been elevated to a strong recommendation. Intravenous ferric carboxymaltose is strongly recommended when serum ferritin is below 100 µg/L** — far above the usual threshold for "low ferritin" — based on five randomised trials. Target **ferritin above 100 µg/L and transferrin saturation above 20%**. Iron studies must be taken **in the morning after a 24-hour avoidance of iron-containing food and supplements**, and should include ferritin, iron and total iron binding capacity.
- **New conditional recommendations: dipyridamole** (an adenosine reuptake inhibitor, addressing the adenosine hypothesis), **extended-release oxycodone and other mu-opioid agonists**, and **bilateral high-frequency peroneal nerve stimulation** — a non-pharmacological device option that is entirely new.
- Where a patient is already established on a dopamine agonist and doing well, guidance is to **monitor regularly for augmentation and impulse-control disorders** rather than to withdraw reflexively; low-dose opioids are often used to facilitate tapering off dopamine agonists.
- **Indian relevance:** RLS is strongly associated with chronic kidney disease and iron deficiency, both highly prevalent in India. In dialysis patients and in iron-deficient older adults, **correcting iron status is both the cheapest and the most effective intervention**, and is consistent with national anaemia control priorities.

Current Practice Update

Aspect	Textbook position	Current evidence / practice (AASM 2025)
First-line drug	Dopamine agonists approved and widely used; α2δ ligands an alternative	α2δ ligands are first-line; dopamine agonists recommended against for standard use
Levodopa	Used less commonly; never as initial agent	Explicitly recommended against
Iron threshold	Oral iron if ferritin <20 ng/mL; individualise 20–50 ng/mL	IV ferric carboxymaltose strongly recommended if ferritin <100 µg/L; target >100 µg/L and TSAT >20%
Augmentation risk	Recognised; minimised by using long-acting agonists	Quantified at 7–10% per year and considered sufficient reason to abandon the class
Non-drug options	Sleep hygiene, baths, massage	Adds bilateral high-frequency peroneal nerve stimulation and dipyridamole

16. Myasthenia Gravis — Presentation, Laboratory Evaluation and Treatment

Fifteen–Twenty High-Yield Points

Definition and epidemiology

1. **Myasthenia gravis (MG)** is an antibody-mediated disorder of neuromuscular transmission. The commonest target antigen is the **postsynaptic muscle nicotinic acetylcholine receptor (AChR)**; these structures are vulnerable because they lie outside the blood-nerve barrier.
2. Overall incidence is **2–10 per 100,000**. It affects all races and can begin at any age after the first year of life. **Incidence rises with age but MG is underdiagnosed in the elderly.**
3. **Late-onset MG (LOMG)** is increasingly recognised; reports of rising incidence may reflect improved diagnosis rather than a true biological change.

Clinical presentation

4. The hallmark is **fatigable weakness** — weakness that worsens with sustained or repeated activity and improves with rest, with characteristic diurnal variation (worse in the evening).
5. **Ocular presentation** is commonest: **ptosis and diplopia**, often asymmetrical, with **Cogan's lid twitch**. MG can mimic blepharospasm.
6. **Bulbar features:** dysarthria (nasal speech that fatigues), dysphagia, nasal regurgitation, jaw fatigue on chewing, and facial weakness with a "myasthenic snarl".
7. **Generalised disease:** proximal limb weakness, **dropped head syndrome**, and respiratory muscle weakness. Unusual presentations include **distal MG** and the **"myasthenic hand"**.
8. **In older patients, MG may present with recurrent falls** — a presentation of major importance in geriatric practice and easily attributed to other causes.
9. Cardiac involvement and cognitive impairment have both been described in MG, and determinants of cognitive impairment in elderly myasthenic patients have been specifically studied.
10. **MG is a treatable disease** — more than 90% of patients return to normal function — so the diagnosis **must be considered in anyone presenting with ptosis, diplopia, dysphagia, or limb or respiratory muscle weakness**.

Laboratory evaluation

11. **Serology: anti-AChR antibodies** are the primary test and are positive in the majority; **late-onset MG is characteristically anti-AChR seropositive**. **Anti-MuSK** (muscle-specific tyrosine kinase) antibodies define a subgroup with predominant facial and bulbar involvement; anti-LRP4 accounts for a smaller fraction.
12. **Neurophysiology: repetitive nerve stimulation** showing a decremental response, and **single-fibre EMG** demonstrating increased jitter, which is the most sensitive test.
13. **Bedside tests:** the **ice pack test** for ptosis (cooling improves neuromuscular transmission) and the **sleep/rest test** — a safe alternative to the edrophonium (Tensilon) test, which is now rarely used because of cardiac risk in older patients.
14. **CT of the thorax is mandatory** in every new diagnosis to look for **thymoma** or thymic hyperplasia. **Paraneoplastic MG** is recognised, including with carcinoid tumour.
15. Additional baseline work: **thyroid function and screening for associated autoimmune disease**; **forced vital capacity** as the objective measure of respiratory reserve; and review of drugs that unmask or worsen MG (aminoglycosides, fluoroquinolones, macrolides, beta-blockers, magnesium, **penicillamine**).

Treatment

16. **Anticholinesterase inhibitors** remain first-line for all patients, acting by inhibiting acetylcholine breakdown at the NMJ. **Pyridostigmine** is started at **30 mg two to four times daily** and titrated. It acts in **10–30 minutes, peaks at two hours, and lasts about four hours**. Muscarinic side effects (abdominal cramps, diarrhoea, sweating, bronchial and oral secretions) can be treated with propantheline, which may however mask overdose; nicotinic effects are fasciculation and cramps. **Chronic high doses may increase weakness by downregulating AChRs.**
17. **Steroids** are short-term immunosuppressives used while other agents take effect. A **"steroid dip"** — temporary worsening **4–10 days** after starting high-dose steroids — is avoided by starting low and going slow, or by alternate-day treatment. **In elderly patients, steroids and immunosuppressives carry greater risk, notably steroid-induced osteoporosis, so prophylaxis is required.**
18. **Steroid-sparing agents:** azathioprine, mycophenolate mofetil, methotrexate, ciclosporin and tacrolimus. **Rituximab** (B-cell depletion) is particularly effective in **MuSK-associated MG**.
19. **Rapid therapies: plasma exchange (PE)** and **intravenous immunoglobulin (IVIG)**. IVIG is given as **0.4 g/kg/day for five days**, improves most patients within four to five days, and lasts weeks to months. Adverse effects of IVIG (fever, headache, nausea, allergic reaction; anaphylaxis in IgA deficiency; volume overload; renal failure; thrombosis and stroke with high infusion rates) are **less severe than those of PE**, whose complications relate mainly to vascular access, fluid shifts, and citrate-induced hypocalcaemia.
20. **Thymectomy** is the treatment of choice for thymoma (radiotherapy if unfit). In non-thymoma patients it is usually performed in generalised, AChR-positive MG **under the age of 50–60**. The randomised trial of transsternal thymectomy plus alternate-day steroids versus steroids alone showed **improved clinical outcomes over three years**. Benefit may take **6–12 months** to appear; predictors of good response are female sex, limb-predominant weakness and AChR antibody positivity.
21. **Crises: myasthenic crisis** (weakness requiring ventilation) is precipitated by infection, intercurrent illness, surgery or

too-rapid reduction of immunotherapy; **cholinergic crisis** results from excessive anticholinesterase. If the two cannot be distinguished, it is **safe to stop anticholinesterases once the patient is ventilated**. Treat infection aggressively and give IVIG or PE. For anaesthesia, prefer local or spinal; if general anaesthesia is needed, insert a nasotracheal tube, keep it for one to two days, avoid anticholinesterases on the morning of surgery and for 24 hours afterwards, and continue immunosuppressants.

Latest Updates (2023 – Present)

- **The treatment landscape has been transformed by three targeted mechanisms — complement inhibition, FcRn blockade and B-cell depletion.**
- **Complement (C5) inhibitors: eculizumab** (2017, REGAIN), **ravulizumab** (extended 8-weekly dosing) and **zilucoplan** (RAISE, 2023) — a cyclic peptide that is the first **self-administered subcutaneous** option. **Meningococcal vaccination is mandatory before starting any C5 inhibitor.**
- **FcRn antagonists** block neonatal Fc receptor-mediated IgG recycling, lowering pathogenic IgG: **efgartigimod** (IV and subcutaneous Vyvgart Hytrulo), **rozanolixizumab** (Rystiggo, 2023 — approved for both AChR- and MuSK-positive disease), and **nipocalimab (Imaavy)**, approved **30 April 2025** for AChR- or MuSK-positive gMG in patients aged 12 and above, with sustained disease control across the broadest population.
- **Inebilizumab (Uplizna)**, an anti-CD19 B-cell depleting antibody, was approved in **late 2025** for AChR- and MuSK-positive gMG, offering long-term control with only **two maintenance doses per year** after loading.
- **CAR-T cell therapy** targeting BCMA and IL-6 receptor blockade are in early trials, raising the prospect of drug-free remission (*Journal of Neurology* 2025;272:226).
- The **2020 International Consensus Guidance** and updated national guidelines (German 2023) integrate these agents for **refractory or highly active disease**, positioning them after failure of conventional immunosuppression rather than as first-line.
- **Geriatric relevance:** reviews now specifically highlight the growing cohort of **older patients with late-onset MG**. Targeted biologics are attractive in this group because they avoid the osteoporosis, diabetes, infection and cognitive effects of long-term steroids — but cost is prohibitive in most Indian settings, where pyridostigmine, prednisolone, azathioprine, IVIG and plasma exchange remain the working armamentarium.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Biologic therapy	Rituximab for MuSK MG; eculizumab and belimumab at early evaluation	Five-plus approved targeted agents across three mechanisms; eculizumab, ravulizumab, zilucoplan, efgartigimod, rozanolixizumab, nipocalimab, inebilizumab
Route of administration	Intravenous, hospital-based	Subcutaneous and self-administered options; twice-yearly dosing with inebilizumab
Position in algorithm	Steroids and azathioprine, then IVIG/PE	Same, with targeted agents for refractory or highly active disease and increasing use to spare steroids in the elderly
Thymectomy	Generalised AChR-positive MG under age 50–60	Unchanged; MGTX trial evidence confirmed at long-term follow-up
Late-onset MG	Noted to be underdiagnosed	Recognised as a distinct, expanding phenotype requiring steroid-sparing strategies

17. Motor Neuron Disease

Fifteen–Twenty High-Yield Points

Definition and classification

1. **Motor neuron diseases (MNDs)** are a heterogeneous group characterised by degeneration or dysfunction of the **upper motor neurons (UMNs) of the precentral gyrus** and/or the **lower motor neurons (LMNs) of the ventral horn**.
2. **Amyotrophic lateral sclerosis (ALS)** is the commonest MND in adults. It is best regarded as a **syndrome** with considerable phenotypic heterogeneity — sporadic and genetic, pure motor and with extra-motor signs, and forms affecting only LMN or only UMN.
3. Related entities include **primary lateral sclerosis (PLS)** (pure UMN), **progressive muscular atrophy (PMA)** (pure LMN) and **progressive bulbar palsy**. Although histopathologically similar, they must be separated because **prognosis differs**.

Clinical presentation

4. Motor symptoms are frequently preceded by months of non-specific features: **fatigue, weight loss secondary to hypermetabolism, cramps and diffuse fasciculation** from LMN loss and hyperexcitability.
5. **Limb-onset ALS** (commonest): difficulty with fine hand movements, raising the arms, or walking.
6. **Bulbar-onset ALS** (about one-third): swallowing and phonation disorders with sialorrhoea. Rarely, **trunk-onset** with isolated restrictive respiratory impairment causing exertional dyspnoea and orthopnoea with unexplained weight loss.
7. **LMN signs:** fasciculation, amyotrophy, weakness and cramps. **UMN signs:** pyramidal signs with spastic hypertonia, stiffness, clonus and gait disorder. At bulbar level, **pseudobulbar** features are dysarthria and dysphagia from hypertonia without atrophy, frequently with **pseudobulbar affect** (inappropriate crying and laughing).
8. **Oculomotor nuclei and Onuf's nucleus are spared** until very advanced disease — hence eye movements and sphincter function are preserved, a key diagnostic point.
9. Progression follows a pattern consistent with **cell-to-cell, prion-like spread**, extending rostrocaudally or contralaterally. The insidious, non-specific onset explains a **diagnostic delay frequently exceeding one year**.

Cognitive involvement

10. Extra-motor involvement is frequent: with appropriate routine tests, **cognitive or behavioural changes are detected in about 50% of patients, and 5–15% have frank frontotemporal dementia (FTD)**.
11. The cognitive profile is dominated by **executive dysfunction and reduced verbal fluency**, with impaired social cognition. **Memory and visuoconstructive disorders are uncommon and non-specific.**
12. Neuropsychological impairment matters clinically: it is associated with **lower quality of life, greater caregiver burden, altered capacity to engage in life-prolonging interventions, and reduced survival**. The revised **Strong criteria** classify this on three axes: Axis I motor neuron disease variant, Axis II cognitive and behavioural dysfunction, Axis III additional non-motor manifestations.

Pathophysiology and genetics

13. **TDP-43** is central: except for SOD1- and FUS-linked familial ALS (under 3% of cases), the neuropathological hallmark is **cytoplasmic inclusions of ubiquitinated, hyperphosphorylated TDP-43**. Nuclear depletion causes aberrant RNA metabolism and impaired chromatin remodelling; cytoplasmic accumulation disturbs autophagy, proteasome function and mitochondrial function, and the aggregates show **seeding and prion-like cell-to-cell transmission**.
14. Common mechanisms are therefore: **disrupted RNA metabolism, aberrant protein quality control, mitochondrial dysfunction, oxidative stress and trafficking abnormalities**.
15. **Genetics:** up to **20% of European ALS patients have a family history** of ALS or FTD. About **10% of apparently sporadic cases carry a known familial ALS mutation**, and first-degree relatives of a sporadic patient have roughly an **eight-fold** increased risk.
16. **Four genes account for up to 70% of familial ALS: C9orf72, SOD1, FUS and TARDBP.** A **GGGGCC hexanucleotide repeat expansion in C9orf72** is found in nearly **40% of familial ALS**, about 25% of familial FTD-ALS, and about 5% of sporadic ALS. C9orf72 is pleiotropic, also causing FTD, PLS, PMA, Huntington phenocopies, parkinsonism and corticobasal degeneration.
17. **Environmental risk factors:** exposure to lead and heavy metals (with PON1 polymorphisms as a susceptibility factor), pesticides, and sports-related trauma. Relative risk is **4.07 for professional sport versus 1.13 for non-professional**, **5.98 for sports with repetitive spinal and head trauma**, and **8.52 when both risks combine**.

Diagnosis and treatment

18. In the **absence of positive diagnostic markers**, diagnosis rests on precise clinical and electrophysiological analysis, observation of the course, and exclusion of **ALS mimics** — cervical spondylotic myelopathy, multifocal motor neuropathy with conduction block, inclusion body myositis, myasthenia gravis, Kennedy's disease and thyrotoxic myopathy.
19. **Riluzole**, approved in 1995, was developed to reduce excitotoxicity by inhibiting glutamatergic transmission and probably acts on Na^+ and K^+ currents. Two pivotal studies in over 1,100 patients showed a **median survival gain of about three months**, confirmed by meta-analysis, with the probability of surviving one year rising by **9% (58% versus 49%)**, and small effects on bulbar and limb function. **Despite more than 200 trials, ALS remains incurable.**

20. **Multidisciplinary symptomatic care is what improves survival and quality of life** — non-invasive ventilation, nutritional support with gastrostomy, secretion management, treatment of spasticity and cramps, pseudobulbar affect, communication aids and mobility support. ALS is also the model disease for **discussing advance directives and palliative end-of-life care early**, because cognitive capacity is preserved in most patients throughout.

Latest Updates (2023 – Present)

- **Tofersen (Qalsody)** — an **intrathecal antisense oligonucleotide targeting SOD1 mRNA** — received FDA accelerated approval in **April 2023**, the first therapy addressing a genetic cause of ALS. SOD1-ALS accounts for about 2% of cases. In **VALOR** it missed its primary endpoint at 28 weeks, but produced a **greater than 50% fall in CSF and plasma neurofilament light**, and open-label extension data showed better outcomes with earlier initiation. It has since been approved in the EU and, in **July 2025**, by the UK MHRA.
- **Neurofilament light chain is now an established pharmacodynamic biomarker** in ALS — it tracks progression, predicts survival, and was the surrogate endpoint that supported tofersen's accelerated approval. This is the clearest example in neurology of a fluid biomarker changing a regulatory decision.
- **The ATLAS trial** is testing tofersen in **presymptomatic** SOD1 carriers with rapidly progressive mutations, asking whether treatment can delay symptom onset — the first true prevention trial in MND.
- **Relyvrio/Albrioza (sodium phenylbutyrate/taurursodiol, AMX0035)** was **withdrawn from the US and Canadian markets in 2024** after the Phase 3 **PHOENIX** trial failed to confirm the Phase 2 CENTAUR result — an important cautionary example of accelerated approval without confirmatory evidence.
- **Reldesemtiv** (fast skeletal muscle troponin activator) was negative in **COURAGE-ALS** (*JAMA Neurology* 2025;82:477–485).
- **Edaravone** (intravenous and oral suspension) remains available in several countries for patients meeting narrow eligibility criteria, with modest slowing of functional decline.
- Emerging strategies include further antisense oligonucleotides (targeting C9orf72 and FUS), **Exportin-1 inhibition** to modulate SOD1 nuclear export, and gene and stem cell therapies.
- **Indian relevance:** riluzole is available and affordable; edaravone and tofersen are not routinely accessible. The realistic priority is **early multidisciplinary care, non-invasive ventilation and gastrostomy**, with advance care planning under the framework established by the Supreme Court's *Common Cause* judgments on advance medical directives.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Disease-modifying drugs	Riluzole only; ALS incurable despite 200+ trials	Riluzole plus edaravone; tofersen for SOD1-ALS — the first gene-targeted therapy
Biomarkers	"No positive diagnostic markers"	Neurofilament light is a validated prognostic and pharmacodynamic biomarker
Genetic testing	For counselling in familial cases	Mandatory before therapy — SOD1 status determines tofersen eligibility
AMX0035	Not discussed	Approved 2022, withdrawn 2024 after negative PHOENIX trial
Presymptomatic treatment	Not conceived	ATLAS trial in asymptomatic SOD1 carriers

18. Dizziness in the Elderly

> **Coverage note:** the uploaded textbooks address dizziness within the chapters on falls, syncope and comprehensive geriatric assessment rather than as a dedicated chapter. Points 1–14 are textbook-derived; points 15–20 and the manoeuvre details are drawn from current peer-reviewed guidance, which is stated explicitly.

Fifteen–Twenty High-Yield Points

Concept and classification

1. **Dizziness in the elderly is a geriatric syndrome, not a single diagnosis** — it usually results from the accumulation of deficits in the visual, vestibular, proprioceptive, cardiovascular and cognitive systems, aggravated by drugs.
2. The classical classification distinguishes four types: **vertigo** (a sensation of rotational movement), **presyncope/light-headedness**, **disequilibrium** (unsteadiness on standing or walking), and **non-specific dizziness** (often psychogenic).
3. **Vertigo is a more specific symptom** and is most commonly associated with inner ear disorders. **Light-headedness is non-specific and should be interpreted with caution.**
4. Screening question in comprehensive geriatric assessment: **"Do you get dizzy, or does your head spin around?"** The recommended assessments are **checking for postural hypotension, the Hallpike manoeuvre for BPPV, haemoglobin, and the Geriatric Depression Scale**.

Peripheral vestibular causes

5. **Benign paroxysmal positional vertigo (BPPV)** is the commonest cause in older people — brief episodes triggered by head position change, from otoconial debris in the posterior semicircular canal. Diagnosed by the **Dix-Hallpike manoeuvre**, which reproduces vertigo with characteristic upbeating-torsional nystagmus.
6. Other inner ear causes: **acute labyrinthitis and vestibular neuritis** (single prolonged episode with nausea and vomiting) and **Ménière's disease** (episodic vertigo with fluctuating hearing loss and tinnitus).
7. Nystagmus can be demonstrated at the bedside by **having the patient lie down quickly with the head turned to one side in a single motion**; patients with vertigo from organic disorders often have nystagmus.
8. Patients with symptoms suggestive of vertigo benefit from a **thorough otological examination including auditory testing**, which helps differentiate inner ear from central nervous system involvement.

Cardiovascular causes

9. **Orthostatic hypotension** is best detected by measuring blood pressure and pulse **supine, after one minute sitting, and after one and three minutes standing**. A fall of **more than 20 mmHg systolic** is significant; many cases are asymptomatic.
10. Causes of orthostatic hypotension: **low cardiac output from heart failure or hypovolaemia, overtreatment with cardiovascular drugs, autonomic dysfunction (diabetes, Parkinson's disease), impaired venous return, and prolonged bed rest with deconditioning**. **Postprandial hypotension** is a distinctly geriatric cause — simply eating a full meal can lower blood pressure enough to precipitate a fall on standing.
11. **Carotid sinus hypersensitivity** and **reflex (vasovagal) syncope** become increasingly common with age; carotid sinus syndrome is a modifiable risk factor for non-accidental falls, and carotid sinus massage should be considered in unexplained or recurrent falls.
12. Cardiac causes include **bradyarrhythmias, tachyarrhythmias and aortic stenosis**. In general, **cardiac monitoring should document a temporal association between a specific arrhythmia and the symptom** before it is accepted as causal. **A precise cause for syncope remains unidentified in 40–60% of older patients.**

Central, drug-related and psychological causes

13. **Central causes:** vertebrobasilar ischaemia and infarction, **cerebellar infarction**, cerebellar degeneration, posterior fossa tumour, and multiple sclerosis. Cerebellar stroke is the diagnosis that must not be missed in an older patient with sudden isolated vertigo.
14. **Drugs are the most important reversible cause.** Culprits are diuretics (hypovolaemia), antihypertensives, antidepressants (postural hypotension), sedatives, antipsychotics (sedation, rigidity, hypotension), hypoglycaemics, anticonvulsants, aminoglycosides (ototoxicity) and alcohol. **Combinations greatly increase the risk.**
15. **Psychological factors:** many older patients with dizziness and unsteadiness are **anxious, depressed and chronically afraid of falling**, which makes evaluation difficult and means that mood must always be assessed. **Drop attacks** — sudden leg weakness causing a fall without loss of consciousness — are often attributed to vertebrobasilar insufficiency but are poorly understood and over-diagnosed.

Evaluation and management

16. **The single most useful clinical discipline is to distinguish falls from syncope from seizure, and "dizziness" from true vertigo.** Take a detailed history of timing, triggers, duration and associated symptoms, and always seek a witness account.
17. **Core examination:** postural blood pressure, cardiovascular examination including murmurs, cranial nerve and cerebellar examination, gait and balance assessment (**Timed Up and Go**, gait speed over 10 metres), visual acuity, otoscopy with removal of **cerumen**, and the Dix-Hallpike manoeuvre.
18. **Targeted investigation only:** haemoglobin, glucose, electrolytes, renal and thyroid function, vitamin B12, ECG; ambulatory monitoring or an implantable loop recorder for suspected arrhythmia; tilt-table testing and carotid sinus massage for unexplained syncope; MRI where central pathology is suspected. **Do not send all patients for extensive**

diagnostic studies.

19. **Management principles:** treat the specific cause; **rationalise medications**; correct visual and hearing impairment; ensure adequate hydration and salt intake; use compression stockings and counter-pressure manoeuvres for orthostatic hypotension; refer for rehabilitation with strengthening, balance and gait training; and address environmental hazards.
20. **Specific therapies** (current literature): **the Epley canalith repositioning manoeuvre** is the treatment of choice for posterior canal BPPV; **vestibular rehabilitation exercises** for unilateral vestibular hypofunction; a short course of vestibular sedatives only for acute vestibular neuritis, since **drugs such as meclizine and benzodiazepines compromise alertness and cognition** and delay central compensation; midodrine or fludrocortisone for refractory orthostatic hypotension; and pacing for documented carotid sinus syndrome with cardioinhibition.

Latest Updates (2023 – Present)

- **HINTS examination** (Head Impulse, Nystagmus, Test of Skew) is now the standard bedside tool in **acute vestibular syndrome**. Performed by a trained clinician, it is **more sensitive than early MRI-DWI** for posterior circulation stroke. A **normal head impulse test, direction-changing nystagmus, or skew deviation** indicates a central cause requiring urgent imaging.
- The Bárány Society's international classification of vestibular disorders has established diagnostic criteria for **persistent postural-perceptual dizziness (PPPD)** — now recognised as a leading cause of chronic dizziness, treated with vestibular rehabilitation, SSRIs and cognitive behavioural therapy rather than vestibular sedatives.
- **Presbyvestibulopathy** has been defined as a distinct Bárány Society entity — age-related bilateral vestibular hypofunction presenting with chronic unsteadiness and oscillopsia — validating "dizziness of ageing" as a diagnosable and rehabilitable condition.
- The **AAO-HNS BPPV clinical practice guideline update** reaffirms that **canalith repositioning is first-line and that vestibular suppressants should not be used for BPPV**; imaging and vestibular testing are not indicated in uncomplicated BPPV.
- The **"TiTrATE" framework** (Timing, Triggers, And Targeted Examination) has largely replaced the older "what do you mean by dizzy?" approach, because symptom-quality descriptions in older people are unreliable and inconsistent. **Timing and triggers, not the quality of the sensation, drive the differential.**
- Evidence continues to support **vestibular rehabilitation** as effective for chronic dizziness in older adults, with benefits for balance confidence and fall reduction, and it is increasingly delivered by telerehabilitation.
- **Deprescribing** is now framed as a therapeutic intervention in its own right: STOPP/START and Beers criteria specifically flag drugs causing orthostatic hypotension and sedation in older patients presenting with dizziness or falls.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Diagnostic approach	Classify by symptom quality (vertigo, light-headedness, unsteadiness)	TiTrATE — classify by timing and triggers; symptom quality is unreliable
Acute vertigo	Nystagmus assessment and otological examination	HINTS examination, more sensitive than early MRI for posterior circulation stroke
BPPV treatment	Diagnosed by Hallpike manoeuvre	Treated definitively with the Epley repositioning manoeuvre; vestibular suppressants contraindicated
Chronic dizziness	Attributed to anxiety, depression, fear of falling	Defined entities: PPPD and presbyvestibulopathy, both with specific treatment
Drug therapy	Vestibular sedatives used symptomatically	Minimised — they impair compensation, alertness and cognition

19. Ring-Enhancing Shadow on CT Brain

> **Coverage note:** the uploaded geriatric textbooks do not cover ring-enhancing intracranial lesions as a discrete topic. This answer is therefore constructed from current neuroradiology and infectious disease literature, with emphasis on the Indian epidemiological context, as instructed.

Fifteen–Twenty High-Yield Points

Definition and mechanism

1. A **ring-enhancing lesion** is a rounded intracranial lesion with a peripheral rim of contrast enhancement and a non-enhancing centre, usually with surrounding vasogenic oedema and mass effect.
2. The mechanism is **breakdown of the blood-brain barrier** in a peripheral zone of vascularised, inflamed or proliferating tissue, surrounding a central core of necrosis, pus or cyst fluid that has no blood supply and therefore does not enhance.

Differential diagnosis — the classical mnemonic

3. **MAGIC DR** is the standard aide-mémoire: **M**etastasis, **A**bscess, **G**lioblastoma, **I**nfarct (subacute), **C**ontusion, **D**emyelination, **R**esolving haematoma. Radiation necrosis and tuberculoma are the two important additions.
4. **In India, neurocysticercosis and tuberculoma together account for the majority of ring-enhancing lesions**, whereas in Western series metastasis and glioblastoma predominate. This epidemiological difference is the single most examinable point.
5. **In an elderly Indian patient specifically**, the probability shifts towards **metastasis, glioblastoma, pyogenic abscess and tuberculoma**, with neurocysticercosis less likely than in a young adult presenting with a first seizure.

Distinguishing features — infective causes

6. **Neurocysticercosis (NCC):** typically a **small (<20 mm) lesion at the grey-white junction**, often solitary in the Indian "solitary cysticercus granuloma" form, with **disproportionately little oedema for its size** and an **eccentric hyperdense scolex** ("hole-with-dot" sign) that is pathognomonic. Presents with seizures; resolves or calcifies over months.
7. **Tuberculoma:** usually **larger, with thick irregular walls**, marked perilesional oedema, and characteristically **T2 hypointense central caseation** on MRI. Often multiple, may be basal, and is frequently accompanied by **basal exudates and hydrocephalus** if there is coexistent tuberculous meningitis. MR spectroscopy shows a **lipid peak with a low choline-to-creatine ratio**.
8. **Pyogenic brain abscess:** a **smooth, thin, uniform ring that is thinner on the ventricular side** (because of poorer vascularity of white matter), with marked oedema. The distinguishing feature is **restricted diffusion on DWI with a low ADC value in the centre** (pus). MR spectroscopy shows amino acid, acetate, succinate and lactate peaks.
9. **Fungal abscess** (aspergillosis, mucormycosis) should be considered in diabetics, transplant recipients and the immunosuppressed; look for sinus and orbital involvement and vascular invasion.
10. **Toxoplasmosis** causes multiple lesions in the basal ganglia and at the corticomedullary junction, with an **"eccentric target sign"**, in HIV-infected patients with CD4 counts below 100/µL.

Distinguishing features — neoplastic causes

11. **Metastasis:** characteristically **multiple, at the grey-white junction**, with **oedema markedly out of proportion to lesion size** and an irregular, often nodular ring. In an elderly patient, the primary is usually lung, breast, kidney, colon or melanoma; a contrast CT chest, abdomen and pelvis is the first staging step.
12. **Glioblastoma:** a **thick, irregular, shaggy ring** with central necrosis, marked oedema, and characteristic **spread across the corpus callosum ("butterfly glioma")**. Perfusion imaging shows increased relative cerebral blood volume in the enhancing rim, and spectroscopy shows a **raised choline-to-creatine ratio with reduced NAA**.
13. **Primary CNS lymphoma** is usually homogeneously enhancing but may show a ring pattern in immunosuppressed patients; it is characteristically periventricular and steroid-responsive, so **steroids should be withheld until biopsy** where lymphoma is suspected.

Distinguishing features — vascular and other causes

14. **Subacute infarct:** ring or gyriform enhancement appearing at **1–3 weeks** ("luxury perfusion"), confined to a vascular territory, with a wedge shape involving cortex and no mass effect out of proportion to the infarct.
15. **Resolving haematoma** and **contusion:** a peripheral enhancing rim around an evolving clot; the history of trauma or hypertension and the changing density on serial imaging give the diagnosis.
16. **Demyelination (tumefactive multiple sclerosis, ADEM):** an **incomplete or open ring** that is open towards the cortex, with **little mass effect relative to lesion size** — the "open ring sign" is highly specific for demyelination.
17. **Radiation necrosis:** occurs months to years after cranial radiotherapy in the previously irradiated field; distinguished from tumour recurrence by low perfusion and low choline on advanced imaging.

Approach and management

18. **MRI with contrast, diffusion-weighted imaging and MR spectroscopy is far superior to CT** and should be requested in every case where the diagnosis is not immediately obvious. **DWI is the single most useful sequence**, since restricted diffusion strongly favours abscess over necrotic tumour.
19. **Work-up:** full history including fever, weight loss, immunosuppression, cancer and travel; examination for a primary tumour, source of sepsis and pulmonary tuberculosis; chest radiograph or CT; HIV testing, blood cultures, ESR, CRP;

and echocardiography if endocarditis is suspected. **Lumbar puncture is contraindicated in the presence of significant mass effect.**

20. **Management** depends on the diagnosis: neurosurgical aspiration plus prolonged antibiotics for abscess; antitubercular therapy with corticosteroids for tuberculoma; albendazole with corticosteroids and antiepileptics for neurocysticercosis; surgery, radiotherapy and oncological referral for tumours. **Where the diagnosis is uncertain and the lesion is accessible, stereotactic biopsy is definitive** — but in India a trial of antitubercular therapy with close radiological follow-up at 8–12 weeks remains an accepted strategy for a probable tuberculoma.

Latest Updates (2023 – Present)

- **Advanced MRI is now standard for lesion characterisation:** DWI/ADC, dynamic susceptibility contrast perfusion, and MR spectroscopy together achieve over 90% accuracy in distinguishing abscess from necrotic tumour, and tumour recurrence from radiation necrosis (multiple systematic reviews, 2023–2025).
- **Amide proton transfer (APT) imaging** and **radiomics/machine-learning classifiers** applied to routine MRI are emerging as non-invasive methods to differentiate ring-enhancing lesions without biopsy.
- **Indian consensus on neurocysticercosis** continues to support albendazole (with or without praziquantel for multiple lesions) plus corticosteroids and antiepileptic drugs for solitary cysticercus granuloma, with antiepileptics usually withdrawn after radiological resolution.
- **WHO and NTEP (National Tuberculosis Elimination Programme) guidance** recommends **12 months of antitubercular therapy for CNS tuberculosis**, with adjunctive corticosteroids; **paradoxical enlargement of tuberculomas on treatment** is well recognised and does not by itself indicate treatment failure — a frequently examined point.
- **Cell-free DNA and next-generation sequencing of CSF** are being introduced for pathogen identification in brain abscess where cultures are negative, and for detection of tumour-derived mutations.
- In the elderly specifically, the **threshold for suspecting metastasis is lower**, and current practice favours early whole-body imaging rather than empirical antimicrobial or antitubercular trials.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Coverage	Not addressed in the uploaded geriatric textbooks	Standard neuroradiology topic; MAGIC DR plus tuberculoma and neurocysticercosis
Imaging modality	—	Contrast MRI with DWI, perfusion and spectroscopy replaces CT for characterisation
Diagnostic confirmation	—	Stereotactic biopsy where uncertain; CSF next-generation sequencing for culture-negative infection
Indian practice	—	Empirical ATT with 8–12 week radiological review accepted for probable tuberculoma; lower threshold for biopsy in the elderly

20. Causes of Coma in the Elderly

Fifteen–Twenty High-Yield Points

Definition and anatomy

1. **Coma is a state of unarousable unresponsiveness** — the deepest grade on the scale of consciousness used in delirium assessment: alert, vigilant, lethargic, **stupor (difficult to arouse)**, and **coma (unarousable)**.
2. Consciousness requires two components: **arousal**, dependent on the ascending reticular activating system in the brainstem and its thalamic projections, and **awareness**, dependent on the cerebral cortex. **Coma therefore requires either a brainstem lesion, bilateral hemispheric dysfunction, or a diffuse metabolic insult.** A single unilateral hemispheric lesion causes coma only if it produces mass effect and herniation.
3. In the elderly, **the threshold for coma is lower** because of reduced neuronal reserve, pre-existing cognitive impairment, polypharmacy and multimorbidity — the same insult that causes mild confusion in a young adult may cause coma in an older person.

Metabolic and toxic causes

4. **Hypoglycaemia** is the single most important immediately reversible cause and must be excluded at the bedside in every patient — particularly in older people on sulphonylureas or insulin with declining renal function or poor intake.
5. Other metabolic causes listed among the causes of delirium and confusion, and which at their extreme produce coma: **hypoxia, hypercarbia, hyperglycaemia, hyponatraemia and azotaemia**.
6. **Hyperglycaemic emergencies: hyperosmolar hyperglycaemic state** is the characteristic presentation in the elderly and carries high mortality; **diabetic ketoacidotic coma** is less common in this age group.
7. **Endocrine: myxoedema coma** (hypothermia, bradycardia, hyponatraemia, precipitated by infection or cold) and **adrenal (Addisonian) crisis**; both are classic geriatric causes of unexplained coma with hypothermia.
8. **Organ failure:** hepatic encephalopathy, uraemic encephalopathy, carbon dioxide narcosis in type 2 respiratory failure, and severe hypothyroidism.
9. **Electrolyte and mineral disturbance:** severe hyponatraemia (and over-rapid correction causing osmotic demyelination), hypercalcaemia (often malignancy-related), and severe hypo- or hypermagnesaemia.
10. **Nutritional: Wernicke's encephalopathy** from thiamine deficiency — frequently missed in older patients with poor intake, malignancy or after refeeding, and not confined to alcohol misuse.
11. **Drugs and toxins** are among the commonest causes: opioids, benzodiazepines, tricyclic antidepressants, anticholinergics, lithium, anticonvulsants, alcohol intoxication, and **carbon monoxide poisoning**. Polypharmacy and altered pharmacokinetics make the elderly especially vulnerable, and drug intoxication is explicitly listed among the causes of acute confusional states.
12. **Thermal: hypothermia and hyperthermia** are listed causes; both are more frequent in older people because of impaired thermoregulation, and heat stroke is an increasing problem in Indian summers.

Structural intracranial causes

13. **Stroke:** massive hemispheric infarction with cerebral oedema (**malignant MCA infarction**) causing midline shift, raised intracranial pressure and **transtentorial herniation with brainstem compression**; and brainstem or bilateral thalamic infarction, where coma occurs directly.
14. **Intracerebral haemorrhage**, especially with intraventricular extension or cerebellar haemorrhage — where **surgical evacuation of a cerebellar haematoma is a life-saving measure**.
15. **Subarachnoid haemorrhage:** sudden severe headache with vomiting, neck stiffness, **altered conscious level and collapse**. Mortality is **35–65%**, and outcome is predicted by **Glasgow Coma Scale score, age and the volume of intracranial blood**.
16. **Subdural haematoma** is a particularly geriatric diagnosis. It **occurs with trivial trauma and sometimes without any trauma**, especially in those taking anticoagulants, and may present as fluctuating consciousness or confusion. Poor outcome is predicted by **advanced age, low GCS at presentation, comorbid injuries and anticoagulant use**.
17. **Intracranial infection:** bacterial meningitis, encephalitis (herpes simplex), cerebral abscess and, in India, tuberculous meningitis with hydrocephalus — where the classical triad may be absent and confusion or coma may be the only feature.
18. **Space-occupying lesions:** primary and metastatic brain tumours; brain tumours are responsible for 10–30% of new seizures in the elderly and may present with progressive obtundation from oedema.

Other causes and approach

19. **Seizure-related:** post-ictal state, and importantly **non-convulsive status epilepticus**, which in older patients may present as unexplained prolonged coma without motor manifestations and requires **EEG** for diagnosis. Cerebrovascular disease is the leading cause of seizures and status epilepticus in later life.
20. **Approach:** stabilise airway, breathing and circulation; **check capillary glucose immediately**; give thiamine before glucose where deficiency is possible; consider naloxone; measure temperature; assess **GCS, pupils, brainstem reflexes and any focal or lateralising signs**; take a full drug and collateral history; obtain urgent **non-contrast CT brain**; and perform lumbar puncture once mass effect is excluded. Remember that **coma in the elderly is frequently multifactorial**, and treatable contributors such as sepsis, hypoxia, hypoglycaemia and drug toxicity should all be corrected simultaneously.

Latest Updates (2023 – Present)

- **Terminology has been standardised** by the European Academy of Neurology and the American Academy of Neurology: "vegetative state" is replaced by **unresponsive wakefulness syndrome**, and **minimally conscious state** and **cognitive motor dissociation** are formally defined. The **Coma Recovery Scale-Revised (CRS-R)** is the recommended assessment instrument for prolonged disorders of consciousness.
- **Cognitive motor dissociation** — covert awareness detectable on task-based fMRI or EEG in patients who appear unresponsive — is now recognised in roughly a quarter of behaviourally unresponsive patients (*NEJM* 2024), with major implications for prognostication and for decisions to withdraw treatment.
- **Full Outline of UnResponsiveness (FOUR) score** is increasingly preferred to the GCS in intubated patients, as it assesses brainstem reflexes and respiratory pattern and can be scored when the verbal component of the GCS is untestable.
- **Point-of-care ultrasound of the optic nerve sheath diameter** and automated pupillometry (neurological pupil index) are being adopted as non-invasive bedside measures of raised intracranial pressure.
- **Middle meningeal artery embolisation** has emerged as an important addition to burr-hole drainage for chronic subdural haematoma, addressing the underlying membrane vascularity and reducing the recurrence rate, which is otherwise as high as **33%** after standard surgery — a significant advance for frail older patients.
- **Serum neurofilament light and neuron-specific enolase**, combined with continuous EEG and MRI, form the current multimodal approach to prognostication after hypoxic-ischaemic brain injury, replacing reliance on single clinical signs.
- **Non-convulsive status epilepticus** is increasingly recognised in older patients with unexplained coma; the **Salzburg criteria** standardise EEG diagnosis, and continuous EEG monitoring is recommended for any unexplained persistent alteration of consciousness.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Terminology	Coma described as a level of consciousness within delirium assessment	Formal taxonomy: coma, unresponsive wakefulness syndrome, minimally conscious state, cognitive motor dissociation
Assessment scale	Glasgow Coma Scale	GCS plus FOUR score in intubated patients; CRS-R for prolonged disorders of consciousness
Covert awareness	Not recognised	Detected by task-based fMRI/EEG in about 25% of unresponsive patients
Chronic subdural haematoma	Burr-hole or twist-drill craniostomy with subdural drain	Middle meningeal artery embolisation as adjunct or alternative, reducing recurrence
Unexplained coma	Structural and metabolic causes sought	Continuous EEG mandated to exclude non-convulsive status epilepticus (Salzburg criteria)

21. Normal Pressure Hydrocephalus

Fifteen–Twenty High-Yield Points

Definition and historical background

1. **NPH is an adult-onset chronic condition** with **enlarged cerebral ventricles on imaging** plus the clinical **Hakim and Adams triad — gait disturbance, cognitive decline and urinary incontinence** — occurring **without high CSF pressure or obstruction** to flow through the ventricular system and subarachnoid space.
2. **It is a potentially reversible neurological disease**, but the mechanisms are unclear and awareness is poor, leading to **under-recognition and undertreatment**. In older people the triad overlaps other age-related diseases and may be wrongly attributed to ageing itself as a result of ageism.
3. **Hakim and Adams** recognised the syndrome in 1957 and published it in 1965, linking the triad definitively to CSF accumulation in the ventricles and showing improvement after lumbar puncture and shunt diversion. **Evans' ratio** was described in 1942 following the introduction of air ventriculography in 1918.

Epidemiology

4. Crude prevalence is **10–22/100,000 for probable NPH and 29/100,000 for possible NPH**. Age-specific rates rise from **3.3/100,000 at age 50–59 to 5.9% in those aged 80 and above**. Incidence rises from 0.07/100,000/year under 60 to **1.2/1,000/year over 70**. In **nursing homes, incidence rates are 9–14%** depending on the criteria used.

Pathophysiology

5. Symptoms **do not result simply from impaired CSF dynamics**. The interacting mechanisms are **altered CSF dynamics and impaired resorption, reduced intracranial compliance, abnormal cerebral perfusion with periventricular ischaemia, altered metabolism, oedema and demyelination, and accumulation of neurotoxic substances** — together producing "cerebral dyshomeostasis".
6. Recognised associations include **cardiac systolic dysfunction** and **obstructive sleep apnoea**, which is frequently co-existent and should be actively sought.

Clinical presentation

7. **Gait disturbance is the earliest and most prominent symptom — wide-based, slow, unsteady and magnetic**, with disturbed tandem walking and turning, small steps, **reduced floor foot clearance**, start hesitation, tendency to fall and disturbed trunk balance. The Dutch NPH study quantified this as **25 steps and 16 seconds for a 10-metre walk versus 15 steps and 8 seconds in controls**.
8. **Cognition** shows an atypical profile combining **frontal-executive, subcortical and posterior cortical impairment**. **Memory and orientation are relatively preserved**; frontal impairment affects **recall disproportionately to recognition**, with attention deficit and reduced psychomotor speed. **In Alzheimer's disease the temporal-lobe profile impairs both recall and recognition** — the key clinical contrast.
9. **Urinary symptoms** begin as frequency and urgency and progress to urge and then complete incontinence as frontal deterioration prevents recognition of the urge. Mechanisms are **reduced bladder capacity (mean 200 mL), detrusor overactivity and enhanced parasympathetic activity**, reversible after LP and shunting. **Faecal incontinence occurs only in advanced stages.**
10. Severity is graded using the **iNPH Grading Scale (iNPHGS)**, which scores gait, cognition and urinary function from 0 to 4 each.

Differential diagnosis

11. Must be distinguished from **Alzheimer's disease, frontotemporal degeneration and vascular cognitive impairment; Parkinson's disease, vascular parkinsonism and Parkinson-plus syndromes; primary progressive freezing gait; and lumbar canal stenosis**. **NPH gait does not respond to external cues or to levodopa**, unlike Parkinson's disease, and there is **no tremor or rigidity**.

Imaging and diagnostic criteria

12. **Imaging features:** ventricular enlargement not entirely attributable to atrophy (**Evans' index >0.3**), no macroscopic obstruction to CSF flow, an **aqueductal or fourth ventricular flow void** on MRI, plus at least one of — enlarged temporal horns, **callosal angle of 90 degrees or less**, or altered brain water content not attributable to microvascular ischaemia or demyelination.
13. **DESH — disproportionately enlarged subarachnoid space hydrocephalus**, i.e. narrowed sulci and subarachnoid spaces over the high convexity and midline with dilated Sylvian fissures — is stressed by the **revised 2012 Japanese criteria** as a very important diagnostic criterion, which can only be overcome by evidence of improvement after a CSF tap or drainage test.
14. **American guidelines (Relkin, Marmarou et al.)** classify NPH as **probable, possible or unlikely**. Supporting history: insidious onset after age 40, duration of at least 3–6 months, progression over time, no antecedent cause of secondary hydrocephalus, and no alternative explanation. **Gait/balance disturbance must be present plus impairment of cognition, urinary function or both.** Probable NPH requires an **opening pressure of 5–18 mmHg (70–245 mm H_2O)**; higher or lower pressures are inconsistent with the diagnosis.
15. **Japanese criteria:** *possible* iNPH — onset in the 60s or later, more than one triad element, Evans' index >0.3, no other explanation, and no obvious antecedent cause; *probable* — adds CSF pressure of 200 mm H_2O or less with normal content, plus either DESH, or improvement after the CSF tap test, or improvement after the drainage test; **definite iNPH — improvement of symptoms after the shunt procedure.**

Supplementary predictive tests

16. **CSF tap test (high-volume LP):** walking speed is assessed in single-task and dual-task conditions, with **maximal improvement 24–48 hours after LP for single-task tests and 48–72 hours for dual-task tests**, returning to the pre-LP state after a few weeks, which further supports the diagnosis. **Sensitivity is low (26–61%), so a negative tap test cannot exclude NPH**; a positive test carries greater certainty of shunt response than clinical examination alone.
17. **Extended lumbar drainage (ELD):** a lumbar catheter draining **100–150 mL of CSF per day for about four days**, with daily assessment of gait and cognition. **Sensitivity 50–100% and positive predictive value 80–100%**, better than LP alone, but a **negative result has deceptively low value** because of frequent false negatives. Discontinue for low-pressure headache, nerve root irritation or signs of meningitis. **Prior stroke predicts a worse outcome; DESH predicts a better one.**
18. **CSF outflow resistance (Ro) by infusion test** has sensitivity **57–100%** and PPV **75–92%**. **Static ICP measurement does not predict surgical outcome** — it is **ICP pulsatility and B-waves** (slow rhythmic oscillations at 0.33–3 cycles/minute) that carry clinical significance, indicating reduced intracranial compliance.
19. **CSF biomarkers: a decrease in A-beta-42 is seen in both NPH and Alzheimer's disease, but a rise in phospho-tau is seen only in Alzheimer's** — useful for differential diagnosis, although **no CSF test has prognostic value before shunting**.

Treatment, outcome and complications

20. **CSF diversion is the only evidence-based curative treatment**; repeated high-volume lumbar punctures have no long-term efficacy in non-operated patients. **Ventriculoperitoneal shunting is standard care and succeeds in about 80% of cases.** Improvement is greatest for **gait (81–86%) and bladder control (70%) and least consistent for cognition (40–44%)**; there is a **96% chance of subjective improvement and 83% chance of improvement on timed walk at six months**, against a **serious adverse event risk of about 11%**. **Age is not a prognostic factor.** Complications include **shunt infection (a neurosurgical emergency), subdural effusion (managed by raising the setting of an adjustable valve), obstruction, catheter fracture and transient hearing loss**; **ventricles do not necessarily shrink after successful shunting**. **Endoscopic third ventriculostomy** avoids shunt hardware but may fail if the stoma closes.

Latest Updates (2023 – Present)

- **The PENS trial is the single most important development and is now the definitive evidence base.** *Placebo-Controlled Effectiveness in iNPH Shunting* (Luciano, Williams and Hamilton et al., ***NEJM*** **2025;393:2198–2209**) randomised **99 patients across 17 centres in the US, Canada and Sweden** — all of whom had responded to temporary CSF drainage — to an **open versus placebo setting on a non-invasively adjustable valve**, keeping patients and assessors blinded.
- **Result:** gait velocity improved by **0.23 m/s with an open shunt versus 0.03 m/s with placebo — treatment difference 0.21 m/s (p<0.001)**. Lateral ventricular volume fell by 27.4 mL versus 4.4 mL. **Falls were significantly fewer with an open shunt (24.5% versus 46%, p=0.03).** The DSMB **stopped enrolment early at the second interim analysis (January 2025)** for efficacy.
- Crucially, PENS confirmed benefit for **gait and balance but NOT for cognition or incontinence at three months** — validating the textbook observation that gait responds best and providing a realistic basis for counselling patients and families.
- PENS answers long-standing scepticism about shunting: there had been **calls for a moratorium** on grounds of variable results, questionable durability of benefit, surgical risk and a potential strong placebo effect. The **2024 Cochrane review (CD014923)** had concluded that further studies were needed to increase certainty; PENS supplies that certainty.
- **Prevalence data have been refined:** a Swedish population-based MRI study of **791 seventy-year-olds (*Neurology* 2024;102:e208037)** confirms possible iNPH is far commoner in the community than clinic-based figures suggest, reinforcing that this is an under-diagnosed treatable cause of disability in old age.
- **Glymphatic dysfunction** is now central to the accepted pathophysiology — impaired perivascular clearance with accumulation of neurotoxic metabolites — linking iNPH mechanistically to Alzheimer's co-pathology and explaining why cognition responds less reliably than gait.
- Contemporary reviews (*Neurosurgery Clinics of North America* 2024) reaffirm that **DESH and reduced callosal angle support the diagnosis but have limited predictive value for treatment response** — the provocative CSF removal tests (tap test, infusion test, extended lumbar drainage) remain what actually stratifies who will respond, and adding them progressively increases predictive power.
- **Programmable, non-invasively adjustable valves with anti-siphon devices are now standard**, allowing pressure adjustment for over-drainage and subdural collections without reoperation — and it is precisely this technology that made the blinded placebo-controlled PENS design possible. **VP versus lumboperitoneal shunting** is being compared head-to-head (COVLINPH-1, primary outcome shunt failure at five years).
- **Indian context:** iNPH is markedly under-recognised, and the practical barriers are access to neurosurgical services and to programmable valves. A **tap test with objective 10-metre gait speed measured before and 24–72 hours after LP** is a cheap, reproducible screening strategy any geriatric unit can implement, and should be considered in every older patient with unexplained gait apraxia plus cognitive or urinary symptoms.

Current Practice Update

Aspect	Textbook position	

		Current evidence / practice
Evidence for shunting	About 80% success from observational series; effectiveness questioned, with calls for a moratorium	PENS trial (*NEJM* 2025) — first adequately powered blinded RCT; confirms benefit and was stopped early for efficacy
Which symptom improves	Gait and bladder best, cognition least consistent	Confirmed and sharpened: significant gain in gait velocity and balance, **no** significant gain in cognition or incontinence at 3 months
Falls	Not a formal endpoint	Shunting roughly halves falls (24.5% versus 46%) — a directly relevant geriatric outcome
Pathophysiology	Altered CSF dynamics, perfusion, ischaemia, neurotoxic accumulation	Adds **glymphatic system dysfunction** as a unifying mechanism
Imaging markers	DESH stressed as a key diagnostic criterion (Japanese 2012)	DESH and callosal angle support diagnosis but **poorly predict shunt response**; CSF removal tests remain the selection tool
Valve technology	Adjustable valves available	Non-invasively adjustable valves with anti-siphon devices are standard, and enabled the placebo-controlled trial design

22. Stroke Rehabilitation

Fifteen–Twenty High-Yield Points

Definition and conceptual framework

1. **Stroke is the leading cause of severe physical disability in adults.** Rehabilitation is defined as a **multidisciplinary problem-solving educational process focusing on disability and intended to reduce handicap** — it is not simply treatment by a therapist or group of therapists.
2. The **WHO/ICF framework** underpins assessment: **impairment** (loss of structure or function), **disability** (inability to perform tasks — the ability to undertake basic self-care is fundamental to any physical rehabilitation programme), and **handicap** (the social consequence, i.e. limitation in fulfilling a normal role in society). Disability and handicap are often combined pragmatically as **social disability**.
3. **Four basic principles:** document and measure impairments, disabilities and handicaps using simple valid scales; **maximise independence and minimise learned dependency**; adopt a **holistic approach** covering physical and psychosocial background, support mechanisms and environment; and **support caregivers**, helping them develop the physical and psychological skills for long-term sustainable care.

Basis of recovery

4. **The brain is capable of significant recovery after stroke, provided appropriate treatments are applied in adequate amounts and at the right time.** Recovery depends on resolution of oedema and penumbral salvage early, then on **neuroplasticity** — cortical reorganisation, unmasking of latent pathways, synaptogenesis and stroke-induced neurogenesis.
5. **The more severe the initial deficit, the less likely complete recovery.** The pattern is not uniform, varying between individuals and between different deficits in the same individual, and **there is no validated method for predicting the precise mode or degree of recovery for a given individual**.
6. **Rates of recovery differ by deficit:** homonymous hemianopia, dysphagia and sitting balance resolve quickly; **arm paralysis and language impairment recover more slowly and less completely**; perceptual problems may persist or take very long. Overall, **62% are independent in self-care at three months and 66% at one year**, despite persisting neurological deficit in some.
7. Day-to-day variation may mask recovery or give false optimism, so **monitor trends over time rather than relying on one-off assessments**. **Comorbidity and stroke-related complications adversely affect recovery. Spontaneous recovery may not plateau until six months**, which is the most appropriate time point for measuring neurological and functional outcome; participation and life satisfaction are best measured once the social situation has stabilised.

The four components of the rehabilitation process

8. **Assessment** defines the nature and severity of deficits and treatment goals before starting. Its three purposes are **prognostication** (type of patient, extent of disability, potential for recovery), identifying the main problems and the expectations of patient and family, and **monitoring and outcome evaluation**. Measures must be **valid, reliable, sensitive, simple and communicable**, and existing measures should be used wherever possible.
9. **Composite global severity scores are unreliable** because speech and language function dominates the index, and because combining very different disabilities into one score loses specific information and ignores their interactions.
10. Predicting when a patient has reached full recovery potential is an imprecise science, and matters most for **chronic stroke patients beyond one year**, who are most likely to be denied further therapy. **Combined TMS and MRI** — motor-evoked potentials in the affected limb with minimal fractional anisotropy asymmetry in the internal capsule — predicted potential for improvement up to **three years** after stroke.
11. **Planning is goal setting.** Immediate goals concern basic ADLs (sitting balance, transfers, toileting); later goals concern household, social, leisure and occupational activity. Three practical domains must be addressed: **accommodation** (where will the patient live and what adaptations are needed), **personal support** (what support exists and what extra help is essential), and **life satisfaction** (what roles will be fulfilled and how will time be occupied).
12. **The two major problems in goal setting are failure to use a common language between professionals and with patients, and failure to agree a time frame.** The goals of the hospital (early discharge), the patient (return to premorbid status) and the carer (minimise input, even at the cost of institutionalisation) frequently conflict; an essential team function is to **identify and modify unrealistically high — and sometimes unjustifiably low — expectations**.
13. **Intervention:** the minimum requirement is to maintain the status quo and prevent deterioration from poorly managed complications; beyond that, to facilitate recovery, minimise disability and prevent handicap. **No rehabilitation technique has been shown to be superior to any other** in physical therapy or in speech and language function, so a **pragmatic functional approach individualised to each patient** is recommended and rigid adherence to unproven theories should be discouraged.
14. **Evaluation** is confounded by spontaneous recovery, differing perceptions of a good outcome, and the profusion of instruments. **ADL scales predominate** because independence in ADLs determines care needs and resource use. Simple assessments used frequently are more useful than complex ones used rarely.

Specific rehabilitation techniques

15. **Early mobilisation** is associated with good functional outcomes in observational and controlled studies, but review of pooled data found **no unequivocal independent benefit**; it is, however, **not harmful to most stroke patients** and contributes as part of routine stroke unit care to good long-term outcomes.

16. **Motor recovery:** balance and motor therapy with or without sensory feedback improves function and mobility; **speed-dependent treadmill training** benefits ambulant hemiparetic patients; robotic devices allow repetitive practice. **Constraint-induced movement therapy (CIMT)** prevents learned non-use; the **EXCITE trial** showed statistically significant and clinically relevant improvement in arm motor function persisting at least one year, but doubts remain about practicality and cost-effectiveness, and meta-analysis suggests benefit is **proportional to the amount of exercise given to the affected limb**, potentially achievable by conventional therapy.
17. **Neuromuscular stimulation:** peripheral electrostimulation improves functional motor ability, motor impairment and normality of movement. **rTMS** aids recovery of motor deficit, visuospatial neglect and aphasia — **low-frequency stimulation over the unaffected hemisphere to restore inhibition, or high-frequency stimulation over the affected hemisphere to reactivate hypoactive regions**.
18. **Motor imagery / mental practice** positively affects arm recovery and shows promise for the leg, with **greater effect when combined with conventional rehabilitation** in subacute patients; **mirror therapy** enhances lower-limb motor recovery.
19. **Spatial neglect:** the conceptual shift is from a spatial lack of awareness to a **generalised reduction in attentional ability**. Spatial techniques such as prism adaptation have limited success, whereas **non-spatial attention training** improves neglect with corresponding change in cortical activation. **There is no effective treatment for apraxia** — management focuses on early recognition, increasing awareness, and teaching adaptive skills and coping strategies.

Complications, organisation and psychosocial care

20. **Complications occur in about 60% of patients undergoing rehabilitation** and are commoner with severe disability. Key problems are **dysphagia** (21–55% clinically, 44–78% on videofluoroscopy, with frequent **silent aspiration**; associated with higher mortality, longer stay and a **three- to fivefold increase in institutionalisation at five years**; videofluoroscopy is the gold standard and the water swallow test the practical bedside screen); **dysphasia** (comprehension is routinely overestimated); **spasticity** (**botulinum toxin has replaced baclofen and dantrolene** for focal spasticity — it reduces upper-limb tone but functional improvement is not established); the **hemiplegic shoulder** (subluxation in about one in five; pain from spasticity, subluxation, shoulder–hand syndrome or rotator cuff pathology, aggravated by careless handling; managed by positioning, avoiding traction on the arm and early passive movement); **post-stroke depression** (**30–60%, pooled prevalence about 33%**, higher in women, younger patients and those with greater disability, lasting seven to eight months untreated and correlating with failure to resume activities); plus central post-stroke pain, **fatigue** (no specific treatment shown to benefit), seizures, VTE, incontinence, pressure sores and **falls with fractures on the hemiplegic side**.
21. **Organised (stroke unit) care both facilitates neurological recovery and expedites discharge.** Audit shows patients spend **over 50% of time in bed, 28% sitting out, only 13% in therapeutic activity, and are alone 60% of the therapeutic day**; the **CERISE study** showed outcomes depend on **therapy actually delivered rather than resources allocated**. **Caregiver training is a proven intervention.** The reaction to stroke is **akin to bereavement**, and staff attitude matters — esteem plummets when patients are depersonalised as "CVAs" or "hemis". **Organised, coordinated rehabilitation in partnership with patients and caregivers offers the only realistic hope of reducing disability and handicap after stroke.**

Latest Updates (2023 – Present)

- **The 2024 VA/DoD Clinical Practice Guideline for the Management of Stroke Rehabilitation** (released July 2024; synopsis in *Annals of Internal Medicine* 2025) is the most current comprehensive guideline, updating the 2019 version using GRADE methodology.
- **Change of direction on antidepressants:** the guideline now **suggests AGAINST antidepressants for the prevention of post-stroke depression** (moved from "neither for nor against" in 2019 to "weak against" in 2024). This follows **FOCUS (n=3,127), AFFINITY and EFFECTS**, which showed **fluoxetine does not improve functional outcome and doubles the risk of bone fracture** — critical in an osteoporotic elderly population. Antidepressants remain indicated to **treat** established depression.
- **Very early mobilisation has been redefined by AVERT phase 3:** very early, high-dose, out-of-bed activity within 24 hours produced **worse** odds of a favourable outcome at three months than usual care. Current practice is **early but not aggressive** mobilisation — short, frequent, lower-dose sessions, avoiding prolonged upright activity in the first 24 hours. This resolves the textbook's uncertainty in a specific direction.
- **Vagus nerve stimulation paired with rehabilitation** is the major new modality. **VNS-REHAB (*Lancet* 2021)** led to approval of the **Vivistim Paired VNS System** for chronic ischaemic stroke with moderate-to-severe upper limb impairment; long-term outcomes (*Stroke* 2025) and a 2025 systematic review and meta-analysis (*Neurosurgery* 2025) support durable gains. The **2024 VA/DoD guideline** gives the clearest stance, noting that pairing VNS with task-specific rehabilitation may enhance motor recovery through neuroplasticity, while cautioning that the evidence is limited in quality and scope. **Transcutaneous auricular VNS** is under trial as a non-implanted alternative.
- **Robotics have been tempered by trial evidence:** the **RATULS trial** showed robot-assisted training did **not** improve upper limb function beyond enhanced conventional therapy, reinforcing that **dose and task specificity — not the device — drive recovery**.
- **Telerehabilitation is now established as non-inferior** to in-clinic therapy for motor recovery, and is the most scalable delivery model where therapists are unevenly distributed. In India, the **ATTEND trial (*Lancet* 2017)** found structured family-led home rehabilitation was **not superior to usual care** — an important negative result cautioning against substituting trained therapy with caregiver delivery alone.
- **Fitness training after stroke** (Cochrane, updated) consistently improves walking speed, endurance and balance and reduces disability — cardiorespiratory and mixed training now carry stronger recommendations than most specific

neurofacilitation techniques.

- Apart from the negative fluoxetine data, **no pharmacological adjunct has been established**; amphetamines, levodopa and citicoline have all failed to show consistent benefit.
- **Aphasia:** high-intensity, high-dose speech and language therapy is supported by Cochrane evidence, with **intensity and total dose** the critical variables; computer- and app-delivered therapy extends dose economically.
- **Indian context:** the Indian Stroke Association and NP-NCD promote a tiered rehabilitation model; the practical constraints are shortage of therapists, out-of-pocket cost and early discharge. **Early supported discharge with structured caregiver training** remains the highest-value model, and low-cost stroke units have been shown in Indian series to reduce dependency without intensive care facilities.

Current Practice Update

Aspect	Textbook position	Current evidence / practice
Early mobilisation	Benefit unproven but "not harmful to most patients"	AVERT 3: very early **high-dose** mobilisation worsens outcome — mobilise early but in short, frequent, low-dose sessions
Antidepressants	Post-stroke depression treated; prophylaxis not addressed	VA/DoD 2024 **suggests against** antidepressants for prevention; FOCUS/AFFINITY/EFFECTS negative, fluoxetine doubles fracture risk
Neuromodulation	rTMS and peripheral electrostimulation described	Adds approved **paired vagus nerve stimulation** for chronic upper limb impairment
Robotic therapy	Listed as an emerging technique	RATULS negative — dose and task specificity matter more than the device
Delivery of therapy	Inpatient, therapist-delivered, unit-based	Telerehabilitation non-inferior; early supported discharge and home-based programmes standard
Exercise and fitness	Mentioned within physical therapy	Cardiorespiratory fitness training has among the strongest evidence for walking and disability outcomes
Guideline framework	Consensus and pooled trial data	Formal GRADE-based VA/DoD 2024 guideline with explicit strength of recommendation

MD GERIATRIC MEDICINE — EXAMINATION REVISION

Nutrition in the Elderly

A Compiled Set of High-Yield Examination Answers

Five Questions · 15-Mark Format

Textbook Content • Latest Updates (2023–Present)

Current Practice Update • Examiner's Tips

Rapid Revision Appendix

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition

Essentials of Clinical Geriatrics, 7th edition

Updates current to August 2026 · Indian clinical context integrated throughout

Contents

Five questions on nutritional medicine in old age, in the order discussed.

#	Question	Core Focus
1	**Various nutritional disorders in the elderly and their management**	Whole spectrum — under- and over-nutrition
2	**Malnutrition in older adults — causes, approach to diagnosis, assessment and management**	Causes → GLIM → CGA → treatment ladder
3	**Nutritional assessment in older persons**	Screen → Diagnose → Grade
4	**Anorexia of ageing**	Physiology, hormones, management
5	**Obesity in the elderly and its management**	Obesity paradox, sarcopenic obesity, therapy
A	**Appendix — Rapid Revision Grid**	Numbers, criteria, trials, mnemonics

How to Use This Document

- Each answer follows the same architecture: **numbered high-yield points from the textbook** → **Latest Updates (2023–present)** with inline citations → **Current Practice Update** table contrasting textbook with current evidence → **Examiner's Tip** panel of verbatim mark-earning lines.
- Textbook content and recent evidence are kept strictly separate. Where they conflict, the conflict is shown explicitly in the comparison table.
- The five answers overlap deliberately — GLIM criteria, weight-loss thresholds and the ONS dose-duration rule recur, because examiners test them from several angles.
- The **Rapid Revision Appendix** at the end compiles every number, cut-off, criterion and named trial for night-before revision.

Question 1. Various Nutritional Disorders in the Elderly and Their Management

15 marks · Source: Pathy's 6th ed. (Ch. 12, 13, 14, 15, 16, 22); Essentials of Clinical Geriatrics 7th ed. (Ch. 3, 12)

20 High-Yield Points

DEFINITION AND SPECTRUM

1. **Definition.** As per **WHO**, malnutrition means **deficiencies, excesses or imbalances** in a person's energy and nutrient intake. It therefore includes **both undernutrition and obesity**.
2. **Spectrum of nutritional disorders in old age.** (a) **Protein-energy undernutrition**, (b) **Anorexia of ageing**, (c) **Cachexia**, (d) **Sarcopenia and sarcopenic obesity**, (e) **Micronutrient deficiencies**, (f) **Dehydration and electrolyte disorders**, (g) **Obesity**.
3. **Epidemiology.** Using MNA, overall prevalence is **22.8%** — highest in **rehabilitation units (50.5%)**, then **hospital (38.7%)**, lowest in **community (5.8%)**. European meta-analysis: community 6%, hospital 22%, nursing home 17.5%, **long-term care 28.7%**. Involuntary weight loss occurs in **5–15% of community elders** and **27% of frail elders**.

ANOREXIA OF AGEING

4. **Anorexia of ageing.** A **physiological**, age-related fall in appetite and energy intake that exceeds the fall in energy expenditure, causing weight loss. Prevalence rises from **3.3% in the community to 33% in nursing homes**. **Loss of appetite is the key predictor of malnutrition.**
5. **Pathophysiology.** Four mechanisms — **loss of homeostatic regulation** (elders do not compensate after underfeeding), the **ageing gut** (myenteric plexus cell loss, early satiation, reduced sensitivity to distension), **declining taste and smell**, and **hormonal changes** — chiefly **raised CCK levels with increased sensitivity to CCK**; leptin, NPY and CART changes are also implicated.
6. **Pathological causes (all at least partly treatable). Depression** (2–10% community, higher in institutions), **dementia** (~2-fold risk of anorexia; up to **50% of institutionalised dementia patients have PEM**), **COPD, CHF** (anorexia in >40% of end-stage CHF), **CKD, cancer**, **drugs and polypharmacy**, **poor dentition and dysphagia**, immobility, tremor, poor vision, poverty and isolation. Use the **"MEALS ON WHEELS" mnemonic** to search for treatable causes.

CLASSIFICATION AND DIAGNOSIS OF UNDERNUTRITION

7. **Classification by inflammatory grade. Starvation** (pure protein-energy deficit, **CRP <3 mg/L**) → **inflammageing** (low–medium) → **cachexia** (medium-grade inflammation, disease-related) → **hypercatabolic malnutrition** (sepsis, trauma; high-grade inflammation).
8. **GLIM diagnostic criteria** — need **one phenotypic + one etiologic** criterion.
   - **Phenotypic:** non-volitional **weight loss >5% in 6 months or >10% beyond 6 months**, **low BMI**, **reduced muscle mass**.
   - **Etiologic: reduced food intake or assimilation**, **inflammation / disease burden**.
9. **Clinically significant weight loss. 5% in 1 month, 7.5% in 3 months, or 10% in 6 months**. **BMI <22 kg/m²** predicts higher one-year mortality and poorer function; **ideal BMI ranges are higher in older than younger adults**. Weight change is preferred to BMI because kyphosis makes height unreliable.
10. **Screening tools. MNA and MNA-SF** are standard: **12–14 normal, 8–11 at risk, 0–7 malnourished**; uses **BMI or calf circumference (<31 cm)**. MNA is **96% sensitive, 60% specific** for weight loss and is a **powerful prognostic factor**, especially in cancer. Alternatives: **SGA, SNAQ**.
11. **Laboratory assessment. Serum albumin** is practical but confounded by liver disease, proteinuria and protein-losing enteropathy; **prealbumin and retinol-binding protein are more sensitive**. **Total lymphocyte count** is a useful marker. **Anaemia is one of the earliest manifestations of protein-calorie malnutrition.**

MICRONUTRIENT DISORDERS

12. **Micronutrients of public health concern in elders. Vitamin D, calcium, B12, folate, B2, B6, vitamin C, vitamin E, vitamin A, choline, zinc, magnesium, potassium, selenium**. An energy intake **<1500 kcal/day generally guarantees micronutrient inadequacy** — hence the emphasis on **nutrient-dense foods**.
13. **Vitamin B12 deficiency. 10–30% of elders malabsorb food-bound B12** (atrophic gastritis); **pernicious anaemia in 1–2%**. Features: **macrocytic anaemia, fatigue, anorexia, weight loss, paraesthesiae, ataxia, depression, dementia, glossitis**. Diagnosis: **low B12 with raised MMA and homocysteine**; **oral high-dose is as effective as intramuscular**.
14. **Folate deficiency.** Stores are small, so deficiency develops in **weeks to months**. **Homocysteine raised, MMA**

normal (distinguishes it from B12 deficiency). Causes: alcohol, malabsorption, **methotrexate, sulfasalazine, trimethoprim, phenytoin**. Treat with **folic acid 1 mg/day**.

15. **Zinc and iron. Zinc deficiency** causes **anorexia through impaired taste and smell**, impaired immunity, poor collagen synthesis and wound healing, diarrhoea and confusion; common in diabetics. **Iron deficiency is less common than in the young** — always exclude **chronic GI blood loss** and distinguish from anaemia of chronic disease (ferritin, CRP).
16. **Calcium and vitamin D.** Recommended intake after age 50: **calcium 1000–1200 mg/day, vitamin D 800 IU/day**; **upper limits 2000 mg and 4000 IU**. Treat **25(OH)D <10–12 ng/mL**; adequacy usually taken as **≥20 ng/mL**. Supplementation reduces **bone loss, fractures and falls** and improves **sarcopenia**.

DEHYDRATION, OBESITY AND MANAGEMENT

17. **Dehydration.** Very common and potentially lethal — **hospital mortality up to 50%**. Due to **reduced thirst**, a **fall in total body water from 60% to 50% after age 75**, and **reduced aquaporin-2 responsiveness to ADH**. Commonest precipitants: **infection, altered consciousness, cognitive impairment, diuretics**. **Acute loss ≥3% body mass or >1 kg/day** suggests dehydration. Advise **~1.5 L fluid daily**. Correct **hypernatraemia by <10 mEq/L/24 h** and **hyponatraemia by 6–8 mEq/L/24 h** to avoid cerebral oedema and osmotic demyelination.
18. **Obesity and sarcopenic obesity.** In those ≥65, **overweight (BMI 25–29) carries no excess mortality** and obesity only a modest increase. **Sarcopenic obesity = low lean mass with increased fat mass.** Weight loss is indicated **only when there is functional impairment or metabolic complication**, using a **modest deficit of 500–700 kcal/day plus resistance exercise** to protect muscle and bone. **Bariatric surgery only for highly selected older patients.**
19. **Management of undernutrition — five steps.**
    - **Step 1 — treat reversible causes** through **comprehensive geriatric assessment** (cognition, depression, drugs, dentition, swallowing, constipation, social and financial support).
    - **Step 2 — food-first measures:** oral and dental care, **texture modification**, **flavour enhancement**, feeding assistance, food fortification, meals-on-wheels.
    - **Step 3 — oral nutritional supplements (ONS):** meta-analysis of 42 trials showed **2.3% weight gain** and **reduced mortality (RR 0.74)** — benefit was significant when **≥400 kcal/day was given for ≥35 days** to **unwell, malnourished patients aged ≥75** in hospital or nursing homes. **No proven improvement in functional status or length of stay.**
    - **Step 4 — exercise: progressive resistance training 2–3 times/week** is the **primary intervention for sarcopenia**, improving strength, gait speed and chair rise even in the very old.
    - **Step 5 — enteral nutrition** if oral intake is inadequate; **parenteral** only if enteral is impossible. **PEG feeding in nursing-home residents with severe cognitive impairment did not improve 24-month survival, and aspiration pneumonia occurred at the same rate with or without tube feeding.**
20. **Palliative/orexigenic drugs and prognosis. Megestrol acetate** is the best studied (increases appetite, weight and quality of life; **oedema** is the significant adverse effect). **Corticosteroids** improve appetite without weight gain; **cyproheptadine** likewise; **cannabinoids (dronabinol, nabilone)** and **thalidomide (anti-TNF)** have limited evidence. **Unintentional weight loss is an independent predictor of mortality, functional decline, disability and institutionalisation** — it is a marker of poor prognosis, not merely a nutritional problem.

Latest Updates (2023–Present)

1. **GLIM criteria — 5-year update.** A 43-member working group reviewed >400 publications (2019–2024) and confirmed strong construct and predictive validity. No revisions were made to the weight loss, low BMI or reduced food intake/assimilation criteria; assessment of low muscle mass should be guided by experience and available technological resources, and clinical judgement may suffice for the inflammation/disease burden criterion. *(Jensen GL, et al. Clin Nutr / JPEN. 2025.)*
2. **Practical bedside GLIM muscle-mass surrogates validated.** Using calf circumference <31 cm in both sexes, or MUAC <23 cm in men and <22 cm in women, gave 84.6% and 83.4% accuracy against SGA, with sensitivity ~89% and ~84%. Directly relevant to Indian practice where DXA/BIA is unavailable. *(Shahraki Jazinaki M, et al. Front Nutr. 2024.)*
3. **GLIS — first global conceptual definition of sarcopenia.** Muscle mass (89.4%), muscle strength (93.1%) and muscle-specific strength (80.8%) were all accepted as components of sarcopenia, whereas impaired physical performance was accepted as an *outcome* rather than a component. This supersedes the textbook's EWGSOP-based framing. *(Kirk B, et al. Age Ageing. 2024.)*
4. **ESPEN practical guideline, geriatrics.** Eighty-two evidence-based recommendations: all older persons shall be routinely screened for malnutrition; oral intake supported by nursing interventions, counselling, food modification and ONS; enteral nutrition if oral is insufficient and parenteral if enteral is insufficient or impossible, when prognosis is favourable; dietary restrictions should generally be avoided. Low-intake dehydration should be diagnosed on serum

osmolality and corrected with hypotonic fluids given orally, subcutaneously or intravenously depending on severity; weight loss should be considered only in obesity with associated health problems, using moderate energy reduction with exercise. *(Volkert D, et al. Clin Nutr. 2022;41:958–989.)*

5. **ESPEN guideline on nutrition and hydration in dementia — Update 2024.** A full guideline update giving evidence-based recommendations for nutritional care in persons with dementia, to prevent and treat malnutrition and low-intake dehydration. *(Volkert D, et al. Clin Nutr. 2024.)*
6. **ESPEN practical guideline: nutritional support for polymorbid medical inpatients (2024).** Reaffirms screening-then-treat. The EFFORT trial showed that reaching ≥75% of estimated nutrition goals, versus lower achievement, significantly lowered the risk of adverse events and mortality. However, the 6-month secondary analysis found that while individualised nutritional support during hospital stay significantly reduced short-term mortality, there was no legacy effect on longer-term outcomes. *(ESPEN. Clin Nutr. 2024; Schuetz P, et al. Lancet. 2019; Clin Nutr. 2020.)*
7. **Vitamin D — Endocrine Society guideline 2024.** Empiric vitamin D supplementation is suggested in the general population aged 75 years and older because of the potential to lower mortality risk, with routine 25(OH)D testing suggested against in this group. For non-pregnant people over 50 in whom vitamin D is indicated, daily administration is suggested rather than intermittent high doses. *(Demay MB, et al. J Clin Endocrinol Metab. 2024.)*
8. **Vitamin D — USPSTF draft recommendation (Dec 2024).** Moderate certainty that vitamin D with or without calcium has no net benefit for primary prevention of fractures, and vitamin D has no net benefit for prevention of falls, in community-dwelling postmenopausal women and men aged 60 and older — a **D grade**. It does not apply to people taking these for other medical reasons, to those in assisted living or nursing homes, or to those diagnosed with osteoporosis or vitamin D deficiency. *(USPSTF Draft Recommendation Statement. 2024.)*
9. **Megestrol now discouraged.** The 2023 AGS Beers Criteria lists megestrol as **avoid** (strong recommendation, moderate quality) — minimal effect on weight, with increased risk of thrombotic events and possibly death in older adults. *(AGS Beers Criteria Update Expert Panel. J Am Geriatr Soc. 2023;71.)*
10. **Indian data — LASI Wave 1.** Among those aged 60 and above, 28% of men and 25% of women are underweight, while 25% of men and 37% of women aged 45–59 are overweight or obese; the urban population is less likely to be underweight and more than twice as likely to be overweight, and older adults from low economic and social strata are more likely to be underweight. Using a modified MUST, about 26% were classified as undernourished high-risk, characterised by low BMI, recent hospital admission and food-insecure households. *(Khan J, et al. Sci Rep. 2023;13; LASI analysis. BMC Public Health. 2023.)*
11. **WHO BMI cut-offs may misclassify Indian elders.** CART analysis of LASI data derived age-appropriate cut-offs — the underweight threshold fell from <18.5 to <17.4 for those aged 60–74 and <13.3 for those 75 and above. *(Singh A, Chattopadhyay A. Sci Rep. 2024;14.)*
12. **ICMR-NIN Dietary Guidelines for Indians 2024.** Seventeen guidelines addressing India's double burden of malnutrition, introducing the **"My Plate for the Day"** model and integrating RDA 2020 (safe protein requirement **0.83 g/kg/day**, EAR 0.66 g/kg/day, with **DIAAS** replacing PDCAAS for protein quality). The guidelines discourage the use of protein supplements and high-protein concentrates for muscle building, citing bone mineral loss and kidney damage with prolonged intake. *(ICMR-NIN. Dietary Guidelines for Indians. 2024.)*
13. **GLP-1 receptor agonists and the older adult — a new nutritional concern.** GLP-1 RAs effectively induce weight loss, but concomitant muscle mass loss is common, raising concerns about sarcopenia and sarcopenic obesity in older adults. A meta-analysis of eight RCTs found participants regained 9.69 kg over 48–52 weeks after stopping semaglutide or tirzepatide. Short-to-mid-term trials show handgrip strength is statistically preserved despite reductions in lean soft tissue, but longitudinal and retrospective studies in older adults with type 2 diabetes report reduced handgrip strength and accelerated sarcopenia with prolonged semaglutide use. **Practical implication: combine with adequate protein and resistance training in elders.** *(Curr Nutr Rep. 2026; Maturitas. 2025.)*

Current Practice Update

Textbook Position (Pathy's 2022 / Essentials 7e)	Current Evidence-Based Practice (2023–present)
GLIM criteria described as newly established (2019)	**GLIM 5-year update 2025** confirms validity; criteria unchanged; muscle mass measured by whatever tool is available, **calf circumference/MUAC acceptable**
Sarcopenia framed by EWGSOP; screening based on muscle performance	**GLIS 2024** — muscle mass + strength + **muscle-specific strength** are components; **physical performance is an outcome, not a component**
Vitamin D supplementation reduces falls and fractures	**USPSTF 2024 (draft, D grade)**: no net benefit for falls/fractures in healthy community-dwelling elders; **Endocrine Society 2024** still supports **empiric vitamin D ≥75 years** for mortality and **against routine 25(OH)D testing**
Megestrol acetate is "the most widely studied" orexigenic and	**AGS Beers 2023: AVOID** — minimal weight effect, thrombotic risk and

improves appetite, weight and QoL	possible increased mortality
Protein requirement stated as 0.5 to >1.0 g/kg/day (conflicting data)	**1.0–1.2 g/kg/day** in healthy elders and **1.2–1.5 g/kg/day** in acute/chronic illness (ESPEN 2022); **ICMR-NIN 0.83 g/kg/day** is a population safe level, not a therapeutic target
Serum albumin used as a practical indicator of malnutrition	Albumin/prealbumin now regarded as **inflammatory (prognostic) markers**, not nutritional markers; **not part of GLIM**
Obesity managed with lifestyle; drug therapy data "insufficient" in elders	**GLP-1 RAs now widely used**, but carry a **lean-mass loss and weight-regain risk**; must be paired with protein + resistance exercise
WHO BMI cut-offs applied uniformly	**Indian LASI-derived age-specific BMI cut-offs (2024)** perform better in those ≥60
Dehydration diagnosed clinically	**ESPEN**: diagnose low-intake dehydration on **serum osmolality**; correct with **hypotonic fluids**

Examiner's Tip — Mark-Earning Lines

- "Malnutrition in the elderly is a **geriatric syndrome**, not a single disease — it requires comprehensive geriatric assessment, not simply calorie counting."
- "**Anorexia of ageing** is physiological; **protein-energy malnutrition** is pathological. The clinical skill lies in separating the two."
- "Diagnosis follows a **two-step approach: screen with MNA-SF, then diagnose with GLIM** (one phenotypic + one etiologic criterion)."
- "**Unintentional weight loss of 5% in 1 month, 7.5% in 3 months or 10% in 6 months** is clinically significant and mandates evaluation."
- "ONS reduce mortality only when given at **≥400 kcal/day for ≥35 days** to genuinely malnourished, unwell elders — dose and duration matter."
- "**PEG feeding in advanced dementia does not improve survival and does not reduce aspiration pneumonia** — the decision belongs in an advance care planning discussion."
- "**Resistance exercise, not nutrition alone**, is the primary intervention for sarcopenia; nutrition is permissive, exercise is the stimulus."
- "In India, **LASI shows roughly one in four elders is underweight**, while overweight is rising — the **double burden of malnutrition** defines Indian geriatric nutrition."

Question 2. Malnutrition in Older Adults — Causes, Approach to Diagnosis, Assessment and Management

15 marks · Source: Pathy's 6th ed. (Ch. 12, 13, 14, 16); Essentials of Clinical Geriatrics 7th ed. (Ch. 3, 10, 12)

20 High-Yield Points

DEFINITION AND CONCEPT

1. **Definition.** As per **WHO**, malnutrition means **deficiencies, excesses or imbalances** in energy and nutrient intake. In geriatric practice, "malnutrition" and **undernutrition (protein-energy malnutrition)** are used interchangeably.
2. **It is a geriatric syndrome, not a single disease.** Like falls or delirium, it is **multifactorial with poor outcomes** and needs a multi-domain approach. Three overlapping presentations exist: **starvation** (pure intake deficit, responds to refeeding), **cachexia** (inflammation-driven, does not respond to refeeding alone), and **sarcopenia** (loss of muscle mass and strength, may occur with normal weight).
3. **Epidemiology.** Using MNA, overall prevalence is **22.8%** — **rehabilitation 50.5%**, **hospital 38.7%**, **community 5.8%**. European meta-analysis: **long-term care 28.7%, rehabilitation 29.4%, hospital 22%, nursing home 17.5%, community 6%**. People aged >70 consume about **one-third fewer calories** than the young, and **16–18% of community elders eat <1000 kcal/day**.

CAUSES

4. **Physiological — the anorexia of ageing.** (a) **Loss of homeostatic regulation** — elders fail to regain weight after underfeeding; (b) **ageing gut** — impaired **fundic accommodation** (raised nitric oxide), **delayed gastric emptying**, early satiation; (c) **declining senses** — over **50% aged 65–80 and >75% aged over 80** have measurable olfactory decline, and **46% of those with olfactory dysfunction have a change in appetite or weight**; reduced **sensory-specific satiety** narrows dietary variety; (d) **hormonal** — raised **CCK (levels + sensitivity), leptin, insulin and PYY**.
5. **Medical and psychiatric causes. Depression** (2–10% of community elders, far more in institutions; the commonest reversible cause), **dementia** (≈2-fold risk of anorexia; up to **50% of institutionalised dementia patients have PEM**), **COPD**, **CHF** (anorexia in >40% of end-stage), **CKD/dialysis (30–40%)**, **cancer**, **chronic infection**, **hyperthyroidism**, **malabsorption**, **constipation and faecal impaction**, **H. pylori infection**.
6. **Oral, swallowing and GI causes. Edentulism and ill-fitting dentures** (denture wearers have poorer protein intake), **xerostomia**, **oral candidiasis**, **dysphagia** (cranial nerves V, VII, IX, X, XI; worsened by stroke and dementia), **atrophic gastritis with hypochlorhydria** impairing B12 and iron absorption.
7. **Functional and social causes. Immobility (stroke), tremor (Parkinson's), impaired vision** all limit shopping, cooking and self-feeding. **Poverty and food insecurity**, **living alone** (elders eat up to **50% more when eating in company**), **social isolation**, institutionalisation, failure of facilities to cater to **ethnic food preferences**, and unnecessary **restrictive therapeutic diets**.
8. **Iatrogenic causes — polypharmacy.** More than **250 prescribed drugs alter taste**. **Digoxin and chemotherapy** cause nausea and anorexia; **aluminium/magnesium hydroxide antacids deplete phosphate and potassium** causing weakness and anorexia; **penicillamine causes zinc depletion and loss of taste**; **high-fibre diets cause excess satiety**.
9. **Bedside mnemonic — "MEALS ON WHEELS"** (recommended by Pathy's to find treatable causes):
   Medications · **E**motional (depression) · **A**norexia tardive/alcoholism · **L**ate-life paranoia · **S**wallowing disorders · **O**ral factors · **N**o money · **W**andering/dementia · **H**yper/hypothyroidism, hyperparathyroidism, hypoadrenalism · **E**nteric (malabsorption) · **E**ating problems (unable to self-feed) · **L**ow-salt/low-cholesterol diets · **S**ocial isolation, **S**tones.
10. **Consequences (why it matters). ↓Muscle mass and strength → falls; ↓bone mass → fractures; immune dysfunction → infection and pneumonia; anaemia; poor wound healing and pressure ulcers** (prevalence up to **30% in long-term care, 19% in home care**); **cognitive impairment; delayed surgical recovery; longer hospital stay; more admissions; increased mortality**. **PEM is a strong independent predictor of mortality** in community, nursing home and hospital settings, and the risk is amplified by renal failure, cardiac failure and stroke.

APPROACH TO DIAGNOSIS — A THREE-STEP SEQUENCE

11. **Step 1 — SCREEN every older person.** Use **MNA-SF**: **12–14 normal, 8–11 at risk, 0–7 malnourished**; body mass entered as **BMI or calf circumference (<31 cm)**. MNA is **96% sensitive and 60% specific** for weight loss and is a **powerful independent prognostic factor**. Alternatives: **MUST, NRS-2002, SNAQ, SGA**. In nursing homes, **weigh monthly** — persistent weight loss must trigger a search for treatable causes.
12. **Step 2 — DIAGNOSE using the GLIM criteria** (need **one phenotypic + one etiologic** criterion):

Phenotypic (any one)	Etiologic (any one)

Weight loss >5% in 6 months, or >10% beyond 6 months	**Reduced food intake** — ≤50% of energy requirement for >1 week, any reduction for >2 weeks, or any chronic GI condition impairing assimilation
Low BMI — <20 if <70 y, <22 if >70 y; **Asia: <18.5 if <70 y, <20 if >70 y**	**Inflammation** — acute disease/injury, or chronic disease-related
Reduced muscle mass — by DXA, BIA, CT or MRI; where unavailable, **MAMC or calf circumference**; handgrip strength as a supportive measure	

Note: diagnosing malnutrition on low BMI alone, without an etiologic cause, overestimates prevalence.

13. **Step 3 — GRADE the mechanism using inflammation (CRP). CRP <3 mg/L → starvation** (responds to refeeding); **low–medium grade → inflammageing** (not itself malnutrition); **medium grade → cachexia** (organ failure, cancer, neurodegenerative disease); **CRP >100 mg/L → hypercatabolic malnutrition** (sepsis, trauma, ICU). This determines whether nutrition alone will work.
14. **Weight-loss thresholds worth quoting.** Loss of **5% in 1 month, 7.5% in 3 months or 10% in 6 months** is serious. **BMI <22 kg/m²** predicts higher one-year mortality and poorer function; **ideal BMI ranges are higher in older than younger adults**; **BMI below the 15th percentile** independently predicts 180-day mortality after hospitalisation.

ASSESSMENT

15. **Assessment is by comprehensive geriatric assessment (CGA).** Systematically cover — **cognition** (MMSE/MoCA), **depression** (GDS), **delirium** (CAM), **function** (Katz, Barthel, Lawton–Brody ADL/IADL), **falls and mobility** (TUG, unipodal stance, SPPB), **medication reconciliation and deprescribing**, **nutrition** (BMI, MNA, weight history, **swallowing test**, **constipation/faecal impaction screen**, **oral examination**), and **social and financial resources**. Each impaired domain has a matching action — meal-texture adaptation, dental treatment, housekeeper for shopping, meals-on-wheels, caregiver education.
16. **Anthropometry. Serial weight is the single most useful measurement** — kyphosis makes height and therefore BMI unreliable. Use **MUAC** when there is oedema (correlates with lean mass), **calf circumference**, **mid-arm muscle circumference**; estimate height by **knee-height formulae**; apply **percentage corrections in amputees**.
17. **Laboratory assessment. Serum albumin** is practical but confounded by **liver disease, proteinuria and protein-losing enteropathy**; **prealbumin and retinol-binding protein are more sensitive**. Add **CRP** (grades inflammation), **total lymphocyte count**, **haemoglobin** (**anaemia is one of the earliest manifestations of PEM**), **creatinine clearance**, **B12, folate, 25(OH)D, iron studies, calcium, TSH**, and **age-appropriate cancer screening** where weight loss is unexplained.
18. **Body composition and muscle function. DXA or BIA** for fat-free mass index; **CT at the L3 slice** for muscle index in cancer patients; where unavailable, **calf circumference is the accepted surrogate**. Function is measured by **handgrip strength, gait speed, chair-rise and SPPB** — these predict outcome better than mass alone.

MANAGEMENT

19. **Principles and targets.**
    - **First, treat reversible causes** — depression, drugs, dysphagia, dentition, pain, nausea, constipation, infection, thyroid disease. Treating depression alone produces weight gain.
    - **Set requirements:** approximately **30–35 kcal/kg/day**, **protein 1.0–1.5 g/kg/day**, **fluid ~1 mL/kcal (about 1.5 L/day)**.
    - **Avoid unnecessary therapeutic diets** (low-salt, low-fat, diabetic) in the frail underweight elder — the risk of undernutrition outweighs the benefit.
20. **Stepwise treatment ladder.**
    - **(a) Food-first and nursing measures** — oral and dental care, **texture modification**, **flavour enhancement** (improves intake and nutritional status in nursing-home residents), fortified/nutrient-dense foods, small frequent meals, **feeding assistance**, **eating in company**, meals-on-wheels and social support.
    - **(b) Oral nutritional supplements (ONS)** — meta-analysis of 42 trials showed **2.3% weight gain** and **reduced mortality (RR 0.74, 95% CI 0.59–0.92)**; benefit was consistent when **≥400 kcal/day was given for ≥35 days** to **unwell, malnourished patients aged ≥75** in hospital or nursing homes. ONS also **reduce pressure-ulcer incidence**. **No proven benefit on functional status or length of stay.**
    - **(c) Exercise — progressive resistance training 2–3 times/week** is the **primary intervention for sarcopenia**; essential amino acids stimulate muscle protein synthesis better than intact protein. Combined nutrition + early mobilisation in hospital **prevents loss of functional independence** even without weight gain.
    - **(d) Enteral nutrition** if oral intake remains inadequate and prognosis is favourable; **parenteral only if enteral is impossible** (higher morbidity than enteral). **PEG in nursing-home residents with severe cognitive**

impairment does not improve 24-month survival, and aspiration pneumonia occurs at the same rate with or without tube feeding — this is an advance-care-planning discussion, not a nutritional one.

- **(e) Orexigenic drugs — palliative only.** Megestrol acetate is the best studied (appetite, weight, quality of life; **oedema**); corticosteroids and cyproheptadine improve appetite without weight gain; cannabinoids and thalidomide have limited evidence.
- **(f) Monitor** weight, intake charts and function; **watch for refeeding syndrome** (falling phosphate, potassium, magnesium) when replenishing the severely depleted.

Latest Updates (2023–Present)

1. **Global burden quantified.** A meta-analysis of 98 studies (n = 79,976) found the global prevalence of malnutrition in older adults to be **18.6% (95% CI 16.4–21.1%)**, highest in Africa at 35.7% followed by the Americas at 20.3%; by instrument, the highest prevalence was 39.9% using NRS-2002. *(Salari N, et al. Public Health in Practice. 2025;9:100583.)*
2. **GLIM criteria — 5-year update.** A 43-member working group reviewed >400 publications (2019–2024). No revisions were made to the weight loss, low BMI or reduced food intake/assimilation criteria; assessment of low muscle mass should be guided by experience and available technological resources, and clinical judgement may suffice for the inflammation/disease burden criterion. Construct and predictive validity are now strong. *(Jensen GL, et al. Clin Nutr / JPEN. 2025.)*
3. **Bedside muscle-mass surrogates now validated — directly usable in Indian practice.** Applying calf circumference <31 cm in both sexes, or MUAC <23 cm in men and <22 cm in women, gave 84.6% and 83.4% accuracy against SGA, with sensitivity ~89% and ~84% and specificity ~81–83%. *(Shahraki Jazinaki M, et al. Front Nutr. 2024;11:1438158.)*
4. **ONS in hospitalised older people — Cochrane individual-participant network meta-analysis.** In older hospitalised people at risk of or with malnutrition, oral nutritional supplements *may* reduce mortality and serious adverse events compared with control at 30 days after randomisation, with little or no difference for other outcomes; the overall certainty of evidence was **low to very low**. This tempers the older, more confident textbook claim. *(Kiesswetter E, et al. Cochrane Database Syst Rev. 2026;CD015468.)*
5. **Individualised in-hospital nutrition works, but the effect does not persist.** Reaching ≥75% of estimated nutrition goals, versus lower achievement, significantly lowered the risk of adverse events and mortality; yet while individualised nutritional support during the hospital stay significantly reduced short-term mortality, there was **no legacy effect on longer-term outcomes**. **Implication: nutritional care must be continued after discharge.** *(Schuetz P, et al. Lancet. 2019; Clin Nutr. 2020; ESPEN practical guideline, polymorbid medical inpatients. Clin Nutr. 2024.)*
6. **ESPEN geriatric guideline — current management standard.** All older persons shall be routinely screened for malnutrition; oral intake is supported by nursing interventions, counselling, food modification and ONS; enteral nutrition is initiated if oral is insufficient and parenteral if enteral is insufficient or impossible, provided the general prognosis is favourable; dietary restrictions should generally be avoided. Low-intake dehydration should be diagnosed on serum osmolality and corrected rapidly with hypotonic fluids given as drinks, subcutaneously or intravenously depending on severity. A dedicated ESPEN update for dementia was published in 2024. *(Volkert D, et al. Clin Nutr. 2022;41:958–989; Volkert D, et al. Clin Nutr. 2024.)*
7. **Sarcopenia reframed — GLIS 2024.** Muscle mass, muscle strength and muscle-specific strength were all accepted as components of sarcopenia, whereas impaired physical performance was accepted as an outcome rather than a component. *(Kirk B, et al. Age Ageing. 2024;53:afae052.)*
8. **Megestrol is no longer acceptable in older adults.** The 2023 AGS Beers Criteria grades it **avoid** (strong recommendation) — minimal effect on weight, with increased risk of thrombotic events and possibly death in older adults. *(AGS Beers Criteria Update Expert Panel. J Am Geriatr Soc. 2023;71.)*
9. **Indian data.** In LASI, 28% of men and 25% of women aged 60 and above are underweight; the urban population is less likely to be underweight, and older adults from low economic and social strata are more likely to be underweight. Using a modified MUST, about 26% of respondents aged 45+ fell into the undernourished high-risk group, characterised by low BMI, recent hospital admission and food-insecure households. CART analysis of LASI further suggests age-specific BMI cut-offs — the underweight threshold falling from <18.5 to <17.4 for ages 60–74 and <13.3 for those 75 and above. *(Khan J, et al. Sci Rep. 2023;13:12820; BMC Public Health. 2023; Singh A, Chattopadhyay A. Sci Rep. 2024;14:15200.)*
10. **ICMR-NIN Dietary Guidelines for Indians 2024.** Seventeen guidelines addressing India's double burden of malnutrition, with the **"My Plate for the Day"** model and RDA 2020 values (**safe protein 0.83 g/kg/day**, EAR 0.66 g/kg/day, DIAAS replacing PDCAAS). The guidelines discourage protein supplements and high-protein concentrates for muscle building, citing bone mineral loss and kidney damage with prolonged intake. *(ICMR-NIN. Dietary Guidelines for Indians. 2024.)*

Current Practice Update

Textbook Position (Pathy's 2022 / Essentials 7e)	Current Evidence-Based Practice (2023-present)
GLIM described as newly established (2019)	**GLIM 5-year update 2025** — criteria unchanged and now validated across >400 studies; **any available method** for muscle mass, **clinical judgement** acceptable for inflammation
Muscle mass ideally by DXA/BIA/CT	**Calf circumference <31 cm** and **MUAC <23 cm (M) / <22 cm (F)** formally validated as accurate surrogates — the practical option in Indian wards
ONS reduce mortality (RR 0.74) based on 2009 Cochrane review of 42 trials	**Cochrane IPD network meta-analysis 2026**: ONS *may* reduce 30-day mortality and serious adverse events, but certainty is **low to very low** — benefit is real but weaker than previously stated
Nutritional support during admission improves outcomes	Benefit is **confined to the hospital episode** — **no legacy effect at 6 months**; current emphasis is on **continuing nutrition after discharge**
Megestrol acetate is the best-studied and most widely used orexigenic	**AGS Beers 2023: AVOID** — minimal weight effect, thrombotic risk, possible increased mortality
Protein requirement quoted as 0.5 to >1.0 g/kg/day (conflicting)	**1.0–1.2 g/kg/day** in healthy elders, **1.2–1.5 g/kg/day** in acute or chronic illness (ESPEN 2022); the **ICMR-NIN 0.83 g/kg/day** figure is a population safe intake, **not a therapeutic target**
Albumin presented as "a practical indicator of malnutrition"	Albumin and prealbumin are now regarded as **inflammatory and prognostic markers**, not nutritional markers, and are **not part of GLIM**
Sarcopenia screening based on low muscle performance (EWGSOP)	**GLIS 2024** — physical performance is an **outcome**, not a component; **muscle-specific strength** added as a component
WHO BMI cut-offs applied to all	**Asian GLIM cut-offs (<18.5 if <70 y, <20 if >70 y)** and **Indian LASI-derived cut-offs (2024)** perform better in our population

Examiner's Tip — Mark-Earning Lines

- "Malnutrition in the older adult is a **multifactorial geriatric syndrome with poor outcomes** — it demands comprehensive geriatric assessment, not calorie counting."
- "The approach is a **three-step sequence: SCREEN (MNA-SF) → DIAGNOSE (GLIM) → GRADE the mechanism by inflammation (CRP)**."
- "**GLIM requires one phenotypic plus one etiologic criterion**; for India, remember the **Asian BMI cut-offs — <18.5 below 70 years and <20 above 70 years**."
- "**Weight loss of 5% in 1 month, 7.5% in 3 months or 10% in 6 months** is clinically significant and mandates evaluation."
- "Use **MEALS ON WHEELS** to systematically uncover reversible causes — **depression and drugs are the two most commonly missed and most treatable**."
- "**Serial weight, not BMI**, is the most reliable anthropometric measure in the elderly because kyphosis makes height unreliable."
- "**Distinguish starvation from cachexia** — starvation responds to refeeding, cachexia does not; the discriminator at the bedside is **CRP**."
- "ONS work when the **dose and duration are right — ≥400 kcal/day for ≥35 days** in genuinely malnourished, unwell elders."
- "**Resistance exercise is the stimulus; nutrition is only permissive** — neither works well alone in sarcopenia."
- "**PEG feeding in advanced dementia does not prolong survival and does not prevent aspiration pneumonia.**"

Question 3. Nutritional Assessment in Older Persons

15 marks · Source: Pathy's 6th ed. (Ch. 12, 13, 14, 16 and Function Assessment Scales appendix); Essentials of Clinical Geriatrics 7th ed. (Ch. 3, Tables 3-11 to 3-14)

20 High-Yield Points

CONCEPT AND FRAMEWORK

1. **Purpose.** Nutritional assessment answers four questions (Essentials, Table 3-12): **Is there reason to suspect malnutrition? Of which nutrient(s) and to what extent? What is the pathophysiological mechanism? What is the underlying etiology?**
2. **Why assessment is different in the elderly.** No single parameter is adequate — **anthropometric variables are not highly correlated with biochemical or haematologic indicators**, and **the effect of ageing on lean body mass is so great that lean mass alone is a poor reflection of nutritional status**. Assessment must therefore be **multi-parameter and multi-domain**.
3. **The standard two-step (now three-step) approach. Step 1 — SCREEN** every older person with a validated tool. **Step 2 — DIAGNOSE** using **GLIM criteria**. **Step 3 — GRADE severity and identify the mechanism**, then plan intervention.

STEP 1 — SCREENING TOOLS

4. **Mini Nutritional Assessment (MNA) — the geriatric standard.** The full MNA is **multidimensional and identifies malnourished elders or those at risk, whatever the cause**. **MNA-SF** has equivalent performance: **12–14 = normal, 8–11 = at risk, 0–7 = malnourished**. Body mass is entered as **BMI (0 = <19, 1 = 19–20.9, 2 = 21–22.9, 3 = ≥23)** or, if BMI is unavailable, **calf circumference (0 = <31 cm, 3 = ≥31 cm)**.
5. **MNA components (six domains). (A)** decline in food intake over 3 months, **(B)** weight loss over 3 months, **(C)** mobility, **(D)** psychological stress or acute illness in 3 months, **(E)** neuropsychological problems (dementia/depression), **(F)** BMI or calf circumference.
6. **Performance and prognostic value.** MNA is **96% sensitive and 60% specific** for body weight loss. Subjects with a normal MNA had **lower mortality (RR 0.35, 95% CI 0.18–0.66)** than those with an abnormal score. Those "at risk" had **more acute illness, more assistance needs and more weight loss**. MNA is a **powerful independent prognostic factor**, especially in cancer, and can assess **cancer cachexia**. A **six-item version** has equivalent predictive value.
7. **Other validated tools. SGA** (predicts mortality but classifies more patients as well-nourished than MNA — those "well-nourished" by MNA had better 3-year survival), **MUST**, **NRS-2002**, and the **Geriatric Nutritional Risk Index (GNRI)**, which predicts healthcare costs and hospitalisation.
8. **SNAQ (Simplified Nutritional Appetite Questionnaire)** — four questions on **appetite, early satiety, taste of food, and number of meals per day**, each scored 1–5. **A score <14 indicates significant risk of weight loss.** Recommended by Pathy's as a rapid appetite screen.
9. **Screening question in routine geriatric review** (Pathy's Function Assessment Scales): ask **"Have you lost weight?"** and record **height and weight**; if positive, proceed to **BMI, MNA, SNAQ**, and use the **"MEALS ON WHEELS" mnemonic** to look for treatable causes.

STEP 2 — DIAGNOSIS BY GLIM

10. **GLIM criteria** — malnutrition requires **≥1 phenotypic + ≥1 etiologic** criterion:

Phenotypic	Etiologic
Weight loss **>5% in 6 months** or **>10% beyond 6 months**	Reduced food intake — **≤50% of energy requirement for >1 week**, any reduction for **>2 weeks**, or any **chronic GI condition** impairing assimilation/absorption
Low BMI — **<20 if <70 y, <22 if >70 y**; **Asia: <18.5 if <70 y, <20 if >70 y**	Inflammation — **acute disease/injury** or **chronic disease-related**
Reduced muscle mass — by validated body-composition technique; where unavailable, **mid-arm muscle or calf circumference**; **handgrip strength as a supportive measure**	

11. **Severity grading (GLIM Stage 1 vs Stage 2). Stage 1 (moderate):** weight loss **5–10% in 6 months or 10–20% beyond 6 months**; BMI **<20 if <70 y, <22 if ≥70 y**; mild–moderate muscle deficit. **Stage 2 (severe):** weight loss **>10% in 6 months or >20% beyond 6 months**; BMI **<18.5 if <70 y, <20 if ≥70 y**; severe muscle deficit.
12. **Caution. Diagnosing malnutrition on low BMI alone, without identifying a cause, overestimates prevalence.** Always pair a phenotypic with an etiologic criterion.

STEP 3 — COMPONENTS OF FULL ASSESSMENT

13. **History. Weight history** (magnitude and rate of loss — **5% in 1 month, 7.5% in 3 months, 10% in 6 months is serious**), **appetite** (SNAQ), chewing and swallowing difficulty, **dietary history**, food fads and restrictive diets, alcohol, **drug review** (>250 drugs alter taste), depression, dementia, **social and financial circumstances**, ability to shop and cook, living alone.
14. **Physical examination.** General appearance and muscle wasting; **oral examination** — dentition, ill-fitting dentures, xerostomia, candidiasis, dental plaque, **loss of occluding pairs**; **swallowing test**; abdominal exam for **faecal impaction**; skin for **pressure ulcers and poor wound healing**; **Braden scale** for pressure-ulcer risk; signs of specific deficiencies (glossitis, cheilosis, neuropathy, ataxia, ecchymoses, oedema).
    Pathy's dental screening tool: dry mouth (2), eating difficulty (1), no dental care within 2 years (1), tooth/mouth pain (2), change in food selection (1), oral lesions (2) — **≥3 points warrants dental referral.**
15. **Anthropometry — what each measure reflects** (Essentials, Table 3-11):

Measure	Reflects
Weight	Global nutritional status
BMI	Total body fat
Triceps and subscapular skinfolds	Percentage body fat
Waist–hip ratio	Central adiposity
Upper-arm (mid-arm) circumference	**Lean body mass** — particularly useful in **oedematous patients where weight misleads**
Calf circumference (<31 cm)	Low muscle mass surrogate

16. **Practical anthropometric pitfalls and corrections.**
    - **Serial weight is preferred to BMI** — kyphosis makes height unreliable; also consider oedema.
    - **Height from knee height:** Men = (2.02 × knee height cm) − (0.04 × age) + 64.19; Women = (1.83 × knee height cm) − (0.24 × age) + 84.88.
    - **Amputee weight corrections:** single below-knee **6%**, at knee **9%**, above knee **15%**, single arm **6.5%**, arm below elbow **3.6%**.
    - **BMI <22 kg/m²** predicts higher one-year mortality; **BMI below the 15th percentile** independently predicts 180-day post-hospitalisation mortality.
17. **Body composition and muscle assessment. DXA** (fat-free mass index, appendicular lean mass index), **BIA**, **CT at the L3 slice** (muscle index, used in cancer follow-up), **MRI**. GLIM/sarcopenia cut-offs: **FFMI <17 (men), <15 (women) kg/m²**; **ASMI <7.0 (men), <5.4–5.7 (women) kg/m²**. Where these are unavailable, **calf circumference or MAMC is acceptable**.
18. **Functional assessment (increasingly the anchor). Handgrip strength**, **gait speed**, **Timed Up and Go**, **unipodal stance**, **chair rise**, and **SPPB** (predicts disability). Function correlates with outcome better than mass alone.
19. **Biochemical assessment.**
    - **Serum albumin** — practical, but **liver disease, proteinuria and protein-losing enteropathy must be excluded**; a **normal or raised albumin does not exclude malnutrition**.
    - **Prealbumin (thyroxine-binding) and retinol-binding protein are more sensitive** than albumin and transferrin.
    - **Haemoglobin** — **anaemia is one of the earliest manifestations of protein-calorie malnutrition**.
    - **Total lymphocyte count** — a good marker of nutritional problems.
    - **CRP** — grades inflammation and separates **starvation (CRP <3 mg/L)** from **cachexia (medium grade)** and **hypercatabolism (CRP >100 mg/L)**.
    - **Micronutrients:** B12 with **MMA and homocysteine**, folate (**red-cell folate reflects the preceding 120 days**), **25(OH)D**, ferritin with CRP, calcium, TSH. **Zinc measurement is unreliable** — cytokines lower serum zinc; leukocyte or hair zinc may help.
    - Also: **creatinine clearance**, blood count, and **targeted cancer screening** where weight loss is unexplained.
20. **Dietary intake and multidomain assessment.**
    - **Intake:** 24-hour recall, food-frequency questionnaire, food diary, plate-waste/intake charts. Limitations in elders: **recall and misclassification bias**, worse with cognitive impairment — hence the value of **objective nutrient biomarkers**.
    - **CGA-based assessment (Pathy's Table 14.3)** — cognition (**MMSE/MoCA**), depression (**GDS**), delirium (**CAM**),

falls (**TUG, SPPB**), function (**Katz, Barthel, Lawton–Brody**), morbidity and drug review, nutrition (BMI, MNA, weight history, swallowing, constipation screen, oral exam), and **social/socioeconomic domains**.

- **Monitoring:** weigh nursing-home residents **monthly**; **persistent weight loss must prompt a search for treatable medical, psychiatric and functional conditions**.

Latest Updates (2023–Present)

1. **GLIM — 5-year update.** Following review of >400 publications from 2019–2024, no revisions were made to the weight loss, low BMI or reduced food intake/assimilation criteria; assessment of low muscle mass should be guided by experience and available technological resources, and clinical judgement may suffice for the inflammation/disease burden criterion. Severity-grading thresholds are unchanged, but a broad distinction between moderate and severe reduction of muscle mass is not yet possible because only some methods allow that level of differentiation, and further research is needed to secure consensus reference BMI data for Asian populations. *(Jensen GL, et al. Clin Nutr / JPEN. 2025.)*
2. **Bedside surrogates for muscle mass formally validated.** Applying calf circumference <31 cm in both sexes, or MUAC <23 cm in men and <22 cm in women, gave 84.6% and 83.4% accuracy against SGA, with sensitivity ~89% and ~84% and specificity ~81–83%. Directly applicable in Indian wards without DXA or BIA. *(Shahraki Jazinaki M, et al. Front Nutr. 2024;11:1438158.)*
3. **Choice of tool changes the answer.** A meta-analysis of 98 studies (n = 79,976) found a global malnutrition prevalence of 18.6% (95% CI 16.4–21.1%) in older adults, with the highest prevalence — 39.9% — obtained using NRS-2002. **Examination point: always state which instrument was used.** *(Salari N, et al. Public Health in Practice. 2025;9:100583.)*
4. **Sarcopenia assessment reframed — GLIS 2024.** Muscle mass, muscle strength and muscle-specific strength were all accepted as components of sarcopenia, whereas impaired physical performance was accepted as an outcome rather than a component. *(Kirk B, et al. Age Ageing. 2024;53:afae052.)*
5. **BIA phase angle and BIVA — emerging bedside tools.** Phase angle is a highly reliable indicator of skeletal muscle quality because it is calculated directly from reactance and resistance and does not depend on an estimation formula. In hospitalised older patients, standardised phase angle carried prognostic significance and BIVA usefully estimated body-composition/nutrition phenotypes; patients with low standardised phase angle had significantly lower BMI and fat mass. BIVA also discriminated sarcopenic from non-sarcopenic elderly in both sexes, supporting 50 kHz phase-sensitive measurements as biomarkers of hydration, catabolic state and nutritional status. *(Front Aging / Clin Nutr cohort studies. 2024–2025; Sensors. 2023;23:7090.)*
6. **Muscle ultrasound entering nutritional assessment.** In hospitalised older adults, ultrasound and bioelectrical impedance analysis are reliable, non-invasive and reproducible for quantitative and qualitative muscle assessment, with rectus femoris cross-sectional area, thickness, echogenicity and compressibility measured combinedly for sarcopenia diagnosis. *(Nutrients. 2024;16:2429.)*
7. **ESPEN — screening is mandatory, not optional.** All older persons shall routinely be screened for malnutrition in order to identify existing risk early. Low-intake dehydration should be diagnosed on the basis of serum osmolality, not clinical signs alone. A dedicated ESPEN update for dementia followed in 2024. *(Volkert D, et al. Clin Nutr. 2022;41:958–989; Volkert D, et al. Clin Nutr. 2024.)*
8. **Indian BMI cut-offs need adjustment.** CART analysis of LASI data lowered the underweight cut-off from <18.5 to <17.4 for ages 60–74 and <13.3 for those 75 and above, based on cardio-metabolic outcomes. Set against LASI prevalence — 28% of men and 25% of women aged 60 and above are underweight, with those from low economic and social strata more likely to be underweight. *(Singh A, Chattopadhyay A. Sci Rep. 2024;14:15200; Khan J, et al. Sci Rep. 2023;13:12820.)*
9. **Indian dietary reference values for interpreting intake.** ICMR-NIN Dietary Guidelines for Indians 2024 with the "My Plate for the Day" model and RDA 2020 (safe protein 0.83 g/kg/day, EAR 0.66 g/kg/day; DIAAS replacing PDCAAS for protein quality). The guidelines discourage protein supplements and high-protein concentrates, citing bone mineral loss and kidney damage with prolonged intake. *(ICMR-NIN. Dietary Guidelines for Indians. 2024.)*

Current Practice Update

Textbook Position (Pathy's 2022 / Essentials 7e)	Current Evidence-Based Practice (2023-present)
"**Serum albumin is a practical indicator of malnutrition**"; prealbumin/RBP more sensitive	Albumin and prealbumin are now regarded as **inflammatory and prognostic markers, not nutritional markers**, and are **excluded from GLIM**; **CRP** is used only to grade inflammation
Muscle mass measurement "difficult in routine practice"; calf circumference proposed as a surrogate	**Calf circumference <31 cm** and **MUAC <23 cm (M) / <22 cm (F)** now have **formal validation data** (accuracy >83% vs SGA); GLIM 2025 explicitly permits **whatever method is locally available**
GLIM presented as a newly published consensus (2019)	**GLIM 5-year update 2025** — criteria confirmed, **severity grading unchanged**, validity established across >400 studies; **Asian BMI reference data still awaited**

Sarcopenia assessed by muscle mass + performance (EWGSOP)	**GLIS 2024** — performance is an **outcome**, not a component; **muscle-specific strength** added as a third component
Body composition by DXA, BIA, CT, MRI	**BIA-derived phase angle and BIVA**, and **muscle ultrasound (rectus femoris CSA, thickness, echogenicity)** are emerging as bedside, radiation-free adjuncts with independent prognostic value
WHO BMI cut-offs applied to all older adults	**Asian GLIM cut-offs (<18.5 if <70 y; <20 if >70 y)** and **Indian LASI-derived cut-offs (2024)** perform better in our population
Screening described as good practice	**ESPEN: routine screening of all older persons "shall" be performed** — now a standard of care; and the **choice of tool materially changes prevalence** (NRS-2002 gives the highest estimates)

Examiner's Tip — Mark-Earning Lines

- "Nutritional assessment in the elderly follows a **three-step sequence: SCREEN (MNA-SF) → DIAGNOSE (GLIM) → GRADE severity and mechanism (CRP)**."
- "**No single parameter suffices** — anthropometric measures correlate poorly with biochemical indices, and ageing alters lean body mass so much that it is a poor marker on its own."
- "**MNA-SF: 12–14 normal, 8–11 at risk, 0–7 malnourished**; use **calf circumference <31 cm** when BMI cannot be obtained."
- "MNA is **96% sensitive and 60% specific** — a good screen, not a diagnostic test."
- "**Severity grading: Stage 1 (moderate) = 5–10% loss in 6 months; Stage 2 (severe) = >10% loss in 6 months.**"
- "**Serial weight, not BMI**, is the most reliable anthropometric measure — use **knee-height formulae** when height cannot be measured."
- "**Mid-arm circumference is the measure of choice in oedema**, where weight misleads."
- "**Albumin is an inflammatory marker, not a nutritional marker** — the single commonest error in ward practice."
- "**Anaemia is one of the earliest manifestations of protein-calorie malnutrition** — it should prompt, not follow, nutritional assessment."

Question 4. Anorexia of Ageing

15 marks · Source: Pathy's 6th ed. Chapter 13 "The Anorexia of Aging", with Chapters 12 and 14; Essentials of Clinical Geriatrics 7th ed. (Ch. 12)

20 High-Yield Points

DEFINITION AND MAGNITUDE

1. **Definition.** In many older adults the **decrease in energy intake is greater than the decrease in energy expenditure**, so body weight is lost. This **physiological, age-related reduction in energy intake is termed the anorexia of ageing** (Morley, 1997).
2. **It is a geriatric syndrome.** Pathy's depicts it as a **multifactorial geriatric syndrome with poor outcomes**, arising from four groups of factors — **physiological changes, changes due to chronic disease, social determinants/environment, and iatrogenic causes/polypharmacy**.
3. **Physiological vs pathological.** The **physiological** component is intrinsic to ageing; the **pathological** component (disease, drugs, depression, dementia) is superimposed and is **at least partly treatable — hence recognition matters**.
4. **Magnitude of intake decline. Energy intake falls by ~30% between ages 20 and 80.** NHANES III: decline of **1321 kcal/day in men and 629 kcal/day in women**. New Mexico longitudinal study: **−25.1 kcal/day/year in men, −19.3 in women**. Swedish cohort (ages 70→76): **−610 kcal/day in men, −440 in women**. Older people eat **smaller meals, more slowly, with fewer snacks**, and consistently report **less hunger**.
5. **Prevalence.** Anorexia occurs in **3.3% of community-dwelling elders rising to 33% in nursing homes**. About **16–18% of community elders consume <1000 kcal/day**. **Loss of appetite is the single key predictor of malnutrition in older adults.**

PATHOPHYSIOLOGY — FOUR PHYSIOLOGICAL MECHANISMS

6. **(i) Loss of homeostatic regulation.** In Roberts' classic experiment, young and old men were underfed by **~750 kcal/day for 21 days**; on refeeding *ad libitum*, **young men over-ate and regained weight, whereas old men returned only to baseline intake and never regained the lost weight**. Consequently, after an anorectic insult (e.g. surgery), older adults **stay undernourished longer** and are more susceptible to superimposed illness.
7. **(ii) The ageing gut. Cell loss in the oesophageal myenteric plexus** and slowed visceral nerve conduction reduce sensory feeding stimuli. **Impaired receptive relaxation of the gastric fundus** — possibly due to **increased fundic nitric oxide** — causes **more rapid antral filling and distension → earlier satiety**, and contributes to **slower gastric emptying**; postprandial hunger is inversely related to the rate of gastric emptying.
8. **(iii) Declining senses.** Smell declines markedly after age 50 — **over 60% aged 65–80 and over 80% aged ≥80 have major reductions** (thinning epithelium, reduced mucus, poor regeneration of olfactory receptor cells). **46% of older adults with olfactory dysfunction report a change in appetite or weight.** Ageing also reduces **sensory-specific satiety** (the normal decline in pleasantness of a food after eating it), favouring a **less varied, monotonous diet** and hence **micronutrient deficiency**.
9. **(iv) Central neurotransmitters. Noradrenaline stimulates, serotonin inhibits, and dopamine has region-specific effects** on feeding. Ageing is associated with **increased satiating effects of serotonin**, without clear changes in dopamine or noradrenaline.
10. **Opioids — reduced feeding drive.** Elderly patients with **idiopathic senile anorexia have lower plasma and CSF β-endorphin** than age-matched controls. Morphine increases food intake in young but **not old** mice; naloxone reduces intake in young but not old rats; older men are less sensitive to naloxone's inhibitory effect on fluid intake. The **stimulatory opioid drive declines with age**.
11. **Cholecystokinin (CCK) — the strongest candidate.** CCK is a **physiological satiety hormone** released by intestinal fat and protein, which also **slows gastric emptying**. **Plasma CCK is higher in healthy older than young adults**, and **significantly higher in elderly people with idiopathic anorexia**. Crucially, **IV CCK-8 suppressed food intake twice as much in older than young adults (31% vs 15%, p = 0.02)**. The combination of **higher levels plus enhanced sensitivity** suggests CCK may cause the anorexia of ageing and raises the possibility of **CCK antagonists** as therapy.
12. **Other gut peptides — largely negative evidence.**
    - **GLP-1:** increases fullness and reduces intake; ageing studies show **no change or increased levels** — unproven as a cause.
    - **PYY:** reduces intake by ~30% acutely, but **no difference in fasting or postprandial PYY between young and old** — no convincing role.
    - **Ghrelin:** the only orexigenic gut hormone; the **effect of healthy ageing on circulating ghrelin is unclarified**

but probably minimal; **ghrelin resistance may occur** (older subjects are less sensitive to its GH-releasing effect). Ghrelin is **positively associated with testosterone**, so falling androgens may lower it.

- **Insulin:** rises with ageing, but this is mainly due to **adiposity-related insulin resistance**; peripheral insulin infusion does not alter appetite — **unlikely to contribute**.

13. **NPY, galanin, orexins and CART. NPY** strongly stimulates feeding and falls with age in male rodents, but **human data show increased, not decreased, NPY** — hence no convincing human role. **Galanin** levels are unchanged. **Orexin A** levels actually *increase* with age. **CART** (inhibitory) rises in old male rats, mediated by the **age-related fall in testosterone** — but human data are absent.
14. **Leptin and testosterone.** Leptin suppresses appetite and rises with fat mass. **In men — but not women — ageing raises leptin even after adjusting for fat mass, because of the age-related fall in testosterone** (leptin is inversely related to testosterone). **Leptin resistance** may also develop with age. Testosterone therapy in frail older men improves **muscle strength, grip, function and rehabilitation outcomes** (Amory, Bakhshi, Srinivas-Shankar) and reduced hospitalisation when combined with a nutritional supplement (Chapman) — **but does not reliably increase appetite**.
15. **Cytokines — "ageing as a form of stress." IL-1, IL-6 and TNF-α** reduce food intake and body weight via central and peripheral pathways and are raised in cancer/AIDS cachexia. Ageing produces **stress-like hormonal changes — raised cortisol and catecholamines, falling sex hormones and growth hormone**. Cortisol and catecholamines **stimulate IL-6 and TNF-α**, while **sex hormones inhibit IL-6**. **Plasma IL-6 rises with normal ageing and correlates inversely with functional ability**; raised CRP and cytokine receptors independently predict physical dysfunction.

PATHOLOGICAL AND ENVIRONMENTAL CONTRIBUTORS

16. **Chronic disease. Depression** (2–10% in community, far more in institutions — the commonest treatable cause; treating it produces weight gain), **dementia** (**~2-fold risk of anorexia**; up to **50% of institutionalised dementia patients have PEM**; apraxia of swallowing, pocketing, spitting; **weight loss may precede dementia as a preclinical marker**), **COPD** (catabolic state, nicotine, opioids, dysmotility), **CHF** (**anorexia in >40% of end-stage**; raised catecholamines, cortisol, renin, aldosterone; hypoxia-driven TNF-α → raised leptin), **CKD** (**30–40% of dialysis patients**, with **four-fold increased mortality**; uraemic toxins; more frequent haemodialysis improves appetite), plus **cancer, rheumatoid arthritis, infection, hyperthyroidism and malabsorption**.
17. **Physical, social and iatrogenic factors. Poor dentition and ill-fitting dentures** (denture wearers had poorer protein intake), **dysphagia**, immobility (stroke), tremor (Parkinson's), poor vision; **poverty and food insecurity**; **~29.3% of non-institutionalised elders live alone**, and **older people eat up to 50% more in company than alone**; institutions often fail to cater to ethnic food preferences. **Iatrogenic: more than 250 prescribed drugs alter taste**; **digoxin and chemotherapy** cause nausea and anorexia; **aluminium/magnesium antacids deplete phosphate and potassium**; **penicillamine causes zinc depletion and loss of taste acuity**; **high-fibre diets cause early satiety**.

CONSEQUENCES, ASSESSMENT AND MANAGEMENT

18. **Consequences.** Anorexia of ageing leads to **impaired muscle function (↓mass, strength, relaxation), decreased bone mass and fracture risk, immune dysfunction and infection, anaemia, poor wound healing, cognitive impairment, delayed recovery from surgery, more falls, more admissions, longer stays and increased mortality**. **Protein-energy malnutrition is a strong independent predictor of mortality** in community, nursing-home, hospital and recently discharged elders, and the risk is amplified by renal failure, cardiac failure and cerebrovascular disease.
19. **Assessment.** Screen appetite with the **SNAQ** — four items on **appetite, early satiety, taste of food and number of meals**, scored 1–5; **a score <14 indicates significant risk of weight loss**. Also use **MNA/MNA-SF item A** (decline in food intake over 3 months). **Differentiate** from **cachexia** (inflammation-driven, CRP raised), **starvation**, **primary depression**, **malabsorption** and **hyperthyroidism**. Apply the **"MEALS ON WHEELS" mnemonic** to uncover treatable causes.
20. **Management.**
    - **First, treat the pathological component:** depression, dementia-related feeding problems, drugs, dentition, dysphagia, constipation, pain, infection, thyroid disease.
    - **Food-first measures: flavour enhancement** (improves intake and nutritional status in nursing-home residents), **eating in company**, small frequent **nutrient-dense** meals, texture modification, oral and dental care, feeding assistance, meals-on-wheels.
    - **Oral nutritional supplements** — mortality benefit when **≥400 kcal/day for ≥35 days** in malnourished, unwell elders aged ≥75.
    - **Resistance exercise** — the primary intervention for the associated sarcopenia.

- **Orexigenic drugs (palliative only): megestrol acetate** is the most studied (increases appetite, weight and quality of life; **oedema** the significant adverse effect); **corticosteroids** improve appetite **without weight gain**; **cyproheptadine** increases appetite without weight gain; **cannabinoids (dronabinol, nabilone)** and **thalidomide (anti-TNF)** have limited evidence. **CCK antagonists remain theoretical.**

Latest Updates (2023–Present)

1. **Prevalence now quantified globally.** A meta-analysis of 36 studies found the overall pooled prevalence of anorexia of ageing to be **22.7%** with an incidence of 3.78%, stable from 2011 to 2024; the highest prevalence was in inpatients at **34.7%**, the most-used tool was the SNAQ, and the authors concluded that a global consensus on diagnosis is needed. *(Maturitas. 2025.)*
2. **SNAQ-based estimates are higher still.** Across 62 studies from 24 countries (n = 80,176), the pooled prevalence of anorexia/appetite loss was **29% (95% CI 26–34%)**, ranging from 22% in South America to 55% in Africa; by setting it was **25% in the community, 38% in nursing homes and 42% in hospitals**, and higher rates were associated with **female sex, lower educational level, eating alone, oral problems and depression**. Note how the "eating alone" and "oral problems" findings validate the textbook's social and dental factors. *(Li W, et al. Age Ageing. 2025;54:afaf249.)*
3. **Formal link with frailty.** In a systematic review of 4,657 community-dwelling older adults, anorexia of ageing was present in 11.3% overall but in **20.5% of frail and pre-frail participants**; robust status was associated with a **63% lower probability** of concomitant anorexia of ageing (OR 0.37, 95% CI 0.21–0.65, p = 0.0005). *(Nutrients. 2023;15:2966.)*
4. **Ghrelin agonism has become a real therapy.** Anamorelin, an oral ghrelin receptor agonist, was approved in Japan in 2021 for cancer cachexia in lung, gastric, colorectal and pancreatic cancers, acting mainly through stimulation of growth hormone secretion and appetite enhancement. In several randomised, double-blind, placebo-controlled trials it significantly improved lean body mass and appetite in cancer cachexia. **Examination point: the textbook's proposed ghrelin/CCK pathways have now produced a licensed drug.** *(Anticancer Res. 2025;45:865; eClinicalMedicine. 2025.)*
5. **GDF-15 identified as a new driver of anorexia-cachexia.** In a phase 2 randomised double-blind 12-week trial, patients with cancer cachexia and elevated GDF-15 (≥1500 pg/mL) receiving ponsegromab, a humanised anti-GDF-15 monoclonal antibody, had significantly greater weight gain than placebo — a median between-group difference of **2.81 kg** in the 400-mg group — with improvements in appetite, cachexia symptoms and physical activity, confirming GDF-15 as a driver of cachexia. **This is a mechanism not present in the textbook at all.** *(Groarke JD, et al. N Engl J Med. 2024;391:2291–2303.)*
6. **Mirtazapine — promising in oncology, disappointing in geriatrics.** A randomised trial supported mirtazapine as an appetite stimulant in NSCLC-related anorexia (JAMA Oncol 2024), but in a multi-site propensity-matched cohort of adults ≥65 started on mirtazapine 7.5 mg, appetite improvement did not differ from controls (20% vs 23%; OR 0.89, 95% CI 0.43–1.82), mean weight change was −1.22 kg, and oversedation prompted discontinuation in 6.3%. *(JAMA Oncol. 2024;10:305–314; companion geriatric cohort. 2026.)*
7. **Cannabinoids should not be recommended.** Randomised controlled trials and meta-analyses in patients with cancer showed that medicinal cannabis did not improve appetite or weight gain, and in the absence of high-quality evidence cannabinoids cannot presently be recommended for cancer-associated cachexia. *(J Thorac Dis. 2025;17:3478–3483.)*
8. **Megestrol is now contraindicated in older adults.** The 2023 AGS Beers Criteria grades it **avoid** (strong recommendation, moderate quality) — minimal effect on weight, with increased risk of thrombotic events and possibly death in older adults. *(AGS Beers Criteria Update Expert Panel. J Am Geriatr Soc. 2023;71.)*
9. **Screening is now mandated.** ESPEN recommends that all older persons shall routinely be screened for malnutrition to identify existing risk early, with oral intake supported by nursing interventions, education, nutritional counselling, food modification and oral nutritional supplements. A dedicated ESPEN dementia update followed in 2024. *(Volkert D, et al. Clin Nutr. 2022;41:958–989; Volkert D, et al. Clin Nutr. 2024.)*
10. **A new iatrogenic cause — the GLP-1 era.** The textbook lists GLP-1 as an unproven endogenous contributor; **exogenous GLP-1 receptor agonists are now a common prescribed cause of anorexia and weight loss in older adults**, with concomitant muscle mass loss raising concerns about sarcopenia and sarcopenic obesity. *(Curr Nutr Rep. 2026.)*

Current Practice Update

Textbook Position (Pathy's 2022)	Current Evidence-Based Practice (2023-present)
Prevalence quoted as **3.3% (community) to 33% (nursing home)** from a single 2013 study	Pooled meta-analyses give **22.7% overall** (36 studies) and **29% by SNAQ** (62 studies) — **community 25%, nursing home 38%, hospital 42%**
Ghrelin's role "unclarified, probably minimal"; therapy	**Anamorelin**, an oral ghrelin receptor agonist, is **licensed in Japan**

theoretical	**(2021)** for cancer cachexia and improves lean mass, appetite and weight
Cytokine mechanism described as IL-1, IL-6, TNF-α	**GDF-15** is now established as a key driver; **ponsegromab (anti-GDF-15) gave up to 2.8 kg weight gain vs placebo** in phase 2 (NEJM 2024)
Megestrol acetate presented as the best-studied and effective orexigenic	**AGS Beers 2023: AVOID** — minimal weight benefit, thrombotic risk, possible increased mortality
Cannabinoids "have shown promise" in cancer and AIDS cachexia	RCTs and meta-analyses show **no improvement in appetite or weight**; not recommended
Antidepressants discussed only via treatment of depression	**Mirtazapine** helps in cancer-related anorexia but showed **no benefit over control in hospitalised older adults**, with **oversedation in 6.3%**
GLP-1 listed as a possible endogenous contributor needing further study	GLP-1 receptor agonists are now a major **iatrogenic** cause of anorexia and lean-mass loss in older adults
Anorexia of ageing described as a syndrome without a formal diagnostic standard	Still true — the 2025 meta-analysis explicitly **calls for a global consensus definition**; **SNAQ <14** remains the most widely used operational criterion
Frailty association implied	Now quantified: **anorexia in 20.5% of frail/pre-frail vs 11.3% overall; robust status carries 63% lower odds**

Examiner's Tip — Mark-Earning Lines

- "The anorexia of ageing is the **physiological, age-related decline in appetite in which the fall in energy intake exceeds the fall in energy expenditure**, resulting in weight loss."
- "**Energy intake falls by about 30% between ages 20 and 80** — anorexia of ageing is the physiological substrate on which pathological causes act."
- "The four physiological mechanisms are **loss of homeostatic regulation, the ageing gut, declining senses, and hormonal/neurotransmitter change**."
- "**Roberts' underfeeding experiment** is the cleanest demonstration of impaired homeostasis — young men regained lost weight, old men did not."
- "**CCK is the strongest single candidate** — levels are higher *and* sensitivity is enhanced; IV CCK-8 suppressed intake **31% in older versus 15% in young adults**."
- "**Impaired fundic accommodation with raised nitric oxide** produces rapid antral filling and early satiety — the mechanical basis of early satiation."
- "**Reduced sensory-specific satiety** narrows the diet, and a monotonous diet is how micronutrient deficiency develops."
- "**Ageing behaves as a chronic stress state** — raised cortisol and catecholamines drive IL-6 and TNF-α, while falling sex hormones remove IL-6 inhibition."
- "**Screen with SNAQ — a score below 14 signals significant risk of weight loss.**"
- "**Depression is the commonest treatable cause**; the simplest effective intervention is **having the older person eat in company — intake rises by up to 50%**."
- "Anorexia of ageing is physiological, but **its consequences are not inevitable** — the aim of management is to prevent protein-energy malnutrition and sarcopenia, not to abolish the appetite decline itself."

Question 5. Obesity in the Elderly and Its Management

15 marks · Source: Pathy's 6th ed. (Ch. 8, 12, 14); Essentials of Clinical Geriatrics 7th ed. (Ch. 12)

20 High-Yield Points

DEFINITION, BODY COMPOSITION AND EPIDEMIOLOGY

1. **Definition.** As per **WHO**, malnutrition includes **excesses** as well as deficiencies — **obesity is a form of malnutrition**. Conventionally defined as **BMI ≥30 kg/m²**; **overweight = 25–29.9 kg/m²**. **The prevalence of obesity among older persons is growing.**
2. **Body composition changes with ageing make BMI unreliable. Fat mass increases and redistributes centrally** (visceral and ectopic — liver, muscle), while **lean mass falls by up to 3 kg per decade after age 50**. Because BMI cannot separate fat from fat-free mass, and **kyphosis makes height measurement unreliable**, **change in weight is preferred to change in BMI** in older adults.
3. **The "obesity paradox."** A meta-analysis showed **BMI 25–29.9 is not associated with a significantly increased mortality risk in older adults**, while **BMI ≥30 carries only a modest (~10%) increase**, irrespective of sex, disease status or smoking. Proposed explanations: **selective survival, cohort effects, a ceiling effect of mortality rates, and the limitations of BMI as a measure of body composition**. In the US NHIS 1997–98, **only 47.2% of those ≥75 were overweight versus 63.5% of those aged 45–64**.
4. **Central adiposity is the better risk marker.** A **higher waist-to-hip ratio was associated with increased mortality independent of smoking, alcohol and oestrogen use** in 31,702 Iowan women followed 11–12 years. But **WHR is hard to interpret in old age** — narrow hips may reflect **gluteal muscle wasting** rather than low fat. The literature on **BMI, WHR and waist circumference in elders remains inconsistent**; waist circumference is nonetheless simple, inexpensive and captures both effects.
5. **Sarcopenic obesity.** Defined as the **coexistence of diminished lean mass and increased fat mass**. At a BMI cut-off of ~27 kg/m², **14% of men <70 and 29% of men >80** were sarcopenic-obese, and **5% of women <70 and 8% of women >80**. It is the phenotype that carries the worst functional prognosis.

PATHOPHYSIOLOGY AND CONSEQUENCES

6. **Visceral fat drives the metabolic syndrome.** While generalised obesity is linked to excess mortality, CVD, osteoarthritis, mobility impairment and disability, it is **predominantly excess visceral fat** that produces **dyslipidaemia, raised fibrinogen, hyperinsulinaemia, glucose intolerance or diabetes, vascular insulin resistance, hypertension and cardiovascular disease**. **All components of the metabolic syndrome are prevalent in older populations.**
7. **Adverse consequences in older adults.**
   - **Metabolic/cardiovascular:** hypertension, type 2 diabetes, dyslipidaemia, coronary artery disease.
   - **Musculoskeletal: high BMI increases knee osteoarthritis risk**; mechanical burden on ageing joints.
   - **Respiratory:** pulmonary function abnormalities, **obesity-hypoventilation syndrome, obstructive sleep apnoea**.
   - **Genitourinary/GI: urinary incontinence rises with BMI**; obesity is associated with **faecal incontinence in women**.
   - **Oncological: breast, colon, pancreas, renal, bladder and prostate cancer**.
   - **Functional: markedly reduced self-reported mobility**, exacerbation of age-related functional decline, **frailty**, **higher rate of nursing-home admission**, and **impaired quality of life**.
8. **Beneficial effects of obesity in old age. Increased bone mineral density with reduced osteoporosis and hip fracture** in older men and women, plus greater nutritional reserve during acute illness. This is why **obesity in older adults is a target for function and quality of life, not primarily for mortality**.

ASSESSMENT

9. **Clinical assessment.** Measure **weight, height (or knee-height estimate), BMI, waist circumference and waist-to-hip ratio**; use **DXA, BIA or CT** for body composition where available. **Assess muscle function — handgrip strength, gait speed, chair rise, SPPB — to detect sarcopenic obesity.** Screen for **metabolic syndrome components, OSA, osteoarthritis, incontinence and depression**; review **drugs causing weight gain (insulin, sulphonylureas, steroids, antipsychotics)**; and establish **the patient's function, goals and life expectancy** before setting a weight target.

MANAGEMENT

10. **The cardinal principle. Weight-loss therapy that minimises muscle and bone loss is recommended only for older persons who are obese AND have functional impairments or metabolic complications that can benefit from weight loss.** In **sarcopenic obesity, prevention of further muscle loss takes priority over weight**

reduction.

11. **Lifestyle change is the primary approach, with modest goals.** A **modest reduction in energy intake of 500–700 kcal/day** is recommended. Note that **short-term caloric restriction improves blood pressure, cholesterol and metabolic rate only when the reduction is at least 20%**.
12. **Exercise is not optional. Regular physical activity is particularly important in obese older persons to improve physical function and help preserve muscle and bone mass. Exercise plus diet is the most effective non-surgical treatment for obesity** and is uniformly advocated by international consensus panels. Adding exercise to diet gives **greater weight loss, preservation of fat-free mass and resting metabolic rate, improved fitness, correction of visceral-obesity-related metabolic abnormalities, and better long-term dietary adherence**.
13. **Choosing the exercise modality.**
    - **Aerobic training may be somewhat better for reducing abdominal fat**, and most robust studies used **moderate- to high-intensity aerobic exercise**; there is no evidence that low-intensity exercise reduces abdominal fat.
    - **Energy restriction causes significant loss of muscle and bone; adding resistance training prevents these adverse body-composition changes, whereas aerobic exercise alone does not.**
    - **Resistance training is more suitable for older obese people with cardiovascular disease, arthritis, osteoporosis or mobility disorders** who cannot tolerate sustained aerobic work.
    - **Combined aerobic plus resistance training is superior to aerobic alone** for trunk fat in older men.
14. **Small weight loss, large visceral benefit. Preferential visceral fat mobilisation** means that a loss of only **~5% of total body weight or fat mass may produce a 25% or greater reduction in visceral fat**, with important metabolic implications for insulin resistance.
15. **Many benefits are independent of weight loss. Blood pressure can be lowered by dietary change (DASH) without weight loss**, and this effect persists for **3–5 years despite weight regain**; coronary prevention effects and **improvements in physical function are also obtainable without weight loss**. **The improvement comes from lifestyle change, not necessarily from the weight falling.**
16. **Evidence from major trials.** In **Look AHEAD**, intensive lifestyle intervention in diabetes produced **sustained weight loss, improved fitness and better cardiovascular risk factors**, but **no reduction in cardiovascular events**, **no difference in objective neuropathy**, and **marginally greater cognitive decline in obese subjects at five years**. In older adults randomised to caloric restriction versus exercise, caloric restriction produced greater weight loss **but also greater loss of lean mass**, with **no long-term difference in physical performance** between the two.
17. **Protect nutrition during weight loss.** Provide **protein 1.0–1.5 g/kg/day**, adequate **calcium (1000–1200 mg) and vitamin D (800 IU)**, and avoid intakes **below ~1500 kcal/day**, since low energy intake **almost guarantees micronutrient inadequacy**. Emphasise **nutrient-dense foods**.
18. **Avoid weight cycling.** Repeated attempts at sustained weight loss cause **loss of lean tissue (muscle and bone) and a fall in metabolic rate**, worsening the energy-balance equation and making long-term dietary management progressively harder.
19. **Pharmacotherapy. The available data are insufficient to determine the efficacy and safety of pharmacotherapy for obesity in older persons.** In obese older adults with type 2 diabetes, weight-loss diets are central; **metformin may act as an appetite suppressant** and **acarbose reduces carbohydrate absorption**. Note that **insulin itself causes significant weight gain**, aggravating the underlying problem.
20. **Bariatric surgery and monitoring. Bariatric surgery is the most effective weight-loss therapy**, but in older patients **perioperative morbidity and mortality are greater, while relative weight loss and improvement in obesity-related complications are lower** than in younger patients. It should therefore be **reserved for a select group of older subjects with disabling obesity that can be ameliorated by weight loss and who meet standard criteria**. Throughout follow-up, **distinguish intentional from unintentional weight loss** — in SHEP, the **excess mortality associated with weight loss was present even in the heaviest subjects (BMI ≥31) and was independent of baseline weight**.

Latest Updates (2023–Present)

1. **Obesity has been formally redefined — clinical vs preclinical.** The Lancet Diabetes & Endocrinology Commission defines **preclinical obesity** as excess adiposity with preserved organ function and generally increased future risk, and **clinical obesity** as a chronic systemic illness with objective signs or symptoms of altered organ function or impaired ability to conduct daily activities directly caused by excess adiposity. Confirmation of excess adiposity requires either direct body fat measurement (DXA or bioimpedance), or at least one anthropometric criterion in addition to BMI, or at least two anthropometric criteria regardless of BMI — using waist circumference, waist-to-hip ratio or waist-to-height ratio with age-, sex- and ethnicity-appropriate cut-offs. Diagnosis of clinical obesity requires at

least one of 18 specified obesity-related conditions in adults. **This directly addresses the textbook's complaint that BMI performs poorly in older adults.** *(Rubino F, et al. Lancet Diabetes Endocrinol. 2025;13:221–262.)*

2. **India has its own revised definition — highly examinable.** In **Stage 1 obesity**, individuals have increased adiposity (**BMI >23 kg/m²**) without discernible effects on organ function or daily activities. **Stage 2 obesity** denotes a more advanced state with generalised and abdominal adiposity affecting physical and organ function and causing functional limitation, requiring **BMI >23 kg/m² plus abdominal adiposity (excess waist circumference or waist-to-height ratio) plus either a mechanical condition such as knee arthritis due to excess weight, or an obesity-associated disease such as type 2 diabetes**. This is "obesity with consequences" and mandates more intensive management. *(Misra A, Vikram NK, Ghosh A, et al. Diabetes Metab Syndr. 2025;19:102989.)*
3. **EASO's parallel framework.** The EASO report retains BMI ≥30 kg/m² but adds BMI >25 kg/m² with a waist-to-height ratio >0.5, with both criteria requiring evidence of medical, functional or mental limitation. *(EASO framework, 2024.)*
4. **Sarcopenic obesity now has consensus diagnostic criteria — but they need validation.** In 2022 ESPEN and EASO issued the first global consensus on diagnostic methods for sarcopenic obesity; applied for the first time in free-living older adults, the algorithm gave a prevalence of 9% and was 100% sensitive for diagnosis, with insulin resistance and an altered ghrelin profile emerging as risk factors. A Western Chinese community validation found a prevalence of 13.2% by ESPEN/EASO criteria, rising with age and BMI and associated with falls. However, the ESPEN/EASO consensus showed **poor diagnostic agreement** with other commonly used sarcopenic-obesity definitions in a 4,155-participant Chinese cohort. *(Donini LM, et al. Clin Nutr / Obes Facts. 2022; Clin Nutr. 2023; Arch Gerontol Geriatr. 2024;127:105557; Front Endocrinol. 2024.)*
5. **GLP-1 receptor agonists work as well in the elderly.** A post hoc analysis of the SURMOUNT and SUMMIT phase 3 trials in adults ≥65 years found that all tests for treatment-by-age-group interaction were non-significant for percent body weight change, waist circumference, systolic blood pressure and HbA1c, indicating comparable efficacy in older and younger participants. Head-to-head, SURMOUNT-5 demonstrated superior efficacy of tirzepatide over semaglutide for percentage weight change and for weight-reduction targets of ≥10%, ≥15%, ≥20% and ≥25% at 72 weeks, with greater improvements in blood pressure, HbA1c, fasting insulin, triglycerides and HDL. *(Alfaris N, et al. Diabetes Obes Metab. 2026; Aronne LJ, et al. N Engl J Med. 2025;393:26–36.)*
6. **But the geriatric caveats are serious.** GLP-1 RAs effectively induce weight loss, but concomitant muscle mass loss is common, raising concerns about sarcopenia and sarcopenic obesity in older adults. A meta-analysis of eight RCTs found participants regained **9.69 kg over 48–52 weeks after stopping** semaglutide or tirzepatide. Handgrip strength appears statistically preserved in short-to-mid-term trials, but longitudinal and retrospective research in older adults with type 2 diabetes has reported reduced handgrip strength and accelerated sarcopenia with prolonged semaglutide use. **Practical rule: never prescribe a GLP-1 RA to an older adult without concurrent adequate protein intake and resistance training.** *(Curr Nutr Rep. 2026; Maturitas. 2025.)*
7. **ESPEN sets the threshold for intervention.** Weight loss in old age should be considered only in cases of obesity with associated health problems, and should be achieved by moderate energy reduction in combination with exercise. Dietary restrictions should generally be avoided in older persons. *(Volkert D, et al. Clin Nutr. 2022;41:958–989.)*
8. **India's double burden in the elderly.** In LASI, about 25% of males and 37% of females aged 45–59 are overweight or obese, while among those aged 60 and above 28% of males and 25% of females are underweight; the urban population is more than twice as likely to be overweight and less likely to be underweight. Age-appropriate Indian BMI cut-offs derived from LASI differ substantially from WHO values in those aged 60 and above. *(Khan J, et al. Sci Rep. 2023;13:12820; Singh A, Chattopadhyay A. Sci Rep. 2024;14:15200.)*

Current Practice Update

Textbook Position (Pathy's 2022 / Essentials 7e)	Current Evidence-Based Practice (2023-present)
Obesity diagnosed by **BMI ≥30**, with acknowledgement that BMI is a poor index in elders	**Lancet Commission 2025**: BMI alone is insufficient — **confirm excess adiposity with a second anthropometric or body-composition measure**, then classify as **preclinical vs clinical obesity** based on organ dysfunction/functional limitation
WHO BMI cut-offs applied uniformly	**India-specific staging (2025): Stage 1 = BMI >23 without organ/functional effect; Stage 2 = BMI >23 + abdominal adiposity + mechanical or disease consequence**
Sarcopenic obesity defined loosely as "diminished lean mass with increased fat mass"	**ESPEN/EASO 2022 consensus algorithm** — screen (obesity + clinical suspicion) → confirm **low handgrip strength + low muscle mass by BIA** → stage by comorbidity; prevalence ~9–13% in older cohorts, though **agreement with other definitions is poor**
"Data are insufficient to determine the efficacy and safety of pharmacotherapy for obesity in older persons"	**GLP-1/GIP receptor agonists are now first-line pharmacotherapy**, with **post hoc analyses in adults ≥65 showing no age interaction** for weight loss or cardiometabolic benefit

Weight loss achieved by **diet + exercise**, with concern about muscle and bone loss	Same principle, but the concern is now **acute for GLP-1-induced weight loss — lean-mass loss, weight regain of ~9.7 kg after discontinuation, and reported grip-strength decline with prolonged use in older diabetics**
Bariatric surgery — greater perioperative risk, lesser benefit in the old; reserve for selected patients	Position broadly unchanged, but **pharmacotherapy now displaces surgery for many older candidates**, with surgery reserved for those failing or intolerant of medical therapy
Obesity in older adults "may not be an important clinical target for reducing mortality"	Still valid — but the **Lancet "clinical obesity"** construct reframes the target as **organ dysfunction and functional limitation**, which is exactly the geriatric endpoint

Examiner's Tip — Mark-Earning Lines

- "**Obesity is a form of malnutrition** — the WHO definition covers excesses as well as deficiencies."
- "**BMI is a poor index of adiposity in old age** because fat mass rises, lean mass falls by up to 3 kg per decade after 50, and kyphosis makes height unreliable — **use weight change and waist circumference instead**."
- "**The obesity paradox: overweight (BMI 25–29.9) carries no excess mortality in those over 65, and obesity only about a 10% increase.**"
- "**Obesity in the older adult is a target for function and quality of life, not for mortality.**"
- "Weight-loss therapy is indicated **only when there is functional impairment or metabolic complication**, and **only if it minimises muscle and bone loss**."
- "**A modest energy deficit of 500–700 kcal/day plus exercise** — never diet alone, because **energy restriction causes significant muscle and bone loss and only resistance training prevents it**."
- "**A 5% loss of body weight can produce a 25% or greater reduction in visceral fat** — preferential visceral mobilisation explains why modest goals still work."
- "**In sarcopenic obesity, protecting muscle takes priority over reducing weight.**"
- "**Blood pressure, lipids, insulin sensitivity and physical function all improve with lifestyle change even when weight does not fall** — the intervention matters more than the number on the scale."
- "**Avoid weight cycling** — repeated attempts lose lean tissue and bone and lower metabolic rate."
- "For India: **Stage 1 obesity is BMI >23 without consequence; Stage 2 is BMI >23 with abdominal adiposity plus a mechanical or disease consequence** — the definition examiners will expect after 2025."

Appendix — Rapid Revision Grid

Every number, cut-off, criterion, mnemonic and named trial from the five answers, compiled for night-before revision.

A. Diagnostic Criteria and Cut-offs

Item	Value to Quote
GLIM — requirement	**≥1 phenotypic + ≥1 etiologic** criterion
GLIM phenotypic	Weight loss >5% in 6 mo or >10% beyond 6 mo · Low BMI · Reduced muscle mass
GLIM etiologic	Reduced intake/assimilation (≤50% requirement >1 wk, any reduction >2 wk, chronic GI disease) · Inflammation/disease burden
GLIM BMI — Western	<20 if <70 y · <22 if >70 y
GLIM BMI — Asian	**<18.5 if <70 y · <20 if >70 y**
GLIM Stage 1 (moderate)	Loss 5–10% in 6 mo (or 10–20% beyond); BMI <20 (<70 y) / <22 (≥70 y)
GLIM Stage 2 (severe)	Loss >10% in 6 mo (or >20% beyond); BMI <18.5 (<70 y) / <20 (≥70 y)
Significant weight loss	**5% in 1 month · 7.5% in 3 months · 10% in 6 months**
MNA-SF score bands	**12–14 normal · 8–11 at risk · 0–7 malnourished**
MNA performance	96% sensitive, 60% specific; normal MNA → mortality RR 0.35 (0.18–0.66)
SNAQ	4 items (appetite, early satiety, taste, meals/day), each 1–5; **<14 = significant risk of weight loss**
Calf circumference	**<31 cm** = low muscle mass (both sexes)
MUAC (2024 validation)	**<23 cm men · <22 cm women**
FFMI cut-off	<17 kg/m² men · <15 kg/m² women
ASMI cut-off	<7.0 kg/m² men · <5.4–5.7 kg/m² women
CRP inflammation grades	<3 mg/L = starvation · medium = cachexia · >100 mg/L = hypercatabolic
Mortality-predictive BMI	<22 kg/m² → higher 1-y mortality; <15th percentile → 180-day post-hospital mortality
Obesity — India Stage 1 (2025)	BMI >23 kg/m², no organ/functional effect
Obesity — India Stage 2 (2025)	BMI >23 + abdominal adiposity (WC or WHtR) + mechanical condition *or* obesity-associated disease
Lancet 2025 obesity	**Preclinical** = excess adiposity, organs preserved · **Clinical** = excess adiposity + organ dysfunction / functional limitation (1 of 18 conditions)
Dental referral score	≥3 points (dry mouth 2, eating difficulty 1, no dental care 2 y 1, pain 2, food change 1, oral lesions 2)

B. Prevalence Figures

Population / Condition	Figure
Malnutrition by MNA — overall	**22.8%**
By setting (MNA)	Rehabilitation 50.5% · Hospital 38.7% · Community 5.8%
European meta-analysis	LTC 28.7% · Rehab 29.4% · Hospital 22% · Nursing home 17.5% · Community 6%
Global malnutrition (2025 meta-analysis, 98 studies)	**18.6%** (Africa 35.7%; highest by NRS-2002 39.9%)
Anorexia of ageing (textbook)	3.3% community → 33% nursing home
Anorexia of ageing (2025 pooled, 36 studies)	**22.7%**; incidence 3.78%; inpatients 34.7%
Appetite loss by SNAQ (2025, 62 studies)	**29%** — community 25%, nursing home 38%, hospital 42%
Anorexia in frail/pre-frail	20.5% (vs 11.3% overall); robust → OR 0.37
Involuntary weight loss	5–15% community · 27% frail ≥65 · 8% of adult outpatient visits
Sarcopenic obesity (ESPEN/EASO applied)	9% free-living Italian cohort · 13.2% Western China community
PEM in institutionalised dementia	up to 50%
Anorexia in end-stage CHF / dialysis	>40% / 30–40% (4-fold mortality)
India — LASI, age ≥60 underweight	28% men · 25% women

India — LASI, age 45–59 overweight/obese	25% men · 37% women
Indian age-specific underweight cut-off (2024)	<17.4 (60–74 y) · <13.3 (≥75 y)

C. Physiology Numbers — Anorexia of Ageing

Parameter	Figure
Fall in energy intake, age 20→80	**~30%**
NHANES III decline	1321 kcal/day men · 629 kcal/day women
New Mexico longitudinal	−25.1 kcal/day/year men · −19.3 women
Swedish cohort (70→76 y)	−610 kcal/day men · −440 women
Roberts' underfeeding experiment	~750 kcal/day deficit × 21 days; old men never regained weight
CCK-8 IV suppression of intake	**31% older vs 15% young (p = 0.02)**
Olfactory decline	>50% aged 65–80; >75–80% aged ≥80; 46% report appetite/weight change
Effect of eating in company	Intake rises up to **50%**
Elders living alone	~29.3% of non-institutionalised
Drugs altering taste	**>250** prescribed drugs
Lean mass loss after age 50	up to **3 kg per decade**
Total body water after 75	falls from 60% to **50%**

D. Therapeutic Targets

Target	Value
Energy requirement	30–35 kcal/kg/day
Protein — healthy elder (ESPEN)	1.0–1.2 g/kg/day
Protein — ill/malnourished (ESPEN)	1.2–1.5 g/kg/day
Protein — ICMR-NIN RDA 2020	Safe intake 0.83 g/kg/day (EAR 0.66)
Fluid	~1 mL/kcal, about **1.5 L/day**
Calcium / Vitamin D after 50	1000–1200 mg / 800 IU (ULs 2000 mg / 4000 IU)
25(OH)D adequacy / deficiency	≥20 ng/mL adequate; treat <10–12 ng/mL
ONS dose-duration rule	**≥400 kcal/day for ≥35 days** in unwell malnourished ≥75 y
ONS effect (2009 meta-analysis, 42 trials)	2.3% weight gain; mortality **RR 0.74 (0.59–0.92)**
Resistance training	Progressive, **2–3 times/week**
Obesity — energy deficit	**500–700 kcal/day** (metabolic benefit needs ≥20% reduction)
Visceral fat response	~5% weight/fat loss → **≥25% visceral fat reduction**
Sodium correction rates	Hypernatraemia <10 mEq/L/24 h; hyponatraemia 6–8 mEq/L/24 h
Folate replacement	1 mg/day
Minimum energy for micronutrient adequacy	~1500 kcal/day

E. Named Evidence — Trials, Guidelines, Consensus

Name	What It Says (one line)
GLIM 2019 / 5-year update 2025	Two-step diagnosis; criteria validated and unchanged; any available muscle-mass method acceptable
GLIS 2024	Sarcopenia = mass + strength + muscle-specific strength; performance is an *outcome*
ESPEN geriatrics 2022	82 recommendations; screen all; food → ONS → enteral → parenteral; avoid dietary restrictions
ESPEN dementia update 2024	Nutrition and hydration guideline specific to dementia
EFFORT trial	Reaching ≥75% of nutrition goals lowers adverse events and mortality; **no legacy effect at 6 months**
Cochrane IPD-NMA 2026	ONS *may* reduce 30-day mortality/SAEs in hospitalised elders; certainty **low to very low**
AGS Beers 2023	**Avoid megestrol** — minimal weight effect, thrombotic risk, possible increased mortality

Endocrine Society 2024 (vitamin D)	Empiric vitamin D at **≥75 years**; against routine 25(OH)D testing; daily > intermittent over 50
USPSTF 2024 draft (vitamin D)	**D grade** — no net benefit for falls/fractures in healthy community-dwelling elders
Ponsegromab (NEJM 2024)	Anti-GDF-15 mAb; up to **2.81 kg** weight gain vs placebo in cancer cachexia
Anamorelin	Oral ghrelin receptor agonist; licensed in Japan 2021; improves lean mass and appetite
Mirtazapine	Works in NSCLC anorexia (JAMA Oncol 2024); **no benefit in hospitalised elders**, 6.3% oversedation
Look AHEAD	Lifestyle intervention improved weight, fitness and risk factors but **no reduction in CV events**
SHEP	Weight loss ≥1.6 kg/yr → **4.9×** mortality; effect present even at BMI ≥31
Cardiovascular Health Study	5% loss → risk-adjusted mortality 1.67×, irrespective of intentionality
Lancet Commission 2025	Clinical vs preclinical obesity; BMI must be paired with a second adiposity measure
Misra et al. 2025 (India)	Stage 1 / Stage 2 obesity for Asian Indians; BMI >23 threshold
ESPEN/EASO 2022	First consensus algorithm for sarcopenic obesity (screen → strength + mass → stage)
SURMOUNT-5 / post hoc ≥65 y	Tirzepatide > semaglutide; **no age interaction** for weight or cardiometabolic benefit
ICMR-NIN 2024	17 guidelines; “My Plate for the Day”; DIAAS; discourages protein supplements
LASI Wave 1	Indian double burden — ~1 in 4 elders underweight, rising urban overweight

F. Mnemonics and One-Line Concepts

MEALS ON WHEELS — Treatable Causes of Weight Loss

Medications · **E**motional (depression) · **A**norexia tardive / alcoholism · **L**ate-life paranoia · **S**wallowing disorders · **O**ral factors · **N**o money · **W**andering / dementia · **H**yper- and hypothyroidism, hyperparathyroidism, hypoadrenalism · **E**nteric (malabsorption) · **E**ating problems (unable to self-feed) · **L**ow-salt / low-cholesterol diets · **S**ocial isolation, **S**tones

Ten Concepts That Earn Marks in Any Nutrition Question

- **Malnutrition is a geriatric syndrome** — multifactorial, poor outcomes, needs CGA.
- **Three-step approach:** SCREEN (MNA-SF) → DIAGNOSE (GLIM) → GRADE (CRP).
- **Starvation responds to refeeding; cachexia does not** — CRP is the bedside discriminator.
- **Serial weight beats BMI** — kyphosis makes height unreliable.
- **Albumin is an inflammatory marker, not a nutritional one** — excluded from GLIM.
- **Anaemia is one of the earliest manifestations of PEM.**
- **ONS need the right dose and duration** — ≥400 kcal/day for ≥35 days.
- **Exercise is the stimulus, nutrition is permissive** — neither works alone in sarcopenia.
- **PEG in advanced dementia neither prolongs survival nor prevents aspiration.**
- **Obesity in the elderly is a target for function, not mortality** — and in sarcopenic obesity, muscle comes before weight.

Three Places Where the Textbook Is Now Outdated — Know These Cold

- **Megestrol acetate:** the textbook calls it the best-studied orexigenic; **AGS Beers 2023 says AVOID**.
- **Albumin:** the textbook calls it a practical indicator of malnutrition; it is now an **inflammatory/prognostic marker excluded from GLIM**.
- **Obesity pharmacotherapy:** the textbook says data are insufficient in older persons; **GLP-1/GIP agonists now have positive ≥65-year post hoc data**, tempered by lean-mass loss and weight regain.

End of document · Textbook content from Pathy’s 6th ed. and Essentials of Clinical Geriatrics 7th ed. · Updates current to August 2026

MD GERIATRIC MEDICINE · EXAMINATION COMPILATION

Palliative Care, End-of-Life Care, Chronic Pain & Bereavement

Six compiled high-yield examination answers
with Latest Updates (2023–present) and Current Practice Updates

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition
Kane's Essentials of Clinical Geriatrics
Supplemented with current international and Indian guidelines

Contents

1 **Palliative care — principles, and interventions to relieve suffering in painful bone metastasis with nausea, vomiting, constipation and breathlessness; evolution in India**

WHO principles · total pain · WHO ladder · pathological fracture · cause-directed antiemetics · opioid-induced constipation · death rattle · NDPS Act and the Kerala model

2 **Management of a terminally ill patient and the issues that need to be addressed**

Diagnosing dying · GSF triggers · anticipatory prescribing · hydration vs nutrition · withholding vs withdrawing · DNACPR · palliative sedation · assisted dying

3 **Management of chronic / persistent pain in the elderly; classification and pathophysiology of pain; role of palliative care**

Nociceptive, neuropathic, nociplastic · wind-up and central sensitisation · gate control · ATMAN framework · Beers 2023 · WHO 2023 low back pain guideline

4 **End-of-life care issues**

Recognition · communication · ethics · futility · rationing and ageism · POLST/MOLST · seven legal myths · culture and spirituality · caregivers

5 **Hospice and respite care**

Hospice vs palliative care · Cicely Saunders · four Medicare levels · interdisciplinary team · caregiver burden · adult day services · Zarit Burden Interview

6 **Bereavement**

Grief, mourning and bereavement · complicated grief red flags · DSM-5 bereavement exclusion · Prolonged Grief Disorder in ICD-11 and DSM-5-TR · grief-focused CBT

HOW TO USE THIS COMPILATION

Each answer follows the same architecture: **high-yield numbered points** organised under labelled subheadings → **Latest Updates (2023–present)** with named trials and guidelines cited inline → **Current Practice Update** comparing textbook position with current evidence → **Exam One-Liners** for rapid recall. The one-liner boxes at the end of each answer are designed for night-before revision.

NOTE ON OVERLAP

Questions 1, 2, 4 and 5 overlap substantially in the syllabus. Where content recurs it has been **pivoted rather than repeated** — symptom-control pharmacology sits mainly in Q1 and Q3; the ethical, legal and service-delivery framework sits mainly in Q2 and Q4; hospice and caregiver structure sits in Q5. Read them as a set.

QUESTION 1 · 15 MARKS

Palliative care — principles, and interventions to relieve suffering in painful bone metastasis with nausea, vomiting, constipation and breathlessness; evolution in India

High-Yield Points

Definition and Principles

1. **WHO definition** — palliative care improves the **quality of life (QOL)** of patients and families facing a life-threatening illness by giving **pain and symptom relief, psychosocial and spiritual support**. It also covers prevention, family support and **bereavement counselling** after death.
2. It advocates **early identification of the dying process and impeccable assessment**. It **affirms life** and treats dying as a **normal process**.
3. Palliative care can be given **alongside curative treatment at any point in the disease trajectory, even from diagnosis**. It does not depend on prognosis, stage of disease, or the need for other therapies.
4. **Four fundamental elements**: (i) systematic control of pain, symptoms, psychosocial distress, spiritual and practical needs; (ii) culturally sensitive information with repeated reassessment of **benefits versus burdens**; (iii) genuine **coordination and continuity of care** across settings; (iv) preparation of patient and family for dying, with **hospice options and bereavement support**.
5. **Generic (primary) palliative care** is delivered by all clinicians; **specialist palliative care** is delivered by trained **interdisciplinary teams** (palliative physician, nurse specialist, physiotherapist, occupational therapist, dietician, pharmacist, social worker, spiritual and psychological support).
6. **Hospice** is a subset of palliative care for those near the end of life (in the US, certified prognosis **≤6 months**). Its focus is **caring, not curing**, and it may be delivered at home, in hospital, in a hospice, or in a nursing home.
7. Palliative care is appropriate not only in cancer but also in **chronic disease, heart failure, COPD, end-stage renal disease, dementia and frailty**. **Best outcomes occur when it is started early.**
8. Effective **communication and advance care planning** are core. Structured frameworks include **REMAP**, the **Serious Illness Conversation Guide**, and **Byock's "Five Things"** (thank you; forgive me; I forgive you; I love you; goodbye).

> **CICELY SAUNDERS' CONCEPT OF "TOTAL PAIN"**
>
> **Physical + psychological + social + spiritual suffering.** Treating only the physical component leaves the patient in pain. This single concept underpins the entire interdisciplinary structure of palliative care and is the most quotable framing device for any palliative care answer.

Painful Bone Metastasis

1. **Standard pain assessment** is essential: accurate pain history, a **validated assessment tool**, clinical examination, and appropriate laboratory and radiological investigation. **Numerical rating, pictorial and verbal descriptor scales are more reliable than visual analogue scales in the elderly**; the **same scale must be used at follow-up**.

2. **25–40% of elderly cancer patients have daily pain** and it is frequently **undertreated**. Risk factors for under-treatment are **age >75 years, minority race and cognitive impairment**. There is **no proven change in pain perception with ageing** — older patients simply complain less. In cognitive impairment, assess frequently and use **behavioural cues** (agitation, altered cognition, changed appearance or respiration).
3. Follow the **WHO Analgesic Ladder** — start with **non-opioids (paracetamol, aspirin)**, then add **opioids such as morphine**. Give drugs **"by the clock" every 2–6 hours, not on demand**, especially in long-term care. Use **sublingual, transdermal, rectal or subcutaneous** routes when the oral route fails.
4. **Opioid use in the elderly**: start low, titrate slowly. Prefer **short-acting immediate-release morphine, oxycodone or hydromorphone**. **Avoid meperidine, propoxyphene, fentanyl patches and methadone** (complex metabolism, active metabolites). Anticipate **delirium, falls, nausea and constipation**.
5. **Adjuvants for bone pain**: **NSAIDs and corticosteroids** are useful for bone and visceral pain (watch GI bleeding and renal failure); **topical lidocaine, NSAID gels, capsaicin**; neuropathic adjuvants with the **lowest anticholinergic burden**; plus massage, heat, cold and focused physiotherapy.
6. **Disease-directed therapy for malignant bone pain** — **surgery, chemotherapy, radiotherapy and/or bisphosphonates**. **Radiotherapy relieves pain in up to 80%** and promotes bone healing. **IV bisphosphonates (pamidronate, zoledronic acid, ibandronate)** reduce pain and **skeletal-related events** in breast cancer and myeloma; **caution if creatinine clearance <30 ml/min**.
7. **Pathological fracture** — bone pain is the commonest presenting feature. **About 50% follow breast cancer metastasis** and the **femur is the commonest site**. Surgery is considered first where a fracture has occurred; **long bones need rigid internal fixation before irradiation**. Radiotherapy alone is used for ribs, scapula and pelvis. Surgery is justified if survival is **≥3 months for non-weight-bearing bones** and even **about 1 month for weight-bearing bones**.

Nausea and Vomiting

1. **Identify the mechanism first** — drugs (opioids, chemotherapy), **constipation, bowel obstruction, electrolyte abnormality, hepatic or renal failure, radiotherapy, CNS/brain lesions and anxiety**. Receptors involved are **dopamine, serotonin, histamine and acetylcholine**, acting via the **chemoreceptor trigger zone, vomiting centre, gut and labyrinth**.
2. **Select the first-line antiemetic by cause**, give it **on a schedule** until controlled, then taper to as-needed. **Add a second agent** if symptoms persist, since nausea is often multifactorial. **Use side effects to advantage** — haloperidol when delirium coexists; **avoid ondansetron when constipation is the cause**.

Cause	First-line agent
Constipation	**Senna, PEG, lactulose, bisacodyl**
Delayed gastric emptying	**Metoclopramide 5–10 mg TDS–QDS**
Uraemia / liver metastases	**Haloperidol 1–2 mg PO or 0.5–1 mg IV/SC TDS**
Brain metastases	**Dexamethasone 2–4 mg QDS**
Vertigo / labyrinthine	Hyoscyamine, scopolamine patch, meclizine
Anxiety	Lorazepam 0.5–1 mg

Inoperable bowel obstruction	**Octreotide + dexamethasone + glycopyrrolate**; olanzapine 2.5–5 mg as needed
Non-drug measures	Small frequent meals, relaxation techniques, **acupuncture / acupoint stimulation** for chemotherapy-induced vomiting

Constipation

1. Defined as **fewer than three bowel movements per week**, hard stool and difficult passage. **Prevention is the main strategy** and **opioid-induced constipation must be anticipated and treated prophylactically** in every patient. Combine a **stimulant laxative (senna, bisacodyl)** with an **osmotic laxative (lactulose, PEG, sorbitol)**. **Stool softeners such as docusate are no better than placebo and are not recommended**; **bulking agents such as psyllium are dangerous at end of life** and can cause impaction. **Methylnaltrexone (SC)** is effective for refractory opioid-induced constipation — it **does not cross the blood–brain barrier** and does not precipitate withdrawal.

Breathlessness

1. **Opioids are the main therapy for dyspnoea** — patients and staff often need education about this indication. **Benzodiazepines** are added when anxiety coexists; the two act **synergistically**, allowing lower doses of each. **Oxygen only when hypoxia is present and the patient finds it helpful**. Non-drug measures: a **cool, well-ventilated room, a fan or open window, upright positioning**, glucocorticoids and bronchodilators for bronchospasm, antibiotics if infection is driving it.
2. **Death rattle** — **avoid deep suctioning** (uncomfortable, causes gagging). **Reposition for postural drainage**. **Antimuscarinics** (atropine, scopolamine, **glycopyrrolate — preferred as it does not cross the blood–brain barrier**) may be used, though **clinical benefit is unproven**. **Stop blood pressure monitoring; monitor only respiratory rate and pulse.**
3. **Watch for iatrogenic harm** — **metoclopramide and haloperidol** cause extrapyramidal and neuropsychiatric toxicity; opioids, anxiolytics, antidepressants, antihistamines, steroids, antipsychotics and fluoroquinolones cause **delirium**. For **terminal agitation**, treat the cause first, use behavioural measures, then **low-dose haloperidol** (chlorpromazine or quetiapine if sedation is required).
4. **Total care** must cover **psychological, social and spiritual domains**. **Caregivers with emotional stress have significantly increased mortality** — identify and refer them. Hospice programmes provide **bereavement follow-up for about one year**; screen for **complicated grief**.

Evolution of Palliative Care in India

Period	Landmark
1985	**NDPS Act** enacted — stiff penalties and 4–5 simultaneous licences; morphine consumption **fell about 92%** (roughly 600 kg to 48 kg in 13 years); India ranked **113 of 131** in per-capita morphine use by 1997
1986	**Shanti Avedna Sadan, Mumbai** — India's first hospice
1991	**Pain and Palliative Care Society, Calicut, Kerala** (Dr M R Rajagopal, Dr Suresh Kumar)
1994	**Indian Association of Palliative Care (IAPC)** founded
1998	**Delhi High Court order** (Ghooi case) triggered state-level simplification of narcotic rules

2001	**Neighbourhood Network in Palliative Care (NNPC)**, Kerala — the largest **community- and volunteer-owned** palliative care network in the world
2008	**Kerala** becomes the **first Indian state and the first in Asia** to declare a palliative care policy; home-based care as its cornerstone (revised 2019)
2012	**National Programme for Palliative Care (NPPC)** launched by MoHFW; later merged under **NP-NCD**
2014	**NDPS (Amendment) Act** — created the class of **"Essential Narcotic Drugs"**, reduced licences from **six to one**, and allowed **Recognised Medical Institutions (RMIs)** to stock and dispense morphine
2017–22	Palliative care included in the **National Health Policy 2017**; MD Palliative Medicine recognised; palliative care made one of the **12 expanded service packages of Ayushman Bharat Health & Wellness Centres**
2018	**Common Cause v Union of India** — Supreme Court recognised the **right to die with dignity (Article 21)**, legalised **passive euthanasia** and gave legal status to **Advance Medical Directives (living wills)**
2023	Supreme Court **simplified** the Advance Medical Directive procedure
2024	**MoHFW draft guidelines** for withdrawal of life support in terminally ill patients

Latest Updates (2023–Present)

Bone metastasis

1. The **ASTRO 2024 clinical practice guideline** (replacing the 2017 version, developed with ASCO and MSTS) confirms that **8 Gy in 1 fraction**, 20 Gy/5, 24 Gy/6 and 30 Gy/10 give **equivalent pain relief** for previously unirradiated bone metastases. **Retreatment is more frequent after single fraction**, but its convenience makes it the preferred option in **limited life expectancy**.
2. For **spinal cord or cauda equina compression** in patients unfit for surgery: 8 Gy/1, 16 Gy/2, 20 Gy/5 or 30 Gy/10. **Surgery plus post-operative radiotherapy is conditionally preferred over radiotherapy alone** where feasible.
3. **SBRT is conditionally recommended over conventional radiotherapy** in selected patients with **good performance status**, no neurological deficit and no surgical indication.
4. **Dexamethasone significantly reduces the incidence of pain flare** when given with single-fraction radiotherapy.
5. **Re-irradiation** is now explicitly endorsed: spine 8 Gy/1, 20 Gy/5, 24 Gy/6 or 20 Gy/8; non-spine 8 Gy/1, 20 Gy/5 or 24 Gy/6.
6. **Shared decision-making** received a **strong recommendation** — regimen choice must weigh prognosis, prior dose, normal-tissue risk, quality of life, cost and patient values.

Breathlessness

1. **BETTER-B trial (Lancet Respiratory Medicine, 2024)** — **mirtazapine 15–45 mg daily for 56 days did NOT improve severe breathlessness** in COPD or ILD and caused **more adverse effects and greater care use**. Mirtazapine is **not recommended** for breathlessness.
2. **MABEL trial (Lancet Respiratory Medicine, 2025)** — **morphine did not improve worst breathlessness intensity** in chronic breathlessness; the findings **do not support its routine use** in this setting.

3. **ABCD trial** — **dexamethasone did not improve dyspnoea in advanced cancer** and caused more toxicity, so routine steroid use for cancer dyspnoea is discouraged.
4. The **ERS 2024 clinical practice guideline** on symptom management in serious respiratory illness emphasises **non-pharmacological first-line measures** — **fan-to-face, breathing techniques, pulmonary rehabilitation, pacing and psychological support** — with opioids reserved for **carefully selected, closely monitored patients**.

Nausea, vomiting and constipation

1. **Olanzapine 5 mg** added to standard triple antiemetic therapy significantly improved control of **carboplatin-induced nausea** in a phase III trial (J Clin Oncol 2024), strengthening olanzapine's place as a **broad-spectrum antiemetic**.
2. The **MASCC/ESMO 2023 updated consensus** incorporates **olanzapine** into antiemetic pathways for moderately and highly emetogenic regimens; **low-dose olanzapine is increasingly used for chronic, non-chemotherapy nausea in advanced cancer**.
3. **Peripherally acting mu-opioid receptor antagonists (PAMORAs)** — **methylnaltrexone, naldemedine, naloxegol** — are now standard second-line therapy for **opioid-induced constipation** unresponsive to combined laxatives.

India

1. **Supreme Court order, 24 January 2023** (*Common Cause v Union of India*) — the **living will no longer needs a Judicial Magistrate's countersignature**; it can be **attested by a notary or gazetted officer**. **More than one guardian** may be named. Approval now rests on a **Primary Medical Board** (treating doctor plus two experts of at least 5 years' experience) and a **Secondary Medical Board** (including a CMO nominee), with defined **48-hour timelines**; courts intervene only in disputes.
2. **MoHFW draft guidelines (September 2024)** operationalise the 2018 and 2023 Supreme Court orders, defining **terminal illness** and the clinical pathway for **withholding or withdrawing life-sustaining treatment**.
3. **Access data (2025) — 7–10 million Indians need palliative care annually; fewer than 4% receive it.** India had **526 palliative care centres in 2022** (density **4 per 10 million**). **44.5% of all centres are in Kerala** (2.5% of the population, with about 95% population coverage). **Median travel time to the nearest centre is 118 minutes**; only **23.6% live within 30 minutes**. **Morphine is stocked in only about 66% of centres.** Rural access is markedly worse; Bihar, Odisha and Madhya Pradesh are the worst served.
4. **Essential medicines gap (2025) — no Indian national or state essential medicines list contains all recommended morphine formulations**, and several states omit **oral morphine** entirely, despite morphine consumption being the **NP-NCD indicator of palliative care coverage**.

Current Practice Update

Area	Textbook position	Current evidence (2023–present)
Bone metastasis RT	Radiotherapy relieves pain in up to 80%; fractionation not specified	**8 Gy single fraction is the default** for uncomplicated painful bone metastases; equivalent to multifraction; **SBRT conditionally added** for selected good-performance-status patients
Pain flare after RT	Not addressed	**Prophylactic dexamethasone** reduces post-radiotherapy pain flare

Bone-modifying agents	IV bisphosphonates emphasised	**Denosumab and bisphosphonates** both standard; denosumab preferred in renal impairment (no dose adjustment); **dental assessment before starting** to prevent osteonecrosis of the jaw
Breathlessness — opioids	Opioids are "the main therapy" for dyspnoea	Benefit is **more modest than previously believed**; **MABEL (2025) was negative**. Opioids are now **individualised, trial-based and monitored**, with **non-drug measures first-line**
Breathlessness — antidepressants	Not discussed	**Mirtazapine should not be used** (BETTER-B, 2024)
Breathlessness — steroids	Steroids for bronchospasm	**Dexamethasone is not effective for cancer dyspnoea** and adds toxicity
Nausea and vomiting	Cause-directed single agent, then add a second agent	**Olanzapine has moved to the front line** as a broad-spectrum agent for both chemotherapy-induced and chronic advanced-cancer nausea
Opioid-induced constipation	Methylnaltrexone as rescue	**PAMORA class** (naldemedine, naloxegol, methylnaltrexone) now established second-line; docusate confirmed ineffective
End-of-life decision-making	Framed around UK, US and Australian law	**India now has its own legally operative framework** — 2023 Supreme Court order plus 2024 MoHFW draft guidelines
India-specific service model	Not covered	**Kerala's community NNPC model** is the WHO-cited exemplar for low-resource settings; national coverage remains **under 4%**

Exam One-Liners

Total pain (Cicely Saunders) = physical + psychological + social + spiritual suffering.

Analgesics by the clock, by the mouth, by the ladder — WHO principle.

8 Gy in a single fraction = standard palliative dose for uncomplicated painful bone metastasis.

Commonest site of pathological fracture = femur; commonest primary = breast.

Glycopyrrolate is preferred for death rattle — it does not cross the blood–brain barrier.

Docusate is no better than placebo; never use bulking agents at end of life.

Ondansetron is the wrong choice when constipation is the cause of nausea.

NDPS Amendment 2014 — the single most important Indian reform for morphine access.

Kerala 2008 — first state in Asia with a palliative care policy.

Supreme Court 2023 — notary or gazetted officer, not a magistrate, for a living will.

QUESTION 2 · 15 MARKS

Management of a terminally ill patient and the issues that need to be addressed

High-Yield Points

Definitions and Recognising the Dying Patient

1. **End of life** refers to the **last 12 months of life**; the **terminal phase** refers to the **last few days or hours**. Not every patient has a recognisable terminal phase — some die suddenly, as in **massive pulmonary embolism or terminal haemorrhage**.
2. **Clinicians often fail to consider that the patient is dying** when the condition deteriorates. Unless this possibility is actively considered, dying patients continue to receive **resuscitation** and are **removed from their homes and admitted to hospital for their last hours and days**.
3. **Gold Standards Framework triggers** to identify a patient needing a palliative approach:
    - The **"surprise" question** — would you be surprised if this patient died in the next 6–12 months?
    - **Choice or need** — the patient chooses comfort care only, or has special supportive care needs
    - **Clinical indicators** of advanced disease
4. **Prognostication** should be expressed as **time, function, or unpredictability**. Use **ePrognosis, the Palliative Performance Scale, Karnofsky and ECOG** plus clinical experience. Always give estimates as **ranges** — hours to days, days to weeks, weeks to months — acknowledging inherent uncertainty.

Assessment, Communication and Care Planning

1. Assessment must be **multidimensional** — physical, psychological, social, spiritual, cultural, informational and practical needs of **both patient and family**, taking account of health literacy and capacity to participate.
2. **Communication is the core intervention.** Use structured frameworks — **REMAP** and the **Serious Illness Conversation Guide**. Contrary to clinician fears, serious illness conversations **reduce patient anxiety and depression** and do not damage the doctor–patient relationship.
3. A **documented care plan** based on the patient's wishes must be shared with family and all providers. It should account for **functional and cognitive status, disease trajectory, cultural and spiritual preferences, family structure, finances, caregiver availability and home support**, and must be revised as the condition changes.
4. Decide **whether and when to refer to specialist palliative care**. Not everyone needs referral; many are well cared for by their usual team. Clinicians must **never say "there is nothing more that can be done"** — specialist palliative care works on the principle that there is **always something, however small**, that can improve comfort and quality of life.

Symptom Control in the Terminal Phase

1. **Anticipatory prescribing is essential** — prescribe in advance for the symptoms likely to develop (**pain, breathlessness, nausea, agitation, secretions**), ensure the drugs are physically available, and **establish a parenteral (subcutaneous) route** before the oral route fails.

2. **Pain** — follow the **WHO ladder**, give opioids **"by the clock" every 2–6 hours, not on demand**, use **sublingual, transdermal, rectal or subcutaneous** routes when swallowing fails, and always co-prescribe a **bowel regimen**.
3. **Breathlessness** — **opioids are the main therapy**; add a **benzodiazepine** if anxiety coexists; use a **cool, well-ventilated room and a fan**; **oxygen only if hypoxic and the patient finds it helpful**.
4. **Respiratory secretions ("death rattle")** — **avoid deep suctioning** (uncomfortable, causes gagging); **reposition for postural drainage**; **glycopyrrolate** is preferred (does not cross the blood–brain barrier, less delirium), though **clinical benefit is unproven**. Stop measuring blood pressure; monitor only **respiratory rate and pulse** to avoid disturbing patient and family.
5. **Terminal agitation and delirium** — first look for **reversible causes** (pain, urinary retention, faecal impaction, drugs, hypercalcaemia, infection). Use **behavioural measures** — limit visitor numbers, music therapy. If these fail, use **low-dose haloperidol** (chlorpromazine or quetiapine if sedation is needed). Remember that many symptom-control drugs themselves cause delirium.
6. **Deprescribe.** Stop **ineffective and burdensome medicines**. Some patients actually **improve** when unnecessary drugs are stopped — showing in retrospect that the drugs, not the disease, caused the deterioration.
7. **Basic comfort care is non-negotiable** — meticulous **mouth care**, pressure-area care, bowel and bladder care, positioning, and a quiet, dignified environment.

Hydration and Nutrition

1. **Consider hydration and nutrition as separate decisions.** When the patient cannot swallow, **maintaining some hydration is an important comfort measure** and a key adjunct to mouth care. **Subcutaneous fluid infusion (hypodermoclysis)** into the abdominal wall can be set up almost anywhere, has a **very low complication rate**, is **as effective as intravenous hydration** for maintenance, yet is **rarely used**. Avoid **fluid overload**, especially in cardiac decompensation.
2. **Nutrition is emotionally charged.** Dying patients have **anorexia, distorted taste and disease-related cachexia**. **Anorexia may be the first sign of subclinical nausea** — exclude **hypercalcaemia, hyperglycaemia, renal failure and infection (especially urinary)**. **Corticosteroids** give only a short-lived appetite effect and cause **hyperglycaemia, muscle wasting, GI erosion and bleeding, labile mood and poor sleep**; **megestrol has no advantage**. **Artificial nutrition rarely improves survival or quality of life**; nasogastric feeding is uncomfortable, disfiguring and risks **aspiration pneumonia**.

Ethical and Legal Issues

1. **Withholding and withdrawing** an ineffective, unduly burdensome treatment are **morally and legally equivalent**. This permits a **time-limited trial** of any treatment of doubtful benefit. In almost all cases the **underlying disease causes death**, not the withdrawal — this must be explained to relatives and team members *in advance*, especially where death follows withdrawal quickly (for example, ventilator withdrawal).
2. **Cardiopulmonary resuscitation (CPR)** is a medical treatment like any other. Two **separate** decisions are involved:
    - **Can CPR work physiologically?** — a clinical judgement. The chance is **markedly reduced in advanced terminal disease**, end-stage organ failure and degenerative neurological disease; in one series **no terminally ill patient survived CPR**.
    - **Is the resulting quality of life worth having?** — **only the patient can decide this**; check first for an advance directive.

    A major harm of unsuccessful CPR is **denying a peaceful and dignified death**. Public expectations are distorted by **television dramas** that grossly overstate success and never show the harms. Where the team judges CPR futile, a discussion that *appears to offer a choice* is inappropriate and misleading

— but the clinician still has a duty to ensure patient and family understand the **terminal nature of the illness** and that care is now aimed at comfort.

3. **Advance care planning (ACP)** — a process of discussing and recording values, goals and wishes in an **advance care directive (ACD)**. An advance decision to refuse treatment (**"living will"**) is legally binding where it is (i) **specific to the situation**, (ii) made **with capacity**, (iii) **voluntary and informed**, and (iv) **not subsequently invalidated by the patient's actions**. It only takes effect **once capacity is lost**. **Values rarely change over a lifetime, but care decisions can** — review the ACD **yearly, on deterioration, and before admission to a care home**. Where no ACD exists, decision-making reverts to the **"best interests" principle**, with a **proxy, enduring power of attorney or durable power of attorney for health care**.
4. **Palliative (terminal) sedation** should **rarely be necessary**. It is indicated where a patient is **exhausted by complex pain**, profoundly distressed after a neurological insult, or has **refractory delirium**. It **requires consent** as a therapeutic intervention; if capacity is lost, proceed via the **legally appointed attorney or proxy** in the patient's best interests. Use a **short-acting agent such as midazolam, titrated upward in increments**, with **regular review so the dose can be reduced**. Small anxiolytic doses of a benzodiazepine usually suffice for terminal restlessness — **deliberate deep unconsciousness is not required**.

> **EXAMINER TRAP — SEDATION VERSUS EUTHANASIA**
>
> **Palliative sedation is titrated to the symptom**, with the aim of symptom relief, and **death results from the underlying disease**. Giving high doses by **continuous infusion without titration** and **without considering hydration** suggests an intent to shorten life. State the distinction in exactly these terms — intent, titration and cause of death.

1. **Assisted dying** — **assisted suicide** = supplying the means (for example, prescribing a lethal dose); **euthanasia** = deliberately administering a lethal drug. Arguments **for** centre on **autonomy, existential distress and futility**; arguments **against** on **public safety, coercion of the vulnerable, absence of watertight safeguards, and respect for life**. Diagnosis and prognosis are imprecise; **3 of 18 Oregon patients** given lethal prescriptions had **unrecognised, untreated depression**; **internal coercion** ("I have a duty to die") is very hard to detect. When a patient requests it, first explore **what they are actually asking** — a confirmed wish to die, or a question about whether life is still worth living.

Place of Care, Family and Bereavement

1. **Preferred place of care and death must be asked about and planned for.** In the UK, **49–100% of cancer patients wish to die at home**, yet only about **26% of cancer deaths and 20% of all deaths** occurred at home. Where a preference had been **documented**, the place of death matched it in **73%**. Before discharge: arrange **beds, oxygen, commodes, shower chairs**, confirm **who will prescribe opioids** and that the pharmacy stocks them, and ensure someone is at home to receive deliveries.
2. **Integrated care pathways** (for example, the **Liverpool Care Pathway**) improved symptom control, communication with relatives and nurses' confidence, but were **phased out in the UK after complaints** — the fault lay in **"tick-box" use rather than the pathway itself**. Replaced by the **Five Priorities for Care of the Dying Person** and a **personalised** approach. **If the patient improves, discontinue the pathway, review, and reconsider active interventions.**
3. **Family and bereavement** — grief **begins at diagnosis**, not at death. Relatives must be told what is happening, encouraged to be involved, and allowed at the bedside — including frail elderly spouses and children. **Warning signs of complicated grief**: sudden or traumatic death, loss of a child, loss of a partner with an **ambivalent relationship**. Bereaved relatives have increased **depression, cardiac events, intercurrent infection and mortality**; **caregivers reporting emotional stress have significantly increased mortality**. Hospices provide bereavement follow-up for about **one**

year. Offer families **Byock's "Five Things"** — thank you; forgive me; I forgive you; I love you; goodbye. As Cicely Saunders said, *the way people die remains in the memory of those who live on*.

Framework: "Issues That Need to Be Addressed"

A revision checklist — if the question says "issues", answer in domains, not in a narrative.

Domain	Key issues
Physical	Pain, breathlessness, nausea and vomiting, constipation, secretions, agitation, fatigue, mouth care, pressure areas
Recognition	Diagnosing dying; prognostication; when to refer to specialist palliative care
Psychological	Fear, anxiety, depression, loss of control, dignity, unfinished business
Social	Caregiver burden, finances, dependants, isolation, place of care
Spiritual and cultural	Meaning, faith, rituals, culturally sensitive disclosure and decision-making
Ethical and legal	Capacity, consent, ACP/ACD, proxy, DNACPR, withholding versus withdrawing, futility, sedation, requests for assisted dying
Practical and logistic	Anticipatory drugs, subcutaneous route, equipment at home, 24-hour access, opioid supply
Therapeutic review	Deprescribing, artificial nutrition and hydration decisions, stopping observations and blood tests
Family and bereavement	Information, involvement, presence at the bedside, children, complicated grief, follow-up
Team	Staff moral distress, documentation, handover, training, avoiding "tick-box" care

Latest Updates (2023–Present)

Palliative sedation

1. The **revised EAPC framework on palliative sedation (Palliative Medicine, 2024)**, developed by international Delphi consensus with **42 statements**, redefines the practice:
    - **Proportionality** is now built into the definition — sedation is the *monitored, proportional* use of medication to reduce consciousness.
    - **"Suffering"** now explicitly includes **physical, psychological and existential** distress; **"refractory"** means **untreatable** (clinician view) *and* **intolerable** (patient view).
    - **No fixed remaining life expectancy is specified** as a criterion — the trigger is refractoriness and proportionality.
    - **Hydration is decided independently** of the decision to sedate.
    - **Patient autonomy is strongly emphasised**, with a **stepwise pharmacological approach** provided.

Hydration at the end of life

1. **NICE guidance (NG31; quality standard QS144)** clarifies that there is **no evidence that clinically assisted hydration prolongs dying, nor that withholding it hastens death**.
    - **Assess hydration status daily** and support **oral drinking** wherever it is safe.
    - Consider a **therapeutic trial** of clinically assisted hydration; **monitor at least 12-hourly**.
    - **Continue if benefit**, **reduce or stop if harm** (fluid overload, infusion-site pain or swelling) or if the patient no longer wants it.
    - **"One-size-fits-all" prescribing proformas are discouraged** — they contributed to the over-sedation concerns raised in the Neuberger review.

End-of-life decision-making in India

1. **Supreme Court of India, 24 January 2023** (*Common Cause v Union of India*) simplified the 2018 framework: the **advance medical directive no longer needs a Judicial Magistrate's countersignature** — a **notary or gazetted officer** suffices; **more than one guardian** may be named; approval runs through a **Primary Medical Board** and a **Secondary Medical Board** with defined timelines.
2. The **ISCCM–IAPC Expert Consensus and Position Statements for End-of-Life and Palliative Care in the ICU (Indian Journal of Critical Care Medicine, 2024)** is now the operative Indian bedside document. It combines **contemporary evidence, ethics and law**, incorporates the January 2023 Supreme Court safeguards, and provides a structured process for **foregoing life-sustaining treatment (FLST)** based on **physician prognostic assessment, patient- and family-centred shared decision-making, documented due process, and integration of palliative care into the ICU**.
3. The **MoHFW draft guidelines for withdrawal of life support in terminally ill patients (September 2024)** operationalise the 2018 and 2023 Supreme Court orders, defining **terminal illness** and the **two-tier medical board pathway**.

Advance care planning

1. Systematic reviews and meta-reviews (2023–2025) show that ACP reliably improves **process outcomes** — documentation rates, patient and surrogate engagement, and concordance between stated preferences and recorded care — but has **limited or inconsistent effects on hospitalisation, health status and survival**.
2. The field has therefore shifted from **"completing a document"** to **iterative goals-of-care communication**, **surrogate preparation**, and **system-level implementation** (trained facilitators, embedded processes, staff education), rather than one-off form-filling.

Symptom management evidence

1. **BETTER-B (2024)** — **mirtazapine 15–45 mg daily for 56 days did not improve severe breathlessness** in COPD or ILD and caused **more adverse effects and greater care use**; it is **not recommended**.
2. **MABEL (2025)** — **morphine did not improve worst breathlessness intensity** in chronic breathlessness; the findings **do not support routine use**.
3. The **ERS 2024 clinical practice guideline** on symptom management in serious respiratory illness places **non-pharmacological measures first** — **fan-to-face, breathing techniques, pacing, rehabilitation, psychological support** — with opioids reserved for carefully selected and monitored patients.

Current Practice Update

Area	Textbook position	Current evidence and practice (2023–present)
Care of the dying	Integrated care pathways (LCP) described, then withdrawn; Five Priorities introduced	Fully **individualised care plans**; **no blanket prescribing proformas**; daily reassessment of hydration, symptoms and goals
Palliative sedation	"Rarely necessary"; consent required; titrated midazolam	**Proportionality** is now central; "refractory suffering" **explicitly includes psychological and existential distress**; **no fixed prognostic window**; **hydration decided separately**; stepwise drug algorithm provided
Clinically assisted hydration	Comfort measure; subcutaneous route under-used	Explicitly stated that clinically assisted hydration **neither prolongs dying nor does withholding hasten death**; **therapeutic trial with 12-hourly monitoring**, stop if harm
Advance care planning	Emphasis on **completing a valid ACD**	Documents alone change little; emphasis on **repeated goals-of-care conversations**, surrogate preparation and organisational implementation
DNACPR communication	UK position: **no legal or moral requirement** to tell a patient that a DNACPR decision was made	Practice has moved decisively toward **transparent discussion and documentation**; the ISCCM–IAPC statement requires **documented shared decision-making**
Legal framework	UK and Australia-centric (Mental Capacity Act, Victorian VAD Act)	**India now has its own operative framework** — Supreme Court 2023 order + MoHFW 2024 draft guidelines + ISCCM–IAPC 2024 position statement
Breathlessness drugs	Opioids are "the main therapy"	Benefit is **more modest than believed** (MABEL negative); **mirtazapine not recommended** (BETTER-B); **non-pharmacological measures first-line**
Terminal delirium	Low-dose haloperidol after treating causes	**Non-pharmacological measures first**; antipsychotics reserved for severe distress, at the lowest dose for the shortest time, recognising they may not improve — and can worsen — delirium
Artificial nutrition	Rarely beneficial; NG feeding uncomfortable and risks aspiration	Reinforced — **"comfort feeding only"** is the preferred humane alternative; tube feeding does not improve survival or quality of life in advanced dementia

Exam One-Liners

End of life = last 12 months; terminal phase = last days to hours.

Surprise question: "Would I be surprised if this patient died within 6–12 months?"

Prognosis in ranges — hours-to-days, days-to-weeks, weeks-to-months.

Withholding = withdrawing, morally and legally — this permits a **time-limited trial**.

In advanced terminal disease **CPR has essentially no meaningful success**; in one series, none survived.

An advance directive only takes effect once capacity is lost.

Values rarely change; care decisions do — review the ACD yearly and on deterioration.

Palliative sedation is titrated to the symptom — that is what separates it from euthanasia.

Hypodermoclysis = simple, safe, as effective as IV, and grossly under-used.

Never say "nothing more can be done" — refer to specialist palliative care.

Death rattle distresses the family, not the patient — reposition, do not suction.

India's operative documents: Supreme Court January 2023 order + ISCCM–IAPC 2024 + MoHFW 2024 draft guidelines.

QUESTION 3 · 15 MARKS

Management of chronic / persistent pain in the elderly; classification and pathophysiology of pain; role of palliative care

High-Yield Points

Definition and Epidemiology

1. **Chronic (persistent) pain** is pain that persists or recurs for **more than 3 months**, beyond the expected period of tissue healing. It is regarded as a **disease in its own right**, not merely a symptom.
2. Prevalence rises steeply with age — roughly **25–50% of community-dwelling older adults** and **up to 80% of long-term care residents**. Commonest causes: **osteoarthritis, degenerative spine disease, osteoporotic vertebral fracture, diabetic neuropathy, post-herpetic neuralgia, peripheral arterial disease and cancer**.
3. Pain in older people is **under-reported, under-diagnosed and under-treated**. Barriers include the belief that pain is a **normal part of ageing**, fear of being labelled "difficult", fear of what the pain signifies, fear of addiction, cognitive and sensory impairment, and the clinician assumption that older patients feel less pain — for which there is **very little evidence**.

Classification

1. **Mechanistic (IASP) classification — three types:**
   - **Nociceptive** — nociceptor activation by actual or threatened tissue damage.
     - *Somatic* (skin, bone, joint, muscle, connective tissue) → **well localised, constant; aching, throbbing, gnawing, stabbing**. Examples: arthritis, fracture, bone metastases.
     - *Visceral* (internal organs) → **diffuse, poorly localised, referred, intermittent; colicky, cramping, squeezing**, often with nausea, vomiting and sweating. Examples: renal colic, bowel obstruction.
   - **Neuropathic** — lesion or disease of the somatosensory nervous system, with **abnormal processing of sensory input → burning, tingling, shooting, electric-shock-like**, with **paraesthesia, dysaesthesia, allodynia, hyperalgesia**, sensory loss, weakness or altered reflexes. Examples: diabetic neuropathy, post-herpetic neuralgia, trigeminal neuralgia, radiculopathy, post-stroke central pain.
   - **Nociplastic** — pain from **altered nociception without demonstrable tissue damage or somatosensory lesion**. Examples: fibromyalgia, myofascial pain syndrome, complex regional pain syndrome.
2. **Other axes of classification** — by **duration** (acute <1 month, subacute, chronic >3 months); by **aetiology** (cancer versus non-cancer); by **ICD-11** (chronic *primary* pain versus chronic *secondary* pain). Most persistent pain in older people is **mixed**.
3. Special categories to recognise: **breakthrough (incident) pain**, **procedural pain**, and **"total pain"** — physical + psychological + social + spiritual suffering.

Pathophysiology

1. **Four processes of nociception:**
   - **Transduction** — noxious stimulus converted into an electrical impulse at peripheral nociceptors. **A-delta fibres** carry fast, sharp, localised pain; **C fibres** carry slow, dull, burning pain. Mediators: **prostaglandins, bradykinin, substance P, histamine, serotonin, hydrogen ions and ATP** (the "inflammatory soup").
   - **Transmission** — impulse passes via the **dorsal root ganglion → dorsal horn (laminae I, II, V) → spinothalamic tract → thalamus → somatosensory cortex**. Key dorsal-horn transmitters are **glutamate (NMDA receptor)** and **substance P (NK1 receptor)**.
   - **Perception** — conscious awareness in cortex and limbic system; explains the **affective and emotional dimension** of pain.
   - **Modulation** — **descending inhibitory pathways** from the **periaqueductal grey and rostral ventromedial medulla**, using **endogenous opioids, noradrenaline, serotonin and GABA**. The **gate control theory** (Melzack and Wall) explains how large A-beta fibre input inhibits nociceptive transmission at the dorsal horn — the basis of **TENS, rubbing and massage**.
2. **Transition from acute to chronic pain:**
   - **Peripheral sensitisation** — inflammatory mediators lower the nociceptor threshold → **primary hyperalgesia**.
   - **Central sensitisation** — repetitive C-fibre input produces **"wind-up"** via NMDA receptor activation, increasing dorsal-horn excitability and expanding receptive fields → **secondary hyperalgesia and allodynia**.
   - **Loss of descending inhibition**, **glial activation**, and **maladaptive cortical reorganisation** then maintain pain independently of the original injury.
3. **Age-related changes in the nociceptive system**: reduced density of **myelinated and unmyelinated peripheral fibres**, slowed conduction, reduced **substance P and CGRP**, and **impaired descending inhibitory modulation with reduced endogenous opioid function**. The net effect is that pain **threshold may be marginally raised but tolerance is reduced**, sensitisation occurs more readily, and established pain resolves more slowly. Older people are therefore **more vulnerable to persistent pain, not less sensitive to it**.
4. **Consequences of untreated pain** — depression, anxiety, sleep disturbance, anorexia and weight loss, **deconditioning, immobility, falls and fractures**, functional decline, social isolation, delirium, increased healthcare use and caregiver burden. **Pain is a key reversible cause of agitation in dementia.**

Assessment

1. AGS recommends that **every older person be screened for persistent pain** on initial presentation or admission to any healthcare service; anyone whose pain affects **physical function, psychosocial function or quality of life** needs a **comprehensive pain assessment**. Pain is treated as the **"fifth vital sign"**.
2. **History** — site and radiation, character, timing, aggravating and relieving factors; **relationship of pain to physical and social function and sleep**; **complete analgesic history** (prescribed, over-the-counter, alternative remedies, alcohol, side effects); **patient's attitudes and beliefs about pain and its treatment**; effectiveness of and satisfaction with current management; **social support and access to healthcare**.
   Examination — the painful site and common referral zones; focused **musculoskeletal** and **neurological** examination; **observation of physical function**; **psychological and cognitive assessment**.

3. **Measurement tools:**
    - **Cognitively intact — self-report is the gold standard.** The **numerical rating scale (0–10)** is the most suitable in older people; verbal descriptor scales, pain thermometer and faces scales are also validated. **Visual analogue scales are the least reliable. Always use the same scale on follow-up.**
    - **Cognitively impaired or non-verbal** — use observational tools: **Abbey Pain Scale, PAINAD, DOLOPLUS-2**, plus caregiver report. Assess **during movement**, assess **frequently** (poor recall), and treat **any unexplained behavioural change in advanced dementia as possible pain** until proved otherwise.

Management — General Principles

1. Set **realistic, function-based goals** (better sleep, mobility and participation — not zero pain). Use a **multimodal, multidisciplinary, biopsychosocial approach**. **Treat the underlying cause where possible.** Follow the geriatric rule of the **fewest agents, by the least invasive route, at the lowest effective dose — start low, go slow, but go.** Give analgesia **regularly ("by the clock") for constant pain**, with breakthrough doses. **Review, titrate, and deprescribe what does not work.**
2. **Non-pharmacological measures are first-line and are always combined with drugs**: patient and caregiver **education**; **structured exercise and physiotherapy** (strengthening muscles around the joint, aerobic and balance training); **weight reduction**; **occupational therapy** — walking aids, appropriate footwear, joint protection, environmental modification; **heat and cold**; **massage, TENS, acupuncture**; **relaxation, guided imagery, distraction, music**; and **psychological therapy — cognitive behavioural therapy (CBT)**, mindfulness and support groups.

Pharmacological Management

> **MNEMONIC — THE ATMAN STEPPED FRAMEWORK FOR CHRONIC NON-CANCER PAIN**
>
> **A** — **A**cetaminophen (paracetamol) and **a**ntidepressants (SNRIs)
> **T** — **T**opical analgesics (diclofenac, lidocaine, capsaicin, methyl salicylate, menthol, cannabidiol)
> **M** — **M**uscle relaxants (cyclobenzaprine, baclofen)
> **A** — **A**nticonvulsants (gabapentin, pregabalin, carbamazepine) and **a**nti-inflammatory drugs (NSAIDs)
> **N** — **N**on-drug interventions (CBT, physiotherapy, mindfulness, support groups, hot and cold remedies)
>
> **Step 1** paracetamol + topicals + non-drug measures → **Step 2** duloxetine, gabapentin/pregabalin, muscle relaxants, interventional therapies → **Step 3** nortriptyline, tramadol, NSAIDs → **Step 4** opioids.

1. **Non-opioids:**
    - **Paracetamol** — first-line for mild-to-moderate musculoskeletal pain. Maximum **4 g/24 h**; reduce to **2–3 g/day** in frailty, low body weight, hepatic impairment or regular alcohol use.
    - **NSAIDs** — effective for **inflammatory, bone and visceral pain**, but hazardous in the elderly: **GI bleeding and peptic ulcer, acute kidney injury, fluid retention, heart failure, hypertension**, and multiple drug interactions. Use the **lowest dose for the shortest time**, prefer **topical formulations**, co-prescribe a **PPI** if systemic use is unavoidable.
    - **Topical agents** — capsaicin, **lidocaine 5% patch**, diclofenac gel, ketamine or combination gels; minimal systemic absorption makes these particularly valuable in old age. **Intra-articular corticosteroid injection** for localised joint pain.

2. **Opioids** — reserved for **moderate-to-severe pain limiting function and quality of life** after non-opioid measures have failed.
    - **Start low and titrate slowly**; prefer **short-acting immediate-release morphine, oxycodone or hydromorphone**; convert to a long-acting preparation with breakthrough cover once requirements are stable.
    - In older adults expect a **higher peak effect** (fewer receptor sites) and a **longer duration of action** (slower elimination).
    - **Avoid meperidine (pethidine) and propoxyphene** (ineffective, neurotoxic); use caution with **fentanyl patches and methadone**, and **never initiate a patch in an opioid-naive patient**.
    - **Anticipate every side effect**: **constipation (never tolerated — always co-prescribe a stimulant plus osmotic laxative)**, nausea, sedation, **delirium, falls and fractures**, respiratory depression, myoclonus, urinary retention. **Methylnaltrexone and other PAMORAs** for refractory opioid-induced constipation.
    - Assess misuse risk (**Opioid Risk Tool**) — risk factors are personal or family history of substance abuse, PTSD or past abuse, and psychiatric comorbidity.
3. **Adjuvants:**
    - **Neuropathic pain** — **gabapentin and pregabalin** (dose-reduce in renal impairment; cause sedation, dizziness, oedema, falls); **duloxetine and venlafaxine (SNRIs)**; **topical lidocaine and capsaicin**; **carbamazepine for trigeminal neuralgia**. **Tricyclic antidepressants should generally be avoided in older adults** because of anticholinergic effects — dry mouth, urinary retention, constipation, delirium, tachycardia, blurred vision and falls; if unavoidable, use **low-dose nortriptyline** (least anticholinergic).
    - **Corticosteroids** — useful for **inflammatory, bone and nerve-compression pain**; watch for delirium, hyperglycaemia, fluid retention and immunosuppression.
    - **Bisphosphonates or denosumab** for metastatic bone pain.
    - Always review **anticholinergic burden**, **Beers and STOPP-START** criteria, and **drug–drug and drug–disease interactions**.
4. **Procedural and interventional modalities** when drugs and rehabilitation fail — **trigger-point and intra-articular injections, epidural steroid injection, medial branch block and radiofrequency ablation, sympathetic and coeliac plexus block, intrathecal drug delivery, spinal cord stimulation, vertebroplasty and kyphoplasty**, and **palliative radiotherapy for bone metastases**. Refer to a **specialist pain clinic** if pain remains uncontrolled.

Role of Palliative Care

1. **Palliative care is not restricted to cancer or to the last days of life.** It can be delivered **alongside disease-modifying treatment from the time of diagnosis**, in any life-limiting illness — **cancer, heart failure, COPD, end-stage renal disease, dementia and frailty** — and the **best outcomes occur when it is started early**.
2. It addresses **"total pain"** — physical, psychological, social and spiritual — through an **interdisciplinary team** (physician, clinical nurse specialist, physiotherapist, occupational therapist, social worker, pharmacist, chaplain, counsellor). It **reduces unnecessary treatment and polypharmacy**, improves quality of life, smooths care transitions and averts avoidable admissions.
3. **What palliative care specifically adds to persistent pain management in old age:**
    - Application of the **WHO analgesic ladder** with adjuvants and interventional techniques
    - Expertise in **opioid titration, opioid rotation** and **alternative routes** (sublingual, transdermal, rectal, subcutaneous) when the oral route fails
    - Systematic prevention and management of **predictable opioid side effects**

- Correction of patient and family **misconceptions about addiction, somnolence and hastened death**
- **Goals-of-care discussion and advance care planning**
- **Caregiver support and bereavement follow-up**
- The guiding principle: a clinician should **never say "there is nothing more that can be done"** — that is the point at which specialist palliative care should be involved

> **INDIAN CONTEXT**
>
> LASI wave-1 documented a heavy burden of **arthritis and musculoskeletal disease** in Indians aged 45 and above. Persistent pain in Indian elders is compounded by **limited access to physiotherapy and rehabilitation**, low awareness of pain services, and **restricted opioid availability** despite the 2014 NDPS amendment, with **fewer than 4%** of those needing palliative care actually receiving it.

Latest Updates (2023–Present)

1. WHO guideline on non-surgical management of chronic primary low back pain (December 2023)

The first WHO guideline in this field, developed explicitly **for adults including older people** in primary and community care. 37 interventions were assessed, yielding 24 recommendations.

- **May be offered**: structured **education and advice**; **structured exercise therapy**; **needling therapies such as acupuncture**; **spinal manipulative therapy**; **massage** (warn about short-term increase in pain); **CBT and operant therapy**; **NSAIDs**; **topical capsaicin**; **multicomponent biopsychosocial care by a multidisciplinary team**; and **quality, affordable mobility assistive products** based on person-centred assessment.
- **Should NOT be used as routine care**: **opioid analgesics**, **SNRI antidepressants**, **tricyclic antidepressants**, **anticonvulsants**, **skeletal muscle relaxants**, **glucocorticoids**, **injectable local anaesthetics**, **traction**, **therapeutic ultrasound**, **TENS**, **lumbar braces, belts and supports**, and **pharmacological weight loss**.
- **Good practice statement**: initiate any new medicine at the **lowest effective dose for the shortest duration**, with **close monitoring for benefit and harm — especially in older people**.
- **No recommendation possible** for **paracetamol, benzodiazepines or cannabis-related preparations** — no eligible trials were identified.

2. ICD-11 chronic pain classification (in force since 2022)

The first systematic coding framework for chronic pain, adding a second axis to the mechanistic classification:

- **Chronic primary pain** — pain is the disease itself (fibromyalgia, **chronic primary low back pain, ICD-11 code MG30.02**, chronic widespread pain).
- **Chronic secondary pain** — six groups: **cancer-related, post-surgical/post-traumatic, neuropathic, headache and orofacial, visceral, and musculoskeletal**.

3. Cochrane network meta-analysis of antidepressants for chronic pain (2023)

176 trials, **over 28,000 participants**, 25 antidepressants compared.

- **Duloxetine was consistently the highest-ranked antidepressant**, with moderate-to-high certainty evidence for both substantial pain relief and reduced pain intensity.
- **Standard-dose duloxetine 60 mg was as effective as higher doses** for most outcomes.

- **Milnacipran** ranked next, with lower certainty.
- There was **insufficient evidence to draw robust conclusions for any other antidepressant**, including **amitriptyline** — despite its long-standing first-line status in neuropathic pain guidelines.

4. OPAL trial (Lancet 2023)

347 adults with acute or subacute low back and/or neck pain, randomised to **modified-release oxycodone up to 20 mg/day (with naloxone)** or placebo for up to 6 weeks, alongside guideline care.

- **No difference in pain severity at 6 weeks.**
- **Pain and quality of life at long-term follow-up were better in the placebo group.**
- **Significantly higher risk of opioid misuse at 12 months** in the opioid arm.
- Conclusion: **opioids should not be recommended for acute non-specific low back or neck pain.**

5. AGS Beers Criteria 2023 update — implications for pain prescribing

- **Avoid non-COX-2-selective NSAIDs for chronic use**, and avoid short-term scheduled NSAIDs combined with **systemic corticosteroids, anticoagulants or antiplatelets**.
- **Avoid indomethacin** (most adverse effects of all NSAIDs, including CNS effects) and **ketorolac** (oral and parenteral).
- **Avoid meperidine** — ineffective at usual doses and higher neurotoxicity and delirium risk than other opioids.
- **Avoid all skeletal muscle relaxants** — carisoprodol, chlorzoxazone, cyclobenzaprine, metaxalone, methocarbamol, orphenadrine — poorly tolerated because of anticholinergic effects, sedation and fracture risk.
- Rationale for anticholinergic drugs expanded to explicitly recognise **cumulative anticholinergic burden**.
- The accompanying **"Alternative Treatments" resource (2025)** states that for **first-line management of chronic pain, non-pharmacological approaches should be used alone or with medication**, and suggests **short-course NSAIDs, topical NSAIDs or COX-2 selective agents** instead of chronic NSAIDs or muscle relaxants.

6–8. Other developments

- **NICE chronic pain guidance (NG193)** remains the reference position for **chronic primary pain** — offer **supervised group exercise, CBT or acceptance and commitment therapy, and acupuncture**, and consider **an antidepressant**; **do not initiate paracetamol, NSAIDs, opioids, gabapentinoids, benzodiazepines, corticosteroid injections or antipsychotics**.
- **Gabapentinoid deprescribing** — accumulating evidence of harm in older adults (sedation, dizziness, **falls and fractures**, peripheral oedema, and **respiratory depression when combined with opioids**, with mandatory dose reduction in renal impairment). Prescribe **only for a defined neuropathic indication, with a planned review and stopping date**.
- **Palliative care evidence** — **early integrated palliative care** continues to show improved symptom burden and quality of life across both cancer and non-cancer illness. In parallel, the negative **BETTER-B (mirtazapine, 2024)** and **MABEL (morphine, 2025)** trials for chronic breathlessness have shifted palliative practice toward **non-pharmacological measures first** — the same direction of travel as in persistent pain.

Current Practice Update

Area	Textbook position	Current evidence and practice
Classification	Nociceptive (somatic/visceral), neuropathic, "undetermined"; nociplastic introduced	**Nociplastic pain** is now a formal third mechanistic descriptor, and **ICD-11 adds the chronic primary versus chronic secondary axis** as a parallel classification
Paracetamol	First-line agent for persistent musculoskeletal pain	Effect size is **small and often not clinically important** in osteoarthritis and back pain; **WHO could make no recommendation** for it in chronic primary low back pain. **Non-drug therapy is the true first line**
NSAIDs	Avoid, or use rarely and with great caution	Position unchanged for **chronic systemic use** (Beers 2023 reinforces this), but **topical NSAIDs are now preferred**, and a **short course of oral NSAID may be offered** for chronic primary low back pain
Antidepressants	TCAs contraindicated; SSRIs and SNRIs "more effective" for pain	**Duloxetine is the only antidepressant with reliable evidence** (60 mg as good as higher doses); evidence for amitriptyline is weak. **But indication matters — WHO advises against both SNRIs and TCAs specifically for chronic primary low back pain**
Opioids	Add when pain limits function and quality of life	Markedly more restrictive: **no benefit in acute back or neck pain (OPAL)**, **WHO advises against routine use in chronic primary low back pain**. Reserve for **cancer pain, end-of-life care, and highly selected, monitored non-cancer pain** with explicit function-based goals and an exit strategy
Muscle relaxants	Listed within the ATMAN framework (step 2)	**All skeletal muscle relaxants are on the 2023 Beers "avoid" list**; WHO also advises against them in chronic primary low back pain
TENS, traction, ultrasound, braces	Included among physical and complementary therapies	**WHO advises against routine use** for chronic primary low back pain; **exercise, education, manual therapy, massage and acupuncture are retained**
Gabapentinoids	Effective for neuropathic pain with fewer side effects than older anticonvulsants	Growing recognition of **falls, fractures, oedema and respiratory depression with opioids**; **not recommended for non-neuropathic chronic primary pain**; needs renal dose adjustment and planned review
Palliative care	Framed largely around cancer and end-of-life care	Now positioned as an **early, concurrent service across all life-limiting illness** — including frailty, dementia, heart failure, COPD and end-stage renal disease

Exam One-Liners

Chronic pain = pain >3 months, persisting beyond expected healing; it is **a disease, not just a symptom**.

Three mechanisms: nociceptive (somatic/visceral) — neuropathic — **nociplastic**.

A-delta = fast, sharp, localised; C = slow, dull, burning.

Wind-up = NMDA-mediated central sensitisation → allodynia and secondary hyperalgesia.

Gate control theory explains why TENS, rubbing and massage work.

Ageing **impairs descending inhibition** — older people are **more vulnerable to persistent pain, not less sensitive**.

Numerical rating scale is the most suitable tool in the elderly; **VAS is the least reliable**.

In advanced dementia use **Abbey, PAINAD or DOLOPLUS-2** — and treat **unexplained behaviour change as pain until proved otherwise**.

ATMAN = Acetaminophen/antidepressants, Topicals, Muscle relaxants, Anticonvulsants/anti-inflammatories, Non-drug.

Avoid meperidine, propoxyphene, indomethacin, ketorolac and all skeletal muscle relaxants in older adults.

Opioids always need a bowel regimen — constipation is never tolerated.

Duloxetine 60 mg is the antidepressant with the best evidence for chronic pain.

OPAL 2023: opioids are no better than placebo for acute back and neck pain.

WHO 2023: for chronic primary low back pain — exercise, education, CBT, acupuncture and NSAIDs **in**; opioids, antidepressants, anticonvulsants, muscle relaxants, TENS, traction and braces **out**.

Never say "nothing more can be done" — that is the cue to involve specialist palliative care.

QUESTION 4 · 15 MARKS

End-of-life care issues

Angled at the issues themselves; the symptom-control detail sits in Question 2 and is only summarised here.

High-Yield Points

I. Recognition and Prognostic Issues

1. **Failure to diagnose dying is the commonest single failure in end-of-life care.** Unless the possibility is actively considered, dying patients continue to receive **resuscitation, futile investigations and transfer out of their homes to hospital for their last hours and days**.
2. Use the **Gold Standards Framework triggers**: the **"surprise" question**, **patient choice or need** for comfort care only, and **clinical indicators** of advanced disease.
3. **Prognostic uncertainty is unavoidable.** Use **ePrognosis, Palliative Performance Scale, Karnofsky and ECOG** with clinical experience, and communicate in terms of **time, function or unpredictability**, always as **ranges**.
4. **Non-cancer trajectories are far less predictable than cancer.** Patients with **organ failure, frailty and dementia** deteriorate in a stuttering, unpredictable way and are therefore **systematically under-referred** to palliative services.

II. Communication and Decision-Making Issues

1. **Goals-of-care conversations occur far too infrequently and far too late.** Barriers cited by clinicians: **uncertainty about prognosis, fear of provoking distress, and fear of jeopardising a long-standing relationship**. The evidence is the opposite of the fear — **serious illness conversations reduce patient anxiety and depression and do not harm the doctor–patient relationship**.
2. **Structured frameworks help**: **REMAP**, the **Serious Illness Conversation Guide**, and the **five-step approach** — (i) initiate the discussion, (ii) clarify the prognosis, (iii) evaluate the patient and family, (iv) identify end-of-life goals, (v) develop a plan of care.
3. **Never say "there is nothing more we can do."** Reframe the discussion around **what will be provided** — analgesia, positioning, non-drug comfort measures, presence.
4. **Do not shift the decisional burden onto relatives.** If families are given the (incorrect) impression that the decision to withhold or withdraw treatment is **theirs to make**, they suffer **significant and lasting distress from the emotional burden**, even when consensus is reached. The decision is a **clinical recommendation made in the patient's best interests**, shared with and explained to the family.

III. Ethical Issues

1. The **four principles — autonomy, beneficence, non-maleficence and justice —** are frequently in conflict at the end of life.
2. **Withholding and withdrawing** an ineffective or unduly burdensome treatment are **morally and legally equivalent**. This permits a **time-limited trial**, and it must be explained that **death results from the underlying disease, not the withdrawal**.
3. **Futility** — clinicians are ethically empowered to decline care that is **medically futile**, but the futility principle is itself contested. Where clinician and patient or proxy disagree, options include **transfer to**

another clinician, the institutional ethics committee, social services, or patient-advocacy agencies.

4. **Palliative sedation versus euthanasia** — sedation is **titrated to the symptom** with regular review, and death results from disease. Administering high doses by continuous infusion **without titration and without considering hydration** implies a different intent.
5. **Assisted dying** — **assisted suicide** = supplying the means; **euthanasia** = administering the lethal drug. Arguments **for**: autonomy, existential distress, futility. Arguments **against**: coercion of the vulnerable, absence of watertight safeguards, imprecision of prognosis. **Three of 18 Oregon patients** given lethal prescriptions had **unrecognised, untreated depression**; **internal coercion** ("I have a duty to die") is very difficult to detect. When a patient asks, first explore **what they are actually asking**.

> **RATIONING AND AGEISM — A HIGH-YIELD ETHICAL POINT EXAMINERS LIKE**
>
> Older adults are **prime targets for rationing** because they consume disproportionate resources and are seen as having "already lived their lives". Outcome measures based on **quality-adjusted life-years or active life expectancy are inherently biased against the elderly**, and treating dependency as the primary outcome implies that **disability is equivalent to death**. Geriatricians must be **vigilant advocates** against this.

IV. Legal and Documentation Issues

1. **Advance care planning and advance directives (ACD)** — an advance decision to refuse treatment (**living will**) is binding where it is **specific to the situation, made with capacity, voluntary, informed, and not subsequently invalidated**. It takes effect **only once capacity is lost**. Review **yearly, on deterioration, and before care-home admission**. **Values rarely change over a lifetime; care decisions can.**
2. **Surrogate decision-making** — a **durable power of attorney for health care or proxy** covers situations a living will cannot (for example, whether an antibiotic is life-supporting or comfort care). Where none exists, the **best-interests standard** and, if necessary, **court-appointed guardianship** apply.
3. **POLST / MOLST** (Physician or Medical Orders for Life-Sustaining Treatment) convert the patient's advance directive into an **actionable, transferable medical order** valid across settings. Especially critical for those who **want to avoid some or all life-sustaining treatment, reside in or need long-term care, or might die within the next year**.
4. **Legislation alone changes little.** The US **Patient Self-Determination Act (1991)** requires institutions to inform patients of their rights to participate in decisions, accept or refuse treatment and prepare an advance directive — but **does not require an advance directive to be made**, and has had **minimal impact on completion rates**. Hence the shift toward **POLST/MOLST and electronic records that travel with the patient**.

SEVEN LEGAL MYTHS THAT OBSTRUCT GOOD END-OF-LIFE CARE (ACP/ASIM) — ALL FALSE

1. Forgoing life-sustaining treatment in an incapacitated patient requires proof of their actual wish
2. Withholding or withdrawing artificial fluids and nutrition is illegal
3. Risk management must be consulted before stopping life-sustaining treatment
4. Advance directives must use specific forms, are not transferable between states, and oral directives are unenforceable
5. A doctor giving high-dose analgesia that results in death will be prosecuted
6. When suffering is overwhelming despite palliative care, no legally permissible options exist
7. The 1997 US Supreme Court decisions outlawed physician-assisted suicide

1. **DNACPR** — two **separate** questions: (i) **can CPR work physiologically?** (a clinical judgement — in advanced terminal disease the chance is markedly reduced, and in one series **no terminally ill patient survived**); (ii) **is the resulting quality of life worth having?** (only the patient can answer). A discussion that implies a genuine choice where CPR is futile is **misleading**. Public expectations are distorted by **television dramas** that grossly overstate success.

V. Clinical and Therapeutic Issues

1. **Symptom burden** — pain, breathlessness, nausea and vomiting, constipation, terminal agitation and delirium, and respiratory secretions. Requires **anticipatory prescribing**, a **subcutaneous route established before swallowing fails**, **deprescribing of burdensome drugs**, and meticulous comfort care (mouth, pressure areas, bowel and bladder). Watch **iatrogenic harm** from the very drugs used — opioids, steroids, anticholinergics, metoclopramide and haloperidol.
2. **Nutrition and hydration must be considered separately. Hydration is a comfort measure** and adjunct to mouth care — **subcutaneous hypodermoclysis** is simple, very low-risk, as effective as IV for maintenance, and **grossly under-used**; avoid fluid overload. **Nutrition is emotionally charged**: exclude reversible causes of anorexia (**hypercalcaemia, hyperglycaemia, renal failure, infection**); **corticosteroids** give only a short-lived appetite effect at significant cost, **megestrol has no advantage**, and **artificial nutrition rarely improves survival or quality of life** while nasogastric feeding is uncomfortable and risks aspiration.

VI. Place of Care and Service-Delivery Issues

1. **Preferred place of death is often not achieved** — **49–100% of cancer patients wish to die at home**, yet only about **26% of cancer deaths and 20% of all deaths** occur there. Where preference had been **documented**, place of death matched it in **73%**. Arrange **beds, oxygen, commodes, drugs, a named prescriber and carers before discharge**.
2. **Care homes** — there is a **strong case for collaborative future care planning for every resident**. Residents are by definition frail with significant disease burden and often cognitive impairment; on deterioration, hospital admission offers **minimal gain in length or quality of life with substantial harm and risk**, and carries an **opportunity cost** for other patients. Document which interventions are **not** to be used (hospital admission, CPR, ventilation, artificial nutrition in advanced dementia) while retaining those that remain appropriate (for example, **antibiotics for a urinary infection**).
3. **Care pathways** — the **Liverpool Care Pathway** improved symptom control, communication with relatives and nurses' confidence, but was **withdrawn in the UK after complaints**; the fault lay in **"tick-box" application, not the pathway concept**. It was replaced by the **Five Priorities for Care of the Dying Person** and personalised plans. **If the patient improves, stop the pathway, reassess and reconsider active treatment.**

VII. Cultural and Spiritual Issues

1. **Culture defines how patients and families understand illness, suffering and dying** — including how pain is experienced and expressed. **Use of life-prolonging technology, the locus of decision-making, and truth-telling are all culturally shaped.** Where adult children ask that a diagnosis be withheld, the practical solution is to ask the patient whether **they are the kind of person who wants all the details, or would prefer a family member to handle the decisions** — this respects culture **without assuming the patient conforms to it**. Practise **cultural humility**, acknowledging one's own unrecognised biases.
2. **Spiritual concerns must be addressed explicitly, not dismissed.** Where a family holds a strong belief in a miraculous cure, a chaplain can explore it and negotiate a plan that is **respectful of the belief yet realistic** — for example, that forgoing further chemotherapy does not change whether a miracle is possible.

VIII. Family, Caregiver and Bereavement Issues

1. **Informal caregivers deliver most end-of-life care with very limited resources**, and **caregivers reporting emotional stress have significantly increased mortality**. **Grief begins at diagnosis, not at death.** Warning signs of **complicated grief**: sudden or traumatic death, loss of a child, and an **ambivalent relationship**. Bereaved relatives have increased **depression, cardiac events, intercurrent infection and mortality**; hospices provide bereavement follow-up for about **one year**. Offer families **Byock's "Five Things"**.

Latest Updates (2023–Present)

Palliative sedation

1. The **revised EAPC framework on palliative sedation (Palliative Medicine, 2024)**, an international Delphi consensus of 42 statements, reframes practice: **proportionality is built into the definition**; **"suffering" now explicitly includes physical, psychological and existential distress**; **"refractory" means untreatable (clinician view) and intolerable (patient view)**; **no fixed remaining life expectancy** is set as a criterion; **hydration is decided independently** of sedation; and **patient autonomy** is strongly emphasised, with a stepwise pharmacological approach.

Hydration at the end of life

1. **NICE guidance (NG31, quality standard QS144)** states clearly that there is **no evidence that clinically assisted hydration prolongs dying, nor that withholding it hastens death**. Practice: **assess hydration daily**, support safe oral intake, consider a **therapeutic trial** with **monitoring at least 12-hourly**, continue if benefit, and **reduce or stop if harm** or if the patient no longer wants it. **"One-size-fits-all" prescribing proformas are explicitly discouraged.**

Advance care planning

1. Systematic reviews and meta-reviews (2023–2025) show ACP reliably improves **process outcomes** — documentation, patient and surrogate engagement, and concordance between stated preferences and delivered care — but has **limited or inconsistent effect on hospitalisation, health status and survival**.
2. The field has consequently shifted from **"completing a document"** to **iterative goals-of-care communication, surrogate preparation and system-level implementation**.

End-of-life decision-making in India

1. **Supreme Court of India, 24 January 2023** (*Common Cause v Union of India*) simplified the 2018 framework: the **advance medical directive no longer requires a Judicial Magistrate's countersignature** — a **notary or gazetted officer** suffices; **more than one guardian** may be

named; approval runs through a **Primary Medical Board** and a **Secondary Medical Board** with defined **48-hour timelines**; courts intervene only in disputes.

2. The **ISCCM–IAPC Expert Consensus and Position Statement for End-of-Life and Palliative Care in the ICU (Indian Journal of Critical Care Medicine, 2024)** is now the operative Indian bedside document, providing a structured process for **foregoing life-sustaining treatment (FLST)** based on physician prognostic assessment, **documented shared decision-making**, due process consistent with the 2023 Supreme Court safeguards, and **integration of palliative care into the ICU**.
3. The **MoHFW draft guidelines for withdrawal of life support in terminally ill patients (September 2024)** operationalise the 2018 and 2023 orders, defining **terminal illness** and the **two-tier medical board pathway**.

Assisted dying — the international legal landscape is moving fast

1. In **England and Wales**, the **Terminally Ill Adults (End of Life) Bill** — which would have permitted assisted dying for mentally competent adults with a prognosis under **six months** — passed the **House of Commons on 20 June 2025 (314 to 291)** but **fell on 24 April 2026** after more than **1,200 amendments** stalled it in the House of Lords and the session was prorogued. A **successor bill was reintroduced in the Commons on 17 June 2026**, with second reading scheduled for **11 September 2026**.
2. **Jersey passed its Assisted Dying Law on 26 February 2026** — eligibility requires terminal illness with unbearable physical suffering and expected death within **6 months (12 months for neurodegenerative disease such as Parkinson's or motor neurone disease)**, assessment by **two independent doctors**, and — uniquely among jurisdictions — permits a **doctor or nurse to administer** the substance. A separate assisted dying bill is before the **Scottish Parliament**.
3. **India's position is unchanged**: **passive euthanasia and withdrawal of life support are lawful** under the Supreme Court framework; **active euthanasia and assisted suicide remain illegal**.

Access and equity

1. Indian access data (2025): **7–10 million people need palliative care annually and fewer than 4% receive it**; **44.5% of all centres are in Kerala**; **morphine is stocked in only about 66% of centres**; **median travel time to the nearest centre is 118 minutes**; and **no Indian national or state essential medicines list contains all recommended morphine formulations**.

Current Practice Update

Issue	Textbook position	Current position (2023–present)
Care of the dying	Integrated pathways (LCP) described, then withdrawn; Five Priorities introduced	Fully **individualised care plans**; **no blanket prescribing proformas**; daily reassessment of symptoms, hydration and goals
Palliative sedation	"Rarely necessary"; consent required; titrated midazolam	**Proportionality now central**; refractory suffering **explicitly includes psychological and existential distress**; **no prognostic window** required; **hydration decided separately**
Clinically assisted hydration	Comfort measure; subcutaneous route under-used	Explicit: it **neither prolongs dying nor does withholding hasten death**; **therapeutic trial with 12-hourly review**, stop if harm

Advance care planning	Emphasis on **completing a valid ACD**; POLST/MOLST as the operational fix	Documents alone change little; emphasis on **repeated goals-of-care conversations**, surrogate preparation and organisational implementation
DNACPR communication	UK position: **no legal or moral requirement** to inform the patient of a DNACPR decision	Practice has moved decisively to **transparent discussion and documentation**; ISCCM–IAPC **requires documented shared decision-making**
Legal framework	UK, US and Australia-centric (Mental Capacity Act, PSDA, POLST, Victorian VAD Act)	**India now has an operative framework** — Supreme Court 2023 order + ISCCM–IAPC 2024 + MoHFW 2024 draft guidelines
Assisted dying	Debate framed around Oregon, the Netherlands and Victoria	Rapidly evolving — **UK bill fell April 2026 and has been reintroduced; Jersey legalised February 2026; Scotland's bill pending**. India: passive euthanasia lawful, active euthanasia and assisted suicide **not**
Artificial nutrition	Rarely beneficial; NG feeding uncomfortable and risks aspiration	Reinforced — **"comfort feeding only"** is the preferred humane alternative; tube feeding does not improve survival or quality of life in advanced dementia
Terminal delirium	Low-dose haloperidol after treating reversible causes	**Non-pharmacological measures first**; antipsychotics reserved for severe distress, lowest dose, shortest time
Breathlessness at EOL	Opioids are "the main therapy"	Benefit more modest than believed (**MABEL 2025 negative**); **mirtazapine not recommended** (BETTER-B 2024); non-drug measures first-line

Exam One-Liners

> **End of life = last 12 months; terminal phase = last days to hours.**

> **Withholding = withdrawing** — this equivalence is what permits a **time-limited trial**.

> **An advance directive takes effect only after capacity is lost.**

> **POLST/MOLST** turns an advance directive into an **actionable, transferable medical order**.

> **The Patient Self-Determination Act obliges institutions to inform, not patients to complete.**

> Do not tell relatives the decision is theirs — that transfers a **lasting emotional burden**.

> **Hypodermoclysis** — simple, safe, as effective as IV, and grossly under-used.

> **Palliative sedation is titrated to the symptom** — that is what separates it from euthanasia.

> **QALY-based rationing is inherently biased against older people** — disability is not death.

> **Cultural humility** — ask the patient how much they want to know, rather than assuming.

> **Care-home residents deserve future care planning by default**, not only when they deteriorate.

> **India's operative documents**: Supreme Court January 2023 order + ISCCM–IAPC 2024 + MoHFW 2024 draft guidelines.

> **Never say "nothing more can be done"** — that is the cue for specialist palliative care.

QUESTION 5 · 15 MARKS

Hospice and respite care

Part 1 — Hospice Care

Definition and Concept

1. **Hospice is a comprehensive care system for patients with limited life expectancy**, living at home or in institutional settings. It is simultaneously a **philosophy of care** and an **organised, highly structured system for delivering care**, whose defining focus is **caring, not curing**.
2. **Hospice is a subset of palliative care** offered to patients **approaching the end of their lives**. Palliative care ideally begins **from the onset of serious life-threatening illness**, alongside disease-modifying treatment; **hospice enrolment is the final piece of that continuum**.

Feature	Palliative care	Hospice
Timing	Any stage, from diagnosis onward	Final phase of illness
Prognosis required	No	Yes — **physician-certified ≤6 months (US)**
Disease-modifying treatment	Continued concurrently	Generally relinquished
Setting	Any care setting	Home, hospice facility, hospital, nursing home, assisted living
Funding (US)	Usual insurance	Defined **Medicare/Medicaid hospice benefit**
Team	Interdisciplinary	Interdisciplinary + **mandatory trained volunteers**

Historical Evolution

1. The term **hospice** was coined by the British physician **Dame Cicely Saunders in 1967** (St Christopher's Hospice, London). **Florence Wald**, Dean of the Yale School of Nursing, brought the model to the United States. In **1979 the Health Care Financing Administration funded 26 hospices as a demonstration programme**, and in **1982 hospice was added as a benefit under Medicare and Medicaid**; it is now a standard benefit of all US health insurance plans. India's first hospice was **Shanti Avedna Sadan, Mumbai (1986)**.

Eligibility and Election

1. Two conditions must be met: (i) the patient's **primary clinician certifies a remaining life expectancy of approximately six months or less**; and (ii) the patient **elects hospice** and **agrees to accept care from an identified hospice team**. The patient's own physician may continue to provide care and work alongside the hospice team.

Services Provided

1. **The hospice service package:**
   - **Nursing** — registered nurses coordinate all care, provide direct care, monitor symptoms and medication, educate patient and family, and act as the **link between the family and the physician**
   - **Social services** — advice and counselling during the crisis period, interpretation of family dynamics for the team, and **advocacy** in accessing community resources
   - **Physician services** — the patient's own physician approves the plan of care; a **hospice medical director** serves as consultant and resource
   - **Spiritual care and counselling** — clergy and counsellors visit at home; churches and congregations engaged as requested
   - **Home health aide and homemaker** — bathing, shampooing, shaving, nail care; light housekeeping and meal preparation
   - **Continuous home health care** — hospice staff provide care in **8- to 24-hour periods on a short-term basis** when the patient's needs escalate or the family can no longer manage round-the-clock care
   - **Therapy and rehabilitation** — helping the patient find new ways to walk, dress or feed themselves
   - **On-call team support** — a team member available **24 hours a day, 7 days a week**, by phone or visit
   - **Respite care** — the hospice arranges a **brief period of inpatient care to give relief to family members**
   - **Bereavement counselling** — support through grieving, with a trained volunteer or counsellor visiting at set intervals **during the first year**, plus telephone and letter contact, support groups, and onward referral if needed
   - **Supplies and medications** are covered (for example, a bedside commode)
2. **The interdisciplinary team (IDT)** comprises the patient's personal physician, the hospice physician or medical director, nurses, hospice aides, social workers, bereavement counsellors, spiritual care providers, and **trained volunteers**. Hospice is unique in that **volunteers are required to provide at least 5% of total patient-care hours**.

Settings, Utilisation and Limitations

1. **Most hospice care is delivered wherever the patient calls home**, but it is also provided in **freestanding hospice facilities, hospitals, nursing homes, assisted living and other long-term care facilities**. Hospice is available to patients with **any terminal illness, of any age, religion or race**.
2. **Utilisation data (2017, US)** — over **4,515 hospice agencies** served **1.49 million Medicare beneficiaries**; **40% were served at home, 19% in long-term care**; **58% were female**; **48% of all Medicare decedents were enrolled in hospice at the time of death**, with an average length of stay of **76 days**. This indicates hospice remains **substantially under-utilised and entered too late**.
3. **The diagnostic mix has shifted** — cancer is the principal hospice diagnosis in only about **30%** of enrolees, having fallen as hospice use for **non-malignant terminal illness such as heart disease and dementia** has risen.
4. **Key practical limitation** — hospice agencies provide nursing, therapy, social services and family support in the home, but are **not capable of providing continuous 24-hour personal care**. Personal-care aides are **not paid for by Medicare or by most private insurance plans**.

5. **Referral is often too late.** Barriers include prognostic uncertainty, clinician reluctance to discuss dying, and the perception among patients and families that enrolment means "giving up". Clinicians must **never say "there is nothing more that can be done"** — that is precisely the moment to introduce hospice.

Part 2 — Respite Care

Definition and Rationale

1. **Respite care is the temporary — planned or emergency — provision of care for a dependent older person, in order to give the usual informal caregiver a break.** Its primary target is **the caregiver**, although the care recipient also benefits.
2. **The caregiver burden that justifies it:**
   - Caring for a relative with dementia or chronic illness is **physically, emotionally and financially stressful**
   - Approximately **35% of those caring for a person aged 50 or over report moderate-to-high financial strain**; about **25% provide more than 40 hours of care per week**
   - Caregivers develop **depression, anxiety, musculoskeletal pain worsened by caregiving tasks, social isolation and loneliness**
   - Many **exit the workforce early**, lose pension and retirement funds to medical costs, and find it hard to re-enter employment
   - **Caregivers reporting emotional stress have significantly increased mortality**
   - Distress **does not end at institutionalisation** — anxiolytic use by caregivers increases, and **nearly half are at risk of disabling depression after placing a relative in long-term care**; almost half of spouses visit daily and continue to provide physical and emotional care
3. **Assess the caregiver formally**, not just impressionistically:
   - **Zarit Burden Interview (ZBI)** — original 29-item, commonly used 22-item, with **12-, 4- and 3-item short versions**; developed for dementia caregivers, now broadened, and validated across many languages and cultures
   - **Caregiver Self-Assessment Questionnaire (CSAQ)** — 18 items, developed by the AMA; effective at detecting **depressive symptoms**
   - **Rapid Screen for Caregiver Burden** — 7 items (from the 25-item original)
   - **Caregiver Well-Being Scale** — a **strengths-based** 43-item tool, with 16-item and 6-item rapid versions

Types of Respite

1. **Forms of respite care:**
   - **In-home respite** — a paid aide or trained volunteer attends the home for a few hours
   - **Adult day care** — supervised recreational and restorative activity for people with **limited functional ability**; some programmes are specifically for the **cognitively impaired**. Improves basic **ADL and social skills**. Most programmes serve a given client **2–3 days a week rather than 5**, to serve more families
   - **Adult day health centre** — an intermediate model combining day care with **nursing, physiotherapy and social work**; may also host periodic ambulatory clinics
   - **Day hospital** — larger medical component, with virtually all hospital services on an ambulatory basis; emphasis on **rehabilitation, physiotherapy and occupational therapy**

- **Institutional / short-stay respite** — planned admission to a care home, community hospital or hospice bed for days to weeks
- **Hospice inpatient respite** — a brief inpatient stay arranged by the hospice expressly to relieve the family
- **Emergency or crisis respite** — when the carer becomes ill or breaks down

Benefits and Place in Care

1. **Respite provides important relief for the primary caregiver and may make the critical difference in allowing an impaired older person to remain at home** rather than be institutionalised. Where **carer stress is high**, **intensive home support or admission to a respite or step-down placement is a better option than hospital admission**, which is disorientating for people with dementia and **carries a higher risk of unnecessary long-term institutionalisation**. Less restrictive options should always be considered first.
2. **Respite is one component of a multidimensional caregiver-support package.** Effective programmes combine **education and psychoeducation, counselling, support groups, problem-solving and behaviour-management training, cognitive behavioural therapy, mindfulness-based stress reduction, telephone support, practical skills training, contingency planning, and respite or adult day care**. A **support group is hard to attend unless care for the recipient is provided at the same time** — a practical argument for pairing the two.
3. **Service context.** Respite sits within the community long-term care continuum alongside **home nursing and homemaking, adult foster care, assisted living, geriatric assessment, hospice, telephone reassurance, caregiver support, congregate housing, home repairs, meals services and emergency alarms**. In the UK, **day hospitals for older people have largely been decommissioned** because the supporting literature was sparse — one of their primary roles had been **carer support and respite for people with dementia and challenging behaviour**. **Voluntary, charitable and private-sector day care and respite services have expanded** as day hospitals closed.
4. **Barriers and practical advice** — services vary widely by community, budgets are constrained, and families often do not know what exists. **Families should be actively encouraged to seek respite periodically, at regular intervals, rather than only at the point of crisis. Where no formal respite programme exists, informal arrangements can usually be made to relieve the primary caregiver for short periods** — and such relief materially helps the caregiver cope. Signposting to the **Alzheimer's Association local chapter and the Area Agency on Aging** (or their national equivalents) is a core clinical task.

> **INDIAN CONTEXT**
>
> Care of dependent elders is overwhelmingly familial, and there is **no organised national respite system**. Day care centres and short-stay facilities are largely **NGO, charitable and urban**. **Kerala's Neighbourhood Network in Palliative Care** provides de facto community respite through trained volunteers. The policy backdrop is the **National Programme for Health Care of the Elderly (NPHCE)** and the **Maintenance and Welfare of Parents and Senior Citizens Act 2007 (amended 2019)**, with palliative and hospice services reaching **fewer than 4%** of those who need them.

Latest Updates (2023–Present)

Hospice utilisation

1. **Facts and Figures 2025** (National Alliance for Care at Home, successor to NHPCO), reflecting **calendar year 2024** data:
   - **1.91 million Medicare beneficiaries** enrolled in hospice for one or more days — a **4.4% increase on 2023**; **1.3 million died while in hospice**
   - **Historic milestone: 53.1% of all Medicare decedents received hospice care and were enrolled at the time of death** — the **first time a majority**, the third consecutive annual rise, and above pre-pandemic levels
   - **Principal diagnoses**: **circulatory 29.8%, neurovascular 25.4%, cancer only 22.3%, respiratory 10.1%, kidney disease 3.0%**
   - (The 2024 edition, reporting CY2022, recorded 1.72 million enrolees and **49.1% of decedents** — the first increase since 2019.)

> **THE FOUR LEVELS OF THE MEDICARE HOSPICE BENEFIT — HIGH-YIELD**
>
> **1. Routine home care (RHC)** — the commonest level, roughly **52% of all patient-days**
> **2. Continuous home care** — for symptom crisis managed at home
> **3. Inpatient respite care** — **maximum 5 consecutive days**, expressly to relieve the caregiver
> **4. General inpatient care (GIP)** — for symptom crises that cannot be managed elsewhere
>
> Payment at each level covers **all care related to the terminal illness** — interdisciplinary team, medication, equipment and supplies.

Hospice ownership, quality and oversight

1. **Commercialisation** — in **1992 about 5% of Medicare-certified hospices were for-profit; by 2024 approximately 73%** were. A two-part **HHS Office of Inspector General report** found that around **20% of hospice agencies had deficiencies posing serious safety risks to patients**.
2. **Hospice Special Focus Program (SFP)** — mandated by the Consolidated Appropriations Act 2021 and finalised in the CY2024 rule, the SFP used a **data-driven algorithm** (survey findings, complaint data and quality measures) to identify the poorest-performing roughly 10% of hospices for **more frequent survey, mandatory quality improvement, loss of accreditor "deemed status", and possible termination from Medicare**. After an initial list of 50 hospices was released and a **multi-state provider lawsuit** was filed in January 2025, **CMS ceased implementation on 14 February 2025** to re-evaluate the methodology, and confirmed it would not resume during 2025. **Hospice quality oversight is now an actively contested policy area.**

Respite care evidence

1. **Updated systematic review of adult day services as respite (2015–2025, more than 25 studies)**:
   - Regular use is associated with **reduced caregiver stress, improved mood, and measurable reduction in physiological stress markers**; on day-service days caregivers report **lower negative affect and higher positive affect**
   - Participation is linked to **delayed nursing home placement**, translating into **cost savings**
   - **Earlier Cochrane reviews were inconclusive** because of limited randomised data; **recent observational and longitudinal studies provide stronger evidence of benefit**
   - **Utilisation remains suboptimal** because of **financial constraints, limited awareness, caregiver reluctance and service availability**; facilitators are **caregiver education, culturally tailored programming, financial assistance and high-quality staff engagement**

2. **Caregiver-intervention meta-analyses** confirm that **multicomponent interventions and respite delay institutionalisation**, but that effect sizes on caregiver outcomes are generally **small to very small**. This has produced a proposed **"tripartite scaffolding" model of caregiver support**: (a) **care coordination and case management**, (b) **psychoeducation**, and (c) **skills training** — with respite embedded rather than standing alone.
3. **Service innovation** — nature-based, community-linked and technology-supported respite models are now being formally evaluated using **DEMQOL** (quality of life) and the **Zarit Burden Interview**, with implementation frameworks such as RE-AIM.

Current Practice Update

Area	Textbook position	Current evidence and practice
Hospice utilisation	48% of Medicare decedents; 1.49 million enrolees (2017); mean length of stay 76 days	**53.1% of Medicare decedents (2024)** — a majority for the first time; **1.91 million enrolled**. Stays remain short, so **late referral persists as the core problem**
Principal hospice diagnosis	Cancer about 30%, falling as heart disease and dementia rise	**Cancer now only 22.3%**; circulatory (29.8%) and neurovascular (25.4%) lead — hospice is now **predominantly a non-cancer service**
Ownership and oversight	Not addressed	**About 73% for-profit by 2024**; OIG found serious deficiencies in roughly 20% of agencies; **the Special Focus Program was created and then suspended in February 2025** amid litigation over its algorithm
Hospice respite	Described qualitatively as "a brief period of inpatient care to relieve the family"	Codified as a **distinct payment level — inpatient respite care, maximum 5 consecutive days per episode**
Respite evidence base	Presented as clearly beneficial for caregiver relief and for delaying institutionalisation	**Direction of benefit confirmed, but effect sizes are small**. Strongest current data are for **adult day services** — reduced stress, improved affect, delayed placement, cost savings. Respite works best **embedded in a multicomponent package**, not alone
Day hospitals	Widely available in the UK, then decommissioned for want of supporting literature	Replaced by **voluntary, charitable and private day care and respite services**, plus crisis resolution and home treatment teams
Caregiver assessment	ZBI, CSAQ, Rapid Screen for Caregiver Burden	**Strengths-based tools (Caregiver Well-Being Scale)** used alongside burden scales; **3-item ZBI** now validated for rapid clinic screening
Access	Framed around US Medicare and UK NHS models	In India, hospice and respite remain **largely NGO-based, urban and severely limited** — under 4% of those needing palliative care receive it

Exam One-Liners

Hospice = caring, not curing — a **subset of palliative care** for patients approaching death.

Cicely Saunders coined "hospice" in 1967; **Florence Wald** brought it to the US; **Medicare hospice benefit 1982**; **India's first hospice — Shanti Avedna Sadan, Mumbai, 1986**.

US eligibility = **physician-certified prognosis ≤6 months + the patient's own election**.

Four Medicare levels: routine home care — continuous home care — **inpatient respite (max 5 days)** — general inpatient care.

Hospice is the **only Medicare provider required to have volunteers deliver at least 5% of patient-care hours**.

Hospice cannot provide continuous 24-hour personal care, and Medicare does not pay for personal-care aides.

Bereavement follow-up for about one year is a core hospice service.

Cancer is now a minority of hospice diagnoses — heart disease and dementia dominate.

Respite care targets the caregiver, not the patient.

Respite may be **the single intervention that keeps a dependent older person at home**.

Where carer stress is high, respite or step-down placement beats hospital admission — admission risks permanent institutionalisation.

Zarit Burden Interview is the standard caregiver burden tool (22-, 12-, 4- and 3-item versions).

Caregiver distress does not end at institutionalisation — nearly half remain at risk of disabling depression.

If no formal respite programme exists, arrange informal relief at regular intervals — before the crisis, not after.

QUESTION 6 · 15 MARKS

Bereavement

High-Yield Points

Definitions and Concept

1. **Bereavement** is the objective state of having lost someone significant through death. **Grief** is the personal emotional, cognitive, physical and behavioural reaction to that loss. **Mourning** is the publicly and culturally patterned expression of grief — rituals, funerals, observances.
2. **The process of grief begins from the time a life-limiting illness is diagnosed** or health starts to deteriorate — not at the moment of death. For elderly couples who have lived together many years this marks **the beginning of a very painful parting**, and for the surviving partner **the loss of a lifelong companion is equivalent to part of their own personal dying**.
3. **Bereavement is formally the final stage of the palliative care continuum** — palliative care runs from diagnosis, through illness progression and end-of-life or hospice care, and culminates in **bereavement support for family and caregivers** (as staged by the Palliative Care Outcome Collaboration, Australia). Such relatives themselves require a **care plan that includes bereavement**.

Epidemiology and Significance in Old Age

1. Bereavement is near-universal in later life — spouse, siblings, friends, sometimes children. **Losses of family and friends** are listed among the **social factors predisposing older people to depression**, alongside isolation, loss of job and loss of income.
2. **Bereavement is associated with declines in health, increased utilisation of healthcare resources, and an increased risk of death.** Grieving relatives have increased rates of **depression, cardiac events, intercurrent infections and mortality**.
3. **Recent death of a spouse and widowhood are major suicide risk factors in older people.** The high-risk profile is: **male, white, widowed or divorced, recently bereaved, living alone, isolated, recently moved, retired, poor physical health, terminal illness, pain, depression, alcohol use and loneliness.** Older adults **give fewer warnings, use deadlier methods, and have an attempt-to-completion ratio of about 4:1 (versus 200:1 in adolescents)** — and **20–50% have seen their primary care physician in the week before suicide**.

Normal versus Complicated Grief

1. **Normal (uncomplicated) grief** presents as waves of yearning, sadness, tearfulness, sleep and appetite disturbance, transient hallucinations of the deceased, guilt and anger — gradually attenuating over months as the person re-engages with life. **Most bereaved people recover with the support of friends and family and need no professional intervention.**
2. **Complicated (prolonged) bereavement may be distinct from major depression**, and formal criteria have been proposed. Its features are:
    - extreme levels of **"traumatic distress"**
    - **numbness**
    - a feeling that **part of oneself has died**
    - **assuming the symptoms of the deceased**
    - **disbelief or bitterness**

- **symptoms enduring beyond six months**

It is listed among the **depressive disorders** in geriatric psychiatry and is one of the conditions in older adults that **does not fit the conventional paradigm of disease**.

3. **The DSM-5 "bereavement exclusion" (criterion E of DSM-IV) has been removed.** The presence of depression during a period of mourning is now judged **entirely by the clinician, regardless of the period of bereavement**. This is of great importance in geriatrics because **a large proportion of older people are dealing with recent loss** and were previously denied both diagnosis and treatment.

Distinguishing the three entities:

Feature	Normal grief	Prolonged / complicated grief	Major depression
Core affect	Yearning for the deceased, in waves	**Persistent yearning and preoccupation with the deceased**	Pervasive low mood and anhedonia
Self-view	Preserved	Identity disruption — "part of me has died"	**Global worthlessness and guilt**
Pleasure	Intermittently retained	Retained outside grief triggers	**Pervasive anhedonia**
Course	Attenuates over months	Persists **beyond 6–12 months** and disabling	Sustained; may be independent of the loss
Suicidality	Passive wish to join the deceased may occur	Wish to join the deceased	**Active ideation with plan**
Treatment	Support and normalisation	**Grief-focused psychotherapy**	Antidepressant with or without psychotherapy or ECT

Risk Factors

FOUR DOCUMENTED WARNING SIGNALS FOR COMPLICATED GRIEF

1. Sudden unexpected death · 2. Traumatic death · 3. Loss of a child · 4. Loss of a partner with an ambivalent relationship ("can't live with, can't live without").

Additional risks: pre-existing depression or anxiety, poor social support, prior caregiver strain, multiple concurrent losses, financial insecurity, and the person's **own previous experience of being bereaved**.

1. **How a person dies shapes how the survivor grieves.** As Dame Cicely Saunders said, "*The way people die remains in the memory of those who live on.*" Until about 20 years ago morphine was rarely used in dying patients because of a mistaken belief that it hastened death; many were left with unrelieved pain and distress, and **those memories still colour older people's perception of death and their fears about their own dying**.

Prevention — Care Before the Death

1. **The most effective bereavement intervention is good care of the dying person.** Relatives must be **made aware of what is happening, encouraged to be involved in care, and have their concerns listened to**. Even when frail and elderly, or a child, they may want to be at the

bedside of the person they love — **to deny them the ability to be present does them a great disservice**.

2. **Identify vulnerable caregivers before the death. Caregivers reporting emotional stress have a significantly increased mortality rate**; physician identification of vulnerable caregivers and referral to social workers and community resources **can be lifesaving**.
3. **The period immediately after hospice referral is one of particular vulnerability** — patients and families feel **abandoned by their physicians**. Make follow-up appointments, telephone the family, **express thanks and appreciation for the privilege of caring for the patient**, and say goodbye to patient and family where appropriate. Clinicians must **be aware of both normal and complicated grief and screen for them appropriately**.

Assessment

1. At follow-up, screen for sleep and appetite change, weight loss, alcohol use, functional decline, financial and social change, and **suicidal thoughts**. Use standard instruments — **Geriatric Depression Scale (GDS-15/30), PHQ-2 and PHQ-9, Cornell Scale for Depression in Dementia** — and for grief specifically the **Inventory of Complicated Grief**. Also screen for **loneliness and social isolation**, which are highly prevalent in older adults and independently associated with **increased mortality and functional decline**; **routine screening with individual and community-based interventions is recommended**.

Management

1. **Most bereaved people need support, not treatment.** Blanket counselling for everyone is neither necessary nor effective — **target intervention at those with risk factors or established prolonged grief**.
2. **Psychological therapies significantly reduce grief symptoms** in complicated bereavement: **brief dynamic psychotherapy, traumatic grief therapy, crisis intervention, and support groups**. Grief-specific therapy combines elements of interpersonal therapy and CBT — revisiting the loss, cognitive restructuring, and restoring relationships and personal goals.
3. **Antidepressants may also be considered** to treat complicated bereavement, and are indicated where **major depression** is present. Apply late-life prescribing rules — SSRIs first, **start low and go slow**, review regularly. **Avoid benzodiazepines**, which do not treat grief and add falls, delirium and dependence.
4. **Spiritual and religious support matters.** Religiosity and spirituality **provide a sense of meaning that buffers stress and assists coping**, and **a network of like-minded people who serve as social resources**, promoting self-esteem and personal growth. Referral to a chaplain or the person's own clergy should be routinely considered. Healthcare professionals have **a moral obligation to address spiritual concerns** — doing so signals concern for the whole person.
5. **Hospice bereavement services** — hospice programmes provide bereavement follow-up for **approximately one year** after the death: a trained volunteer or counsellor visits the survivors at specific intervals, plus telephone and letter contact, the opportunity to join **support groups**, and **onward referral to medical or professional care** where necessary.
6. **Byock's "Five Things"** — *thank you; forgive me; I forgive you; I love you; goodbye* — offered to families before the death, ease the grief that follows.

Special Groups and Context

1. **Bereaved grandchildren.** For many children a grandparent is **the most secure adult in their life**, as social disintegration and mobility may leave the child very dependent on them. On average, **in every UK school class about two children are bereaved of someone close such as a grandparent, and one of a parent or sibling**. The way clinicians care for the dying patient and their family therefore **influences the next generation's ability to cope with illness and death**.

2. **Bereavement and sexuality** — **depression, bereavement and grief reactions** are recognised **psychological inhibitors of sexual activity** in older people, alongside poor self-image, cultural beliefs and social isolation.

> **INDIAN AND CULTURAL CONTEXT**
>
> Mourning in India is highly ritualised and time-structured (10–13 day rites, annual observances), and these rituals are **protective** — providing social scaffolding and explicit permission to grieve. Grief must be judged against **the person's own societal, cultural and religious norms**, not a Western template. Practically, **widowhood in India carries social and economic disadvantage**, family ties are strong so depression in one member strongly affects the rest, and **formal bereavement services are almost entirely absent outside hospice and NGO programmes**.

Latest Updates (2023–Present)

Prolonged Grief Disorder is now a formal diagnosis

1. **Prolonged Grief Disorder (PGD)** has been added to both **ICD-11** and **DSM-5-TR (2022)** — the single most important change in this field. Core features: **yearning for, or persistent preoccupation with, the deceased**, accompanied by **intense emotional pain** (sadness, anger, bitterness, disbelief, **identity disruption**, avoidance of reminders, emotional numbness, **loss of meaning and purpose**, difficulty re-engaging socially), causing **clinically significant functional impairment**, and persisting **beyond what is expected given the person's social, cultural or religious norms**.
2. **The two systems differ in their time criterion — a favourite exam point:**
    - **ICD-11** — the reaction must persist for an atypically long period, **minimum 6 months**
    - **DSM-5-TR** — the death must have occurred **at least 12 months ago** (6 months for children and adolescents), with symptoms present nearly every day for at least the past month
    - Consequently the **prevalence differs**: point prevalence among the bereaved ranges roughly **4.7–6.8%**, with **DSM-5-TR yielding significantly lower rates than ICD-11**. Raising the ICD-11 threshold to 12 months brings the two into near-perfect agreement.
3. **The time thresholds are now actively contested.** A cross-national study (UK, Ireland, Ontario, 2025) found grief symptoms were **not markedly higher in those bereaved within the previous 6 months**, and that bereaved people themselves **do not regard 6 months as the normative point at which one should have come to terms with a loss**. The argument advanced is that **grief symptoms are pathological by their nature, not by their chronicity** — so rigid time thresholds are unlikely to prevent false-positive diagnoses but will **increase false negatives**, with under-treatment as the practical consequence.
4. **Criterion validity favours ICD-11.** In longitudinal analysis controlling for depression and insomnia, **ICD-11 prolonged grief symptoms predicted quality of life at 6-month follow-up, whereas DSM-5-TR symptoms did not**.
5. A **2025 Lancet Review** endorses the current conceptualisation: PGD is a **diagnosable mental health condition** with core symptoms of **yearning and/or preoccupation**, associated with **emotional pain, identity disturbance, loss of meaning and purpose, and functional impairment**, with a **typical onset 6 to 12 months after the death**.

Treatment

1. **Psychotherapy is first-line, and it must be grief-specific.** Grief-focused CBT and **Prolonged Grief Disorder Therapy (PGDT, formerly Complicated Grief Therapy)** — combining **exposure and revisiting the loss, cognitive restructuring, behavioural activation and restoration of**

personal goals — have the strongest evidence. Internet-delivered CBT is effective, with **more sessions producing greater benefit**.

2. **Bryant et al., JAMA Psychiatry 2024** — head-to-head randomised trial of **grief-focused CBT versus mindfulness-based cognitive therapy** in 100 adults with PGD:
    - **Both treatments produced substantial symptom reduction** (large effect size)
    - **Grief-focused CBT was superior at 6-month follow-up** for **core PGD symptoms, depression and grief-related cognitions** — though not for anxiety
    - Interpretation: mindfulness works, but **grief-specific exposure and cognitive work works better**
3. **Pharmacotherapy is secondary.** The landmark four-arm randomised trial (**citalopram + clinical management, citalopram + PGDT, placebo + PGDT, placebo + clinical management**; 333 patients aged 18–95) established that **PGDT drives the benefit — an antidepressant alone is not sufficient**. A 2025 machine-learning re-analysis found that **higher baseline depression severity, greater grief-related functional impairment, and not receiving PGDT** each predicted poorer response. **Tricyclic antidepressants and benzodiazepines have not proved effective for PGD.**
4. **New neurobiological hypothesis** — PGD may involve the **reward and attachment circuitry** rather than classical depression pathways, i.e. it may be conceptually closer to a **disorder of attachment or addiction**. This underpins randomised, triple-blinded, placebo-controlled trials of **oral naltrexone** (opioid receptor antagonist, 8-week course) for PGD. The evidence remains **preliminary and not yet practice-changing**.
5. **Validated diagnostic instruments now exist** for both criteria sets — notably the **Aarhus Structured Clinical Interview for Prolonged Grief Disorder (A-PGDi, 2024)**, covering both ICD-11 and DSM-5-TR.

Current Practice Update

Area	Textbook position	Current position (2023–present)
Nomenclature	"Complicated bereavement"; formal criteria "have been proposed"	**Prolonged Grief Disorder is now a formal, coded diagnosis** in both ICD-11 and DSM-5-TR (2022)
Time criterion	Symptoms enduring for **six months**	**ICD-11 at least 6 months; DSM-5-TR at least 12 months** — and both thresholds are now openly challenged as arbitrary, risking **under-diagnosis**
Prevalence	Not quantified	Roughly **4.7–6.8%** of bereaved adults, varying with the algorithm; DSM-5-TR yields substantially lower rates
Relation to depression	"may be distinct from major depression"	**Confirmed as a distinct disorder** with its own criteria, trajectory, treatment response and probable neurobiology
First-line treatment	Brief dynamic psychotherapy, traumatic grief therapy, crisis intervention, support groups; "antidepressants may also be considered"	**Grief-focused CBT and PGDT are first-line**, and are **superior to non-specific therapy**; **antidepressants alone are not sufficient** — the psychotherapy drives the benefit

Mindfulness-based therapy	Not addressed	Effective, but **significantly less effective than grief-focused CBT** (Bryant 2024)
Pharmacology	Antidepressants may be considered	SSRIs only where depression coexists; **TCAs and benzodiazepines ineffective for grief itself**; **naltrexone under investigation** on a reward-circuitry hypothesis
Diagnosis in practice	Clinical judgement, Inventory of Complicated Grief	**Validated structured interviews now available** (for example A-PGDi) for both criteria sets
Cultural framing	Implicit	Now **explicit in the criteria** — the reaction must exceed the person's own **social, cultural and religious norms**; guidance warns against applying Western-normed timeframes
DSM bereavement exclusion	Noted as removed, with impact "yet to be settled"	Settled — **depression during mourning is diagnosed and treated on clinical grounds**, and prolonged grief is coded separately alongside it

Exam One-Liners

Bereavement = the fact of loss; grief = the reaction; mourning = the culturally patterned expression.

Grief begins at diagnosis, not at death.

Bereavement is the **final stage of the palliative care continuum**.

Bereavement raises **healthcare use, cardiac events, infection risk and mortality**.

Widowhood and recent spousal death are major suicide risk factors, especially in older men.

Older adults' **suicide attempt-to-completion ratio is about 4:1** (versus 200:1 in adolescents).

Four red flags for complicated grief: sudden death — traumatic death — loss of a child — ambivalent relationship with the deceased.

Complicated grief hallmark: **feeling that part of oneself has died** and **assuming the symptoms of the deceased**.

The DSM-5 bereavement exclusion has been removed — judge depression during mourning clinically.

PGD time criterion: ICD-11 at least 6 months, DSM-5-TR at least 12 months; core symptom is **yearning or preoccupation**.

Grief-focused CBT / PGDT beats antidepressants and beats mindfulness.

> **Benzodiazepines have no role in grief.**

> **Hospice bereavement follow-up runs for about one year.**

> **"The way people die remains in the memory of those who live on"** — Cicely Saunders.

> How we care for the dying patient shapes **the next generation's** ability to cope with death.

MD GERIATRIC MEDICINE

High-Yield Examination Answers

Perioperative Medicine · Periprocedural Care · Constipation
Viral Hepatitis · Liver Transplantation · Eye Donation · Sleep Protocol

Primary sources: **Pathy's Principles and Practice of Geriatric Medicine, 6th edition** | **Essentials of Clinical Geriatrics, 7th edition**
Supplemented with current guidelines and peer-reviewed literature (2023 – 2026)

Eight questions · 15-mark format · Structured for night-before revision

Contents

1.	Perioperative / Pre-operative Care and Assessment of the Elderly
2.	Checklist for Older Adults Undergoing Diagnostic and Therapeutic Procedures — Periprocedural Medical Issues (including Antiplatelet Management)
3.	Constipation in the Elderly — Prevention and Management
4.	Recent Trends in the Treatment of Hepatitis C Infection
5.	Treatment of Chronic Hepatitis B Infection — Older and Newer Modalities
6.	Liver Transplantation
7.	Eye Donation
8.	Sleep Protocol

How to use this document

- Each answer runs: **Question → High-Yield Points → Latest Updates (2023–Present) → Current Practice Update → Examiner's Tip**.
- Textbook-derived content sits in the numbered High-Yield Points. Content added from guidelines and journals is confined to the **Latest Updates** and **Current Practice Update** sections, so the two are never mixed.
- Where the uploaded textbooks do not cover a topic, this is stated explicitly in an italic note beneath the question heading.
- Laboratory values are given in conventional/Indian units throughout.

Q1. Perioperative / Pre-operative Care and Assessment of the Elderly

High-Yield Points

Principles and Risk

1. Perioperative care of an older person means three things — **pre-operative risk assessment and optimisation, intra-operative safety, and post-operative recovery**. It is a team job involving the physician, surgeon and anaesthetist.
2. **Age above 70 raises the risk** of complications and death after major non-cardiac surgery. But the actual mortality is low even beyond 80 years if the surgery is planned.
3. **Comorbid conditions matter far more than age itself.** The type of operation, the local complication rate, and whether surgery is emergency or elective decide the outcome.
4. **Emergency surgery carries a much higher risk** than elective surgery. Wherever possible, stabilise the patient and operate electively.
5. Always ask first whether the operation is appropriate. The **risk–benefit ratio** must be weighed against the patient's goals, life expectancy and functional status.

What to Assess and Optimise Before Surgery

6. Optimise underlying disease before non-emergency surgery: **cardiovascular disease (especially heart failure), lung function, kidney function, diabetes, thyroid disease (often occult), anaemia, nutrition, and hydration/volume status** — the last is especially important in patients on diuretics.
7. **Cardiac conditions that greatly increase risk** are: myocardial infarction within 6 months, pulmonary oedema, angina (especially unstable), and severe aortic stenosis.
8. The **Revised Cardiac Risk Index (Lee index)** uses six factors — ischaemic heart disease, heart failure, cerebrovascular disease, insulin-treated diabetes, renal insufficiency (creatinine >2.0 mg/dL), and high-risk surgery.
9. **Assess exercise tolerance.** The classical bedside test is the ability to climb one flight of stairs. Poor exercise capacity predicts poor outcome.
10. Order tests only if the result will change management. **Pre-operative pulmonary function tests and arterial blood gases are rarely of prognostic value.** Non-invasive cardiac testing is reserved for intermediate- and high-risk patients.
11. **Coronary revascularisation (CABG or PCI) should be done only if it is indicated independently of the planned surgery** — not merely to 'get the patient through' the operation.

Medications and Prophylaxis

12. Plan the drug chart carefully — **some drugs are continued, some withheld, and some need dose adjustment**.
13. Three prophylactic measures have documented value: **beta-blockade in appropriately selected patients, antithrombotic (VTE) prophylaxis, and antimicrobial prophylaxis**.

Frailty, Cognition and Delirium

14. **Frailty independently predicts post-operative complications, longer hospital stay and discharge to a nursing facility** (Makary). It is assessed by weight loss, weak grip strength, exhaustion, low physical activity and slow walking speed.
15. **Pre-operative impaired cognition, recent falls, low albumin, greater anaemia, functional dependence and multiple comorbidities** predict higher mortality at 6 months (Robinson).
16. Four items independently predict **post-operative delirium** — prior stroke or TIA, low MMSE score, abnormal serum albumin, and a high Geriatric Depression Scale score (Rudolph). Preventing delirium is a core aim of perioperative care.
17. In cardiac surgery, frailty is scored by **Katz ADL ≤4 of 6, low grip strength, 5-metre walk ≥6 seconds, 6-minute walk <150 metres, timed get-up-and-go ≥15 seconds, and cognitive impairment**. Frailty gives a **two- to four-fold rise in operative mortality**.

Anaesthesia, Cardiac Surgery and Outcome

18. **Regional anaesthesia is not clearly superior to general anaesthesia** in older people. It may need added sedation, can cause significant cardiovascular changes, and does not clearly reduce DVT or blood loss. The choice must be individualised.

19. After cardiac surgery the most feared complication is **stroke**, usually embolic. Risk factors are cerebral atrophy, reduced cerebrovascular reserve, and atherosclerosis of the aorta or neck vessels. Screen with **carotid duplex**; severe ascending aortic atheroma raises neurological events to 10%.

20. **Confusion of uncertain cause or early dementia is a relative contraindication to cardiac surgery**, as open-heart surgery may worsen it. **Late referral independently worsens both operative risk and late outcome.**

21. In the elderly the aim of cardiac surgery is **relief of symptoms and improvement in quality of life**, not longevity. After cardiac surgery 84–94% of octogenarian survivors continue living independently and 83–98% would undergo the operation again.

22. A **comprehensive geriatric consultation** completes the assessment — medication review, functional assessment, environmental and caregiver assessment, and a **discussion of advance directives**.

Latest Updates (2023 – Present)

- **2024 AHA/ACC/Multisociety Perioperative Guideline (JACC 2024; Circulation 2024)** — the fourth major revision, superseding the 2014 guideline. It uses a **stepwise algorithm** and stresses a multidisciplinary, shared decision-making approach.
- **Timing definitions were redefined:** emergency = less than 2 hours (was 6 hours); urgent = 2–24 hours; time-sensitive = up to 3 months (was 1–6 weeks); elective = can be delayed indefinitely.
- **'Active cardiac conditions' are back in the algorithm** — acute coronary syndrome, decompensated heart failure and unstable arrhythmia. Elective surgery must be postponed until these are treated.
- A new step called **'risk modifiers'** was added: severe valvular disease, pulmonary hypertension, congenital heart disease, prior PCI/CABG, recent stroke, cardiac implantable electronic device, and **frailty**. Frailty is now formally part of the cardiac risk pathway.
- **Functional capacity should be measured, not estimated.** The METS study showed that clinician-estimated exercise capacity does not predict complications; the **Duke Activity Status Index (DASI)** does. DASI >34 indicates low risk. Basel-PMI and MET-REPAIR showed that **inability to climb two flights of stairs** predicts cardiac complications and death.
- **Cardiac biomarkers are a new step.** BNP or NT-proBNP (ACC/AHA preference) or troponin (ESC preference) may be measured in elevated-risk patients with poor exercise capacity. **BNP <92 ng/L or NT-proBNP <300 ng/L means low risk and no further testing.**
- **Post-operative troponin surveillance may now be considered in high-risk patients**, even without symptoms — a change from 2014 (myocardial injury after non-cardiac surgery, MINS).
- **Revascularisation before surgery is recommended only for acute coronary syndrome or left main stenosis >50%.** Coronary CT angiography is accepted as an alternative to pharmacological stress testing.
- **Medication guidance (2024):** continue beta-blockers if already on them but never start on the day of surgery (start ≥8 days before); continue statins; do not start clonidine; withhold ACE inhibitors/ARBs 24 hours before if taken for hypertension but continue for HFrEF; **withhold SGLT2 inhibitors 3–4 days before surgery** to prevent euglycaemic ketoacidosis.
- **Blood pressure:** consider delaying surgery if BP ≥180/110 mmHg; maintain intra-operative mean arterial pressure ≥60–65 mmHg and treat post-operative hypotension promptly.
- **GLP-1 receptor agonists:** the 2023 ASA advice to hold them was replaced by **2024 multisociety guidance (AGA, ASMBS, ASA, ISPCOP, SAGES)** — a risk-based, shared decision-making approach; most patients can continue, with a 24-hour clear-liquid diet and gastric point-of-care ultrasound if aspiration risk is a concern.
- **Prehabilitation** (structured exercise, nutrition and psychological preparation for 4–6 weeks before major elective surgery) reduces complications and length of stay in frail older adults; combined with **ERAS** protocols and the American College of Surgeons **Geriatric Surgery Verification** standards, which mandate routine screening for frailty, cognition, delirium risk, nutrition and goals of care.

- **Indian context:** around 10.5% of India's population is now 60 years or older (LASI/NSO projections). Pre-operative anaemia, undiagnosed diabetes and malnutrition are highly prevalent and correctable; surgical packages are covered under **PM-JAY**, and NP-NCD/NPHCE services support pre-operative optimisation at the primary level.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
Perioperative beta-blockade is recommended for high- and intermediate-risk patients with negative non-invasive tests.	Beta-blockers are **continued if already prescribed** but are **never started on the day of surgery**; if newly indicated, start at least 8 days before to allow titration (POISE trial showed excess stroke and death with day-of-surgery initiation).
Exercise tolerance is judged by the ability to climb one flight of stairs.	A **structured questionnaire (DASI >34)** or the ability to climb **two flights** is preferred; clinician-estimated METs do not predict outcome (METS study).
Risk is estimated clinically, with non-invasive cardiac testing for intermediate/high-risk patients.	Risk is calculated with a validated tool (RCRI, MICA, ACS-SRC, AUB-HAS2) and refined with **BNP/NT-proBNP or troponin**; stress testing only if the result will change management.
Emergency surgery is defined as surgery needed within 6 hours.	Emergency is now defined as **less than 2 hours**; urgent 2–24 hours; time-sensitive up to **3 months**.
Frailty is described as a predictor of complications in research studies.	Frailty is a **formal risk modifier** in the 2024 algorithm and a mandatory screening domain under ACS Geriatric Surgery Verification standards.
Textbook lists beta-blockade, antithrombotic and antimicrobial prophylaxis as the prophylactic measures.	The list now also includes **SGLT2 inhibitor and GLP-1 agonist management, delirium prevention bundles, prehabilitation and ERAS pathways**.
Post-operative troponin is checked only if there are signs or symptoms of ischaemia.	**Routine troponin surveillance may be considered in high-risk patients** to detect myocardial injury after non-cardiac surgery (MINS), which is usually silent.

Examiner's Tip — verbatim mark-earning lines

- "In the older surgical patient, **comorbidity and urgency, not chronological age, determine outcome**."
- "The four cardiac conditions that substantially raise risk are **myocardial infarction within 6 months, pulmonary oedema, unstable angina and severe aortic stenosis**."
- "**Frailty confers a two- to four-fold increase in operative mortality** and is now a formal risk modifier in the 2024 ACC/AHA perioperative guideline."
- "Pre-operative pulmonary function tests and arterial blood gases are **rarely of prognostic value** — order a test only if it will change management."
- "**Prophylactic revascularisation is indicated only when it would be indicated in the non-surgical setting** — ACS or left main >50%."
- "Quote the four delirium predictors of Rudolph: **prior stroke/TIA, low MMSE, abnormal albumin and high GDS score**."
- "Withhold **SGLT2 inhibitors 3–4 days** before surgery; withhold ACE inhibitors/ARBs 24 hours before if given for hypertension."
- "In the elderly, the goal of cardiac surgery is **symptom relief and quality of life, not longevity** — and late referral independently worsens outcome."

Q2. Checklist for Older Adults Undergoing Diagnostic and Therapeutic Procedures — Periprocedural Medical Issues (including Antiplatelet Management)

High-Yield Points

Framework of the Checklist

1. A periprocedural checklist for an older adult has five headings — **appropriateness, antithrombotic management, organ-system optimisation, geriatric syndromes, and post-procedure care**.
2. **Appropriateness first:** confirm the indication, the risk–benefit balance, life expectancy and lag time to benefit, capacity and informed consent, and advance directives. Ask whether the result will change management.

Antiplatelet and Anticoagulant Management

3. **Anticoagulants should be stopped before most invasive procedures**, but they may be continued for low-risk procedures where bleeding would be very minor or clinically insignificant.
4. **Heparin bridging is only for patients with high thromboembolic risk.** In a patient on a vitamin K antagonist, start LMWH or unfractionated heparin when the INR falls below 2, or after two to three doses have been omitted.
5. **Bridging is never needed for DOACs**, because their half-lives are short and the anticoagulant-free interval is brief.
6. **Restart anticoagulation about 24 hours after the procedure.** Delay to 48–72 hours only when the risk of post-operative bleeding is high.
7. **Mechanical prosthetic valves:** do not stop the VKA for minor surgical, superficial, dental or ophthalmic procedures — use local haemostasis and check that the INR on the day is not more than 0.5 above target. Major surgery needs an INR below 1.5.
8. For mechanical valves, stop warfarin **3–5 days** before surgery and bridge once the INR falls more than 0.5 below target. **Intravenous unfractionated heparin is preferred** because the effect of LMWH cannot be fully reversed. Restart oral anticoagulation the day after surgery.
9. Target INR for a mechanical prosthesis is **2.5–4.0** depending on prosthesis thrombogenicity and patient factors; **mitral or tricuspid position needs a higher target of 3.0**. **DOACs are contraindicated with mechanical valves.**
10. For a **surgical aortic bioprosthesis**, low-dose aspirin 75–100 mg daily for three months is now favoured over oral anticoagulation, provided the patient is in sinus rhythm.
11. **Duration of DAPT after PCI:** aspirin 75–100 mg plus clopidogrel 75 mg — one month after a bare-metal stent, at least six months after a drug-eluting stent, and 12 months after ACS irrespective of revascularisation strategy. Thereafter lifelong single antiplatelet therapy.
12. In older people **bleeding is commoner than recurrent thrombosis**, so a **short DAPT** course is appropriate — 6 months for stable IHD and 12 months for ACS, and as short as 1 and 6 months respectively with newer drug-eluting stents. **The evidence no longer supports bare-metal stents in the elderly.**
13. **Prasugrel is not recommended in patients aged 75 or above** — it was not superior to clopidogrel and increased major and fatal bleeding. **Ticagrelor** may be used; its bleeding risk is similar to clopidogrel.
14. **Add a proton pump inhibitor** to reduce gastrointestinal bleeding in older patients on DAPT, particularly with a previous GI bleed.
15. **Use the trans-radial approach** for PCI. Bleeding is the commonest non-cardiac complication of PCI and predicts death, MI, stroke, longer stay and higher cost in the elderly.
16. After **intracranial bleeding**, restarting anticoagulation is associated with fewer thromboembolic events and a similar risk of recurrent haemorrhage; the optimal timing is not established and the type of bleed matters (recurrence risk is higher after subarachnoid than intraparenchymal haemorrhage).

Organ-System and Drug Optimisation

17. **Renal protection:** estimate creatinine clearance, hydrate before contrast, withhold nephrotoxics and metformin, and dose-adjust all renally excreted drugs. Acute heparin dosing must be adjusted to renal function.
18. **Medication reconciliation and deprescribing:** stop or reduce anticholinergics, benzodiazepines and sedating antihistamines before the procedure; continue essential cardiac and antiepileptic drugs; plan insulin and oral hypoglycaemic adjustment; avoid prolonged fasting.
19. **Bowel preparation in elderly patients:** avoid sodium phosphate preparations (hyperphosphataemia, acute phosphate nephropathy) and avoid phosphate enemas in renal impairment; use PEG-based split-dose preparation with careful attention to volume status.

Geriatric Syndromes and Post-procedure Care

20. Screen for and address **frailty, cognitive impairment and delirium risk, falls, malnutrition, pressure-injury risk, sensory impairment (hearing aids, spectacles, dentures returned promptly), and continence**. Minimise sedation depth and duration.
21. Provide **VTE prophylaxis and antimicrobial prophylaxis** where indicated, ensure normothermia, and use short-acting anaesthetic and sedative agents.
22. After the procedure: **early mobilisation, early oral intake, removal of catheters and lines, multimodal opioid-sparing analgesia, delirium screening (4AT or CAM), and a clear plan for restarting antithrombotics**.

Latest Updates (2023 – Present)

- **2024 AHA/ACC Perioperative Guideline — antiplatelet recommendations: continue aspirin perioperatively where possible in all patients with stents**, regardless of stent type or timing. Continue DAPT if surgery is required within 30 days of a bare-metal stent or 3 months of a drug-eluting stent.
- **Elective non-cardiac surgery requiring interruption of antiplatelet therapy within 30 days of stent placement is classified as harmful** (risk of stent thrombosis).
- **Stop times before surgery (2024):** prasugrel 7 days, clopidogrel 5 days, ticagrelor 3 days, aspirin 4–5 days. **Ticagrelor is the only reversible platelet inhibitor** of this group.
- **Timing of surgery after PCI:** at least 14 days after balloon angioplasty; at least **12 months after a drug-eluting stent placed for ACS** or complex PCI; at least **6 months after a drug-eluting stent for chronic coronary disease**; time-sensitive surgery may proceed at **3 months** (ESC allows 1 month).
- **Aspirin for primary prevention should be stopped before surgery** (except carotid surgery), and should not be newly started pre-operatively. Aspirin for secondary prevention may reasonably be continued if the cardiac risk outweighs bleeding risk (based on POISE-2).
- If a patient after PCI is on **oral anticoagulant monotherapy** that must be stopped, **substitute aspirin** until the anticoagulant can be resumed.
- **Bridging:** the BRIDGE trial and the **PAUSE** study established that **routine bridging is not indicated** — a standardised, interval-based DOAC interruption without bridging or routine coagulation testing gives low rates of both thromboembolism and major bleeding. Bridging is reserved for high thrombotic risk on a vitamin K antagonist.
- **Endoscopy-specific guidance (ASGE/ESGE/BSG):** for **low-risk endoscopic procedures** (diagnostic endoscopy ± biopsy, ERCP with stent placement without sphincterotomy) antiplatelets and anticoagulants are **continued**. For high-risk procedures (polypectomy, EMR/ESD, sphincterotomy, PEG insertion, EUS-FNA) they are interrupted; aspirin is usually continued throughout.
- **GLP-1 receptor agonists:** the 2024 multisociety guidance (AGA/ASMBS/ASA/ISPCOP/SAGES) replaced blanket withholding with a **risk-stratified approach** — continue in most patients, use a 24-hour clear-liquid diet, and consider gastric point-of-care ultrasound or rapid-sequence induction if there are GI symptoms or high aspiration risk.
- **SGLT2 inhibitors** should be withheld **3–4 days** before an elective procedure (4 days for ertugliflozin) to prevent euglycaemic ketoacidosis.
- **Left atrial appendage occlusion** is an accepted alternative for patients with non-valvular AF who cannot tolerate long-term anticoagulation, and increasingly allows procedures without antithrombotic interruption.

- **Indian practice point:** generic clopidogrel and ticagrelor are widely used; warfarin remains common because of cost, so **INR-based planning, patient literacy and reliable follow-up** must be built into the checklist. Andexanet alfa and idarucizumab availability is limited outside large centres, which favours interval-based DOAC interruption over reliance on reversal agents.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
Anticoagulation should be stopped before the vast majority of invasive procedures.	Many **low-risk procedures (including diagnostic endoscopy with biopsy, cataract surgery, dental extraction, pacemaker implantation)** are now performed **without interrupting** anticoagulation, using local haemostasis.
Bridging with heparin is used for high thromboembolic risk.	**PAUSE and BRIDGE** confirmed that **routine bridging is unnecessary and increases bleeding**; it is confined to mechanical valves and very high-risk VKA patients.
DAPT is 1 month after a bare-metal stent and at least 6 months after a drug-eluting stent.	**Bare-metal stents are obsolete.** With current drug-eluting stents, DAPT of **1–3 months followed by single antiplatelet monotherapy** is safe and reduces bleeding in older people (MASTER-DAPT, TWILIGHT).
The textbook does not give specific pre-operative stop intervals for oral antiplatelets.	**Prasugrel 7 days, clopidogrel 5 days, ticagrelor 3 days, aspirin 4–5 days** (2024 ACC/AHA).
Aspirin is broadly continued for patients on antiplatelet therapy.	Aspirin taken for **primary prevention should be stopped**; aspirin for **secondary prevention and in all stented patients is continued** wherever bleeding risk allows.
No guidance is given on newer antidiabetic agents.	**SGLT2 inhibitors are withheld 3–4 days; GLP-1 receptor agonists** are managed by a risk-based multisociety pathway rather than routine withholding.

Examiner's Tip — verbatim mark-earning lines

- "**Bridging is not needed with DOACs** — their short half-life makes the anticoagulant-free interval brief."
- "For a mechanical prosthetic valve, use **intravenous unfractionated heparin** for bridging, because the effect of LMWH cannot be fully reversed."
- "**Prasugrel should not be used in patients aged 75 or above** — no ischaemic benefit and more major and fatal bleeding."
- "**Elective surgery needing antiplatelet interruption within 30 days of stenting is harmful.**"
- "Memorise the stop intervals: **prasugrel 7, clopidogrel 5, aspirin 4–5, ticagrelor 3 days**."
- "In the elderly undergoing PCI, **bleeding is commoner than recurrent thrombosis** — hence radial access, short DAPT, a PPI and a drug-eluting stent."
- "Avoid **sodium phosphate bowel preparations and phosphate enemas** in older patients — they cause hyperphosphataemia and acute phosphate nephropathy."
- "Every periprocedural checklist in geriatrics must include **capacity, advance directives, delirium risk and a plan for restarting antithrombotics**."

Q3. Constipation in the Elderly — Prevention and Management

High-Yield Points

Definition and Epidemiology

1. Constipation is defined by **difficult, infrequent or incomplete defecation**. Rome IV criteria require two or more of straining, hard or lumpy stools, sensation of incomplete evacuation, sensation of anorectal blockage, manual manoeuvres, and fewer than three spontaneous bowel movements a week, for at least three months.
2. **Complaints of constipation and laxative use are very common in older people.** Twenty to thirty per cent of community-dwelling elders use laxatives at least weekly, and up to 50% of elderly women use them.
3. **When comorbidities are controlled for, constipation is no more common in elders than in younger people. Stool frequency does not change with age** — what elders complain of is **straining and hard stools**.

Physiology and Aetiology

4. **Colonic transit is generally well preserved with ageing.** The change is in the pelvic floor — older women show reduced opening of the anorectal angle and greater perineal descent, and **pudendal neuropathy** becomes commoner.
5. Most causes relate to **medication use or coexisting medical illness**. The commonest drugs are **opiates, calcium channel blockers (verapamil is the worst), NSAIDs and drugs with anticholinergic effects**.
6. Diseases that contribute include **diabetes mellitus, Parkinson's disease, stroke, hypothyroidism, hypercalcaemia, depression and dementia**. Hysterectomy in women over 50 prolongs colonic transit.
7. **Immobility and reduced fluid and fibre intake are traditionally blamed but the evidence is weak**, and increased physical activity does not reliably improve constipation.
8. Changes can be mapped anatomically — **central nervous system** (awareness of the need to defecate: stroke, dementia, Parkinson's), **peripheral nerves** (pudendal injury), **enteric nervous system** (rectal desensitisation, diabetes), and **skeletal muscle/incoordination** (birth trauma, sphincterotomy, scleroderma).

Consequences

9. Constipation **reduces quality of life and self-perceived health**, increases urinary frequency, urgency and dysuria, and worsens mood — all of which improve with treatment.
10. **Faecal impaction is common — about 7% of institutionalised elderly have impacted faeces on rectal examination.** The first sign may be **overflow diarrhoea and rectal incontinence**; if a rectal examination is not done, this is misdiagnosed and wrongly treated with antidiarrhoeals.
11. Immobile or cognitively impaired patients risk **faecal impaction, stercoral ulceration and colonic perforation**.

Evaluation

12. History, drug review and a **digital rectal examination are mandatory**. In patients whose colorectal cancer screening is up to date and who have no worrisome symptoms such as bleeding or weight loss, **an empirical therapeutic trial is appropriate**; investigate only those who fail to respond.
13. For non-responders: colonic transit study, anorectal manometry and balloon expulsion test, defecography, and a **plain abdominal radiograph to assess stool burden**.

Stepwise Management

14. **Step 1 — review and stop constipating medications** and substitute a less constipating alternative where one exists; then increase dietary fibre and fluid intake. Use the **safest, best-tolerated and least expensive laxatives first**.
15. **Step 2 — bulking agents:** bran 4–10 g, psyllium 3–6 g, methylcellulose 2–4 g, calcium polycarbophil 2–4 g, hydrolysed guar gum 3–6 g. **Avoid bulking agents in faecal impaction, in bedbound patients and where fluid intake is poor.** Side effects are bloating and flatulence.

16. **Stool softeners such as docusate have no randomised evidence of efficacy** — one trial showed no improvement over placebo and another found psyllium superior. Their therapeutic role is limited.
17. **Step 3 — osmotic laxatives: polyethylene glycol (PEG) 17–34 g is the best tolerated in elders** and improves both stool consistency and frequency. Lactulose 10–40 g and sorbitol 70% 15–60 mL are alternatives but cause bloating and cramps from bacterial fermentation. **Magnesium and saline salts should generally be avoided** — hypermagnesaemia occurs even with normal renal function; avoid in renal disease, end-stage liver disease and heart failure.
18. **Step 4 — stimulant laxatives:** senna 15 mg, bisacodyl 5–10 mg, sodium picosulfate 5–10 mg. In practice the commonest effective combination is an **osmotic plus a stimulant** laxative.
19. **Secretagogue:** lubiprostone 8–24 µg twice daily, a chloride channel activator, has good evidence in older people.

Special Situations

20. **Opioid-induced constipation: peripherally acting mu-opioid receptor antagonists (PAMORAs)** — methylnaltrexone, naloxegol and naldemedine — reverse constipation **without reducing analgesia or precipitating withdrawal**, and are superior to placebo. Methylnaltrexone is given by injection and is reserved for refractory symptoms. PEG and stimulant laxatives are also used.
21. **Faecal impaction:** give PEG or another osmotic laxative with or without enemas; a hard or large rectal bolus needs **manual removal**; water-soluble hyperosmotic contrast enemas may also relieve it. **Bulking agents must be avoided.**
22. **Enemas:** limit to acute situations and institutional care. **Phosphate enemas cause serious hyperphosphataemia, particularly in renal impairment; soap-sud enemas should never be used.** Small-volume tap water enemas are useful; large-volume ones can cause hyponatraemia; arachis oil retention enemas lubricate and soften impacted faeces (check nut allergy). Any enema carries a risk of colonic perforation.
23. **Dyssynergic defecation: biofeedback is the established mainstay**, given over four to six sessions, and improves defecatory function in about 70%. It is superior to diet, exercise, laxatives or diazepam. If both slow transit and dyssynergia coexist, **treat with biofeedback first**.
24. **Refractory slow-transit constipation:** nearly 90% respond to laxatives. Subtotal colectomy with ileorectal anastomosis is rarely needed and works best in patients without upper gut dysmotility or major psychological symptoms. Antegrade enemas through a caecostomy are an alternative.
25. **Dementia: prevention is the preferred strategy** because the patient may not recognise or communicate symptoms. Review drugs, increase fibre, fluid and activity, and use a **regular osmotic laxative** rather than rectal preparations. Non-verbal signs of the need to defecate include **fidgeting, pacing and pulling at clothes**; educate relatives and carers.
26. **Stroke:** constipation is associated with dependency, bedpan use for defecation, high NIHSS score, polypharmacy, dehydration and inactivity, and predicts a poor outcome at 12 weeks. **Abdominal massage and visceral mobilisation** improve frequency and reduce pain and incomplete evacuation.
27. **Other agents:** large randomised trials of **probiotics have failed to show benefit**. Misoprostol and colchicine are reserved for refractory cases and are limited by cramping. **Neostigmine is reserved for acute colonic pseudo-obstruction** in hospitalised patients.
28. **Prevention:** maintain mobility, use the **gastrocolic reflex** by toileting 20–30 minutes after meals, ensure privacy and an appropriate toilet position, provide a commode rather than a bedpan, keep hydration and fibre adequate, correct hypothyroidism and hypercalcaemia, and review the drug chart at every visit.

Latest Updates (2023 – Present)

- **AGA–ACG Joint Clinical Practice Guideline on Chronic Idiopathic Constipation (Gastroenterology 2023;164:1086–1106; Am J Gastroenterol 2023;118:936)** — ten GRADE-based recommendations, the first joint guideline of its kind.
- **Strong recommendations: polyethylene glycol** (the only over-the-counter agent strongly recommended for chronic use), **bisacodyl and sodium picosulfate** (short-term, under 4 weeks, or as rescue therapy), and the prescription agents **linaclotide, plecanatide and prucalopride** after over-the-counter agents fail.

- **Conditional recommendations:** fibre supplements (especially psyllium), **magnesium oxide**, lactulose, **senna** and lubiprostone. This was the first guideline to endorse magnesium oxide and senna as evidence-based options.
- **Docusate is not recommended** — the guideline found no evidence of benefit, confirming long-standing geriatric teaching.
- **Prucalopride**, a highly selective 5-HT4 agonist, has a reassuring cardiovascular safety profile (unlike cisapride and tegaserod) and is therefore acceptable in older adults; the guideline notes no signal of excess cardiovascular events.
- **Evaluate for a defecatory disorder before escalating drugs** — oral agents work poorly in dyssynergic defecation; refer for **anorectal manometry, balloon expulsion and pelvic floor biofeedback**.
- **Newer options:** the **vibrating capsule** (FDA-cleared, drug-free, uses vibration to stimulate colonic motility) is attractive in polypharmacy; **elobixibat**, an ileal bile acid transporter inhibitor, is available in some Asian markets; **tenapanor** (NHE3 inhibitor) is approved for IBS-C.
- **Opioid-induced constipation:** network meta-analyses continue to support PAMORAs over placebo; **oral naldemedine and naloxegol** have largely replaced injectable methylnaltrexone for routine use, and are useful in palliative and cancer care in the elderly.
- **Constipation as a prodrome:** accumulating cohort data confirm constipation may precede motor Parkinson's disease by 10–20 years and is associated with cognitive decline — it should prompt a neurological review rather than being dismissed.
- **Indian context:** the Indian Society of Gastroenterology consensus and routine Indian practice place **lactulose, PEG and ispaghula (isabgol) husk** as the mainstays, chosen for cost and availability; linaclotide, prucalopride and lubiprostone are marketed in India but cost is a limiting factor. Rising urban prevalence is linked to low dietary fibre in refined-cereal diets, reduced physical activity and polypharmacy.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
A stepwise approach — bulking agent first, then osmotic, then stimulant.	**PEG is now first-line** and the only OTC agent with a strong recommendation for chronic use; **fibre has only a conditional recommendation** and is often poorly tolerated in frail elders.
Stool softeners have limited evidence; docusate is of doubtful value.	**Docusate is explicitly not recommended** and should be deprescribed (2023 AGA/ACG).
Magnesium salts are generally avoided in elders.	**Magnesium oxide is conditionally recommended** as an effective, inexpensive option — but the geriatric caution stands: **avoid in eGFR <30 mL/min**, and monitor for hypermagnesaemia.
Lubiprostone is listed among the agents with the best evidence in elders.	Lubiprostone has been **downgraded to a conditional recommendation** (low certainty); **linaclotide, plecanatide and prucalopride carry strong recommendations**.
Methylnaltrexone (injection) is the important advance for opioid-induced constipation.	**Oral PAMORAs — naldemedine and naloxegol — are now preferred** for routine use; injectable methylnaltrexone is reserved for refractory or terminal care settings.
Stimulant laxatives are the third step in chronic use.	Bisacodyl and sodium picosulfate carry a **strong recommendation but for short-term (<4 weeks) or rescue use**; long-term daily use is not endorsed.

Examiner's Tip — verbatim mark-earning lines

- "**Stool frequency does not change with normal ageing** — elders complain of **straining and hard stools**, not of infrequency."
- "When comorbidity is controlled for, **healthy elders are no more likely to develop constipation than younger people**."
- "**Always do a rectal examination** — overflow diarrhoea from faecal impaction is otherwise misdiagnosed and treated with antidiarrhoeals, which is dangerous."
- "**Avoid bulking agents in faecal impaction, in bedbound patients and where fluid intake is poor.**"
- "**Docusate is ineffective and should not be prescribed.**"
- "**PEG is the best-tolerated osmotic laxative in the elderly**; magnesium salts should be avoided in renal disease and saline salts in heart failure and end-stage liver disease."
- "**PAMORAs reverse opioid-induced constipation without affecting analgesia or precipitating withdrawal.**"
- "**Biofeedback is the mainstay for dyssynergic defecation** and works in about 70% — treat dyssynergia before considering colectomy for slow transit."
- "**Never use soap-sud enemas; avoid phosphate enemas in renal impairment.**"
- "In dementia, **prevention is the strategy** — non-verbal cues that a patient needs to defecate are **fidgeting, pacing and pulling at clothes**."

Q4. Recent Trends in the Treatment of Hepatitis C Infection

*The uploaded textbook covers hepatitis C only briefly — it states that chronic HCV is prevalent in the elderly, that up to 85% of patients are asymptomatic with at least half having normal liver function tests, that screening should be offered, and that **newer therapies can halt disease progression and cure most patients**. It does not detail individual regimens. The regimen-level content below is therefore drawn from AASLD/IDSA, EASL, WHO and Indian national guidance, as permitted.*

High-Yield Points

Background and Goal of Therapy

1. HCV is a blood-borne RNA virus with **six major genotypes**. In India **genotype 3 predominates**, followed by genotype 1; genotype 4 is seen in some regions.
2. **Acute hepatitis C is uncommon but chronic infection is prevalent in the elderly.** Up to 85% are asymptomatic and at least half have normal transaminases, so it is missed unless actively sought.
3. The end point of treatment is **sustained virological response at 12 weeks (SVR12)**, which equals cure. Cure reduces all-cause mortality, hepatic decompensation, hepatocellular carcinoma and the need for transplantation.
4. Fibrosis is now staged **non-invasively** — **FIB-4, APRI and transient elastography (FibroScan)** have largely replaced liver biopsy.

The Older Modalities (of historical and viva importance)

5. **Interferon-alfa, then pegylated interferon plus ribavirin** gave SVR of only about 40–55% in genotype 1 and needed 24–48 weeks. It was **particularly poorly tolerated in the elderly** — flu-like symptoms, cytopenias, depression, thyroid and autoimmune disease, and ribavirin-induced haemolytic anaemia.
6. The **first-generation protease inhibitors boceprevir and telaprevir** (2011) added efficacy but also anaemia, rash and a heavy pill burden. Both interferon-based therapy and first-generation protease inhibitors are now **obsolete**.

Direct-Acting Antivirals — the Current Standard

7. Three DAA classes are combined: **NS3/4A protease inhibitors ('-previr')**, **NS5A inhibitors ('-asvir')**, and **NS5B polymerase inhibitors ('-buvir')**, of which sofosbuvir is the nucleotide backbone.
8. **Pan-genotypic regimens are now standard, so routine genotyping is no longer required:**
9. **Sofosbuvir 400 mg + velpatasvir 100 mg**, one tablet daily for **12 weeks** — the most widely used pan-genotypic regimen.
10. **Glecaprevir 300 mg + pibrentasvir 120 mg** daily for **8 weeks** in treatment-naive patients without cirrhosis or with compensated cirrhosis — the shortest course, and safe in **severe renal impairment and dialysis**.
11. **Sofosbuvir 400 mg + daclatasvir 60 mg** for 12 weeks — WHO-recommended, generic, inexpensive, and the workhorse regimen of India's national programme.
12. **Simplified treatment algorithms** allow treatment of all patients aged 12 and above with minimal baseline testing and minimal on-treatment monitoring; the SVR12 rate exceeds **95%** across genotypes.

Special Groups

13. **Compensated cirrhosis (Child–Pugh A):** the same pan-genotypic regimens are used, usually for 12 weeks.
14. **Decompensated cirrhosis (Child–Pugh B or C): protease inhibitors are contraindicated** (glecaprevir, voxilaprevir) because of hepatotoxicity. Use **sofosbuvir/velpatasvir with weight-based ribavirin for 12 weeks**, or 24 weeks without ribavirin if ribavirin is not tolerated.
15. **Retreatment after DAA failure: sofosbuvir/velpatasvir/voxilaprevir for 12 weeks** is the salvage regimen, with SVR of 96–98%.
16. **Renal disease:** glecaprevir/pibrentasvir requires no dose adjustment at any level of renal function including dialysis; sofosbuvir-based regimens are now also considered safe at eGFR below 30.

Issues Specific to Older Patients

17. **DAAs are as effective and as well tolerated in older patients as in the young** — age is not a reason to withhold treatment. The dominant issue is **drug–drug interaction**, not toxicity.
18. **Key interactions: amiodarone with sofosbuvir causes severe symptomatic bradycardia and is contraindicated**; proton pump inhibitors and antacids reduce absorption of velpatasvir and ledipasvir; statins (especially rosuvastatin and atorvastatin) need dose reduction; **rifampicin, carbamazepine, phenytoin, phenobarbitone and St John's wort are contraindicated** as enzyme inducers.
19. **Screen for HBsAg before starting a DAA** — **HBV reactivation is a black-box warning** and can be fulminant. Give prophylactic antiviral cover or monitor closely.
20. **After cure, hepatocellular carcinoma surveillance must continue lifelong** with six-monthly ultrasound in patients with cirrhosis or advanced (F3) fibrosis, because SVR reduces but does not abolish HCC risk. Varices screening also continues in cirrhotics.

Screening, Prevention and Programmes

21. The textbook cites the **CDC birth-cohort recommendation (one-time anti-HCV testing for all adults born 1945–1965)**. This has since been widened to **one-time testing of all adults at least once in a lifetime**, plus periodic testing for those at ongoing risk.
22. **There is no vaccine for hepatitis C**, and cure does not confer immunity — **reinfection is possible**. Prevention rests on injection and blood safety, single-use needles, sterile dental and salon practice, and harm-reduction services.
23. **India's National Viral Hepatitis Control Programme (NVHCP)**, launched in 2018 under the National Health Mission, provides **free diagnosis and free treatment** with generic pan-genotypic DAAs, targeting elimination as a public health threat by 2030.

Latest Updates (2023 – Present)

- **AASLD–IDSA HCV Guidance (2023 update, and subsequent revisions):** a **simplified treatment algorithm** for treatment-naive adults without cirrhosis or with compensated cirrhosis — no genotyping, minimal pre-treatment work-up and reduced monitoring.
- **Shortened salvage therapy:** based on POLARIS-3, **8 weeks of sofosbuvir/velpatasvir/voxilaprevir** gave the same SVR12 (96%) as 12 weeks of sofosbuvir/velpatasvir in treatment-naive genotype 3 patients with compensated cirrhosis — useful where resistance-associated substitution testing is unavailable.
- **Lancet 2025 factorial randomised non-inferiority trial: sofosbuvir–daclatasvir was non-inferior to sofosbuvir–velpatasvir**. This is a major finding for low- and middle-income countries, as it validates the cheapest generic first-line combination.
- **Shortening therapy:** the Indian **RESOLVE** multicentre randomised trial (ILBS-led) compared **8 versus 12 weeks of sofosbuvir/velpatasvir in treatment-naive non-cirrhotic adults**; shorter courses reduce cost and improve completion rates in programme settings.
- **WHO Global Hepatitis Report 2024:** viral hepatitis deaths are rising, and although curative therapy exists, **diagnosis and treatment coverage remain low** — only a minority of infected people worldwide have been diagnosed or treated. Hepatitis is now the second leading infectious cause of death globally.
- **Point-of-care HCV RNA testing** (GeneXpert, molecular finger-stick platforms) enables **same-visit 'test-and-treat'**, removing the loss to follow-up that has been the main programme bottleneck.
- **Reflex RNA testing** from the same anti-HCV-positive sample is now recommended, replacing the two-visit model.
- **HCV-viraemic donor organs** (kidney, liver, heart) are now transplanted into HCV-negative recipients with short-course DAA prophylaxis, expanding the donor pool — directly relevant to older transplant candidates.
- **Elderly-specific data:** real-world cohorts and meta-analyses confirm **SVR rates above 95% in patients over 65 and over 75**, with no increase in serious adverse events; the barrier is drug–drug interaction and under-referral, not efficacy.
- **Cure improves extrahepatic outcomes** — cohort data show reduced cardiovascular events, improved glycaemic control in type 2 diabetes, improved cognition and quality of life, and resolution of cryoglobulinaemic vasculitis and HCV-related lymphoproliferative disease.

- **Indian data:** HCV prevalence is estimated at roughly 0.3–0.5% nationally with regional clustering (Punjab, north-east, Andhra Pradesh). Punjab's **Mukh Mantri Punjab Hepatitis-C Relief Fund** demonstrated large-scale public-sector cure and became a model for NVHCP scale-up.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
Newer therapies can halt progression and cure most patients with hepatitis C.	Cure is now the routine expectation — **SVR12 exceeds 95%** with 8–12 week all-oral, once-daily, interferon-free pan-genotypic regimens.
CDC recommends one-time anti-HCV testing for adults born between 1945 and 1965.	The birth-cohort strategy has been replaced by **universal one-time adult screening**, with reflex RNA testing on the same sample and repeat testing for ongoing-risk groups.
Genotype-specific approaches and treatment guided by specialist referral.	**Genotyping is no longer required.** Simplified, decentralised, pan-genotypic treatment can be delivered by non-specialists, including at primary care level.
The textbook does not specify regimens.	First line: **sofosbuvir/velpatasvir 12 weeks, glecaprevir/pibrentasvir 8 weeks, or sofosbuvir/daclatasvir 12 weeks**; salvage: **sofosbuvir/velpatasvir/voxilaprevir 12 weeks**.
No specific caution is given regarding pre-treatment testing.	**HBsAg must be checked before starting a DAA** — HBV reactivation carries a black-box warning; and **amiodarone with sofosbuvir is contraindicated** (severe bradycardia).
Screening for hepatitis C should be done in most patients; treatment cures the disease.	After cure, **six-monthly HCC surveillance continues lifelong** in those with cirrhosis or F3 fibrosis, and reinfection remains possible as there is no vaccine.

Examiner's Tip — verbatim mark-earning lines

- "**SVR12 equals cure** — and cure reduces all-cause mortality, decompensation and hepatocellular carcinoma, but does **not** abolish HCC risk in the cirrhotic."
- "Name the three pan-genotypic first-line regimens: **sofosbuvir/velpatasvir 12 weeks, glecaprevir/pibrentasvir 8 weeks, sofosbuvir/daclatasvir 12 weeks**."
- "**Protease inhibitors are contraindicated in decompensated cirrhosis** — use sofosbuvir/velpatasvir with ribavirin."
- "**Sofosbuvir/velpatasvir/voxilaprevir is the salvage regimen** after DAA failure — SVR 96–98%."
- "**Glecaprevir/pibrentasvir needs no dose adjustment even on dialysis** — the regimen of choice in advanced CKD."
- "Two examination-favourite interactions: **amiodarone plus sofosbuvir causes severe bradycardia**, and **PPIs reduce velpatasvir absorption**."
- "**Always check HBsAg before a DAA** — HBV reactivation is a black-box warning."
- "India's **National Viral Hepatitis Control Programme (2018)** provides free diagnosis and generic pan-genotypic DAA treatment, targeting elimination by 2030."
- "**There is no hepatitis C vaccine** — cure does not prevent reinfection."

Q5. Treatment of Chronic Hepatitis B Infection — Older and Newer Modalities

The uploaded textbook covers hepatitis B briefly — it notes that around 257 million people worldwide are HBsAg positive, lists the high-risk groups to be screened, states that ***the screening tests are surface antigen and antibody****, that* ***HBsAg-positive patients need six-monthly ultrasound for hepatocellular carcinoma (which can occur even without cirrhosis)****, and that* ***patients with cirrhosis or persistently raised transaminases with detectable HBV DNA should be treated with oral once-daily antivirals such as tenofovir, which prevent progression of and reverse fibrosis****. Detail on individual regimens and newer agents is supplemented from WHO, AASLD, EASL and APASL guidance.*

High-Yield Points

Virology and Natural History

1. HBV is a partially double-stranded DNA hepadnavirus. It persists as **covalently closed circular DNA (cccDNA)** in the hepatocyte nucleus and integrates into host DNA — this is **why complete cure is not achievable** with current drugs.
2. The infection passes through phases: **HBeAg-positive chronic infection (immune tolerant), HBeAg-positive chronic hepatitis, HBeAg-negative chronic infection (inactive carrier), HBeAg-negative chronic hepatitis, and the HBsAg-negative (occult) phase**. Phase determines whether to treat or to monitor.
3. **Elderly patients are usually in the HBeAg-negative phase**, with fluctuating ALT and HBV DNA, longer duration of infection, and therefore a higher cumulative risk of cirrhosis and hepatocellular carcinoma.

Goals and End Points

4. **The realistic goal is durable suppression of HBV DNA**, which prevents progression, reverses fibrosis, reduces decompensation and lowers HCC risk. Cirrhosis regression on long-term therapy is well documented.
5. End points are **virological (undetectable HBV DNA), biochemical (normal ALT), serological (HBeAg seroconversion; and the ideal, HBsAg loss with or without anti-HBs)**, and histological.
6. **'Functional cure' means sustained HBsAg loss with undetectable HBV DNA off treatment.** It is achieved in only about 1% per year with current nucleos(t)ide analogues, and is the target of all new drug development.

Older Modalities

7. **Conventional interferon-alfa** and then **pegylated interferon alfa-2a 180 µg subcutaneously once weekly for 48 weeks** — the advantages are a **finite duration, no resistance, and the highest rate of HBsAg loss**.
8. **Interferon is largely unsuitable for older patients** — flu-like illness, cytopenias, depression, thyroid dysfunction and autoimmune flares. It is **absolutely contraindicated in decompensated cirrhosis and autoimmune disease**.
9. **Lamivudine 100 mg daily** — the first oral nucleoside analogue; low genetic barrier, with resistance in about 70% by five years (YMDD mutation). **No longer first-line.**
10. **Adefovir dipivoxil** — weak antiviral effect and dose-dependent nephrotoxicity; **telbivudine** — potent but high resistance and myopathy/neuropathy. Both are obsolete.

Current First-Line Oral Therapy

11. Three high-barrier agents are first-line: **tenofovir disoproxil fumarate (TDF) 300 mg daily, tenofovir alafenamide (TAF) 25 mg daily, and entecavir 0.5 mg daily** (1 mg if lamivudine-experienced). All are once-daily, oral, and produce virtually no resistance over a decade.
12. **Choice in the elderly is decided by renal and bone safety.** TDF causes proximal tubular dysfunction, hypophosphataemia and loss of bone mineral density — a real hazard in patients already at risk of falls and fracture. **Prefer TAF or entecavir if eGFR is below 60, if there is osteoporosis, or if other nephrotoxic drugs are being used.** Entecavir itself needs dose reduction in renal impairment.

13. **Duration is usually indefinite.** In HBeAg-positive patients, treatment may be stopped after seroconversion plus at least 12 months of consolidation; in HBeAg-negative patients and in all cirrhotics, treatment is **lifelong** unless HBsAg is lost.
14. **Decompensated cirrhosis:** treat with **entecavir or tenofovir immediately and lifelong; never use interferon**. Refer simultaneously for transplant assessment.

Indications for Treatment and Monitoring

15. Classical indications: **any cirrhosis with detectable HBV DNA; HBV DNA above 2000 IU/mL with ALT above the upper limit of normal; significant fibrosis or inflammation; extrahepatic manifestations; and a family history of cirrhosis or HCC**.
16. **Antiviral prophylaxis is mandatory before immunosuppression.** All HBsAg-positive patients receiving chemotherapy, **rituximab**, high-dose steroids, TNF inhibitors or transplantation need prophylactic tenofovir or entecavir; anti-HBc-positive, HBsAg-negative patients need monitoring or prophylaxis depending on the regimen. This is a common and lethal omission in older oncology patients.
17. **Hepatocellular carcinoma surveillance every six months with ultrasound (with or without alpha-fetoprotein) is required in HBsAg-positive patients even without cirrhosis** — HBV causes HCC more often than other liver diseases in the absence of cirrhosis. Continue surveillance even after HBV DNA becomes undetectable.
18. Monitoring on therapy: **HBV DNA and ALT every 3–6 months, creatinine and serum phosphate on TDF, and quantitative HBsAg** where available; assess adherence at every visit.

Coinfection and Prevention

19. **Hepatitis D** is the most severe form of viral hepatitis; test every HBsAg-positive patient for anti-HDV. **Bulevirtide**, an entry inhibitor blocking the NTCP receptor, is the first specific approved therapy for chronic hepatitis D.
20. **HIV coinfection:** use an antiretroviral regimen containing tenofovir plus lamivudine or emtricitabine, so that both viruses are treated. Never treat HBV alone with lamivudine in a coinfected patient.
21. **Prevention:** hepatitis B vaccine with a **timely birth dose** (part of India's Universal Immunisation Programme), plus antiviral prophylaxis in highly viraemic pregnant women, is the foundation of elimination. Older adults who are non-immune and at risk should be vaccinated; response rates are lower with age, so post-vaccination anti-HBs testing and double-dose or adjuvanted schedules may be needed.

Newer Modalities in Development

22. **Antisense oligonucleotide — bepirovirsen.** The phase 2b B-Clear study showed sustained HBsAg and HBV DNA loss in roughly 9–10% of patients; phase 3 programmes are ongoing.
23. **Small interfering RNA (siRNA) — xalnesiran, imdusiran, elebsiran.** Xalnesiran with or without an immunomodulator produced HBsAg loss in a subset of patients (NEJM 2024). These silence viral transcripts and reduce HBsAg.
24. **Capsid assembly modulators** (core protein allosteric modulators) block nucleocapsid formation and cccDNA replenishment; **entry inhibitors** (bulevirtide) block NTCP; **nucleic acid polymers** (REP 2139) block subviral particle release.
25. **Immunotherapeutic approaches** — therapeutic vaccines, TLR7/TLR8 agonists, PD-1 checkpoint inhibitors and engineered T cells — aim to restore the exhausted HBV-specific T-cell response. Most current strategies use **combination therapy** on a nucleos(t)ide analogue backbone.

Latest Updates (2023 – Present)

- **WHO Guidelines on the prevention, diagnosis, care and treatment of chronic hepatitis B (released March 2024 at APASL, Kyoto)** — the single most important recent change. They **substantially simplify and expand eligibility for treatment**.
- **Expanded eligibility (WHO 2024):** treat **all adults and adolescents with cirrhosis or significant fibrosis (APRI >0.5 or transient elastography >7 kPa)**; treat where **HBV DNA >2000 IU/mL with ALT above the upper limit of normal**; and treat those with coinfection (HIV, HCV, HDV), a family history of cirrhosis or HCC, extrahepatic manifestations, or immunosuppression.
- **Simplified criteria for resource-limited settings:** where HBV DNA testing is unavailable, treatment may be started on **APRI alone, or on persistently abnormal ALT alone** — designed to overcome the

fact that **only about 3% of people with chronic hepatitis B globally were on treatment in 2022**.

- **Comparative analyses (JAMA Network Open 2024)** confirm the WHO 2024 criteria make a markedly higher proportion of treatment-naive patients eligible than AASLD 2018, EASL 2017 or APASL 2015 — the practical consequence is that many patients previously 'monitored' now qualify for antivirals.
- **Expanded PMTCT:** antiviral prophylaxis for pregnant women is broadened, with simpler criteria to determine eligibility, alongside universal timely birth-dose vaccination.
- **Point-of-care HBV DNA (viral load) testing and reflex testing** are recommended to decentralise care; **routine HDV testing** of all HBsAg-positive people is now advised.
- **Journal of Hepatology 2024** commentary on the WHO update sets out the implications for the next AASLD/EASL/APASL revisions — the direction of travel internationally is towards **'treat more, treat earlier, treat simply'**.
- **Treat-all debate:** multiple expert panels (including the broad Chinese Society of Hepatology 2022 criteria, which use any detectable HBV DNA) argue for further expansion, on the basis that even 'immune-tolerant' patients accumulate HBV integration and HCC risk.
- **TAF is increasingly preferred over TDF in older adults** because of superior renal and bone safety, though with a small unfavourable lipid effect; entecavir remains an excellent, inexpensive alternative in nucleos(t)ide-naive patients with normal renal function.
- **Functional cure pipeline (2023–2025):** siRNA and antisense agents (bepirovirsen, xalnesiran, imdusiran) combined with immunomodulators are in phase 2b/3; none is yet approved, and **nucleos(t)ide analogues remain the standard of care**.
- **Bulevirtide** has full European approval for chronic hepatitis D, with improving long-term combined virological and biochemical response data.
- **Indian context:** HBsAg prevalence is approximately 1–3%, classing India as intermediate endemicity with an estimated 3–4 crore people infected. The **National Viral Hepatitis Control Programme** provides free tenofovir and free testing, and the hepatitis B birth dose is part of the Universal Immunisation Programme. Cost and access make **generic tenofovir the practical first-line agent** in most Indian settings.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
Treat patients who have cirrhosis or persistently elevated transaminases with detectable HBV DNA.	**WHO 2024 substantially widened eligibility** — treat all with cirrhosis or significant fibrosis (APRI >0.5), and treat on ALT or APRI alone where HBV DNA testing is unavailable.
Tenofovir is named as the oral once-daily antiviral of choice.	Three first-line options exist — **TDF, TAF and entecavir**. **TAF or entecavir is preferred in older adults** with eGFR <60, osteoporosis or concurrent nephrotoxic drugs.
Six-monthly ultrasound surveillance for HCC in HBsAg-positive patients.	Unchanged and reinforced — **surveillance continues lifelong even after HBV DNA becomes undetectable**, because HBV DNA integration means HCC risk is reduced but not eliminated.
Screening tests for hepatitis B are surface antigen and antibody.	Add **anti-HBc, HBV DNA, HBeAg/anti-HBe, and anti-HDV testing in all HBsAg-positive people** (WHO 2024); point-of-care viral load testing is now recommended for decentralised care.
Antivirals prevent progression of and reverse fibrosis.	Confirmed, and extended — long-term nucleos(t)ide therapy is now documented to produce **regression of established cirrhosis** and to reduce decompensation, HCC and transplant need.
The textbook does not discuss newer agents.	**siRNA and antisense agents (bepirovirsen, xalnesiran) and capsid assembly modulators** target functional cure, but remain investigational; **bulevirtide** is the first approved therapy for hepatitis D.

Examiner's Tip — verbatim mark-earning lines

- "**cccDNA in the hepatocyte nucleus is why hepatitis B cannot be cured** — the achievable goal is durable viral suppression, and the aspirational goal is functional cure, meaning HBsAg loss."
- "Name the three first-line agents: **tenofovir disoproxil fumarate, tenofovir alafenamide and entecavir** — all high genetic barrier, once daily."
- "In an older patient with reduced eGFR or osteoporosis, **choose TAF or entecavir over TDF**."
- "**Interferon is contraindicated in decompensated cirrhosis**; use entecavir or tenofovir and refer for transplantation."
- "**Every HBsAg-positive patient starting rituximab, chemotherapy or high-dose steroids needs antiviral prophylaxis** — reactivation can be fulminant."
- "**HBV causes hepatocellular carcinoma even without cirrhosis** — hence six-monthly ultrasound surveillance in all HBsAg-positive patients."
- "The **WHO 2024 guidelines expanded and simplified treatment eligibility**, allowing initiation on APRI or ALT alone where viral load testing is not available."
- "**Test every hepatitis B patient for hepatitis D** — bulevirtide is the first specific approved therapy."

Q6. Liver Transplantation

High-Yield Points

Definition, Types and Indications

1. **Liver transplantation is often the best treatment for advanced cirrhosis, acute hepatic failure, and some liver cancers.** It is the only definitive therapy for end-stage liver disease.
2. Types are **deceased-donor transplantation (whole or split graft)**, **living-donor transplantation (usually right lobe from a near relative)**, auxiliary transplantation, and domino transplantation. **In India the large majority of liver transplants are living-donor**, because of the shortage of deceased donors.
3. Indications are: decompensated cirrhosis of any cause; **acute liver failure**; **hepatocellular carcinoma within Milan criteria** (a single lesion ≤5 cm, or up to three lesions each ≤3 cm, with no vascular invasion or extrahepatic spread); metabolic liver disease; and intractable complications such as refractory pruritus or recurrent cholangitis.
4. The commonest indications in older recipients are now **metabolic dysfunction-associated steatohepatitis (MASH/NASH), alcohol-related liver disease and hepatocellular carcinoma**. Hepatitis C as an indication has fallen sharply since direct-acting antivirals.

Selection and Timing — the MELD Score

5. The decision on when to offer transplantation is based on the **Model for End-stage Liver Disease (MELD)**, a mathematical formula that grades life expectancy in a cirrhotic patient.
6. **MELD parameters are creatinine, sodium, bilirubin and INR.** Multiple online calculators exist.
7. **At a MELD score of 17, a patient is likely to do better with a transplant than without one.** Practice is to **refer to a transplant clinic once MELD exceeds 15**, provided the patient is a reasonable candidate.
8. **A 'reasonable candidate' is one who is otherwise healthy — with no cancer, no dementia and no cardiovascular disease.** Kidney disease is not a bar, as such patients can be listed for a combined liver–kidney transplant.
9. **In patients over 70, additional requirements are a good performance status, a stable and supportive home life, and a reasonable likelihood of living 10 years with the transplant.**
10. Referral should also be triggered by the **first episode of decompensation** — ascites, variceal bleeding, hepatic encephalopathy or spontaneous bacterial peritonitis — even if MELD is still low.

Outcomes and the Age Question

11. **Carefully selected patients over 65 have a good prognosis, with about 80% five-year survival.**
12. In the Mayo Clinic study comparing **42 patients over 70 with 42 matched patients under 60, five-year survival was identical**. **Chronological age alone is therefore not a contraindication.**
13. **Donor age is likewise not an absolute bar** — Eurotransplant data show that **using livers from donors older than 70 should not be discouraged**, because survival rates are good. The liver is less affected by age than other organs.
14. **Geriatric patients who are otherwise healthy should be considered for liver transplantation** — under-referral on grounds of age alone is a recognised failure of care.

Pre-transplant Evaluation in the Older Candidate

15. The work-up must cover: **cardiac assessment** (echocardiography, stress testing, coronary angiography where indicated — coronary disease is the commonest reason for exclusion), **pulmonary assessment** for hepatopulmonary syndrome and portopulmonary hypertension, renal function, **malignancy and infection screening**, dental clearance, bone density, and psychosocial and caregiver assessment.
16. Assess **nutrition, sarcopenia and frailty** formally — these predict waitlist mortality and post-transplant recovery better than age. Assess cognition, because dementia is an exclusion, and confirm **abstinence, insight and social support** in alcohol-related disease.

Immunosuppression and Complications

17. Immunosuppression uses **induction (basiliximab or anti-thymocyte globulin)** and **maintenance with a calcineurin inhibitor (tacrolimus), an antimetabolite (mycophenolate) and tapering steroids**; mTOR inhibitors (everolimus, sirolimus) are used to spare renal function and in HCC.

18. **Older recipients need less immunosuppression** because of immunosenescence — they have **less acute rejection but more infection, more de novo malignancy and more calcineurin-inhibitor nephrotoxicity**. Drug–drug interactions with tacrolimus (azoles, macrolides, calcium channel blockers, statins) are a major practical hazard in the polypharmacy setting.

19. Complications: **primary non-function, hepatic artery thrombosis, biliary strictures and leaks, acute and chronic rejection, CMV and opportunistic infection, post-transplant lymphoproliferative disorder, recurrence of the original disease, chronic kidney disease, metabolic syndrome, osteoporosis and de novo malignancy**.

Legal Framework in India and Alternatives

20. In India, transplantation is governed by the **Transplantation of Human Organs Act 1994, amended in 2011 (Transplantation of Human Organs and Tissues Act, THOTA) with Rules 2014**. It defines brain-stem death, requires certification by a **board of four medical experts**, permits near-relative and swap donation, requires **authorisation committee approval for non-near-relative (altruistic) donation**, and makes **commercial dealing in organs a punishable offence**.

21. The organisational network is **NOTTO at national level, ROTTOs regionally and SOTTOs at state level**, under the National Organ Transplant Programme.

22. For patients who are not candidates, the alternatives are **optimal medical management of cirrhosis** (beta-blockers and band ligation for varices, diuretics and albumin for ascites, TIPS for refractory ascites or bleeding, lactulose and rifaximin for encephalopathy), **locoregional therapy for HCC (TACE, radiofrequency ablation, SBRT)**, and **early palliative care with advance care planning**. Median survival in untreated decompensated cirrhosis is about two years.

Latest Updates (2023 – Present)

- **MELD 3.0 was implemented for organ allocation in 2023.** It adds **female sex and serum albumin** to the existing variables, updates the creatinine ceiling and the interactions between components. It corrects the systematic disadvantage that MELD-Na imposed on women, who were being under-prioritised because of lower muscle mass and hence lower creatinine.
- **Machine perfusion has transformed organ preservation. Normothermic machine perfusion (NMP)** allows ex-vivo perfusion at body temperature with viability testing before implantation; **hypothermic oxygenated perfusion (HOPE)** reduces ischaemia–reperfusion injury and biliary complications.
- **UNOS/OPTN analyses (Transplantation Direct 2024; World J Transplant 2025)** show that NMP increases the use of donation-after-circulatory-death and extended-criteria grafts, and is associated with **better two-year patient and graft survival** in DCD recipients after propensity matching.
- **Machine perfusion is directly relevant to older recipients** — matched analyses show that despite receiving more marginal grafts (older donors, more DCD), elderly NMP recipients had **similar graft survival and a shorter length of stay**, so NMP may mitigate donor risk factors that would otherwise be relative contraindications.
- **Normothermic regional perfusion (NRP)** in the donor before retrieval, alone or combined with NMP, is now an established DCD strategy.
- **The Liver Frailty Index (grip strength, timed chair stands, balance testing)** is now a standard, validated waitlist assessment; **CT-measured sarcopenia at the L3 level** independently predicts waitlist and post-transplant mortality. Structured **prehabilitation** before transplantation is increasingly offered.
- **Early liver transplantation for severe alcohol-associated hepatitis** is now accepted in carefully selected patients, replacing the rigid six-month abstinence rule; selection is by psychosocial assessment rather than by a fixed time interval.
- **Allocation reform:** the United States has moved from regional boundaries to **acuity circles** and is moving towards **continuous distribution**, reducing geographic inequity.

- **Expanded donor pool: HCV-viraemic donors** are now used for HCV-negative recipients with short-course DAA prophylaxis, and **anti-HBc-positive donors** are used with antiviral prophylaxis — both are especially valuable for older candidates who cannot afford a long wait.
- **MASH/MASLD is now among the leading indications for liver transplantation** in high-income countries and is rising rapidly in India; these recipients are older and carry more cardiovascular and metabolic risk, so cardiac work-up standards have tightened.
- **Indian context:** India performs roughly 3,000–4,000 liver transplants a year, **the great majority living-donor**, and is second only to the USA in absolute LDLT numbers. Deceased-donation rates remain below one per million population. Recent national policy changes have **removed the upper age limit of 65 years for registration for deceased-donor organs**, removed the domicile requirement so a patient may register in any state, and removed the registration fee — all of which improve access for older Indian patients.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
MELD is based on creatinine, sodium, bilirubin and INR.	**MELD 3.0 (2023)** additionally incorporates **female sex and serum albumin**, correcting the disadvantage previously experienced by women on the waitlist.
Refer to a transplant clinic when MELD exceeds 15; transplant benefit begins around MELD 17.	Unchanged, but now supplemented by **referral at the first decompensating event** regardless of MELD, and by exception points for HCC and other conditions.
A reasonable candidate has no cancer, no dementia and no cardiovascular disease.	HCC **within Milan criteria is an indication, not an exclusion**; criteria have been extended (UCSF, up-to-seven) and downstaging protocols are accepted. Cardiovascular disease is assessed and treated rather than being an automatic bar.
Patients over 70 need good performance status and a likely 10-year survival.	Age-based thresholds have been replaced by **objective frailty and sarcopenia measurement (Liver Frailty Index, L3 skeletal muscle index)**, which predict outcome far better than chronological age.
Livers from donors older than 70 give good survival and should not be discouraged.	Reinforced, and extended — **machine perfusion allows objective viability testing** of marginal and older grafts before implantation, further safely expanding the donor pool.
Alcohol-related liver disease requires a period of abstinence before listing.	**Early transplantation for severe alcohol-associated hepatitis** is now accepted with psychosocial selection, without a mandatory six-month rule.

Examiner's Tip — verbatim mark-earning lines

- "**MELD uses creatinine, sodium, bilirubin and INR** — refer above 15, and transplant benefit exceeds risk at 17."
- "**Carefully selected patients over 65 achieve about 80% five-year survival**, and the Mayo series showed identical five-year survival in patients over 70 compared with matched patients under 60."
- "**Age is not a contraindication to liver transplantation — frailty is.**"
- "**Livers from donors older than 70 should not be discouraged** — the liver ages better than most other organs."
- "**Milan criteria: one lesion ≤5 cm, or up to three lesions each ≤3 cm, with no vascular invasion or extrahepatic spread.**"
- "Older recipients have **less rejection but more infection and malignancy** because of immunosenescence — reduce immunosuppression accordingly."
- "In India, transplantation is governed by **THOTA 1994/2011 with Rules 2014**; brain death is certified by a **board of four experts**, and commercial dealing is punishable."
- "Quote **MELD 3.0 and machine perfusion** as the two practice-changing advances since 2023."

Q7. Eye Donation

Eye donation is not covered as a topic in the uploaded textbook. *The textbook refers to corneal transplantation only in passing — noting that the corneal endothelium undergoes degenerative change with ageing, that these cells seldom proliferate in adult life so the cell population falls, and that in some patients* ***endothelial dystrophy progresses spontaneously to corneal oedema, and such cases require corneal transplants****. The content below is therefore drawn from the Transplantation of Human Organs and Tissues Act, the Standards of Eye Banking in India (DGHS/NPCB&VI;), Eye Bank Association of India documents and current peer-reviewed literature.*

High-Yield Points

Definition and Need

1. **Eye donation is the voluntary donation of the eyes after death**, for corneal transplantation, for research, or for training. **Only the cornea is transplanted — the whole eye cannot be transplanted**, because the optic nerve cannot be reconnected.
2. **Corneal blindness is a leading cause of avoidable blindness in India**, with a large accumulated backlog and a substantial annual incidence. Demand for donor tissue far exceeds supply, and **the utilisation rate of collected corneas is only about 50%**.
3. Corneal blindness is important in geriatrics because **pseudophakic and aphakic bullous keratopathy, Fuchs endothelial dystrophy, corneal degeneration and infective keratitis** are the typical indications in older Indian patients — and because **most donors are older adults**.

Legal and Organisational Framework in India

4. Eye banking is governed by the **Transplantation of Human Organs Act 1994, amended in 2011 (THOTA), with Rules 2014**. Eye banks and eye donation centres must be registered under the Act, and **commercial dealing in tissue is a punishable offence**.
5. **The National Programme for Control of Blindness and Visual Impairment (NPCB&VI;)** provides grants-in-aid for eye collection and infrastructure; the **Eye Bank Association of India (EBAI)** sets professional standards; and the **National Eye Bank at AIIMS, New Delhi** is the apex institution.
6. The service structure is a three-tier one — **eye donation centres** (motivate and collect), **eye retrieval centres** (retrieve tissue) and **eye banks** (retrieve, evaluate, preserve and distribute). Only a registered eye bank may distribute tissue.
7. **Service fees may be charged only to recover the cost** of retrieval, processing, storage and distribution; **there must be no profiteering**, and the charging policy must be approved by the competent authority.

Who Can Donate and Who Cannot

8. **Anyone can donate — any age, any sex, any blood group.** Spectacle wearers, people who have had cataract surgery, and those with diabetes or hypertension can all donate. Pledging during life is encouraged but is not legally binding.
9. **Absolute systemic contraindications:** death of unknown cause; **HIV; hepatitis B; hepatitis C; active syphilis; rabies; septicaemia; leukaemia and lymphoma; disseminated malignancy; Creutzfeldt–Jakob disease and other prion disease; active viral encephalitis; subacute sclerosing panencephalitis; congenital rubella; Reye syndrome; and tetanus**.
10. **Ocular contraindications:** retinoblastoma and other ocular malignancy, active ocular or intraocular inflammation, and previous anterior segment surgery of unknown nature. Prior refractive surgery is a relative contraindication for optical grafts.
11. **Even where an absolute contraindication exists, the family must be told clearly, and the eyes are not retrieved unless the family is fully informed and still wishes to donate.** Tissue unsuitable for transplantation may be used for research and training.

Procedure — What to Do at the Time of Death

12. **Inform the nearest eye bank immediately.** Eyes should be retrieved **within 6 hours of death** (this may be extended when the body is refrigerated).
13. Simple measures while awaiting the team: **close the eyelids; switch off the fan; raise the head of the body by about six inches; place moist cotton or a cold pack over the closed lids; instil**

antibiotic drops if available; and keep a copy of the death certificate ready.

14. **Written consent must be obtained on the prescribed form from the legal custodian or next of kin**, even if the deceased had pledged. Death must be certified by a registered medical practitioner, or the retrieval team must satisfy itself that life is extinct.
15. **Retrieval is by either enucleation (removal of the whole globe) or in-situ corneoscleral rim excision.** Corneoscleral excision is preferred in hospital programmes — it is quicker, uses less tissue and gives better cosmesis. It is performed by trained personnel using sterile technique, in a laminar flow hood or operating room where done in a laboratory.
16. **A donor blood sample is mandatory** and is tested for **HIV 1 and 2, HBsAg, anti-HCV and syphilis (VDRL/TPHA)**. The tissue is graded on **slit-lamp and specular microscopy**; **endothelial cell density (generally above 2000–2500 cells/mm²) determines whether tissue is optical grade or usable only for tectonic or therapeutic purposes**.

Preservation and Use

17. **Preservation options:** moist chamber (up to 24–48 hours), **McCarey–Kaufman medium (2–4 days)**, **Optisol-GS at 2–8°C (up to 14 days)** and **organ culture at 31–37°C (up to 4 weeks)**.
18. **Uses:** optical keratoplasty (penetrating keratoplasty, DALK, DSAEK, DMEK), therapeutic and tectonic grafts, patch grafts for glaucoma drainage devices, limbal stem cell transplantation, and research and surgical training.
19. **One donor traditionally gives sight to two people.** With modern component (lamellar) surgery, a single cornea can be split so that **one donor may benefit more than two recipients**.

Sources, Barriers and Promotion

20. **Voluntary (home-death) donation** gives lower yield and poorer tissue quality because of delay. **The Hospital Cornea Retrieval Programme (HCRP), launched by EBAI in 1991, is the main source of good-quality tissue** — trained grief counsellors approach the families of all patients dying in hospital.
21. **HCRP advantages:** no potential donor is missed; a detailed medical history is available to assess eligibility; younger donors are accessed; the death-to-retrieval interval is short; and it is cost-effective. **Structured grief counselling is the single most effective intervention** for raising consent conversion.
22. **Barriers:** lack of public awareness; family refusal at a time of grief; myths about disfigurement, religious objection and beliefs about rebirth; failure of hospital staff to intimate the eye bank; shortage of trained counsellors; non-uniform standards between eye banks; and inadequate accreditation.
23. **Promotion: National Eye Donation Fortnight is observed from 25 August to 8 September** every year. Other measures are pledge registration, mass media and community campaigns, involvement of religious and community leaders, and **sensitisation of ICU, casualty and ward staff** to identify and refer every eligible death.

Geriatric and Ethical Aspects

24. **Donor age is not a bar.** The Cornea Donor Study showed that graft survival at five and ten years is comparable across donor ages from 12 to 75 years — so older donors are entirely acceptable and are in fact the main donor pool.
25. The geriatrician's role is practical: **raise eye donation during advance care planning**, include it in advance directive discussions alongside organ and tissue donation, counsel families sensitively, and ensure timely intimation to the eye bank after an expected death.
26. **Ethical principles:** voluntary and informed consent; no reward, inducement or coercion; dignity and respect for the body; confidentiality between donor and recipient families; equitable allocation on clinical need; and complete **documentation, traceability and recall** systems.

Latest Updates (2023 – Present)

- **Standards of Eye Banking in India (2020, NPCB&VI; with EBAI)** — an updated national standard replacing the 2009 DGHS document. It sets accreditation criteria (an eye bank must collect at least **25 surgical-grade tissues a year** to be accredited, otherwise it is re-designated as an eye retrieval centre), mandates periodic re-inspection, restates that **service fees may only recover cost with no profiteering**, and requires documented tissue tracking and recall.

- **AIOS–EBAI consensus statement on cornea and eye banking during the COVID-19 era (Indian Journal of Ophthalmology 2020)** — added respiratory-infection screening of donors, deferral criteria, PPE requirements and safe restart protocols. It remains the template for pandemic preparedness in eye banking.
- **Shift from penetrating keratoplasty to endothelial and lamellar keratoplasty: DSAEK and DMEK for endothelial disease and DALK for stromal disease** now dominate practice. Because these use only part of the cornea, **a single donor cornea can be split between recipients**, effectively multiplying the impact of each donation.
- **Pre-cut and pre-loaded tissue** prepared by the eye bank (eye-bank-prepared DMEK/DSAEK grafts) reduces intra-operative tissue loss and surgeon preparation time, and is being adopted by larger Indian eye banks.
- **Cell-based therapy: cultivated human corneal endothelial cell injection** (pioneered in Japan) has shown durable restoration of corneal clarity in bullous keratopathy, and further trials are ongoing. If successful at scale, a single donor cornea could treat dozens of recipients.
- **Bioengineered corneal implants** from medical-grade porcine collagen (reported in Nature Biotechnology, 2022, with two-year outcomes in India and Iran) restored vision in advanced keratoconus with a minimally invasive, suture-free technique — a potential low-cost alternative to donor tissue in resource-limited settings.
- **National Organ Transplant Programme policy changes (2023–2024)** — the Union Health Ministry directed states to **remove the upper age limit of 65 years for registration for deceased-donor organs**, to **remove the domicile requirement** so that a patient may register in any state, and to **abolish registration fees**. These reduce structural barriers for older patients across transplantation.
- **2025 prospective Indian studies (including from Gandhi Medical College, Bhopal)** confirm that **dedicated grief counselling within the HCRP significantly increases both willingness to donate and actual conversion to donation** — supporting investment in counsellor posts rather than in mass publicity alone.
- **Persisting gap:** India procures a substantial number of corneas each year but the **utilisation rate remains around 50%**. Current policy emphasis has therefore shifted from raising collection numbers to **improving tissue quality, shortening death-to-preservation time, standardising medical criteria and strengthening HCRP**.
- **Regenerative and alternative approaches** — simple limbal epithelial transplantation (SLET), cultivated limbal epithelial transplantation (CLET) and keratoprosthesis (Boston KPro, LVP-KPro) — reduce dependence on donor tissue in bilateral limbal stem cell deficiency and repeated graft failure.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
The textbook mentions only that corneal endothelial dystrophy progressing to corneal oedema requires a corneal transplant.	Endothelial disease is now treated by **DSAEK or DMEK rather than full-thickness penetrating keratoplasty**, with faster visual recovery, lower rejection rates and the ability to split a single donor cornea between recipients.
No guidance is given on the source of donor tissue.	The **Hospital Cornea Retrieval Programme (HCRP)**, not voluntary home-death donation, is now the principal source of surgical-grade tissue in India.
No preservation guidance is given.	**Optisol-GS at 2–8°C allows storage up to 14 days** and organ culture up to 4 weeks, replacing moist-chamber storage for planned surgery.
No donor age guidance is given.	The **Cornea Donor Study** established that graft survival is comparable for donors aged 12 to 75 — **older age is not a bar to corneal donation**.
Corneal transplantation depends entirely on donor tissue.	**Cultivated corneal endothelial cell therapy, bioengineered collagen implants, SLET/CLET and keratoprosthesis** are emerging alternatives that will reduce dependence on donor corneas.

Examiner's Tip — verbatim mark-earning lines

- "**Only the cornea is transplanted — the whole eye cannot be transplanted**, because the optic nerve cannot be reconnected."
- "**Eyes must be retrieved within 6 hours of death.** Close the lids, switch off the fan, raise the head six inches, apply moist cotton or ice packs, and inform the eye bank at once."
- "**Consent must come from the legal custodian even if the deceased had pledged** — a pledge is not legally binding in India."
- "Name the absolute contraindications: **death of unknown cause, HIV, hepatitis B and C, rabies, septicaemia, syphilis, leukaemia and lymphoma, disseminated malignancy, CJD, viral encephalitis, SSPE, congenital rubella and tetanus**."
- "**Age is not a bar to eye donation** — spectacle wearers, cataract-operated patients, diabetics and hypertensives can all donate."
- "**The Hospital Cornea Retrieval Programme (EBAI, 1991) is the main source of good-quality tissue** — it avoids missing donors, gives a full medical history and shortens the death-to-retrieval interval."
- "**National Eye Donation Fortnight runs from 25 August to 8 September** each year."
- "Eye banking is regulated under **THOTA 1994/2011 with Rules 2014**, supported by NPCB&VI;, with EBAI setting standards and the National Eye Bank at AIIMS as the apex centre."
- "**One donor gives sight to two people** — and with lamellar surgery, to more than two."

Q8. Sleep Protocol

*In geriatric practice a 'sleep protocol' means a **standardised, non-pharmacological package of measures used to promote sleep in older people — particularly hospitalised older people — so that sedative-hypnotic drugs can be avoided**. It has two components: the ward-level non-pharmacological sleep protocol (a core element of delirium prevention), and the sleep hygiene and behavioural programme used for chronic insomnia. Both are covered below.*

High-Yield Points

Definition and Rationale

1. A sleep protocol is a **written, nurse-delivered, non-drug bundle of measures given at bedtime** to any older patient who has difficulty initiating sleep or who requests a sedative, with the aim of avoiding hypnotic drugs.
2. It is needed because **hospitalised older people sleep badly** — noise, light, nocturnal observations and blood sampling, pain, nocturia, unfamiliar environment and daytime inactivity all fragment sleep — and because **sedative-hypnotics in older people cause delirium, falls, fractures, daytime sedation, cognitive impairment and increased mortality**.
3. **Normal ageing changes in sleep** must be distinguished from disease: **increased sleep latency, reduced deep (slow-wave) sleep, reduced REM sleep, more frequent awakenings, reduced sleep efficiency, phase advance (early to bed and early to rise), and more daytime napping**. Total sleep need does not change much.

The Classical Non-pharmacological Sleep Protocol

4. The original protocol (McDowell and Inouye, JAGS 1998) has **three components — a warm drink (milk or herbal tea), relaxation music or tapes, and a back rub or massage**.
5. **It is given to any patient complaining of difficulty initiating sleep or requesting a sedative; the sedative is given only if the patient still requests it after one hour.** Adherence in the original study was 74%, and it **substantially reduced the use of sedative-hypnotic drugs** with no toxicity.
6. The sleep protocol is one of six standardised protocols in the **Hospital Elder Life Program (HELP)**, alongside those for cognitive impairment, immobility, visual impairment, hearing impairment and dehydration. **HELP prevents delirium in 30–40% of cases** and reduces falls, length of stay and cost.

Environmental and Unit-Level Measures

7. **Reduce noise:** silent pagers and mobile phones, lowered alarm and television volume, soft-close bins and doors, staff conversation moved away from the bedside, and designated **'quiet hours' (typically 10 pm to 6 am)**.
8. **Control light:** dim corridor and bay lights at night, use torches rather than overhead lights, and provide **eye masks and earplugs** to willing patients.
9. **Cluster nursing activities** so that patients are not woken repeatedly. **Avoid non-essential night-time observations, blood sampling, weighing and medication rounds**; give diuretics early in the day and avoid overnight intravenous fluids where possible.
10. **Treat what wakes the patient:** pain (multimodal analgesia), dyspnoea, cough, nocturia, gastro-oesophageal reflux, pruritus, cramps and anxiety.

Daytime Measures — Chronotherapy

11. **Increase daytime activity, especially outdoors and in sunlight;** get the patient out of bed, dressed in day clothes, and mobilised. **Avoid prolonged daytime sleep and going to bed too early.**
12. **Scheduled bright-light therapy** resynchronises the circadian rhythm by entraining the suprachiasmatic nucleus to the light/dark cycle, and is particularly useful in institutionalised elders and in dementia. Timing must be individualised.
13. **Exercise timing matters:** afternoon exercise advances the biological clock, while exercise at night delays the circadian phase. Light exercise should be finished **at least three hours before bedtime**.

Sleep Hygiene Measures

14. **Keep a regular schedule** — go to bed and wake at the same time daily; constant changes increase the probability of severe, chronic sleep difficulty.
15. **Optimise the environment** — temperature about 18–21°C, no noise or light, a proper mattress. **Avoid heavy meals, but do not go to bed hungry or thirsty**; dairy products contain tryptophan, which helps induce sleep.
16. **Limit stimulants** — coffee, tea, cola, alcohol and nicotine, especially after 5 pm. Alcohol is often self-prescribed for insomnia but **shortens latency and then fragments the second half of the night**.
17. **Remain in bed no more than eight hours** — spending too long in bed produces fragmented, light sleep. **Allow a nap after the midday meal of no more than 30 minutes.** Follow a fixed **bedtime ritual**.

Assessment Before and During the Protocol

18. **Take a full sleep history** from the patient and, where possible, the bed partner or caregiver. Ask specifically about mood, since insomnia and depression have a two-way relationship.
19. **Rule out treatable specific sleep disorders** — **obstructive sleep apnoea** (loud snoring, witnessed apnoea, daytime sleepiness; treat with CPAP), **restless legs syndrome** (check iron; dopaminergics), **periodic limb movement disorder**, **REM sleep behaviour disorder** (clonazepam; and it predicts Parkinson's disease and dementia), and **advanced sleep phase**.
20. **Review the drug chart** — beta-blockers, corticosteroids, NSAIDs, bronchodilators, diuretics, SSRIs, cholinesterase inhibitors, decongestants and caffeine-containing preparations all disturb sleep.
21. **Keep a sleep diary for a minimum of two consecutive weeks**, because of day-to-day variability. Actigraphy or wrist accelerometers may help. **Polysomnography, multiple sleep latency testing and maintenance of wakefulness testing are not routinely required** for insomnia unless another disorder is suspected.

When Drugs Are Considered

22. **Cognitive behavioural therapy for insomnia (CBT-I) is the first-line treatment** — sleep restriction, stimulus control, relaxation, cognitive restructuring and sleep hygiene. **It is effective even in patients with cognitive decline**, and its benefit outlasts drug therapy.
23. **Melatonin is the hypnotic of first choice when a drug is indicated in a patient over 55.** It improves sleep latency and quality without altering sleep architecture, shows efficacy for up to six months with **no tolerance, rebound or withdrawal**, does not impair next-morning psychomotor performance or driving, and **does not increase postural instability (unlike zolpidem)**. In mild-to-moderate Alzheimer's disease it was associated with significantly less cognitive impairment.
24. **Avoid benzodiazepines and Z-drugs.** They shorten sleep latency and increase total sleep time but **do not improve, and may worsen, daytime function**. Z-drugs such as zolpidem cause awakenings, complex behaviours (sleepwalking, hallucinations) and rebound; the class causes memory and cognitive impairment, disinhibition, delirium, falls, accidents and increased mortality.
25. **Avoid antihistamines** — their anticholinergic effect causes urinary retention, constipation and delirium. **Avoid quetiapine even at low doses**, and use other antipsychotics only with great caution because of the risk of sudden death in the elderly.
26. If a hypnotic is unavoidable, use the **lowest effective dose for the shortest possible time, with a documented review date and exit plan**, and never continue a hospital-initiated hypnotic on the discharge prescription.

Special Settings and Outcomes

27. **Institutionalised elders** are at particular risk because of comorbidity, polypharmacy and the institutional environment (loud noise, low light exposure, few circadian cues). They need an **integrated pharmacological and environmental approach**; circadian disorders respond well to chronotherapy, melatonin and properly scheduled light therapy, **thereby avoiding the need for sedative-hypnotics**.
28. **Outcomes of a sleep protocol:** reduced hypnotic use, less delirium, fewer falls, shorter length of stay, better patient satisfaction, and no adverse events — at negligible cost. Monitor with a sleep diary, the **Pittsburgh Sleep Quality Index, Insomnia Severity Index and Epworth Sleepiness Scale**, and hand over the sleep plan at every nursing shift change.

Latest Updates (2023 – Present)

- **2023 AGS Beers Criteria** — benzodiazepines, non-benzodiazepine 'Z-drug' hypnotics (zolpidem, zopiclone, eszopiclone) and first-generation antihistamines remain **potentially inappropriate medications in all older adults** and should be avoided for insomnia. This reinforces the non-pharmacological protocol as the default.
- **Digital CBT-I (dCBT-I)** delivered by app or web is now shown to be effective in older adults and addresses the chronic shortage of trained therapists; it is increasingly recommended as a first step where face-to-face CBT-I is unavailable.
- **Dual orexin receptor antagonists (DORAs) — suvorexant, lemborexant and daridorexant — are the most important new drug class.** A systematic review and meta-analysis in older adults showed that compared with placebo they **reduce wake after sleep onset and latency to persistent sleep and increase total sleep time at both 1 and 3 months**, including subjective total sleep time.
- **Safety profile of DORAs in the elderly: daridorexant showed a favourable safety profile**, whereas lemborexant and suvorexant had higher rates of treatment-emergent adverse events than placebo, without an increase in serious adverse events. Class effects to counsel about are **nightmares, abnormal dreams, sleep paralysis, hallucinations and next-day somnolence**.
- **Agent selection by sleep parameter:** network meta-analyses suggest **lemborexant is best for sleep onset** and **daridorexant for sleep maintenance**; daridorexant also has the lowest rebound risk, and is therefore the preferred agent when switching during deprescribing.
- **Deprescribing guidance:** expert consensus opposes a blanket prohibition on long-term use of DORAs and some non-benzodiazepine agents, but requires **periodic re-evaluation of the risk-benefit balance, particularly in older adults**; when stopping, **taper gradually** rather than stopping abruptly.
- **DORAs and delirium:** small studies of suvorexant and lemborexant in critically ill and post-operative patients suggest a possible reduction in delirium incidence, in contrast with benzodiazepines; the evidence is not yet strong enough for routine recommendation.
- **Melatonin and ramelteon for delirium prevention** have shown inconsistent results across trials and meta-analyses, and melatonin is not universally endorsed for this indication — but it remains the preferred hypnotic in older adults with insomnia.
- **Multicomponent non-pharmacological bundles** — earplugs and eye masks, relaxation and guided imagery, massage, music therapy, aromatherapy and warm milk-based drinks — were confirmed in 2024–2025 systematic reviews to improve sleep quality and duration in hospitalised adults, **with no adverse events reported**. Back massage in one study increased total sleep time by more than an hour.
- **Sleep and dementia risk:** longitudinal data continue to link insomnia and short sleep with subsequent cognitive impairment, and short sleep (under six hours) with higher cardiovascular mortality — strengthening the case for treating sleep as a modifiable risk factor rather than a nuisance symptom.
- **Indian context:** hypnotic and benzodiazepine prescribing to older adults remains high and is often over-the-counter; alprazolam and diazepam are widely used despite their long half-lives. Practical priorities are **deprescribing benzodiazepines, screening for OSA (which is underdiagnosed in India), and building simple ward sleep protocols into NPHCE geriatric wards and district hospital care**.

Current Practice Update

Textbook Position	Current Evidence / Guideline Position
Sleep hygiene and cognitive behavioural therapy are the first level of action.	Unchanged and strengthened — **CBT-I is first-line for chronic insomnia at every age**, and **digital CBT-I** now extends access. Sleep hygiene alone is insufficient as monotherapy for chronic insomnia.
Melatonin is the treatment of first choice when a hypnotic is indicated in patients over 55.	Still the preferred first hypnotic, but **dual orexin receptor antagonists are now a validated second option** with meta-analytic support in older adults and a better safety profile than Z-drugs.

Textbook Position	Current Evidence / Guideline Position
Benzodiazepines and Z-drugs are listed with dosing in the pharmacological table but with cautions.	The **2023 AGS Beers Criteria classify all benzodiazepines and Z-drugs as potentially inappropriate in older adults** — they should be avoided for insomnia, and existing prescriptions should be actively deprescribed with a taper.
Antihistamines should be avoided because of anticholinergic effects; quetiapine is not recommended.	Unchanged and reinforced by anticholinergic burden and antipsychotic mortality data.
Polysomnography and MSLT are not routinely recommended for insomnia.	Unchanged, but **consumer wearables and validated actigraphy** are increasingly used for longitudinal monitoring, complementing the two-week sleep diary.
The pharmacological table does not include the orexin antagonist class.	**Suvorexant, lemborexant and daridorexant** are now available; select **lemborexant for sleep-onset insomnia and daridorexant for sleep-maintenance insomnia and where deprescribing is planned**.

Examiner's Tip — verbatim mark-earning lines

- "The classical non-pharmacological sleep protocol has **three components — a warm drink, relaxation music, and a back rub** — and the sedative is given only if the patient still asks for it after one hour."
- "The sleep protocol is one of the **six HELP protocols**; the other five target cognitive impairment, immobility, visual impairment, hearing impairment and dehydration. **HELP prevents delirium in 30–40% of cases.**"
- "Name the ageing changes in sleep: **increased sleep latency, less slow-wave and REM sleep, more awakenings, reduced sleep efficiency, and phase advance**."
- "**CBT-I is first-line, and is effective even in patients with cognitive decline.**"
- "**Melatonin is the hypnotic of first choice in patients over 55** — no tolerance, no rebound, no withdrawal, and unlike zolpidem it does not increase postural instability."
- "**Benzodiazepines and Z-drugs do not improve daytime function and may worsen it**, and are potentially inappropriate in all older adults under the 2023 Beers Criteria."
- "**Avoid antihistamines and avoid quetiapine even at low doses** for sleep in older people."
- "Keep a **sleep diary for a minimum of two consecutive weeks**; polysomnography is not routinely needed for insomnia."
- "In institutionalised elders, use an **integrated environmental and pharmacological approach with chronotherapy, melatonin and timed light therapy — thereby avoiding sedative-hypnotics**."

Rehabilitation in Geriatric Medicine

MD Geriatric Medicine — Examination Compilation

High-Yield Answers with Latest Updates (2023–2026)

Ten Questions • Textbook Core + Current Evidence + Indian Context

Primary references: Pathy’s Principles and Practice of Geriatric Medicine (6th edition)
Kane’s Essentials of Clinical Geriatrics

Prepared for Dr. Sudarsan | Compiled 19 August 2026

Contents

1.	Definition, evaluation and components of rehabilitation in the elderly	15 marks
2.	Heading an interdisciplinary rehabilitation ward — team selection, job responsibilities, conflict management and care planning	15 marks
3.	Role of the occupational therapist on the team caring for the older person, on the ward and at discharge	15 marks
4.	Stroke rehabilitation — factors to consider before initiating long-term rehabilitation	15 marks
5.	Rehabilitation of an older adult with low vision	15 marks
6.	Rehabilitation of a patient with osteoarthritis of the knee joints	15 marks
7.	Community-based rehabilitation	15 marks
8.	Mobility aids	15 marks
9.	Assistive devices for the elderly	15 marks
10.	Artificial limb — rehabilitation of the elderly amputee	15 marks

How to use this compilation

Each answer follows the same architecture: **High-Yield Points** (textbook core) → **Latest Updates (2023–present)** with named trials and guidelines → **Current Practice Update** comparing textbook position with current evidence → **Exam One-Liners** for rapid recall. All laboratory and clinical values are in Indian conventional units. Indian epidemiology, programmes and legal frameworks are integrated throughout.

Five threads that run through every answer in this module

1. **WHA76.6 (May 2023)** — the first-ever World Health Assembly resolution on rehabilitation; rehabilitation is now an essential service within Universal Health Coverage.
2. **2.41 billion people** worldwide would benefit from rehabilitation (up 63% since 1990); **over half in LMICs receive none**.
3. **“No rehabilitation potential” is no longer an acceptable reason to deny access** (BGS 2024).
4. **Geriatric rehabilitation now reduces mortality, care-home admission and functional impairment** (BMC Medicine meta-analysis 2024).
5. **Indian delivery web:** NPHCE (19 Regional Geriatric Centres, 2 National Centres for Ageing) + DDRCs in all districts + ADIP/ALIMCO + Rashtriya Vayoshri Yojana + AB-PMJAY extended to all aged ≥70 years (2024).

Q1. Definition, evaluation and components of rehabilitation in the elderly

High-Yield Points

A. Terminology and Definition

1. **Rehabilitation** is a process that seeks to **minimise activity and participation restrictions resulting from impairment**.
2. **UN definition:** a **goal-oriented and time-limited process** enabling an impaired person to reach an **optimum mental, physical and/or social functional level**, giving them the tools to change their own life. Includes measures to **compensate for lost function** (technical aids) and to **facilitate social adjustment or readjustment**.
3. The current framework is the **WHO ICF (2001)**, replacing ICIDH (1980). Part 1 — Functioning and Disability: (a) Body Functions and Structures, (b) Activities and Participation. Part 2 — Contextual Factors: (a) Environmental, (b) Personal.
4. **Key definitions: Impairment** = problem in body function/structure; **Activity** = execution of a task; **Activity limitation** = difficulty executing activities; **Participation** = involvement in a life situation; **Participation restriction** = problem in that involvement. **Functioning** is the umbrella positive term; **disability** the collective negative term.
5. Functioning results from a **dynamic interaction between the health condition and contextual factors**. **Vicious cycles** develop easily — e.g. Parkinson's disease → fall → hip fracture → loss of confidence → isolation → depression → further decline.
6. **Why the elderly differ:** the biggest single reason is **lack of physiological reserve** to combat a disabling insult. Recovery is **prolonged** and often **does not return to the premorbid state**; ongoing limitations from osteoarthritis, Parkinson's disease and other comorbidities coexist.

B. Determinants of Disability

7. **Determinants of activity restriction:** type of impairment (nature and severity), **presence of associated impairments**, **degree of physiological reserve**, and **level of physical fitness**. Weight training improves muscle strength and functional capacity even in old age.
8. **Determinants of participation restriction:** *Intrinsic* — attitude, personality, **ability to adjust**, cultural issues. *Extrinsic* — financial resources, housing, other resources, **social supports** (spouse, family, neighbours, friends, pets). **Elderly women are particularly disadvantaged**, often widowed and living alone.
9. **Psychological aspects:** loss of function produces a **grief-like reaction** — denial → anger → depression → acceptance. Over **40% become depressed after myocardial infarction**; depression is high after stroke and worsens prognosis. **Kemp's model:** motivation is driven by **wants, beliefs and rewards**, counteracted by the **cost** in pain and effort.

C. Principles of Rehabilitation

10. **Early intervention is crucial** — avoidable restriction occurs soon after impairment and once established may be irremediable (e.g. correct positioning of a flaccid hemiplegic arm prevents **shoulder subluxation**).

11. **The team approach is essential** — medical and nursing staff, **physiotherapist, occupational therapist, speech and language therapist**, clinical psychologist, dietician, social worker. **Doctors treat impairment; remedial therapists treat activity restriction; social workers treat participation restriction; nurses have a holistic role.** Regular **formal team meetings** review progress, revise goals, plan discharge and arrange follow-up.

D. The Rehabilitation Process — Eight Steps

12. **Assessment → Goal setting → Therapy → Aids and adaptations → Education → Psychological support → Evaluation → Follow-up.** These overlap in practice and must be revisited **at least weekly**.

E. Evaluation / Assessment

13. **Purpose:** to confirm the problem is **remediable**, to select suitable patients, and to record a **baseline functional status** so progress can be measured. It must address both *"the problem in the individual"* and *"the individual with the problem"*. Denying rehabilitation to those who may benefit even slightly is unjustified.
14. **Assessment of activity restriction** begins with the clinical history, comparing **premorbid** and **current** function using **ADLs** (washing, grooming, dressing, toileting, feeding) and **IADLs** (cooking, telephone, laundry, shopping, housework, transport). Ask **how the person manages** — is the task neglected, or is help given?

Standardised scales endorsed by the Royal College of Physicians and British Geriatrics Society:

Domain	Scale	Comment
Basic ADLs	**Barthel Index**	Observation of what the patient *does*; **ceiling effect** in ambulatory patients
Vision, hearing, communication	**Lambeth Disability Screening Questionnaire**	Postal questionnaire
Memory and cognition	**Abbreviated Mental Test (AMT)**	10 items from the longer Roth–Hopkins test
Depression	**Geriatric Depression Scale**	30 items; 15-item short form
Subjective morale	**Philadelphia Geriatric Center Morale Scale**	Distinct from depression

15. The **Functional Independence Measure (FIM)** scores **18 functions** across **self-care, sphincter control, mobility, locomotion, communication and social cognition**. **Assessment of participation restriction is subjective, unstable over time and largely neglected** in clinical and research settings.

F. Components / Remaining Steps

16. **Goal setting:** goals must be **realistic**, agreed by **the patient and all team members**, split into **short-term (intermediate)** and **long-term (final)** goals with **flexible time frames**, reviewed regularly. Patients with ambitious goals progress more — so set goals that are **ambitious but achievable** (e.g. wheelchair independence rather than walking for some amputees).
17. **Therapy:** the doctor manages disease, comorbidity, risk factors and complications; **OT** enhances ADL competence; **physiotherapist** targets cardiorespiratory, neuromuscular and

locomotor function; **speech and language therapist** manages communication and swallowing.

18. **Aids and adaptations:** a **prosthesis** replaces a body part; an **orthosis** is applied externally to support, improve function, or restrict/promote movement. Aids may **foster dependence if wrongly prescribed**, yet many in real need never obtain even basic aids. **Home modification** (handrails, ramps, shower/toilet access) after an early **OT home visit** facilitates timely discharge.
19. **Education and secondary prevention:** teach disease, aetiology, risk factors, management and prognosis; individual or group formats; **discussion groups allow mutual support**. **Psychosocial support:** good listening, regular reassurance, **honest positive feedback without false expectations**, the ward **"therapeutic community"**, and **self-help groups** after discharge.
20. **Discharge planning and follow-up:** discharge is a **transition, not the conclusion**, of rehabilitation. **Evaluation:** rehabilitation is **resource-intensive**, so at minimum **entry versus discharge data** must be collected using standardised measures.
21. **Settings:** rehabilitation hospitals, designated units in general hospitals, general wards, nursing homes, **day hospitals**, community day centres, outpatient centres and the patient's own home. **Stroke units improve survival and functional outcome**; evidence for ortho-geriatric units is described as less convincing. **Intermediate care** = intensive, short-term, community- or home-based rehabilitation that prevents admission, enables early discharge and maximises independent living.
22. **Emerging technologies:** wearable **sensors** giving objective quantitative data, **virtual reality platforms**, and **video-capture technology** — overcoming the subjectivity and inter-observer variability of existing scales.

Latest Updates (2023–Present)

1. WHO / policy — the biggest change

The **first-ever resolution dedicated to rehabilitation, WHA76.6 "Strengthening rehabilitation in health systems", was adopted by all 194 Member States at the 76th World Health Assembly in May 2023**. As much as **half of those needing rehabilitation do not receive it**, especially in LMICs. It calls for **expanding and integrating rehabilitation into health systems as part of Universal Health Coverage**, stressing **primary care** and **emergency preparedness and response**, and names the **critical shortage of rehabilitation workforce**. WHO will report progress in **2026, 2028 and 2030**. The **3rd Global Rehabilitation 2030 meeting (July 2023)** launched the **World Rehabilitation Alliance**.

2. Efficacy now proven for hard outcomes

A **2024 systematic review and meta-analysis (BMC Medicine)** of RCTs in adults ≥65 years found that **geriatric rehabilitation in inpatient and day-hospital settings reduced mortality, long-term care home admission and functional impairment**, with **no difference in length of stay, mood or quality of life**.

3. End of "no rehabilitation potential" as a rationing tool

The **British Geriatrics Society 2024 report "Reablement, Rehabilitation and Recovery — everyone's business"** argues that rehabilitation **reduces hospital admissions, length of stay and carer burden while improving function**, should be **a component of every service caring for older people**, and that **rationing access on the dubious basis of "no rehabilitation potential" must end** (Age and Ageing, 2025).

4. Prehabilitation — rehabilitation moved *before* the insult

The **PREHAB randomised clinical trial (JAMA Surgery, 2023)** showed multimodal prehabilitation reduced postoperative complications and enhanced functional capacity after colorectal cancer surgery. A **2025 JAGS meta-analysis** confirmed that multimodal prehabilitation before colorectal cancer surgery **shortens hospital stay, lowers complication rates and speeds bowel recovery, particularly in older populations**. A **2025 meta-analysis in frail older adults** used the **6-minute walk test and length of stay** as endpoints, noting that frailty reduces resilience to surgical stress and the **preoperative window is a better opportunity than the postoperative period**. **Psychological prehabilitation** (mainly CBT) reduced length of stay, pain, anxiety and depression (Annals of Surgery, 2025).

5. Technology and telerehabilitation — from "emerging" to mainstream

A **network meta-analysis of 52 RCTs (npj Digital Medicine, 2023)** compared **VR exergaming, serious gaming, wearables and telerehabilitation** for balance and functional mobility in adults ≥60. A growing body of evidence supports **eHealth improving outcomes in geriatric rehabilitation** (Age and Ageing, 2025). However, a **2025 JMIR Aging rapid review** flags **ethics and equity concerns — internet access, technology adoption and digital literacy**.

6. Related guideline updates

A **clinical practice guideline on Comprehensive Geriatric Assessment in hospital** (issued May 2024, published Dtsch Arztebl Int 2025) provides 12 evidence-based and 8 consensus-based recommendations, including a **screening-CGA algorithm to determine operability and indication for surgery**. **Guidelines for Rehabilitation Interventions in Older Adults with Sarcopenia (2025)** address sarcopenia as a driver of falls, disability and mortality — **resistance training plus protein supplementation** remains the core intervention.

7. Indian context

NPHCE delivers promotional, preventive, curative and **rehabilitative** services through **19 Regional Geriatric Centres** and **2 National Centres for Ageing (AIIMS New Delhi; Madras Medical College, Chennai)**, with coverage extended to **713 districts**. **AB-PMJAY was extended in 2024 to all senior citizens aged ≥70 years**, giving **₹5 lakh per family per year free treatment irrespective of socioeconomic status**. **LASI wave-1 (2017–18, n = 31,477 aged ≥60): 7.4% had ADL dependency**; injurious falls 5.7%, impaired vision 13.7%, impaired hearing 9.6%, impaired cognition 9.3%, incontinence 4.0%; a higher number of geriatric and chronic conditions predicted ADL dependency.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Framework	ICF (2001) with impairment–activity–participation	ICF retained, now nested within the WHO Healthy Ageing / intrinsic capacity model and **WHA76.6**, making rehabilitation an **essential health service within UHC**
Evidence base	"Research is coming of age"; efficacy still being proven	**Proven** — 2024 meta-analysis shows reduced mortality, reduced institutionalisation, better function
Patient selection	Assess first to ensure the problem is "remediable"	Selection retained, but **"no rehabilitation potential" is no longer an acceptable reason to deny access** (BGS 2024)
Timing	Early intervention *after* the impairment	Extended **backwards to prehabilitation** — pre-operative exercise, nutrition and psychological support in frail surgical patients
Technology	"Emerging" — sensors, VR, video capture	**Mainstream** — telerehabilitation, exergaming and wearables have RCT/NMA evidence; **digital equity** is now the limiting issue
Ortho-geriatric units	Evidence "less convincing" than stroke units	**Superseded** — orthogeriatric co-management is standard of care in hip fracture pathways
Setting	Range of options; intermediate care emerging	Strong push toward **primary-care-integrated and home-based rehabilitation**, explicitly named in WHA76.6
Funding (India)	Not addressed	**AB-PMJAY ≥70 years (2024)** + NPHCE Regional Geriatric Centres provide delivery and financing

Exam One-Liners

- **Rehabilitation** = goal-oriented, time-limited process to restore optimum physical, mental and social function (UN definition).
- **ICF 2001** = Functioning/Disability + Contextual Factors; replaced ICIDH 1980.
- **Impairment → activity limitation → participation restriction** is the core chain.
- Greatest difference in elderly rehabilitation = **reduced physiological reserve**.
- **8 steps:** Assessment, Goals, Therapy, Aids, Education, Psychological support, Evaluation, Follow-up.
- **Barthel Index** = basic ADLs, has a **ceiling effect**; **FIM** = 18 items, 6 domains.
- **AMT** = 10 items; **GDS** = 30 items (15 short form); **PGC Morale Scale** = subjective morale.
- **Prosthesis** replaces a body part; **orthosis** is applied externally.
- **Intermediate care** = short-term intensive community rehab to prevent admission and enable early discharge.
- **Stroke units improve survival and function** — the strongest single evidence in geriatric rehabilitation.
- **WHA76.6 (May 2023)** = first-ever WHO resolution on rehabilitation; ~50% of global need unmet.

- **Prehabilitation** is the 2023–2025 paradigm shift — intervene before the surgical insult.
- Discharge is a **transition, not the end**, of the rehabilitation process.

Q2. Heading an interdisciplinary rehabilitation ward — team selection, job responsibilities, conflict management and care planning

High-Yield Points

A. Concept and Rationale

1. **Geriatric care implies team care.** No single discipline can address the impairment–activity–participation chain in a frail older person. Team care means **trusting other disciplines** with the tasks for which they are trained, while ensuring they **never work in isolation**.
2. **Terminology:** *Multidisciplinary* = each discipline assesses and treats in parallel. **Interdisciplinary** = disciplines assess separately but **plan and set goals jointly at a common team conference**, with shared responsibility for a single care plan.
3. **The ward runs on the 8-step process:** Assessment → **Goal setting** → Therapy → Aids and adaptations → Education → Psychological support → Evaluation → Follow-up. The head of the ward must ensure every step has a **named owner and a target date**.

B. Team Selection and Composition

4. **Minimum core team:** physician (geriatrician), nurses, physiotherapist, occupational therapist and social worker. **Optimal team** adds speech and language therapist, clinical psychologist, dietician, pharmacist, prosthetist/orthotist, podiatrist and home-care coordinator. **Dedicated administrative support is essential** and often forgotten.
5. **Special geriatric expertise among team members is crucial** — a therapist trained in general adult practice is not automatically competent in frailty, delirium and multimorbidity. Select on **interest, aptitude and training in ageing**.
6. **Optimum working team size is 4–7 members**, united by a **common sense of direction and purpose**. Every member must be able to state **their specific and their general contribution**. A **flexible working style crossing conventional professional boundaries** gives the greatest job satisfaction and the most effective patient care.
7. **Staffing must be structurally supported:** dedicated units require **additional therapist establishment** and **environmental adaptations** (handrails, non-slip flooring, orientation clocks and calendars, safe walking circuits).

C. Job Responsibilities

The core rule: doctors manage impairment; remedial therapists manage activity restriction; social workers manage participation restriction; nurses have a holistic brief influencing both.

Member	Core responsibility on a rehabilitation ward
Geriatrician (team head)	Diagnose and treat impairment and comorbidity; **deprescribe**; anticipate and prevent complications; medical fitness for therapy; chair the team conference; governance and audit
Rehabilitation nurse	**24-hour rehabilitation nursing** — reinforce therapy goals between sessions; skin, continence, nutrition, delirium prevention; **encourage the patient to *do* rather than be *done for***
Physiotherapist	Relieve pain; maintain and improve **joint range of motion, strength, endurance, coordination**; **gait and balance training**; assess need for and teach use of walking aids and wheelchairs
Occupational therapist	Assess and enhance **basic ADLs and IADLs**; **environmental assessment and home visit**; prescribe **assistive devices** and home modifications
Speech and language therapist	**Communication disorders and dysphagia**; swallow assessment; diet-texture recommendations
Clinical psychologist	Mood, motivation, cognition; adjustment and grief reaction; behavioural interventions
Dietician	Nutritional assessment, oral nutritional supplementation, protein adequacy for muscle rebuilding
Social worker	**Participation restriction**; family and carer assessment; finances, benefits, placement, community linkage
Pharmacist	Medication reconciliation, **anticholinergic burden**, falls-risk drugs, adherence aids
Prosthetist / orthotist	Design, construction and fitting of **prostheses** (replace a body part) and **orthoses** (support, improve function, restrict or promote movement)
Patient and family carer	**Full team members** — they set the goals that matter and continue therapy after discharge

D. Team Process and Leadership

9. **Effective teams do not arise spontaneously.** They evolve through **forming → storming → norming → performing**, and reaching the performing stage needs **commitment, skill and time**. The **storming phase is normal and expected**, not a sign of failure.
10. **The interdisciplinary team conference is the single most critical structure.** Held **after each member has completed their individual assessment**, it brings all perspectives together, **generates new ideas, sets priorities, disseminates the full assessment, and avoids duplication or incongruity.** Most successful trials of geriatric assessment included such a conference.
11. **The team leader must strike a balance** between **over-structuring** ward activity and allowing individuals to **function totally independently in a non-hierarchical vacuum**. Both extremes damage care.
12. **Efficient team care does not mean endless meetings. Co-location** allows frequent informal exchange, supplemented by **regular formal meetings**. What the team needs is a **common language and a common playbook**.

E. Care Planning

13. **Five elements for every problem in the care plan:** (i) the **problem**, (ii) the **goal**, (iii) the **approach/intervention**, (iv) the **target date**, (v) the **discipline responsible**.
14. **Timing:** initial assessment within days of admission; **formal care-planning meeting within 1–2 weeks**; therapy review **daily to weekly**; full care plan review **at least every 3 months** or on significant change. Reassessment at least **weekly** during active rehabilitation.
15. **Goal-setting rules: realistic**, based on **premorbid function**, **agreed by the patient and every team member**, split into **short-term** and **long-term** goals with **flexible, regularly reviewed time frames**. Set goals that are **ambitious but achievable**.
16. **Not every patient can improve.** For those who cannot, the plan must shift explicitly to **maintenance of function and prevention of further decline**. **Small functional gains still improve the chance of discharge home and quality of life.**
17. **WHO ICOPE 5-step pathway:** screen → detailed person-centred assessment → set goals and build a personalised care plan with the older person, caregiver and team → implement and monitor with specialist referral → enlist community and support the caregiver.
18. **Documentation: SOAP format** for progress notes; a **face sheet** carrying the essential database (diagnoses, drugs, contacts, treatment-intensity preferences) that travels with the patient; and **flow sheets** with serial functional scores (**Barthel Index, FIM**).

F. Conflict Management

19. **The commonest source of conflict is goal divergence** — *"a programme can be seriously compromised if key people differ on what each is trying to achieve."* The primary preventive strategy is **explicit, documented, jointly agreed goals** with the patient present. Other recurring sources: **role blurring**, **discharge-timing pressure**, **family-versus-patient wishes**, and **resource competition** for therapy slots.

> **Textbook-derived conflict prevention on the ward**
>
> - Ensure every member knows **what the other professions can do and when to call on their skills** — ignorance of others' scope drives most territorial disputes.
> - Use the **team conference to eliminate duplication and incongruity** before it becomes friction.
> - Accept **role flexibility across boundaries** as a strength, but keep **core accountability clearly assigned**.
> - Involve the **patient and carer** at some stage of every plan, preserving the **principle of choice** — this pre-empts family conflict.
> - In ethical disagreements, **the older person's own wishes are paramount**. **Avoid paternalism and the temptation to infantilise the frail patient.**
> - Build **trust deliberately** — like a sports team, healthcare teams must practise together.

G. Evaluation and Governance

20. **Rehabilitation is resource-intensive and must prove its effectiveness.** At minimum, collect **standardised entry and discharge data** on every patient.
21. **Run a team-based QAPI cycle:** each discipline reports its data → team reviews **quality indicators** → sets targets → develops a plan and a measurement method → **assigns an individual or subcommittee** → progress report at the next meeting. Use **run charts,**

fishbone diagrams and root-cause analysis. Ward indicators: **falls with injury, pressure ulcers, restraint use, Barthel/FIM gain, discharge-to-home rate, length of stay, 30-day readmission.**

22. **Geriatricians are ideally placed to lead** because **interdisciplinary management and teamwork are at the core of geriatric training**, and geriatricians are comfortable **entrusting responsibility to team members and sharing the problem-solving process**.

Latest Updates (2023–Present)

1. Chairing the team meeting is an evidence-based skill

A **2025 observational study of interprofessional collaboration during multidisciplinary team meetings in geriatric rehabilitation (BMC Geriatrics)** found collaboration **improves when the meeting is led by a designated person with leadership skills** — the ability to organise and to build strong team relationships. The **chair is accountable for coordination and adherence**, and **involving complementary participants — professionals, patients and informal caregivers — shifts the discussion from monodisciplinary or multidisciplinary objectives to common interprofessional goals.**

2. Psychological safety is the current framework for team climate

A **2025 Frontiers in Medicine** paper applies **Clark's four stages — inclusion safety, learner safety, contributor safety and challenger safety** — and identifies **well-defined roles and responsibilities as a direct driver of psychological safety**. **AHRQ's TeamSTEPPS** was developed to overcome the difficulty of speaking up in a hierarchical system, **empowering every team member to voice observations and concerns**.

3. Named conflict-management tools for clinical teams

AHRQ TeamSTEPPS (reviewed 2023) provides: **formative feedback**, **CUS** (when conflict places the patient at risk), the **Two-Challenge Rule** (differing information), and the **DESC script**.
DESC = **D**escribe the specific situation → **E**xpress your concern → **S**uggest alternatives → state **C**onsequences in terms of patient/team goals.
CUS = "I am **C**oncerned… I am **U**ncomfortable… this is a **S**afety issue."

4. Conflict-management styles in practice

A **2024 systematic review in Nursing Reports** (22 studies, 2014–2024) found **accommodation and collaboration/integration are the most common styles among nurses, with compromising also frequent**, and recognises **five styles: dominating, integrating, compromising, avoiding and obliging**. **Avoidance was most common among experienced and managerial nurses**, while **collaboration was favoured by more highly educated nurses**; younger nurses tended toward compromising and accommodating, older nurses toward collaboration. **Competing was the least prevalent**. **Proactive strategies are more effective at preventing conflict than reactive ones**, and tailored conflict-management training is recommended.

5. Interdisciplinary care written into guidelines, and the case for the ward

The **2024 VA/DoD Clinical Practice Guideline for Stroke Rehabilitation** is written with **explicit emphasis on an interdisciplinary care approach**. The **2024 BMC Medicine meta-analysis** showed geriatric rehabilitation **reduced mortality, care-home admission and functional impairment**; the **BGS 2024 report** argues rehabilitation should be a component of every service for older people and that denying access on the basis of "no rehabilitation potential" should end. A **2023 BMC Geriatrics focus-group study** identified **involvement of the person with dementia in goal setting** and the **mediating role of team members** as the key challenges, but found the refined model achieved **well-functioning, competence-enhancing and time-saving teamwork**.

6. Indian context

NPHCE delivers rehabilitative geriatric services through **19 Regional Geriatric Centres** and **2 National Centres for Ageing**. **AB-PMJAY extended to all citizens aged ≥70 years** (₹5 lakh per family per year) creates a funding pathway for post-acute rehabilitation. Practical constraints in Indian units: **absent or shared therapist posts, no dedicated clinical psychologist or prosthetist, and heavy dependence on family attendants** — so **task-sharing and structured family training** must be built into the care plan from day one.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Team meeting leadership	Leader is "usually the senior physician"; balance structure vs autonomy	**A designated, trained chair with organisational and relational skills** is the key determinant of collaboration — can be any discipline
Team development	Forming–storming–norming–performing	Retained, supplemented by **psychological safety (Clark's 4 stages)** as the measurable team climate outcome
Conflict management	Addressed indirectly — align goals, avoid duplication, build trust	**Named, teachable tools**: TeamSTEPPS **DESC, CUS, Two-Challenge Rule**; **collaboration** preferred, **avoidance** commonest but least effective
Patient in the team	Involve patient "at some stage"	Patient and informal caregiver are **participants in the team meeting itself**, converting disciplinary objectives into **common interprofessional goals**
Patient selection	Assess first to confirm the problem is remediable	**"No rehabilitation potential" is no longer an acceptable exclusion criterion** (BGS 2024)
Evidence for the ward	Stroke units proven; ortho-geriatric units less convincing	**Geriatric rehabilitation proven to reduce mortality and institutionalisation**; orthogeriatric co-management is standard care
Team size	4–7 members	Unchanged, but **pharmacist and dietician are now near-core**, given deprescribing and sarcopenia evidence

Exam One-Liners

- **Multidisciplinary** = parallel working; **interdisciplinary** = shared goals and one common care plan.
- **Doctors treat impairment, therapists treat activity restriction, social workers treat participation restriction, nurses do all three.**
- **Optimum team size = 4–7**, with a shared sense of direction.
- **Team stages:** forming → storming → norming → performing; storming is normal.
- The **interdisciplinary team conference** sets priorities, shares assessments and **prevents duplication and incongruity**.
- **Every care-plan entry needs:** problem, goal, approach, **target date**, responsible discipline.
- **Care plan timing:** meeting within **1–2 weeks**, review **3-monthly** or on change; therapy review **weekly**.
- **Commonest cause of team conflict = divergent goals.**
- **DESC** = Describe, Express, Suggest, Consequences; **CUS** = Concerned, Uncomfortable, Safety issue.
- **Five conflict styles:** dominating, integrating, compromising, avoiding, obliging. **Collaboration is best; avoidance is commonest.**
- **QAPI cycle:** report data → set targets → plan → assign owner → re-measure at next meeting.
- Effective team care needs **a common language and a common playbook** — it never happens spontaneously.

Q3. Role of the occupational therapist on the team caring for the older person, on the ward and at discharge

High-Yield Points

A. Conceptual Basis

1. **Occupational therapy (OT) views humans as "occupational beings" — who we are is defined by what we do. Occupations** are the ordinary and extraordinary things people do daily that occupy time, ensure survival, maintain well-being, nurture others, contribute to society and carry cultural meaning.
2. **The core aim of OT in old age is to enable the elder to keep doing the activities that are personally meaningful to them**, thereby preserving **quality of life** — not merely to restore muscle power.
3. **In ICF terms, the doctor works on impairment while the OT works on the Activity and Participation boxes** — OT converts a treated disease into a life that can actually be lived.
4. **The guiding model is PEOP (Person–Environment–Occupation–Performance/ Participation)**, complementary to the WHO ICF:
   Elder quality of life = f (Personal attributes × Environmental factors × Occupational performance/participation)
   - **Person (intrinsic):** physiological, motor, **cognitive**, neurobehavioural, psychological and spiritual capacity; plus **motivation, roles, habits and routines**.
   - **Environment (extrinsic):** social support, economic systems, **culture and values**, technology, the **built environment** and the natural environment.
5. **OT services span the whole continuum: primary** (health promotion, home-safety and fall prevention, driver screening), **secondary** (arthritis, stroke, dementia), **tertiary** (rehabilitation, long-term care, palliative and hospice care). Delivered at **three levels**: to individuals and families, as **consultation to community organisations**, and as **consultation to government agencies**.

B. The OT Process

6. **The process:** patient identification → **occupational profile** → **occupational performance assessment** → identification of needs, problems and priorities → **collaborative goal setting** → occupation-based intervention → ongoing assessment and refinement → outcomes met → **final/discharge assessment**. The **Occupational Therapy Practice Framework (OTPF)** is the guiding protocol.
7. **The occupational profile is the first and most distinctive step.** It records the person's **occupational history, current patterns of daily living, interests, values and needs**, then their **own priorities and concerns**. The approach is **top-down and client-centred** — the elder names the activities that matter, and the plan is built backwards from them.
8. **Occupational performance assessment** uses **valid, standardised instruments**, but crucially **the therapist observes the actual performance of the selected activity** — skilled observation covering **affect, cognitive/executive function and motor function**

together. **Assessment is ideally done in the person's own environment, since performance in an unfamiliar setting can be quite different.**

9. **The third focus is identifying barriers — biological, psychological and social —** between the older person and their desired activities.

C. Role on the Ward

10. **Baseline and premorbid functional assessment.** Establish competence in **basic ADLs** (feeding, dressing, bathing, grooming, toileting, transfers) and **IADLs** (cooking, cleaning, shopping, telephone, laundry, medication and money management, transport), comparing **premorbid with current** status.
11. **Core ward objectives (Kane):** restore, maintain and improve **independent function**; evaluate and improve **sensory and perceptual-motor function**; evaluate and improve **ADL performance**; **fabricate and fit upper-limb splints**; improve **coping and problem-solving skills**; improve **use of leisure time**.
12. **Ward modalities:** assessment of **bed mobility, transfers and wheelchair propulsion**; **ADL practice in actual or simulated environments** (a mock kitchen or bathroom on the ward); **task-oriented activities** such as crafts and projects; and **teaching the use of assistive and safety devices**.
13. **Prescribing and training in aids is the OT's specific expertise.** Common items: **long-handled reacher, sock aid, built-up cutlery and cooking utensils, dressing stick, raised toilet seat with rails, shower chair/tall stool, handheld shower, grab bars and rails. Devices are recommended only if they improve participation in an activity the elder or family has identified as important. A wrongly chosen aid fosters dependence rather than independence** — yet many with real need never obtain even basic aids.
14. **Disease-specific ward work:** reinforcing **hip precautions** after arthroplasty; **upper-limb positioning and splinting** in hemiplegia to prevent contracture and subluxation; **task simplification, sequencing cues and environmental orientation** in dementia; **energy conservation and joint protection** in arthritis, COPD and heart failure; **transfer devices** (trapeze, transfer pole, raised quarter-length siderail) and **bed/toilet height matched to lower-leg length** as part of **restraint reduction**.
15. **Education and secondary prevention: body mechanics, joint protection, energy conservation, activity and exercise guidance, sleep hygiene**; psychosocially — **role adjustment, balanced purposeful activity, time management, mastery and self-esteem, and socialisation skills**.
16. **Team role:** the OT feeds directly into the **interdisciplinary team conference**, translating medical impairment into functional terms. **The OT's functional verdict frequently decides the discharge destination.**

D. Role at Discharge

17. **The pre-discharge home visit is the OT's signature intervention. Early OT input, usually including a home visit, ensures that modifications are appropriate and timed to facilitate hospital discharge** — done late, it becomes a cause of delayed discharge rather than a solution.
18. **Home environmental assessment and modification:** improved **lighting in halls and stairways**, **grab bars in the bathroom**, **removal of loose rugs and clutter**, **ramps and railings**, non-slip surfaces, covers on electrical sockets and locks on cupboards where cognition is impaired. **Interventions that assess and modify home safety features**

reduce falls, and are more effective when carried out specifically by an occupational therapist.

19. **Practical discharge preparation:** review **all ADL and IADL implications immediately before discharge**; arrange equipment to be in place **before the patient goes home**; advise on **furniture height for sitting, rising, eating and leisure** (including chair-leg extensions); train the **family carer**; and arrange a **separate community OT visit after discharge** for tasks assessable only at home, such as kitchen work.
20. **Post-discharge and community role:** graded return to **IADLs and valued roles**, **carer education and coping support**, adaptation of **technology** (smartphone, appliances, voice-activation software), **driving assessment** (OT and neuropsychology form the second tier, after clinical assessment and before on-road testing), and helping the person **come to terms with driving cessation by focusing on preserved areas of achievement** while the social worker arranges alternative transport.
21. **Discharge from OT itself is a defined step.** Services are discontinued when **targeted outcomes are met**, *or* when the elder **cannot achieve them despite refinement of the plan**. A **final assessment** is performed, and outcome data are used to plan future therapy, discontinue services and **evaluate the service programme**.
22. **The commonest cause of failed OT discharge planning is well-meaning over-help.** If caregivers bathe and dress a patient who has independence goals, **those goals will not be achieved** — "helping" produces **deconditioning, dependency, contractures and the sequelae of immobility**. A **restorative philosophy of care must continue at home**.
23. **Fundamental principle:** OT supports the older person's **autonomy in setting priorities and making decisions**, and preserves their **mastery and control over their own environment and lifestyle**.

Latest Updates (2023–Present)

1. Home hazard reduction — high-certainty evidence and OT's strongest card

The **2023 Cochrane review (Clemson et al., CD013258)** included **22 studies from 10 countries with 8463 community-dwelling older people** (mean age 78, 65% women). **Home fall-hazard interventions reduce the overall rate of falls by 26% (RaR 0.74, 95% CI 0.61–0.91; 12 studies, 5293 participants; moderate-certainty evidence)**, and are **substantially more effective in people selected for higher fall risk, with a 38% reduction (RaR 0.62, 95% CI 0.56–0.70)**. In contrast, **assistive devices alone (eyeglasses, specialised footwear, bed alarms) and education alone do not reduce falls.**

2. NICE NG249 (April 2025) — the OT is named in guideline text

NICE recommends **offering a home hazard assessment and intervention using a validated tool**, and states: **"consider having the home hazard assessment and intervention… carried out by an occupational therapist."** If not an OT, it may be done by an **appropriately trained healthcare professional, or a trained therapy assistant or technician under supervision**. The rationale is explicit: **greater clinical benefit was seen when the intervention was delivered by an occupational therapist**, and **health economic modelling found OT delivery both less costly and more effective** than delivery by an assistant or technician. Benefit was greatest in people who had **fallen at**

least once in the previous year. NG249 also **advises against standalone falls risk-prediction tools**.

3. Real-world implementation, ED extension and early supported discharge

A **pilot implementation study of OT-led environmental assessment and modification** in a regional Australian health service (2019–2022; 279 chart audits of people ≥65 at high fall risk) found **71% had sustained ≥1 fall and 52% ≥2 falls** in the preceding year; the intervention was **delivered per protocol, embedded and sustained**, with **OT precision in selecting recipients improving over time**; a **national implementation study began in 2025**. A **Geriatric ED Guidelines 2.0 systematic review (Academic Emergency Medicine, 2025)** appraised **PT/OT evaluations introduced into ED care for fall-risk evaluation and prevention** — promising but not yet definitive. A **2024 BMC Geriatrics systematic review and meta-analysis** examined **early supported discharge** after orthopaedic surgery, where OT is the pivotal discipline.

4. Policy and Indian context

WHA76.6 (May 2023) calls for expanding and integrating rehabilitation into health systems within **Universal Health Coverage**, with emphasis on **primary care**; the **World Federation of Occupational Therapists (WFOT)**, with ReLAB-HS, has issued guidance translating the resolution into advocacy for **inclusion of occupational therapy services within UHC**. In India, **Rashtriya Vayoshri Yojana** provides **free assisted-living devices** to BPL senior citizens (monthly income ≤ ₹15,000) with **doorstep delivery for those aged ≥80**, **ALIMCO** as sole implementing agency; at least **30% of beneficiaries in each district must be women**. The OT must **prescribe within what RVY, ALIMCO and the family can actually obtain**, and must **train the family attendant**, since one-to-one community OT follow-up is rarely available.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Home hazard assessment	Home modification promotes activity and participation; more effective when done by an OT	**Quantified and guideline-mandated — 26% fall reduction overall, 38% in high-risk people** (Cochrane 2023); NICE NG249 names the OT
Who should do it	Advice on aids "best left to OTs or others with expertise"	**Health-economic modelling shows OT delivery is both cheaper and more effective** than assistant/technician delivery
Assistive devices alone	Aids reduce activity and participation restriction	**Devices or education alone do not reduce falls** — they work only inside a targeted, individualised package
Targeting	Assess before entry to ensure the problem is remediable	**Target by fall history** — benefit is concentrated in those who fell in the last year
Risk prediction tools	Not addressed	**NICE 2025 advises against standalone falls risk-prediction tools** — assess and act, don't score
Setting of assessment	Ideally in the person's own environment	Reinforced, plus **remote/video and 3D home assessment** emerging where OT numbers limit home visits
Timing	Early OT input including a home visit facilitates discharge	Extended into **ED-based OT evaluation** and **early supported discharge** models
Scope	Individual, community and agency levels	**Named in global policy** — WHA76.6 and WFOT advocacy place OT inside UHC packages

Exam One-Liners

- **OT enables occupation; physiotherapy restores movement.** OT owns the **Activity and Participation** domains of the ICF.
- **PEOP model:** Person–Environment–Occupation–Performance/Participation; complementary to the WHO ICF.
- **Occupational profile** = the client-centred, **top-down** first step.
- **Assess by observation, and assess at home** — performance in an unfamiliar environment differs.
- **OT ward objectives:** independent function, sensory-perceptual motor function, ADLs, **upper-limb splinting**, coping/problem-solving, leisure.
- **Classic OT aids:** long-handled reacher, **sock aid**, built-up cutlery, dressing stick, raised toilet seat with rails, shower chair, grab bars.
- **A wrongly prescribed aid fosters dependence, not independence.**
- **The pre-discharge home visit must be early**, or it becomes a cause of delayed discharge.
- **Home fall-hazard reduction: 26% fewer falls overall, 38% fewer in high-risk older people** (Cochrane 2023).
- **NICE NG249 (2025):** offer home hazard assessment with a validated tool; **consider having an OT do it** — cheaper and more effective.

- **Devices alone and education alone do not prevent falls.**
- **OT is the second tier of driving assessment**, between clinical evaluation and the on-road test.
- **Over-helping at home undoes rehabilitation** — deconditioning, dependency, contractures.
- **OT discharge criteria:** goals met, **or** goals unachievable despite refinement — then final assessment and discontinuation.
- **India: Rashtriya Vayoshri Yojana** supplies free assistive devices to BPL elders through **ALIMCO**.

Q4. Stroke rehabilitation — factors to consider before initiating long-term rehabilitation

High-Yield Points

A. Principle of Selection

1. **Every stroke patient deserves an assessment and consideration for intensive rehabilitation.** Selection is about *matching the programme to the person*, never about denying entry.
2. **Formal assessment before entry is essential** — to confirm the problems are **remediable** and to determine optimal management. **It is unfair to subject a person who cannot benefit to a demanding programme, raise false expectations and waste resources; equally, those who can benefit even to a limited extent must not be denied access.**

B. Factors Determining Prognosis Before Starting Long-Term Rehabilitation

The five classical prognostic factors (Kane):

Factor	What to assess
1. Availability and implementation of a sound programme	Is a properly resourced multidisciplinary team, unit and follow-up service actually available? A good candidate with no programme gains nothing
2. Mentation	Cognition, comprehension, **memory and learning capacity** — rehabilitation is **motor relearning**, so a patient who cannot retain instruction cannot progress
3. Motivation	The patient's drive to engage; the strongest modifiable predictor of outcome
4. Prognosis for neurological return	Site, size and type of lesion; severity of deficit; time since onset
5. Vigour	Physiological reserve, stamina, cardiorespiratory fitness, nutrition — the capacity to *tolerate* daily therapy

4. **Mentation in detail:** assess **conscious level, orientation, attention, memory, comprehension and executive function**, using tools such as the **Abbreviated Mental Test**. Look for **pre-existing dementia, post-stroke delirium and post-stroke dementia** (roughly **a quarter of stroke survivors are demented after stroke, of whom about 10% were already demented before the first stroke**). **Aphasia must be distinguished from cognitive failure** — a patient with pure expressive dysphasia may have intact learning capacity.
5. **Motivation in detail:** use **Kemp's model** — motivation is driven by the patient's **wants, beliefs and rewards**, opposed by the **cost in pain and effort**. Modify each element: set attainable goals, correct false beliefs, create rewards, reduce the physical and emotional cost. At one extreme are patients who set ambitious goals; at the other, those who **surrender autonomy and adopt the "sick role"**.
6. **Screen for depression before and during rehabilitation. Depression is common after stroke, persists despite participation in a rehabilitation programme, and worsens**

prognosis — an untreated depression will be misread as “poor motivation” and wrongly used to exclude the patient. Use the **Geriatric Depression Scale**; treat before concluding the patient is unsuitable.

7. **Prognosis for neurological return depends heavily on timing. Most neurological recovery occurs in the first month after stroke; by the end of the third month, little if any further return can be expected.** Rehabilitation must therefore be **started early**.
8. **Not all deficits are equally disabling. Motor loss is often the least disabling. Sensory and perceptual loss, aphasia, loss of balance, hemispatial (hemicorporeal) neglect, hemianopia and cognitive impairment cause more severe and often untreatable disability.**
9. **Vigour and reserve:** assess **premorbid functional status, cardiorespiratory fitness, nutrition, anaemia, sarcopenia, pain and continence**. The elderly patient’s core problem is **lack of physiological reserve**. **Coexisting impairments** (osteoarthritis, Parkinson’s disease, visual and hearing loss, prior stroke) each **multiply** disability.
10. **Medical stability and complication risk must be settled first.** Confirm **swallowing safety, control of blood pressure and glycaemia, absence of active sepsis, adequate cardiac status, control of seizures**. **Complications to prevent actively: pressure sores, contractures, phlebitis, pulmonary embolism, aspiration pneumonia and faecal impaction**.
11. **Social and environmental factors decide participation.** *Intrinsic:* attitude, personality, **ability to adjust**, cultural factors. *Extrinsic:* **financial resources, housing, availability of a carer, social supports**. **Elderly women living alone are especially disadvantaged.**
12. **Set the goals before starting.** Goals must be **realistic, agreed by the patient and every team member, ambitious but achievable**, split into **short-term** and **long-term** goals with **flexible, regularly reviewed time frames**. Goal divergence between team members is the commonest cause of a failed programme.
13. **Decide the discharge destination and the endpoint at the start** — home with family, home with supports, day hospital, or long-term care. Assessment must address **both “the problem in the individual” and “the individual with the problem”**.

C. Content of Stroke Rehabilitation

14. **Acute phase measures:** change position **at least 2-hourly**; **position joints to prevent contractures**; **position to prevent aspiration pneumonia**; perform **range-of-motion exercises**. **A flaccid hemiplegic limb is at risk of shoulder subluxation** — proper handling and limb positioning in the immediate post-stroke period minimises this risk.
15. **Later phase measures: ADL training, ambulation training, functional activities for the affected side, muscle re-education exercises, perceptual training, and training in transfer technique.** Treatment aims both to **re-educate affected muscles** and to **enhance remaining capacity in unaffected areas**.
16. **Specific evidence-based techniques: constraint-induced movement therapy** produces significant and clinically relevant improvement in arm motor function **in patients 3–9 months after a first stroke**; **treadmill training** repeatedly improves **gait and balance**; **robot-assisted motor training** and **brain–computer interfaces** show early positive results.
17. **Long-term: ongoing exercise and physical activity after the formal programme are critical** — they maintain function and quality of life **and help prevent further strokes**.

D. Setting and Endpoint

18. **Organised stroke unit care improves survival and functional outcomes** (Stroke Unit Trialists' Collaboration). **Patients cared for in stroke centres are more likely to be alive, independent and living at home one year after the stroke.**
19. **Stroke patients may do better in dedicated acute rehabilitation facilities than in skilled nursing facilities.** Whatever the setting, **the basic principles and the multidisciplinary team remain the same**.
20. **When the patient stops making progress despite intensive therapy, the goal shifts from restoration to coping.** Assess the need for **braces, orthoses and assistive devices** for both ambulation and ADLs, and switch to **maintenance of function and prevention of decline**.
21. **Even the most severely affected can gain something.** Complete functional recovery occurs in **less than half** of stroke patients, but **immobility and its complications can almost always be prevented or minimised**.
22. **Discharge is a transition, not the conclusion.** Follow-up is essential so that any new or worsening activity or participation restriction is detected and remedied.

Latest Updates (2023–Present)

1. NICE NG236 (18 October 2023) — the biggest change is *dose*

NICE's stroke rehabilitation guideline, which **replaces CG162**, recommends: **offer needs-based rehabilitation for at least 3 hours a day, on at least 5 days a week**, covering a range of multidisciplinary therapy including **physiotherapy, occupational therapy and speech and language therapy**. Once the person has left hospital, **care and rehabilitation should continue for as long as it continues to help them achieve their treatment goals**. **Early supported discharge should be offered to people who can move from bed to chair independently or with assistance**, provided a safe environment can be arranged, with **therapy continued at the same intensity and level of skilled support as in hospital**. The previous daily target of **40–45 minutes has been raised to 3 hours**.

2. NG236 rationale and the ESD evidence

The committee found that **early supported discharge reduced physical dependency and length of hospital stay**, and either improved or did not worsen health-related quality of life, with **no difference in mortality, carer quality of life, Caregiver Strain Index or readmission rates**, though **a clinically important increase in falls** was seen in a limited number of studies. Rehabilitation **should not be withdrawn after a fixed period**. NG236 also recommends **NMES as an option for shoulder pain**, and a **trial of NMES, FES or TENS for focal spasticity**.

3. VA/DoD 2024 and drugs for motor recovery

The **2024 VA/DoD Clinical Practice Guideline**, updating the 2019 version, provides recommendations for rehabilitation management after stroke with **explicit emphasis on an interdisciplinary care approach**. AHA/ASA guidance holds that the effectiveness of **fluoxetine or other SSRIs to enhance motor recovery is not well established**, the effectiveness of **levodopa is not well established**, and **dextroamphetamine or**

methylphenidate to facilitate motor recovery is not recommended. **NMES may be considered for shoulder pain**; a **formal fall-prevention programme during hospitalisation** is recommended, with **exercise plus balance training after discharge**.

4. Neuromodulation has entered clinical practice

The **2021 FDA approval of the Vivistim paired vagus nerve stimulation system** was the first regulator-approved VNS therapy for **upper-extremity motor recovery** after stroke. **Long-term follow-up shows sustained benefit at one year, with 66% of patients achieving clinically meaningful improvement.** Transcutaneous approaches remain investigational. Current evidence supports **implantable VNS paired with rehabilitation in carefully selected patients with chronic upper limb impairment**.

5. India — the ATTEND trial is the key cautionary result

India has only about 35 stroke units, mainly in urban centres, so most people have no access to specialised stroke care or conventional rehabilitation. The **ATTEND trial randomised 1250 patients within one month of stroke** to family-led, trained caregiver-delivered, home-based rehabilitation across **14 Indian hospitals**. It **more than doubled inpatient rehabilitation time (5 hours vs 2 hours)** and added **30 minutes daily for one month after discharge — yet produced no improvement in modified Rankin Scale outcome.**

Exam interpretation: *quantity of therapy alone is not enough* — the **skill and specificity of the therapy delivered** matters, which is why NG236 specifies “multidisciplinary therapy”, not simply “3 hours of activity”.

6. Delivering the dose is the current bottleneck

The **first six months after stroke is the optimum window for neuroplasticity**, and exercise must be **repetitive, task-specific and high-dose**. However, delivering three hours a day in community settings is difficult, and **around 40% of stroke survivors are discharged home without any further rehabilitation**. **Telerehabilitation is recommended in the new guidance** as one way to bridge this gap.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Therapy dose	Not quantified; "early and multidisciplinary"	**NICE NG236 (2023): at least 3 hours/day on at least 5 days/week** — up from 45 minutes
Duration	Most neurological return by 1 month; little after 3 months	Neurological timeline holds, but **functional gains continue** — continue as long as goals are being met, not to a fixed cut-off
Patient selection	Assess to ensure the problem is remediable	Reinforced, but **"no rehabilitation potential" is no longer an acceptable exclusion** (BGS 2024)
Early supported discharge	Not specifically addressed	**Standard of care** — reduces dependency and length of stay; **watch for increased falls**
Drugs for motor recovery	Not emphasised	**Fluoxetine, levodopa: not established. Amphetamines/methylphenidate: not recommended**
Neuromodulation	Neuromuscular stimulation mentioned	**Paired VNS (Vivistim) is FDA-approved** for chronic upper limb deficit, with 1-year sustained benefit
CIMT	Effective 3–9 months after first stroke	Unchanged; remains a **selected-patient** therapy requiring some active wrist and finger extension
More therapy = better?	Implied	**ATTEND (India): doubling therapy hours via untrained family caregivers did not improve outcome** — dose must be *skilled* dose
Setting	Stroke units improve survival and function	Confirmed; extended to **stroke centres with better 1-year independence**, plus **telerehabilitation**

Exam One-Liners

- **Five prognostic factors: availability of a sound programme, Mentation, Motivation, Prognosis for neurological return, Vigour.**
- **Most neurological recovery occurs in the first month; little further return after 3 months.**
- **Motor loss is the least disabling deficit**; neglect, hemianopia, aphasia, sensory loss, balance loss and cognitive damage are far more disabling.
- **Depression is not poor motivation** — screen with GDS and treat before excluding a patient.
- **Kemp's model:** motivation = wants + beliefs + rewards − cost.
- **Acute phase:** 2-hourly turning, joint positioning, aspiration-preventing posture, range-of-motion exercises.
- **Later phase:** ADL training, ambulation, affected-side functional activity, muscle re-education, perceptual training, transfer technique.
- **Flaccid hemiplegia → shoulder subluxation**; prevented by correct handling and positioning from day one.
- **CIMT works 3–9 months after a first stroke** for arm motor function.

- **Stroke units improve survival and function** — the strongest evidence in rehabilitation.
- **NICE NG236 (2023): ≥3 hours of multidisciplinary therapy per day, ≥5 days per week.**
- **ATTEND (India): family-led rehabilitation doubled therapy time but did not improve mRS.**
- **When progress stops, shift the goal from restoration to coping** — braces, orthoses and assistive devices.
- **Complete functional recovery occurs in fewer than half**, but complications of immobility are almost always preventable.

Q5. Rehabilitation of an older adult with low vision

High-Yield Points

A. Definition and Concept

1. **Low vision** is visual impairment that **cannot be corrected by spectacles, contact lenses, medical treatment or surgery**, but where **useful residual vision remains** — irreversible vision loss with retained function, distinct from total blindness.
2. **Vision rehabilitation** enables a person with irreversible low vision to **maximise use of residual vision, learn compensatory skills, adapt the environment, and continue participating in daily and social life.** The goal is **function and quality of life, not visual acuity.**
3. **First rule: exclude and treat every reversible cause.** In India, **around 93% of blindness and 97% of visual impairment in people aged ≥50 years is avoidable** — chiefly **untreated cataract and uncorrected refractive error**. *Low vision rehabilitation is never a substitute for cataract surgery or a pair of spectacles.*

B. Epidemiology and Burden

4. **As many as 75% of older adults have significant visual or auditory dysfunction that they never report to their physician** — hence **active screening is essential**. These impairments **limit functional activity and lead to social isolation and depression**, and **correcting remediable conditions improves the ability to perform daily activities.**
5. **Indian data:** In the **National Blindness and Visual Impairment Survey (RAAB, 2015–19)**, among those aged ≥50 years, **blindness prevalence was 1.99%** and **more than one-quarter were visually impaired**. Causes of blindness: **cataract 66.2%, corneal opacity 8.2%, cataract surgical complications 7.2%, posterior segment disease 5.9%, glaucoma 5.5%. LASI wave-1** found **impaired vision in 13.7%** of Indians aged ≥60.

C. Age-Related Changes and Common Causes

6. **Normal ageing changes:** reduced **visual acuity** (choroid, pigment epithelium, retina, rod/cone function); **difficulty gazing upward and sustaining convergence**; **rising intraocular pressure**; **presbyopia** from nuclear sclerosis and ciliary muscle atrophy; **increased hyperopia or myopia**; **reduced tear secretion** (dry eye); **corneal endothelial degeneration**.

Condition	Functional deficit	Rehabilitation implication
Cataract	**Glare intolerance**, gradual acuity loss	Mostly reversible — **surgery when it interferes with activities**; interim: optimum eyeglasses, UV lenses, glare control
Open-angle glaucoma	**Peripheral field loss first**, central acuity preserved long	**Mobility and falls training** are the priority; magnification helps little in tunnel vision
Age-related macular degeneration	**Central acuity loss** — reading, driving and **recognising faces**	**Magnification and eccentric viewing training**; **total blindness does not occur** — peripheral vision is retained
Diabetic retinopathy	Central loss from macular oedema/ischaemia; patchy field loss	**Tight glycaemic and BP control** plus laser; allow for **neuropathy and reduced tactile substitution**

D. Consequences That Rehabilitation Must Target

8. **Visual impairment is an established risk factor for falls and fractures**, and **patients who have had cataract surgery have a lower risk of hip fracture.**
9. **Depression is a predictable consequence, not an incidental one.** Clinical depression occurs as a result of the fall in quality of life in AMD **and should be actively treated** — a core part of the rehabilitation plan.
10. **Other consequences:** loss of ADLs and IADLs (reading, cooking, medication identification, finances), **loss of driving**, social withdrawal, malnutrition, and **increased dependency and institutionalisation risk.**

E. Assessment

11. **Ophthalmological screening: visual acuity; lens and fundus; intraocular pressure; ophthalmoscopy; tonometry; visual fields;** and the simple functional test — **ability to read newspaper-sized print.**
12. **Functional assessment goes beyond acuity: near and distance acuity, contrast sensitivity, glare sensitivity, visual fields, reading ability, light and dark adaptation**, and what the person can actually do at home. Tools: **Lambeth Disability Screening Questionnaire** and the **Vision Function Questionnaire**.
13. **Assess vision as part of intrinsic capacity.** Under **WHO ICOPE**, **vision is a critical component of person-centred assessment**; **Step 2** assesses visual impairment and eye disease, and **Step 3 interventions include reading glasses, referral for comprehensive eye and vision care, vision rehabilitation for irreversible low vision, and home adaptation to prevent falls. Treating visual impairment enables maintaining family and social relationships, accessing information, moving safely and performing manual tasks.**
14. **Always screen for coexisting hearing loss — dual sensory impairment** multiplies disability, isolation and cognitive risk, and changes every rehabilitation strategy.

F. Components of Low Vision Rehabilitation

Category	Examples
Magnification	**Hand-held, stand and spectacle-mounted magnifiers; telescopes for distance; electronic/CCTV magnifiers**
Lighting	**Lighting intensifiers without glare**; task lighting behind and to the side; **night light to assist dark adaptation**
Glare control	**Tinted glasses**, filters, matt surfaces, avoiding polished floors
Contrast and size	**Large-print newspapers, books and magazines**; bold-tip pens; dark plate on light tablecloth
Non-optical/ tactile	Talking clocks and watches, talking BP and glucose meters, **tactile markers on appliances and medication boxes**, needle threaders, signature guides
Digital	Screen readers, smartphone magnification and text-to-speech, voice assistants

16. **Environmental modification and home safety.** Interventions that **assess and modify home safety features reduce falls, especially among older adults with severe visual impairment**, and are **more effective when carried out specifically by occupational therapists.** Measures: **improved lighting in halls and stairways, grab bars, removal of rugs and clutter, contrast marking of stair edges, covers on electrical sockets, locks on cupboards.**
17. **Optical correction pitfalls in falls prevention: routine vision screening alone did not reduce falls**; assessment and treatment of vision impairment **reduces falls only when coupled with an exercise programme**. **Replacing multifocal lenses with single-vision lenses for outdoor activity is effective**, and **cataract surgery reduces falls in older women — though second-eye surgery does not show the same effect.**
18. **Training and skills teaching: visual skills training** (**eccentric viewing**, steady fixation, scanning for field loss); **orientation and mobility training** (**long cane**, sighted-guide technique, safe road and stair negotiation); **ADL retraining** (labelling, pouring, cooking, grooming, **safe medication identification**); and **reading rehabilitation** — **prescribing a magnifier without training usually fails.**
19. **Psychological and social support: counselling, adjustment support, treatment of depression, self-help and peer groups**, family education, and linkage to **welfare benefits and disability certification**. Address the **grief reaction** to lost independence and lost driving.
20. **Review the drug chart — ophthalmic drops are systemically absorbed:**

Drop	Systemic effects relevant to the older person
β-blockers (timolol)	**Bradycardia, hypotension, syncope, heart failure**, bronchospasm; **confusion, depression, fatigue, hallucinations, memory impairment**; hyperkalaemia
Adrenergics (phenylephrine, epinephrine)	Extrasystoles, palpitation, **hypertension, myocardial infarction**, tremor, sweating
Cholinergics (pilocarpine)	Bronchospasm, salivation, nausea, vomiting, diarrhoea, abdominal pain
Anticholinergics (atropine)	**Ataxia, restlessness, confusion, hallucinations, aggression**, insomnia, photophobia, **urinary retention**

→ Assess other illnesses and medicines, **use the minimum effective dose, and monitor for systemic toxicity.**

21. **The team: ophthalmologist and optometrist**, **low vision therapist**, **occupational therapist**, **orientation and mobility instructor**, **nurse**, **clinical psychologist/social worker**, **dietician**, and the **family carer**. **Devices should be prescribed only if they improve participation in activities the person and family have identified as important.**
22. **Outcome measures:** vision-specific quality of life (**Impact of Vision Impairment, VFQ-25**), **reading speed**, **ADL/IADL independence**, **falls rate**, and **depression scores** — not visual acuity, which by definition will not improve.

Latest Updates (2023–Present)

1. WHA78.7 (May 2025) — the landmark policy change

At the **78th World Health Assembly (19–27 May 2025)**, Member States endorsed a landmark resolution on **“Primary prevention and integrated care for sensory impairments, including vision impairment and hearing loss, across the life course.”** It recognises **cost-effective interventions such as cataract surgery, assistive technologies (spectacles, hearing aids, implants) and rehabilitative services**, and promotes **integrated systematic vision and hearing screening and early intervention within health benefit packages and health information systems**. Over **2.2 billion people are affected by vision impairment and 1.5 billion by hearing loss**.

2. WHO’s framing of vision rehabilitation

WHO describes **vision rehabilitation as an essential component of eye care services** enabling people with **irreversible low vision** to **maximise functional abilities, enhance quality of life and participate fully in society**, and notes it is **very effective** for irreversible loss from **diabetic retinopathy, glaucoma, trauma and AMD**. Frameworks: the **World Report on Vision (2019)** and **WHA73.4 on Integrated People-Centred Eye Care (2020)**. WHO has issued a **Planning guide for integrated vision rehabilitation** for integrating services within national health systems.

3. SPECS 2030 — the refractive error target

Only about **one-third of people with vision impairment due to refractive error have spectacles that effectively correct it**. The **WHA74 (2021) global target** is to increase

effective coverage of refractive error by 40 percentage points by 2030, supported by **WHO SPECS 2030**. WHO and the **Universal Postal Union partnered in 2025** to improve access to eyeglasses.

4. What low vision rehabilitation achieves — the Cochrane position

The Cochrane review of **44 studies** (mostly older adults with AMD) covered **psychological therapies and group programmes, methods of enhancing vision, multidisciplinary rehabilitation programmes, and balance/home-safety programmes**. Key message: **low vision rehabilitation does not appear to have an important impact on health-related quality of life (very low-certainty evidence)**, but there is **low-certainty evidence that some interventions — particularly psychological therapies and methods of enhancing vision — may improve vision-related quality of life**.
*Exam interpretation: measure the **right** outcome — vision-specific QOL, not generic health QOL.*

5. Occupational therapy has the strongest single evidence base

Practice guidelines conclude that **strong evidence supports the role of occupational therapy for older adults with low vision**, recommending: **routine low vision rehabilitation for ADL and IADL impairments; multicomponent interventions for ADL/IADL performance and leisure and social participation; stand-based electronic magnification to enhance reading; visual skills training for central field impairment; and client-centred problem-solving training**, with mainstream technology considered case by case.

6. Telerehabilitation and mood

A **multicentre randomised controlled trial (Bittner et al., 2024)** randomised **61 patients with visual impairment** to **telerehabilitation or in-office magnifier training** 1–4 months after receiving new magnifiers: **reading ability improved significantly, and outcomes did not differ between telerehabilitation and in-office care.** A **2025 systematic review and meta-analysis** of low-vision rehabilitation techniques (**magnifiers, telescopes, microperimeter feedback**) in AMD found that **low-vision rehabilitation improves depression**, while improvement in reading speed was non-significant because of heterogeneity.

7. Falls guidance and Indian context

The **2023 Cochrane review** showed **home fall-hazard interventions reduce falls by 26% overall and 38% in higher-risk people**, while **assistive devices alone and education alone do not**. **NICE NG249 (April 2025)** recommends **offering a home hazard assessment with a validated tool**, **considering an occupational therapist to carry it out**, and referring to an ophthalmologist if visual impairment is **caused by cataract**. In India, the **RAAB 2015–19 survey** found blindness prevalence **1.99%** in those ≥50, with **cataract (66.2%)** leading, and **untreated cataract (48.0%) and uncorrected refractive error (41.5%)** the major contributors to visual impairment; **about 93% of blindness and 96% of visual impairment was avoidable, and more than half of avoidable causes were treatable. Rashtriya Vayoshri Yojana** supplies **free spectacles** and other devices through **ALIMCO**; services run through **NPCBVI** alongside **NPHCE**.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Framing	Vision problems managed disease-by-disease within "sensory impairment"	**Vision rehabilitation is a named health system service** integrated into UHC — WHA78.7 (2025) plus WHO's planning guide
Aids	Magnifier, lighting intensifiers, tinted glasses, night light, large print	Retained, but **device prescription alone is insufficient — training produces the gain**; **stand-based electronic magnification** specifically recommended
Central field loss	Reading glasses or magnification for AMD	**Visual skills training (eccentric viewing) is now specifically recommended**
Psychological care	"Depression may occur and should be treated"	**Psychological therapy is one of the two intervention types with evidence of improving vision-related QOL**; rehabilitation itself **improves depression in AMD**
Outcome measured	Not specified	**Vision-related QOL, reading, ADL/IADL and mood** — generic health QOL shows no important change
Service delivery	Clinic-based	**Telerehabilitation is non-inferior to in-office care** for magnifier training and reading
Falls	Visual impairment is a risk factor for falls and fractures	**Vision correction alone does not reduce falls** — works with **exercise** and **OT-led home hazard modification**; **single-vision lenses outdoors**; first-eye cataract surgery helps, second-eye does not
Refractive error	Optimum eyeglasses mentioned	**SPECS 2030: a 40-percentage-point increase in effective refractive error coverage by 2030**

Exam One-Liners

- **Low vision = irreversible visual impairment with useful residual vision** — rehabilitation targets **function, not acuity**.
- **Treat the treatable first** — in India **~93% of blindness in those ≥50 is avoidable**, mostly cataract and refractive error.
- **75% of older adults have unreported visual or hearing dysfunction** — screen actively.
- **AMD → central loss** (reading, faces, driving); **glaucoma → peripheral loss** (mobility, falls).
- **Total blindness does not occur in AMD** — peripheral vision is retained.
- **Aids:** magnifier, **lighting intensifiers without glare**, tinted glasses, **night light**, large print.
- **Eccentric viewing training** is the specific technique for central scotoma.
- **A magnifier prescribed without training usually fails.**
- **Visual impairment predicts falls and fractures; cataract surgery lowers hip-fracture risk.**
- **Vision correction reduces falls only when combined with exercise and home hazard modification.**

- **Timolol drops can cause bradycardia, heart failure, bronchospasm, confusion and depression.**
- **Depression in AMD is expected and treatable** — and rehabilitation itself improves it.
- **Telerehabilitation is as effective as in-office low vision training.**
- **WHA78.7 (2025)** = first WHA resolution combining **vision and hearing** care across the life course.

Q6. Rehabilitation of a patient with osteoarthritis of the knee joints

High-Yield Points

A. Definition and Pathology

1. **Osteoarthritis (OA)** is characterised by **cartilage destruction with subsequent joint space loss, osteophyte formation and subchondral sclerosis.** It is the **most common joint disease of older adults** and the **major cause of knee, hip and back pain.**
2. **OA is not, by definition, an inflammatory disease**, although **synovial hypertrophy and joint effusions are typical.** Progression involves **chondrocyte regulation of the extracellular matrix, genetic influences, local mechanical factors and inflammation.**

Feature	Osteoarthritis	Inflammatory arthritis
Duration of stiffness	**Minutes**	Hours
Pain	**Usually with activity**	Even at rest and at night
Fatigue	Unusual	Common
Swelling	Common, **little synovial reaction**	Very common, with synovial proliferation
Erythema and warmth	Unusual	Common

B. Burden

4. **Musculoskeletal disorders are the commonest cause of disability in old people** — almost **60% of people aged ≥65 report arthritis or chronic joint symptoms. High BMI is associated with an increased risk of knee OA in older persons.**
5. **Indian context:** the **pooled prevalence of knee OA among elderly Indians is about 47%.** Contributing factors specific to India: **squatting, cross-legged floor sitting, Indian-style toilets, heavy manual labour, obesity and postmenopausal status.**

> **C. The Vicious Cycle — the central concept in OA rehabilitation**
>
> **People with arthritis avoid activities that provoke joint pain → muscles weaken → joints become unstable and easily injured → pain increases → exercise is avoided further → cardiorespiratory fitness falls critically**, particularly in the very old, **in whom even simple ADLs demand oxygen uptakes close to the age-associated maximum. The end result is an unfit, inactive, arthritic person whose independence is compromised.**
>
> *Rehabilitation exists to break this cycle, and every component below is aimed at one of its links.*

7. **The good news that drives the whole programme:** pathological OA changes occur against a background of **age-related loss of flexibility that is itself reversible**. **Exercise increases joint flexibility and improves the strength, size and resilience of cartilage, ligaments and muscles.** Arthritic patients should be **encouraged to develop physical fitness and set realistic goals.**

D. Assessment

8. **History:** nature and duration of disability, **pain (site, pattern, aggravating and relieving factors)**, comorbidities, **drugs that affect mobility**, motivation and psychological factors, and the home environment.
   Examination: skin, cardiopulmonary status, **musculoskeletal assessment — muscle tone and strength (MRC 0–5, especially knee extension), joint range of motion, foot deformities and lesions** — neurological deficits, and **levels of mobility: bed mobility, transfers, standing balance, gait, stair climbing, and pain with movement.**
9. **Investigations: plain radiography** remains the main modality for assessing severity and progression; **MRI and ultrasound are more accurate and comprehensive** but not needed routinely.
10. **Outcome tools: WOMAC** (pain, stiffness, physical function), **Timed Up and Go, 30-second chair stand, 6-minute walk test**, and **Barthel Index/FIM**.

E. Goals and Therapeutic Exercise

11. **The goal is to restore function and prevent further disability**, using a **restorative philosophy of care**: **careful assessment of function and underlying capability, realistic goals, prevention of secondary disability and the complications of immobility, evaluation and adaptation of the environment, and ongoing motivation of both patient and caregivers.**
12. **Non-pharmacological management should be the focus of intervention** — weight loss, physical therapy to strengthen the related musculature, local ice and heat, and exercise programmes to maintain strength and function.
13. **Physiotherapy objectives: relieve pain; evaluate, maintain and improve joint range of motion; improve strength, endurance, motor skills and coordination; improve gait and stability; assess the need for and teach the use of assistive devices. Modalities: active exercise (isometric and isotonic) and passive exercise**, sitting exercise programmes, heat (hot packs, paraffin, diathermy, ultrasound), hydrotherapy and TENS.
14. **A practical knee OA exercise prescription:**
    - **Quadriceps strengthening** — static quadriceps sets, straight-leg raises, **inner-range quadriceps**, progressing to sit-to-stand and step-ups
    - **Hip abductor and extensor strengthening** — reduces the adduction moment across the knee
    - **Daily range-of-motion exercises** — **particularly important in restoring function in arthritic joints**
    - **Balance and proprioceptive training** — the knee is unstable and falls risk is high
    - **Low-impact aerobic exercise** — walking, cycling, aquatic exercise
    - **Flexibility** — hamstring and calf stretching; avoid fixed flexion contracture
15. **Adherence is the biggest problem, not the prescription. Compliance with range-of-motion exercise is low at all ages. Joining others in group activities adds a social component and increases compliance** — hence supervised group programmes rather than a printed home sheet.
16. **Weight management: weight-loss therapy improves physical function, quality of life and the medical complications of obesity in older persons**, but **must minimise muscle and bone loss.** Primary approach is **lifestyle change** with a **modest energy reduction of**

500–700 kcal/day, and **regular physical activity is particularly important in obese older people to preserve muscle and bone mass.**

F. Pain Management

17. **Time the analgesia to the exercise.** Because **OA pain is typically exacerbated by exercise, it is best to medicate beforehand** — this single measure converts a failed physiotherapy session into a successful one.
18. **Pharmacological adjuncts:** simple analgesics, **topical and oral NSAIDs, intra-articular corticosteroid injection, viscosupplementation. Glucosamine and chondroitin show no evidence of significant pain improvement** beyond a possible placebo effect, and **vitamin D does not reduce pain or repair structural damage. Refractory pain is best managed by a multidisciplinary pain team.**

G. Orthoses, Footwear and Walking Aids

19. **Footwear: patients with painful knees benefit from soft-soled shoes with cushioned heels (e.g. jogging shoes).** A **rocker-bottom shoe** reduces forefoot pain by assisting weight transfer from posterior to anterior. **Metatarsalgia** is reduced by an **internal pad placed proximal to the MTP joints**, and **medial arch collapse** by a **medial arch-supporting orthosis.**
20. **Walking stick rules:**
    - A cane **held in the contralateral hand reduces weight on an arthritic hip**
    - **For knee pain, the patient should experiment with holding the cane in either hand** — the contralateral rule is not automatic for the knee
    - **Cane length must equal the distance from the wrist crease to the floor** — a wrong length creates secondary problems in other joints
    - **Ferrules (stick rubbers) must be checked regularly and replaced when worn, to reduce the risk of falls**
21. **Occupational therapy and the home: a home-based assessment by an occupational therapist is often invaluable. Simple ergonomic measures and aids — tap turners, zipper pulls, sock pulls, stretch laces, long-handled shoe-horns and Velcro fasteners — notably reduce joint strain and consequent pain.** Add **raised toilet seat, grab bars, shower chair, raised chair and bed heights, and first-floor living.** *In the Indian setting, converting an Indian-style squatting toilet to a Western-style commode is one of the highest-yield single modifications.*
22. **Physical modalities — know the evidence limits. Heat, including baths and spas, has traditionally been used for arthritic joints. There is no evidence that hydrotherapy produces measurable functional improvement in arthritic joints, although it does promote self-confidence.** Use these as **adjuncts that enable exercise**, not as treatments in their own right.
23. **Surgery: total knee arthroplasty** is reserved for severe symptoms and functional failure despite optimal conservative care, requiring **pre-operative optimisation (prehabilitation, quadriceps strengthening, weight and comorbidity control)** and structured post-operative rehabilitation. **Arthroscopic surgery for knee OA has been shown in a controlled trial to be of no benefit.**
24. **Honest evidence position: there is little evidence for the efficacy of structured multidisciplinary rehabilitation programmes in musculoskeletal disorders generally. Time-limited, goal-directed multidisciplinary rehabilitation is of proven benefit only**

in chronic back pain, other chronic pain, and after hip fracture in frail older people — which is why **exercise, weight loss and self-management, not the programme label, carry the evidence in knee OA.**

Latest Updates (2023–Present)

1. Guideline consensus — the "core set"

OARSI emphasises a **core set of non-pharmacological management for all patients**: **formal exercise (aerobic, strengthening, neuromuscular, aquatic or mind-body), weight reduction in overweight or obese patients, and continuing education**. **Assistive devices such as bracing and walkers are recommended only in select cases. Pharmacological therapy is adjunctive — oral and topical NSAIDs**, with **short-course intra-articular corticosteroid** if these fail. Critically for geriatrics: **for individuals with cardiovascular comorbidities or frailty, no oral NSAID is recommended**; for gastrointestinal comorbidity, **COX-2 inhibitors or an NSAID plus PPI**.

2. ACR/Arthritis Foundation — the specific do's and don'ts

Strongly recommended for knee and hip OA: exercise, self-efficacy and self-management programmes, weight loss, and use of a cane. Tai chi is strongly recommended; **yoga is conditionally recommended for knee OA.** The guideline **strongly recommends against TENS**, and **conditionally recommends against manual therapy, massage, modified shoes and weighted insoles**, and (for knee OA) **against pulsed vibration therapy.**

3. The biggest single change — GLP-1 receptor agonists (STEP 9, NEJM 2024)

The **STEP 9 trial** randomised **407 adults with obesity (mean age 56, 81.6% women, mean BMI 40.3) and moderate knee OA with moderately severe pain** 2:1 to **once-weekly subcutaneous semaglutide 2.4 mg or placebo**, alongside physical activity and lower-calorie diet counselling, for **68 weeks**. **Body weight fell by 13.7% versus 3.2%** (treatment difference −10.5; P<0.001), and the **WOMAC pain score improved by −41.7 versus −27.5** (treatment difference −14.2, 95% CI −20.0 to −8.3; P<0.001). **SF-36 physical function also improved more with semaglutide (+12.0 vs +6.5 points; P<0.001).** This **may reduce the need for NSAIDs and opioids**; an earlier trial of **liraglutide 3.0 mg showed no significant pain difference.**
*Exam framing: in the obese older patient with knee OA, **weight loss is now a pharmacologically achievable rehabilitation intervention** — but its role in frail, sarcopenic elders is unproven and it must be paired with **resistance exercise and protein adequacy** to protect muscle.*

4. GLA:D® — the reference model for structured OA rehabilitation

The Danish **GLA:D programme** delivers **guideline-aligned group education and supervised exercise therapy** for hip or knee OA through **2–3 education sessions of 90 minutes plus 12 supervised neuromuscular exercise sessions of 60 minutes, twice weekly for six weeks.** Around **6000 participants enrol annually across nearly 300 Danish physiotherapy clinics**, with a national registry at baseline, 3 and 12 months.

5. Digital delivery and injectables

A **2025 single-blind RCT** randomised **42 older adults (mean age 68.4) with mild-to-moderate knee OA** to a **sensor-augmented telerehabilitation system (electromyographic and inertial sensing)** or **conventional face-to-face physiotherapy for eight weeks**. Systematic reviews in **2024–2025** support **digitally delivered exercise** and **telerehabilitation for pain, strength and balance**; the limiting factor is **digital readiness**. Recent reporting indicates **platelet-rich plasma shows no long-term advantage over standard care in early knee OA**.

6. Indian epidemiology and a practical intervention target

A **2025 systematic review and meta-analysis (14 studies, 5029 participants)** found the **pooled prevalence of knee OA among elderly persons in India to be 47% (95% CI 38.4–55.8%)**, attributing the burden partly to **strenuous manual labour and cultural practices such as sitting cross-legged and squatting.** A **2024 community study in rural South India** found knee OA in **more than one-third of adults aged ≥40**, with predictors including **obesity, diabetes, hypertension, sedentary lifestyle, menopause and use of Indian-style toilets**; the authors recommend **affordable alternatives to squatting toilets, knee-strengthening exercise tailored to postmenopausal women, and better rural access to physical therapy.**

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Core treatment	Non-pharmacological management should be the focus	Reinforced — **exercise + weight management + education is the universal "core set"**
Exercise type	Daily range-of-motion exercise; general fitness	Broadened to **aerobic, strengthening, neuromuscular, aquatic or mind-body**; **tai chi strongly recommended**
Exercise dose	Not specified	**GLA:D template: 12 supervised neuromuscular sessions over 6 weeks plus structured education**
Weight loss	Lifestyle change, 500–700 kcal/day deficit	**Semaglutide 2.4 mg produced 13.7% weight loss and clinically meaningful WOMAC pain reduction (STEP 9, NEJM 2024)**
NSAIDs in the elderly	Analgesics/NSAIDs listed as options	**Oral NSAIDs not recommended in cardiovascular comorbidity or frailty**; **topical NSAIDs first-line**
TENS and heat	Listed among physiotherapy modalities	**TENS is strongly recommended against**; heat and hydrotherapy remain **enablers of exercise**
Glucosamine/ chondroitin, vitamin D	No evidence of benefit	Unchanged — **do not prescribe**
Injections	IA steroid and viscosupplementation listed	**IA steroid = short-term adjunct only**; **PRP shows no long-term advantage**
Delivery	Clinic and group programmes	**Digital and sensor-augmented telerehabilitation** now have RCT support
Programme evidence	Little evidence for structured MDT rehabilitation in musculoskeletal disease	Still true at programme level, but **individual components have strong, replicated evidence**

Exam One-Liners

- **The OA vicious cycle:** pain → activity avoidance → muscle weakness → joint instability → more pain → deconditioning → lost independence.
- **Age-related joint stiffness is reversible** — exercise improves strength, size and resilience of cartilage, ligaments and muscle.
- **Give the analgesic before exercise**, because OA pain is exacerbated by activity.
- **OA stiffness lasts minutes; inflammatory stiffness lasts hours.**
- **Quadriceps + hip abductor strengthening + aerobic exercise + weight loss** is the core prescription.
- **Compliance is the limiting factor — group exercise improves it.**
- **Cane length = wrist crease to floor**; check and replace worn ferrules.
- **For hip pain hold the cane contralaterally; for knee pain, try either hand.**

- **Soft-soled shoes with cushioned heels** for painful knees; **rocker-bottom sole** for rigid forefoot.
- **OT aids:** tap turners, zipper pulls, sock pulls, stretch laces, long-handled shoe-horn, Velcro fasteners.
- **Hydrotherapy improves confidence, not measurable joint function.**
- **Glucosamine, chondroitin and vitamin D do not reduce OA pain.**
- **Avoid oral NSAIDs in the frail or cardiovascularly comorbid elder** — topical NSAIDs first.
- **Arthroscopic surgery for knee OA is of no benefit.**
- **STEP 9 (2024): semaglutide 2.4 mg → 13.7% weight loss and WOMAC pain −41.7 vs −27.5.**
- **GLA:D dose: 12 supervised neuromuscular exercise sessions over 6 weeks + education.**
- **India: knee OA affects about 47% of elderly** — target **squatting, cross-legged sitting and Indian-style toilets**.

Q7. Community-based rehabilitation (CBR)

High-Yield Points

A. Definition and Concept

1. **Community-Based Rehabilitation (CBR)** is defined (ILO/UNESCO/WHO Joint Position Paper, 2004) as **a strategy within general community development for the rehabilitation, poverty reduction, equalisation of opportunities and social inclusion of all people with disabilities.**
2. **CBR is implemented through the combined efforts of people with disabilities themselves, their families, organisations and communities, and the relevant governmental and non-governmental health, education, vocational, social and other services.** It is **not** simply "physiotherapy delivered at home" — it is a **multisectoral development strategy**.
3. **Evolution:** CBR began after **Alma-Ata (1978)** to extend basic rehabilitation to people who could never reach an institution. It has since **evolved into a comprehensive, multisectoral approach now recognised as the core strategy for Community-Based Inclusive Development (CBID)** — a shift from *delivering services to the disabled* to *making the community itself inclusive*.
4. **Policy anchors:** the **Helsinki International Consultation (2003)**, the **ILO/UNESCO/WHO Joint Position Paper (2004)**, **World Health Assembly resolution WHA58.23 (2005)** urging Member States to promote and strengthen CBR, and the **WHO CBR Guidelines (2010)** developed with over 180 individuals from nearly 300 organisations, mostly in LMICs. **CBR is now implemented in over 90 countries**, and the guidelines position CBR as a means of implementing the **UNCRPD (Article 26 — Habilitation and Rehabilitation)**.

B. The CBR Matrix — the core framework

Five components, each with five elements (5 × 5 = 25 elements). It is a **flexible "pick-and-mix" framework, not a sequential programme** — no single agency delivers all 25 elements, so **partnership across sectors is essential**.

HEALTH	EDUCATION	LIVELIHOOD	SOCIAL	EMPOWERMENT
Promotion	Early childhood	Skills development	Personal assistance	Advocacy & communication
Prevention	Primary	Self-employment	Relationships, marriage & family	Community mobilisation
Medical care	Secondary & higher	Wage employment	Culture & arts	Political participation
Rehabilitation	Non-formal	Financial services	Recreation, leisure & sports	Self-help groups
Assistive devices	Lifelong learning	Social protection	Justice	Disabled people's organisations

6. **The WHO CBR Guidelines comprise 7 booklets** — an Introduction with a **Management chapter**, **one booklet per matrix component**, and a **Supplementary booklet** covering

HIV/AIDS, mental health, leprosy and disasters — areas historically neglected by CBR programmes.

7. **Core principles: inclusion, participation, sustainability, self-advocacy, empowerment, non-discrimination**, use of **local resources and appropriate technology**, **community ownership**, **intersectoral collaboration**, and **referral linkage to secondary and tertiary services**.
8. **Three-tier structure:** the **person with disability and family** at the centre → the **community and CBR worker → linkage upward to district and referral services**. The programme fails if the referral link is missing.

C. Community-Based Rehabilitation in the Older Person

9. **The rehabilitation setting should be a menu, not a single option** — stand-alone rehabilitation hospitals, designated rehabilitation units, general wards, nursing and residential homes, **day hospitals, community day centres, outpatient rehabilitation centres, and the patient's own home. Ideally a range of options should be available to meet the needs of individual patients at a given time.**

> **Critical caveat for the exam**
>
> **Community-based rehabilitation has come of age as a *complement to*, not a replacement for, hospital-based rehabilitation. In practice it only suits patients at the least disabled end of the spectrum who are otherwise well supported in the community.** A severely disabled elder living alone is not a CBR candidate for the acute phase.

11. **Intermediate care** is **intensive, short-term, community- or home-based rehabilitation that aims to prevent hospitalisation, facilitate early discharge from hospital, and/or maximise independent living.** It is the geriatric bridge between hospital and home.
12. **Community long-term care programmes that support CBR (Kane): home care (home nursing and homemaking), adult day care, adult foster care, assisted living, geriatric assessment, hospice, telephone reassurance, caregiver support, congregate housing, home repairs, congregate and home-delivered meals, respite care, and emergency alarms.**

Service	Who it is for and what it delivers
Senior centre	For the **well** elderly; recreational, usually recreation-department run
Adult day care	For those with **limited functional ability** (some specifically for cognitive impairment); supervised activities that **improve basic ADL and social skills**, and at minimum provide **respite for the primary caregiver — which may make the critical difference in allowing an impaired older person to remain at home.** Most attend **2–3 days a week**
Adult day health centre	Day care **plus nursing, physiotherapy and social work**
Day hospital	Virtually all hospital services on an ambulatory basis, with **emphasis on rehabilitation, especially physiotherapy and occupational therapy**

14. **Home-based assessment and the home visit.** A **hospital-to-home assessment programme** shortens hospital stay, allows **evaluation of the home itself and how the**

patient actually functions within it, and can be **targeted at those who will derive maximal benefit**. **Preventive home visitation** aims at primary prevention (immunisation, exercise), secondary prevention (detecting untreated problems) and tertiary prevention (improving medication use) — **but its benefits have not been definitively confirmed, so it cannot be recommended as routine practice.**

15. **Case management is the glue.** In most cases a **strategy for long-term follow-up and often formal case management should be developed to ensure that needs and services are appropriately matched and followed through. Discharge from hospital is a transition in rehabilitation, not its conclusion**, and **some follow-up is essential.**
16. **Integrated models: PACE (Program of All-Inclusive Care of the Elderly)** uses **pooled capitated Medicare and Medicaid funding to deliver integrated health and social services to older people who are nursing-home eligible but still living in the community** — the best example of creative integration, though **expensive and targeting a narrow group**. **Hospital-in-the-Home (Australia)** delivers hospital-level care at home with **quality at least equivalent to traditional hospital care** in cost, satisfaction and medical outcomes.
17. **Technology extends CBR's reach. Remote sensors, wireless data transfer, GPS, robotics and mobile computer systems facilitate early transfer from hospital-based to home-based rehabilitation**, with **cost savings, fewer hospital-acquired infections, and return to a familiar environment**. The same technology then **maintains independence, reduces caregiver burden and prevents institutionalisation.**
18. **CBR team:** the **CBR worker / community rehabilitation worker** (in India an **ASHA, ANM or Multipurpose Worker**), **family caregivers**, **physiotherapist, occupational therapist, speech therapist**, **community nurse**, **social worker**, **primary care physician with geriatric linkage**, **Panchayati Raj and self-help groups**, and **Disabled People's Organisations**. **Even in low-resourced settings, health workers can be trained to detect declines in physical and mental capacity and deliver effective interventions** — the premise of the **WHO ICOPE package**, deliberately **based in community and primary care to maximise accessibility**, with **Step 5 devoted to enlisting the community and supporting caregivers**.

D. Why CBR Matters Especially in LMICs

19. **Institutional care is almost absent in low- and middle-income countries** — only **0.1% of older people live in institutions in Iran, 0.6% in Botswana and about 1% in Brazil and Mexico, compared with 7.5% in Switzerland. This very lack of infrastructure opens the way to create alternative community-based long-term care systems.**
20. **Informal family care is the cornerstone.** In dementia, **informal care accounts for 58% of all costs in low-income and 65% in middle-income countries, versus 40% in high-income countries**, while **direct social care costs are only 4% in LMICs versus 42% in high-income countries. Most family care in developing countries is provided by women**, and this supply is shrinking with female labour-force participation, migration and smaller families.
21. **Advantages of CBR:** low cost, wide coverage, culturally appropriate, uses local resources, keeps the person in their own environment and roles, reduces institutionalisation, empowers families, and addresses **participation restriction**, which hospital services never reach.
    Limitations: variable quality and supervision, dependence on committed community workers, weak referral pathways, **poor evidence base for programme-level effectiveness**, funding

insecurity, risk of **shifting the burden onto already-overloaded women in the family**, and unsuitability for severely disabled or unsupported patients.

Latest Updates (2023–Present)

1. The scale of the need has been formally quantified

A landmark study jointly developed by **WHO and the Institute for Health Metrics and Evaluation** established that **one-third of the world's population — about 2.41 billion people — live with a health condition that would benefit from rehabilitation**, and that this **need has risen 63% since 1990 (from 1.48 billion)**. The study **establishes rehabilitation as a key strategy for universal health coverage in the 21st century and challenges the view that rehabilitation is an optional service needed only by a minority.** The main drivers are **ageing, rising non-communicable disease, and the consequences of injury**, and **more than half of those needing rehabilitation in LMICs do not receive it.**

2. WHA76.6 (May 2023) — the first-ever WHA resolution on rehabilitation

It calls for **expanding and integrating rehabilitation into health systems as part of universal health coverage**, with emphasis on **rehabilitation in primary care** and in **emergency preparedness and response**, and highlights the **critical shortage of rehabilitation workforce**. It was the **first resolution to directly address rehabilitation in 75 years of the World Health Assembly**, found global need **largely unmet — in many countries fewer than half receive the care they require** — and commits Member States to **expand financing, integrate rehabilitation into national health systems, minimise the prohibitive costs of assistive technologies such as hearing aids, glasses, wheelchairs and prosthetics, and promote research.**

3. World Rehabilitation Alliance and the Package of Interventions for Rehabilitation

Following the **3rd Global Rehabilitation 2030 meeting (July 2023)**, WHO launched the **World Rehabilitation Alliance (WRA)**, conducting evidence-based advocacy through **five workstreams: (1) rehabilitation workforce, (2) rehabilitation in primary care, (3) rehabilitation in health policy and systems research, (4) rehabilitation in emergencies, (5) external relations.** WHO's **Package of Interventions for Rehabilitation (PIR)** helps ministries of health integrate rehabilitation into health systems, **with particular focus on LMICs**. PAHO has issued a **Basic package of interventions for rehabilitation: a toolkit for primary care professionals (March 2025)**.

4. CBR is now framed as CBID; the evidence base is broadening but still thin

CBR is described as a **community development strategy** promoting **inclusion, participation and empowerment of persons with disabilities by addressing both physical and sociological barriers**, now recognised as a **core strategy for community-based inclusive development (CBID)**, with components **not implemented sequentially but as a flexible "pick-and-mix" framework** linking community resources with existing government services. A **2024 systematic review of the grey literature (International Journal of Mental Health Systems)** examined **CBR for people with psychosocial disabilities in LMICs** — reflecting the continuing reliance on non-peer-reviewed programme evidence. Alongside this, the **2024 BMC Medicine meta-analysis** showed geriatric

rehabilitation in inpatient *and day-hospital* settings **reduced mortality, care-home admission and functional impairment**, and the **BGS 2024 report** argues rehabilitation should be a component of every service for older people.

5. India — the operational structures to name in an exam

District Disability Rehabilitation Centres (DDRCs) were initially planned for 325 districts, but **with effect from 9 December 2020 all districts were approved** for DDRCs, funded under the **Deendayal Disabled Rehabilitation Scheme (DDRS) from 2020–21**. Services include **survey and identification of persons with disabilities through a camp approach, awareness generation, assessment/provision/fitment/repair of assistive devices, support to ADIP/ALIMCO camps, vocational identification and training, and referral services**. Each DDRC provides **therapeutic services — physiotherapy, occupational therapy and speech therapy** — and facilitates **disability certificates, bus passes and concessions**. Each is run by a **District Management Team headed by the District Magistrate/Collector**.

Other Indian structures: **NPHCE** (19 Regional Geriatric Centres, 2 National Centres for Ageing), **Ayushman Arogya Mandir / Health and Wellness Centres** as the primary-care delivery point, **ASHA/ANM** as the CBR workforce, **Rashtriya Vayoshri Yojana** and **ADIP/ALIMCO** for assistive devices, **Composite Regional Centres (CRCs)**, and **AB-PMJAY extended to all aged ≥70 years (2024)**.

Key legal gap: the **Rights of Persons with Disabilities Act, 2016** governs disability services, but **age-related functional decline does not automatically confer "disability" status**, so many frail elders fall outside the DDRC pathway — an argument for **explicitly linking NPHCE and DDRC services**.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Scale of need	Not quantified	**2.41 billion people worldwide (one-third of the population); need up 63% since 1990; >50% unmet in LMICs**
Status of rehabilitation	A service within geriatric medicine	**An essential health service within UHC** — WHA76.6 (2023)
CBR concept	A complement to hospital care	Reframed as **Community-Based Inclusive Development (CBID)** — a multisectoral development strategy
Who CBR suits	"Only the least disabled end of the spectrum, well supported in the community"	Still broadly true for *acute* rehabilitation, but **hospital-at-home, early supported discharge and telerehabilitation have widened the eligible group**
Delivery point	Day hospitals, day centres, home, outpatient	**Primary care is now the named priority setting** — WRA workstream 2, PAHO toolkit, WHO PIR
Preventive home visits	Benefits not confirmed; not routine	Broadly unchanged; evidence has shifted to **targeted home-hazard assessment by an OT (26–38% fall reduction)**
Assistive technology	Aids and adaptations as a rehabilitation step	**Cost of assistive technology is a named policy target**; spectacles, hearing aids, wheelchairs and prosthetics framed as core UHC entitlements
Workforce	Multidisciplinary team	**Global workforce shortage explicitly named**; task-sharing endorsed — **but ATTEND (India) showed untrained family-delivered therapy alone does not improve outcomes**
India	Not covered	**DDRCs now approved in all districts**; NPHCE, RVY/ADIP and AB-PMJAY ≥70 years form the practical CBR web

Exam One-Liners

- **CBR = a strategy within general community development** for rehabilitation, poverty reduction, equalisation of opportunities and social inclusion (**ILO/UNESCO/WHO, 2004**).
- **CBR Matrix = 5 components × 5 elements = 25:** Health, Education, Livelihood, Social, Empowerment.
- **Health component elements:** promotion, prevention, medical care, **rehabilitation, assistive devices**.
- **Empowerment elements:** advocacy and communication, community mobilisation, political participation, **self-help groups, Disabled People's Organisations**.
- **WHO CBR Guidelines (2010) = 7 booklets**; supplementary booklet covers **HIV/AIDS, mental health, leprosy and disasters**.
- **WHA58.23 (2005)** urged Member States to strengthen CBR; **CBR runs in over 90 countries**.
- **CBR is the operational vehicle for UNCRPD Article 26.**

- **CBR complements, never replaces, hospital rehabilitation.**
- **Intermediate care** = short-term intensive community/home rehabilitation to **prevent admission, enable early discharge and maximise independence**.
- **Day care may make the critical difference in keeping an impaired elder at home** — often through **carer respite** alone.
- **Senior centre = well elderly; day care = functionally limited; day hospital = rehabilitation-focused ambulatory hospital care.**
- **Institutional care is ~0.1–1% in LMICs versus 7.5% in Switzerland.**
- **Informal care = 58–65% of dementia costs in LMICs versus 40% in high-income countries.**
- **2.4 billion people need rehabilitation; over half in LMICs do not receive it.**
- **India: DDRCs are now approved in every district.**

Q8. Mobility aids

High-Yield Points

A. Definition and Purpose

1. **Mobility aids are assistive products that support or substitute for lost locomotor function**, enabling the older person to transfer, stand, walk and move about safely. They are one arm of the wider category of **“aids and adaptations”**.
2. **Purposes: widen the base of support and improve balance**; **unload a painful or weak limb**; **compensate for reduced proprioception and reaction time**; **increase confidence and reduce fear of falling**; **extend walking distance and endurance**; and **enable participation**.
3. **Aids reduce activity and participation restriction**, and range **from the simple and inexpensive to the technologically advanced**.

> **Two cardinal cautions — both examinable**
>
> • **“The provision of an aid is not always the best option, as it can foster dependence rather than independence.”**
> • **“Those in real need often do not avail themselves of even basic aids and appliances.”**
> → Under-provision and over-provision are both errors; the answer is **assessment, not reflex prescription**.

5. **Lack of mobility aids is itself listed as a cause of immobility**, alongside medical orders, restrictive devices and chemical restraints. Immobility produces **muscle atrophy, loss of strength and endurance, bone loss, joint contractures, impaired balance and coordination, more falls, and — through reduced bone mass — more serious injury when falls occur.**
6. **About one-quarter of community-dwelling older adults use at least one mobility device. The incidence of falls and recurrent falls is not associated with any particular device or with the use of multiple devices.**
7. **Older adults who own devices fall more often when they are *not* using them**, and **those who fall in the absence of their device suffer more serious injuries.** This is likely confounded, because **consistent and effective use of an assistive device itself requires robust cognitive and functional capability.**

B. Classification

8. **Ambulatory (walking) aids** — sticks/canes, crutches, walking frames and rollators. **Wheeled mobility** — manual wheelchairs, powered wheelchairs, scooters. **Transfer aids** — trapeze/monkey pole, transfer pole or bar, transfer board, hoist, raised bed and toilet seats. **Environmental aids** — handrails, ramps, grab bars, stair lifts. **Orthoses and prostheses** — an **orthosis** is applied to the external surface to **support, improve function, or restrict or promote movement**; a **prosthesis replaces a body part**.

C. Choosing the Device — Match the Aid to the Deficit

Principle: prescribe the least restrictive device that gives adequate safety. A device more supportive than needed accelerates deconditioning; one less supportive causes falls.

Device	Best indication	Support given	Main drawbacks
Single-point cane	Mild unilateral weakness or pain; slight balance loss	Widens base a little; **unloads the opposite limb by roughly 20–25%**	Minimal stability; useless in bilateral weakness
Quadripod (quad) cane / tripod	Hemiplegia; moderate unilateral weakness	Greater lateral stability, **free-standing**	Heavier, slower gait; all four tips must contact evenly; poor on stairs
Hemi-walker (walk cane)	Dense hemiplegia with one functional arm	Maximum one-handed support	Bulky, encourages asymmetric gait
Axillary crutches	Short-term non/partial weight-bearing after fracture or surgery	Large unloading	High energy cost; **axillary nerve/vessel compression** if leant on; rarely tolerated by frail elders
Elbow (Lofstrand) crutches	Longer-term partial weight-bearing with good upper-limb strength	Good unloading, frees hands	Needs coordination and grip strength
Standard (pick-up) frame	Bilateral weakness, poor balance, generalised frailty	**Maximum stability of the walking aids**	**Abolishes reciprocal arm swing, promotes flexed posture, slow, unusable on stairs**
2-wheeled front-wheeled walker	Frail elder who cannot lift a frame	Good stability with smoother gait	Slight loss of stability versus standard frame
4-wheeled rollator	Cardiorespiratory limitation, Parkinson's disease, long distances	Enables **rest stops**, better speed, carries belongings	**Can run away downhill; needs intact grip, cognition and braking ability**
Manual wheelchair	Cannot walk functional distances	Total substitution	Deconditioning if over-used; pressure and seating problems
Powered wheelchair / scooter	Adequate cognition and vision, poor upper-limb power or endurance	Independence over long distances	Cost, transport, safety and cognitive screening required

10. **The Berg Balance Scale gives a practical decision rule: 0–20 = wheelchair-bound; 21–40 = walking with assistance (needs an aid); 41–56 = independent.**

D. Fitting and Measurement

11. **Cane length should equal the distance from the wrist crease to the floor**, standing upright in usual footwear with arms hanging. **Cane length matters because a wrong length creates secondary problems in other joints.**

Parameter	Standard
Handle height (cane, crutch, walker)	Level of the **distal wrist crease / ulnar styloid**; approximately the level of the **greater trochanter**
Elbow flexion when gripping	**20–30°**
Cane tip position	About **2 inches lateral and 6 inches anterior** to the toes
Axillary crutch pad	**About 2 finger-breadths (≈5 cm) below the axilla** — never weight-bear on the axilla
Forearm crutch cuff	**1–1.5 inches distal to the olecranon**
Walker width	Roughly **2 inches wider** than the patient; front legs level with the midpoint of the shoes

12. **Which hand? A cane held in the contralateral hand limits pain by reducing weight on an arthritic hip. For knee pain, the patient should experiment with holding the cane in either hand.** In hemiplegia, the cane goes in the **unaffected hand**.
13. **Gait sequences: cane and affected leg advance together, then the sound leg** ("cane–bad–good"); **three-point gait** for non-weight-bearing; **partial weight-bearing gait** for protected loading; **four-point gait** for maximum stability. **Stairs: "up with the good, down with the bad"** — the aid goes with the affected limb.
14. **Maintenance is a safety issue. Ferrules must be checked regularly and replaced when worn, to reduce the risk of falls.** Also check **wheel locks, brakes, screws, handgrips and folding mechanisms**, and ensure the device is **stored where the patient will actually reach for it**.

E. Wheelchairs and Seating

15. **Wheelchairs were originally designed for transport, not for prolonged sitting** — their **sling-back seats do not provide appropriate support.** In nursing homes, **over 50% of residents use a wheelchair and most spend the majority of the day in it**, frequently in chairs that do not fit.
16. **Seating problems cause pain and agitation — and therefore falls and restraint use:** poor back support; a chair **too tall, too heavy or too wide**; **footrests set too high**; and the **hammock effect of the sling seat.** The uncomfortable patient attempts to transfer unsafely.
17. **Seating solutions:** a **wedge cushion under the buttocks and thighs tilts the resident backwards**; a **wedge seat prevents sliding forward**; **lateral supports or cushions correct leaning to one side**; and in **hemiplegia at risk of shoulder subluxation**, an **arm trough, elevated armrest, lateral arm support or half tray** protects the flaccid limb. **Anyone spending considerable time in a wheelchair must be referred to a physiotherapist or occupational therapist for a formal seating evaluation.**
18. **Related bed and transfer aids:** overlay mattress cushions, air or sheepskin mattresses, **pillows and leg separator cushions**, **heel pads and bed cradles** in peripheral vascular disease or pressure ulcers; **trapeze, transfer pole or bar, raised quarter- or half-length siderail**; and **bed and toilet seat height matched to the patient's lower-leg length**.

F. Who Prescribes, and Complications

19. **Advice on the suitability of aids is best left to occupational therapists or others with particular expertise. Physiotherapists advise on mobility aids**, speech therapists on communication aids, audiologists on hearing aids and continence advisors on continence aids. **These professionals also provide follow-up and ensure that aids are properly used and maintained.**
20. **Prescription is a process, not an event:** assess → select → **measure and fit → train the patient and carer → check the home environment** (thresholds, rugs, narrow doorways, stairs, Indian-style toilet) → **review use, condition and continued suitability**. **Devices should be recommended only if they improve participation in activities the person and family have identified as important.**
21. **Environmental adaptation must accompany the aid — handrails, ramps, and improved access to shower and toilet areas. Early occupational therapy input, usually including a home visit, ensures modifications are appropriate and timed to facilitate hospital discharge.**
22. **Device-related hazards:** falls from incorrect height or worn ferrules; **tripping over the frame**; **shoulder, wrist and hand overuse pain**; **carpal tunnel syndrome and ulnar neuropathy**; **axillary crutch palsy**; increased energy cost of walking; loss of reciprocal arm swing with frames; **deconditioning and learned dependence**; stigma and non-use; and, for wheelchairs, **pressure ulcers, contractures, shoulder subluxation and functional incontinence.**

Latest Updates (2023–Present)

1. The global access gap has been quantified

The **WHO–UNICEF Global Report on Assistive Technology (2022)** revealed that **more than 2.5 billion people need one or more assistive products**, and that **nearly one billion of them are denied access**, particularly in LMICs, **where access can be as low as 3% of need** versus **90% in some high-income countries**. By **2050 an estimated 3.5 billion people will need assistive technology**. **Most users need more than one product, making integrated services important. Of the 80 million people who need a wheelchair, only 5–35% have access to one depending on the country.**

2. WHO Wheelchair Provision Guidelines (2023) — the new reference standard

WHO estimates that **80 million people, about 1% of the world's population, are likely to require a wheelchair**, a number **set to grow as the global population ages**. The guidelines help Member States **increase access to wheelchairs as a priority product**, supporting the **UNCRPD** and **SDGs 3, 4 and 10**, and **complement the 2008 WHO guidelines on manual wheelchairs in less-resourced settings**, supported by **WHO Training in Assistive Products (TAP)**. Data from the **WHO rapid Assistive Technology Assessment (rATA) across 27 countries** found **1.6% of all participants reported needing a wheelchair, rising to 6.5% among those aged 65 and older**, and that **12.0% had some degree of mobility difficulty**. An appropriate wheelchair is framed **not merely as equipment but as a means of exercising human rights**.

3. The WHO "4P" framework and cost as a policy target

WHO's strategy **places people at the centre and gives equal attention to Policy, Products, Provision and Personnel as interconnected elements that must be aligned to ensure equitable access**. WHO is also Secretariat for the **Global Cooperation on Assistive Technology (GATE)**. **WHA76.6 (May 2023)** specifically commits Member States to **minimise the prohibitive costs of assistive technologies such as hearing aids, glasses, wheelchairs and prosthetics**.
*Exam use: if asked "how would you improve mobility aid provision in your district?", structure the answer as **Policy, Products, Provision, Personnel**.*

4. What mobility aids do *not* do — the falls evidence

The **2023 Cochrane review** found that **assistive devices alone — eyeglasses, specialised footwear, bed alarm systems — and patient education alone do not decrease the rate of falls**, whereas **home fall-hazard assessment and modification reduces falls by 26% overall and 38% in those at higher risk**. **NICE NG249 (April 2025)** found **insufficient evidence on assistive technologies such as footwear, foot devices and self-care and assistive devices** in community settings and issued a **research recommendation**.
*Exam framing: a mobility aid **prevents falls only as part of a package** — exercise, medication review, vision correction and home hazard modification.*

5. Guideline gaps and technology on the horizon

A **2025 scoping review (Frontiers in Rehabilitation Sciences)** searched guidelines published between **January 2008 and March 2024** across five databases and found **only 24 usable guidelines from 291 records**, concluding that **guideline development must accelerate** if assistive technology is to be delivered within UHC. Textbook-flagged directions are maturing: **robotic walking-assist devices** (with potential both to augment recovery in neuromuscular deficit and to assist ADLs including stair walking), **sensor-based gait analysis to select the most appropriate orthosis**, and **robotic gloves combined with virtual reality and arm orthoses that counterbalance limb weight** after hemiparetic stroke. **Smart canes and rollators with fall detection and GPS** are entering practice but lack older-adult validation.

6. India — the operational provision system

The **ADIP Scheme (Assistance to Disabled Persons for Purchase/Fitting of Aids and Appliances)** has operated **since 1981**, providing **durable, scientifically manufactured standard aids and appliances** to promote physical, social and psychological rehabilitation, **arrest the extent of disability and prevent secondary disability**. Grants go to **ALIMCO, National Institutes, Composite Regional Centres, District Disability Rehabilitation Centres, State corporations and NGOs**; the scheme **also funds corrective surgery where required before a device is provided**, and was **last revised with effect from 1 April 2024 and continued to 31 March 2026**.

ALIMCO is the largest manufacturer of mobility and rehabilitation aids in South Asia. Over the seven years to 2020, **ADIP spent about ₹10.8 billion and benefited 1.8 million people, largely through 9460 camps**. ALIMCO is the **implementing agency for ADIP and nodal agency for Rashtriya Vayoshri Yojana**, and has begun opening **Pradhan Mantri Divyasha–Vayoshri Kendras (PMD-VK)**. Under **RVY**, BPL senior citizens with income ≤ ₹15,000/month receive **walking sticks, elbow crutches, walkers, tripods/**

quadpods, wheelchairs, hearing aids, spectacles and dentures free, with **doorstep delivery for those aged ≥80 years**.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Framing	"Aids and adaptations" — one step in the rehabilitation process	**Assistive technology is a named entitlement within UHC**; wheelchairs are a **priority product** with dedicated WHO guidelines (2023)
Scale of need	Not quantified	**2.5 billion need assistive products (3.5 billion by 2050); ~1 billion denied access; 80 million need a wheelchair, only 5–35% have one**
Wheelchair need in older people	Not quantified	**6.5% of people aged ≥65 report needing a wheelchair** (WHO rATA)
Do aids prevent falls?	Implied benefit	**Assistive devices alone do NOT reduce falls**; they work only within a multifactorial package
Non-use	"Those in real need often do not obtain even basic aids"	Confirmed and extended — **people who own devices fall more when not using them, and those falls are more injurious**
Who prescribes	OT for aids generally, PT for mobility aids	Unchanged, but the **4P framework** makes **trained personnel an explicit system requirement**, supported by **WHO TAP**
Wheelchair seating	Referral for seating evaluation if prolonged use	Reinforced — poor seating causes pain, agitation, unsafe transfers and restraint use
Technology	Emerging robotics and sensors	Moving into practice; **guideline coverage remains sparse (only 24 AT guidelines in 16 years)**
India	Not covered	**ADIP (revised April 2024) + ALIMCO + RVY + PMD-VK**; **DDRCs** assess and fit devices at district level

Exam One-Liners

- **A mobility aid can foster dependence rather than independence** — prescribe the **least restrictive device that is safe**.
- **Lack of a mobility aid is itself a listed cause of immobility.**
- **Cane length = wrist crease to floor**; handle at the **ulnar styloid/greater trochanter**; **elbow flexed 20–30°**.
- **Cane in the hand opposite the painful hip; for the knee, try either hand; in hemiplegia, the unaffected hand.**
- **Cane–bad leg–good leg** on the flat; **up with the good, down with the bad** on stairs.
- **Axillary crutch pad sits ~2 finger-breadths below the axilla** — never bear weight on the axilla (crutch palsy).
- **A standard frame gives the most stability but abolishes arm swing and cannot be used on stairs.**

- **A rollator needs intact grip, cognition and braking ability** — it can run away downhill.
- **Berg Balance Scale: 0–20 wheelchair-bound, 21–40 walking with assistance, 41–56 independent.**
- **Worn ferrules cause falls** — check and replace at every review.
- **About a quarter of community-dwelling elders use a mobility device**; falls are **not** linked to any particular device.
- **Wheelchairs were designed for transport, not for sitting all day.**
- **Hemiplegic arm in a wheelchair needs an arm trough, elevated armrest or half tray** to prevent shoulder subluxation.
- **Assistive devices alone do not prevent falls.**
- **WHO 4P framework: Policy, Products, Provision, Personnel.**
- **India: ADIP (since 1981, revised 2024) and RVY, delivered through ALIMCO, DDRCs and CRCs.**

Q9. Assistive devices for the elderly

High-Yield Points

A. Definitions

1. **Assistive technology** is the umbrella term for **assistive products together with the systems and services that deliver them.** An **assistive product** is any product that **maintains or improves functioning and independence** — from a pair of spectacles to a powered wheelchair.
2. **Assistive devices reduce activity and participation restriction**, ranging **from the simple and inexpensive to the technologically advanced**, and help **from carrying out ADLs to maintaining mobility and promoting continence.**
3. **Two cardinal cautions: "The provision of an aid is not always the best option for an impaired person, as it can foster dependence rather than independence"**; and **"Those in real need often do not avail themselves of even basic aids and appliances."** Both under-provision and over-provision are errors.
4. **The golden rule of prescription: devices should be recommended only if they support improved participation in the activities identified as crucial to the elder and/or their family or support system.** A device that does not serve a valued activity will be abandoned.

B. Classification — the WHO Six Functional Domains

The WHO Priority Assistive Products List (APL) classifies devices into six functional domains: mobility, vision, hearing, communication, cognition and self-care.

Domain	Devices for the older person
Mobility	**Canes (single-point, quad, tripod), hemi-walker, elbow and axillary crutches, walking frames, rollators, manual and powered wheelchairs, scooters**; transfer aids (**transfer board, trapeze, transfer pole, hoist**); **prostheses and orthoses (AFO, knee brace, foot orthoses)**; **therapeutic footwear, rocker-bottom shoe**, medial arch supports
Vision	**Reading glasses and optimum spectacles**; **hand-held, stand and spectacle-mounted magnifiers; telescopes; electronic/CCTV magnifiers**; **lighting intensifiers without glare**; **tinted glasses**; **night light to aid dark adaptation**; **large-print books and newspapers**; talking watches; **white cane**
Hearing	**Behind-the-ear, in-the-ear and body-worn hearing aids**; **pocket talkers/ personal amplifiers**; **middle-ear and cochlear implants**; **amplified telephones, doorbells and TV listeners**; **closed captioning**
Communication	Communication boards and books, **speech-generating devices**, text-to-speech and voice-amplification apps, writing aids
Cognition	**Pill organisers and automated dispensers, memory aids, calendar clocks, labelled and picture-marked cupboards, medication alarms, GPS locators, simplified telephones**
Self-care	**Long-handled reachers, sock aid, dressing stick, button hook, built-up-handle cutlery, non-slip mats, plate guards**; **raised toilet seat, commode, shower chair, handheld shower, grab bars**; **absorbent continence pads**; **upper-limb splints**; **therapeutic footwear for the diabetic foot**

6. **A prosthesis replaces a body part; an orthosis is applied to the external surface of the body to provide support, improve function, or restrict or promote movement.** Their **design, construction and fitting require particular skill and technological expertise**; well-resourced centres include **prosthetists and orthotists** in the team.
7. **Environmental adaptation is part of the same prescription: handrails and ramps, improved access to shower and toilet areas, additional lighting, grab bars, and removal of loose rugs and clutter. Early occupational therapy input, usually including a home visit, ensures that modifications are appropriate and timed to facilitate hospital discharge.**

C. Domain-Specific Prescribing Points

8. **Vision — simple measures maximise residual vision:** a **magnifying device, large-print reading material, lighting intensifiers and reduction of glare.** Aids must be **combined with training** (eccentric viewing, device use) or they fail.

Hearing aid evaluation — the classic checklist

- **Exclude any contraindicating medical or correctable problem** (e.g. cerumen)
- **Greatest satisfaction if the loss is 55–80 dB; only partial help if the loss exceeds 80 dB**
- **Less satisfaction when speech discrimination is poor**
- The aid is **designed for face-to-face conversation** — set **realistic expectations**
- **May need to be combined with lip reading**
- **Loudness perception abnormalities (recruitment) may make the aid unacceptable**
- **More severe loss requires a body-worn aid** rather than behind-the-ear
- Decide **monaural versus binaural**; assess the **patient's ability to handle the aid independently**; assess **motivation**

10. **Practical hearing aid points: hearing aids are most useful in one-to-one conversation and least useful in noisy group settings. The old adage that hearing aids do not help sensorineural loss is simply not true** — modern digital aids can be **tuned to specific frequencies rather than amplifying all frequencies**. **Binaural aids improve sound localisation and discrimination. Body-worn aids give the greatest amplification and have large controls; in-the-ear aids are cosmetically preferred but harder to manipulate. Patients are often initially resistant — patient and family counselling improves use and satisfaction. Middle-ear and cochlear implants are safe and effective options** when hearing aids fail in severe loss.
11. **Continence:** absorbent pads and washable absorbent products, **bedside commode and urinal to shorten the distance to the toilet**, raised toilet seat and adequate night lighting. **Continence advisors are the correct experts.**
12. **Wheelchair seating is a device issue, not a comfort issue. Wheelchairs were designed for transport, not prolonged sitting; sling-back seats give inadequate support.** Poor back support, a chair **too tall, heavy or wide**, **footrests set too high** and the **hammock effect** cause **pain and agitation — and hence unsafe transfers, falls and restraint use.** Corrections: **wedge cushion, wedge seat, lateral supports**, and in hemiplegia an **arm trough, elevated armrest, lateral arm support or half tray**. **Prolonged users need a formal seating evaluation by a physiotherapist or occupational therapist.**
13. **Falls-related devices — know the evidence limits. Hip protectors** show **uncertain benefit in nursing home residents and no clear benefit in community dwellers**, but **for high-risk older people willing to wear them, they may reduce fear of falling**. **An anti-slip shoe device reduces outdoor falls in icy conditions**, and **compression stockings plus tools to aid slow rising** help in postural hypotension.

D. Who Prescribes, and Why Devices Fail

14. **Advice on the suitability of aids is best left to occupational therapists or others with particular expertise: physiotherapists advise on mobility aids, speech therapists on communication aids, audiologists on hearing aids, and continence advisors on continence aids. These professionals also provide follow-up and ensure that aids are properly used and maintained and continue to serve their purpose.**

15. **The four provision steps are select → fit → use (train) → follow-up. Without all four, assistive products are often of no benefit, are abandoned, or may cause physical harm.** *This one line answers most exam questions on device failure.*
16. **Common causes of device abandonment:** wrong device or wrong size; no training; **cosmetic stigma**; cost; the device not serving a valued activity; **cognitive or dexterity failure** (hearing aid batteries, walker brakes); lack of maintenance; and **carer over-help that removes the reason to use it.**
17. **Device-related complications:** falls from **worn ferrules** or wrong height; **carpal tunnel syndrome, ulnar neuropathy and shoulder pain**; **axillary crutch palsy**; **pressure ulcers, contractures and functional incontinence** from prolonged wheelchair use; **skin damage from pads**; **otitis externa and cerumen impaction** from hearing aid moulds; and **learned dependence and deconditioning.**
18. **The over-help trap:** if caregivers bathe and dress an older person who has independence goals, **those goals will not be achieved** — "helping" creates **deconditioning, dependency, contractures and the other sequelae of immobility.** A **restorative philosophy must accompany every device.**

E. Integration into Geriatric Care

19. **The WHO ICOPE pathway builds assistive devices into intrinsic-capacity management: provide an assistive device to aid mobility; reading glasses and vision rehabilitation for irreversible low vision; hearing aids and auditory aids around the house (telephone, doorbells); home adaptation to prevent falls. Treating visual impairment enables maintaining family and social relationships, accessing information, moving safely and performing manual tasks.**
20. **Emerging technology: remote sensors and accelerometers for objective progress measurement**, **virtual reality platforms** giving visual, auditory and tactile input, a **robotic glove combined with VR attached to an arm orthosis that counterbalances arm weight** after hemiparetic stroke, and **walking assist devices with potential to augment recovery and assist ADLs including stair walking.** Sensor-based gait analysis can **indicate the most appropriate orthotic device to prescribe.**

Latest Updates (2023–Present)

> **1. The global access gap**
>
> The **WHO–UNICEF Global Report on Assistive Technology (2022)** found that **more than 2.5 billion people need one or more assistive products**, yet **nearly one billion are denied access**, with access **as low as 3% of need in some low-income countries versus up to 90% in some high-income countries**. **An estimated 3.5 billion people will need assistive technology by 2050**, driven by **population ageing and rising non-communicable disease**. **Timely provision of assistive technology for older people improves independence and safety and enables them to live at home for as long as possible.**

> **2. The Priority Assistive Products List and its ongoing update**
>
> WHO introduced the **Priority Assistive Product List (APL) in 2016**, featuring **50 crucial products across mobility, vision, hearing, communication, cognition and self-care**, followed by the **Assistive Product Specifications (APS) in 2021** and the **Training in**

Assistive Products (TAP) programme in 2022. The APL is **modelled on the WHO Model List of Essential Medicines**. On **6–7 May 2025 WHO convened the first in-person meeting of the Technical Advisory Group on Assistive Technology in Geneva — 24 independent experts from all six WHO regions** — who **assessed and prioritised 300 assistive products grouped by the six functional domains** for an **updated APL**. **Since 2016, 23 countries have adopted national lists based on the WHO model.**

3. The workforce is the bottleneck — and the four provision steps

Only about 1 in 10 people worldwide have access to appropriate assistive products, and **workforce shortages are one of the biggest reasons**. WHO states that **trained personnel are essential for the proper assessment, fitting, user training and follow-up**, and that **without these four key steps assistive products are often of no benefit or abandoned, and may cause physical harm. WHO TAP** covers the provision steps — **select, fit, use, follow-up** — for **25 basic products from the APL across cognition, communication, vision, hearing, continence and mobility**, is **open-access in 10 languages**, and has been deployed in **Tanzania, Ukraine, India, Iraq, Papua New Guinea and Romania**.

4. Hearing aids and cognition — the ACHIEVE trial (Lancet 2023)

ACHIEVE randomised **977 adults aged 70–84 with untreated mild-to-moderate hearing loss and without substantial cognitive impairment** at four US sites to **hearing intervention (audiological counselling plus hearing aids)** or **health education control**, with **3-year change in global cognition** as the primary endpoint. **The result was negative in the total study population**, **but in the pre-specified subgroup of 238 participants drawn from the ARIC cardiovascular cohort — at increased risk of cognitive decline — hearing intervention slowed cognitive decline by 48% over three years. Hearing loss is present in 65% of adults over 60.**
*Exam framing: hearing aids are **not proven to prevent dementia in everyone**, but are a **reasonable intervention in the at-risk older adult** — and remain unequivocally indicated for communication, mood and social participation.*

5. Assistive devices alone do not prevent falls

The **2023 Cochrane review** found that **assistive devices alone — eyeglasses, specialised footwear, bed alarm systems — and education alone do not reduce the rate of falls**, whereas **home fall-hazard assessment and modification reduces falls by 26% overall and 38% in high-risk older people**. **NICE NG249 (2025)** found **insufficient evidence on assistive technologies in community settings** and issued a formal **research recommendation**.

6. Policy anchors and Indian provision

WHA71.8 (2018) committed Member States to improving access to assistive technology; **WHA76.6 (2023)** calls for integrating rehabilitation into health systems within UHC and specifically commits to **minimising the prohibitive costs of assistive technologies such as hearing aids, glasses, wheelchairs and prosthetics**. WHO's strategy uses the **4P framework — Policy, Products, Provision and Personnel**.

India: the **ADIP Scheme** (since **1981**, **revised with effect from 1 April 2024** and

continued to 31 March 2026) provides **durable, scientifically manufactured standard aids and appliances** and **funds corrective surgery where needed before a device is provided**, with grants to **ALIMCO, National Institutes, Composite Regional Centres, DDRCs, State corporations and NGOs**. **ALIMCO is the largest manufacturer of mobility and rehabilitation aids in South Asia**; over seven years to 2020, **ADIP spent about ₹10.8 billion and benefited 1.8 million people through 9460 camps**, and ALIMCO is opening **Pradhan Mantri Divyasha-Vayoshri Kendras (PMD-VK)**. **Rashtriya Vayoshri Yojana** supplies **free walking sticks, elbow crutches, walkers, tripods/ quadpods, hearing aids, wheelchairs, artificial dentures and spectacles** to **BPL senior citizens with income ≤ ₹15,000/month**, with **doorstep delivery for those aged ≥80 years**. **DDRCs, now approved in every district**, assess need, **fit and repair assistive devices**, and provide **physiotherapy, occupational therapy and speech therapy**.

Current Practice Update

Issue	Textbook Position	Current Evidence (2023-present)
Framing	"Aids and adaptations" — a step in the rehabilitation process	**Assistive technology is an entitlement within UHC**; the **APL is modelled on the Essential Medicines List**
Classification	Descriptive by need	**Six WHO functional domains: mobility, vision, hearing, communication, cognition, self-care**
Scale of need	Not quantified	**2.5 billion now, 3.5 billion by 2050; ~1 billion denied access; only 1 in 10 have appropriate products**
Why devices fail	"Aids may foster dependence"; "many in need do not obtain them"	Reframed as the **four provision steps — select, fit, use, follow-up**; omit any one and the device is abandoned or causes harm
Workforce	OT/PT/audiologist/continence advisor advise	**Workforce shortage named as the single biggest barrier**; **WHO TAP** trains primary care and community workers for 25 basic products
Hearing aids and cognition	Not addressed	**ACHIEVE (Lancet 2023): no effect overall, but 48% slower cognitive decline over 3 years in the at-risk subgroup**
Devices and falls	Aids implied to help	**Devices alone do not reduce falls** — benefit comes from the **package**
Wheelchairs	Seating evaluation if prolonged use	**WHO Wheelchair Provision Guidelines (2023)**; **6.5% of people ≥65 need a wheelchair**; only **5–35%** of those needing one have one
Priority product list	Not addressed	**APL under formal revision — 300 products reviewed by the WHO Technical Advisory Group in May 2025**

Exam One-Liners

- **Assistive technology = assistive products + the systems and services that deliver them.**

- **WHO APL (2016): 50 priority products across six domains** — mobility, vision, hearing, communication, cognition, self-care. Under revision; **300 products reviewed in May 2025**.
- **The four provision steps: select, fit, use, follow-up.** Miss one and the device is **abandoned or harmful**.
- **An aid can foster dependence rather than independence** — but **those in real need often never obtain even basic aids**.
- **Prescribe a device only if it serves an activity the person and family value.**
- **Prosthesis replaces a body part; orthosis supports, improves function, or restricts/promotes movement.**
- **Hearing aid: best satisfaction at 55–80 dB loss; only partial help above 80 dB; poor discrimination predicts poor satisfaction.**
- **Hearing aids work best one-to-one and worst in noisy groups.**
- **Binaural aids improve sound localisation and discrimination.**
- **ACHIEVE (2023): 48% slower cognitive decline with hearing aids in the at-risk subgroup only.**
- **Vision aids: magnifier, lighting intensifiers without glare, tinted glasses, night light, large print** — always with training.
- **Self-care classics: long-handled reacher, sock aid, dressing stick, built-up cutlery, raised toilet seat, shower chair, grab bars.**
- **Assistive devices alone do not prevent falls.**
- **WHO 4P framework: Policy, Products, Provision, Personnel.**
- **India: ADIP (since 1981, revised 2024), ALIMCO, Rashtriya Vayoshri Yojana, PMD-VK and DDRCs.**

Q10. Artificial limb — rehabilitation of the elderly amputee

High-Yield Points

A. Definition

1. **A prosthesis is a device that replaces a missing body part**, in contrast to an **orthosis**, which is applied to the external surface of the body to **provide support, improve function, or restrict or promote movement.** Their **design, construction and fitting require particular skill and technological expertise**, and well-resourced rehabilitation centres include **prosthetists and orthotists** in the multidisciplinary team.

B. Aetiology and Epidemiology

2. **Most lower-limb amputations in older people are a consequence of peripheral vascular disease.** Limb-threatening ischaemia is only occasionally due to a sudden embolic event; **most patients have a long period of worsening ischaemia before amputation. Many are diabetic with coexisting cardiac and vascular disease**, and others have **smoking-induced chronic lung disease.**
3. **Despite this, rehabilitation has much to offer older amputees, and many rise to the challenge of walking even with bilateral below-knee prostheses.**
4. **Elderly amputees are nonetheless a high-risk group: perioperative mortality 10–30%, two-year survival 40–50%, five-year survival 30–40%** — and **these rates have not changed significantly in the past 50 years despite better anaesthetic and surgical techniques.**

C. Level of Amputation — the critical surgical decision

5. **Preservation of the knee is critical** for **proprioceptive and neuromuscular control** and above all for **minimising energy expenditure**. **It takes 40% more energy to walk with an above-knee (transfemoral) than with a below-knee (transtibial) prosthesis.**
6. **But do not over-reach for the knee. Injudicious efforts to salvage a knee joint can produce an ischaemic stump that fails to heal and later requires a more proximal amputation. A second procedure is potentially disastrous — it increases anaesthetic risk, prolongs immobility, increases deconditioning and delays entry into rehabilitation.**

D. Pre-Prosthetic Phase

7. **Stump management** uses **rigid removable dressings** to **reduce oedema, promote healing and protect against incidental trauma.**
8. **Early physiotherapy must strengthen the arms, abdominal muscles, lower back and the remaining leg** — not merely the stump, because transfers and frame work depend on the upper body.
9. **Prevent contracture from day one. For a below-knee amputee the full range of knee extension must be maintained** — therefore **avoid prolonged sitting without corrective exercises**, and perform **a minimum of 20–30 minutes of prone lying twice daily** to promote full extension. In transfemoral amputees, guard against **hip flexion and abduction contracture**.

10. **Stump conditioning: the skin contacting the prosthesis must become durable and toughened, best achieved by graded use of the prosthesis. Massaging the stump improves circulation and prevents adhesions during healing**, and patients should be encouraged to do it themselves.

E. Selecting the Patient for a Prosthesis

11. **“Irrespective of age, prescription of a lower limb prosthesis is almost always indicated, even in the presence of other major medical problems.”** Yet **older amputees are less likely than younger ones to receive a prosthesis, even after adjusting for comorbidity and functional status** — an ageism issue.
12. **The prosthesis facilitates transfers, standing and walking, and has cosmetic value** — the transfer benefit alone justifies fitting in many frail patients.
13. **The old criterion is invalid.** It used to be argued that an older amputee should demonstrate **crutch-walking capacity before being offered a prosthesis. However, walking without bearing weight on the amputated side has a higher energy cost than walking on the prosthesis, so this criterion is invalid.**
14. **Respect patient choice. Some refuse a prosthesis and accept wheelchair mobility, but most older people — particularly those with few comorbidities — are happy with their prosthesis and use it well. A prosthesis should never be prescribed without considering each patient’s unique needs and wishes, and the demands of using it must be fully explained.**

F. Components of the Prosthesis

A modern trans-tibial prosthesis has three parts: a socket, a shank, and an ankle-and-foot mechanism.

Component	Key facts
Socket	**The major determinant of comfort and stability.** Designed to **transfer most of the weight onto the patellar tendon**; **a good fit is critical.** The stump is **oedematous early and shrinks over time**, so **temporary sockets are needed until shrinkage is complete before a permanent socket is cast. Plastic laminate is the commonest material.** May incorporate a **suction device for suspension**; with a **non-suction socket an interface (stump socks or resilient plastic) is required**
Shank	**Exoskeletal** — traditional, willow or lightweight balsa wood covered with laminated plastic. **Endoskeletal** — modern, a **central pillar of carbon fibre or lightweight metal** bearing body weight, surrounded by a **soft cover approximating the feel of a normal limb**
Ankle–foot	**Rigid, or an ankle allowing movement in one or more planes.** Prescription depends on **the level of activity and the condition of the stump**; **there is no evidence that any one design is inherently superior. Advantages of a rigid ankle: lightness, low initial and maintenance cost, easy fitting, good appearance.** The **SACH (solid ankle–cushion heel) foot** has a **rigid ankle, compressible heel and light foot**, is **particularly suited to frail, less active patients who do not take long steps**, gives **long service**, and is **almost always used for below-knee limbs**

16. **Prosthesis hygiene: stump socks should be washed daily with mild soap and warm water, rinsed thoroughly and dried flat**, and **the inner surface of the socket cleaned each evening with a warm soapy cloth.**

G. Gait Training and Protecting the Remaining Limb

17. **Once a comfortable, stable and functional limb has been provided, the next stage is teaching the patient to walk on it properly** — progressive weight transfer in parallel bars, then frame, then sticks.
18. **Protect the remaining limb — it is the one that matters most.** When peripheral vascular disease causes amputation, **the remaining limb is often significantly ischaemic: 15–20% undergo contralateral amputation within two years and about 40% within four years. Viability can be enhanced by revascularisation surgery and by minimising vascular risk factors (poor diabetic control, smoking). Promote foot hygiene and avoid trauma, particularly by wearing appropriate footwear.**
19. **Comprehensive rehabilitation involves more than the provision of a prosthesis. Comorbidity, prosthetic component selection, and resettlement with tenuous or absent social supports all present formidable challenges.**

H. Phantom Limb Phenomena

20. **Phantom limb sensation is normal and non-painful after amputation.** Initially it can be **so deceptive that the patient inadvertently attempts to walk on or scratch the missing limb. Over time the limb is felt to retract or "telescope" into the stump.**
21. **Phantom pain is a separate but perhaps related phenomenon affecting 50–80% of amputees.** Pathophysiology is poorly understood, with **central and peripheral nervous system factors plus psychological factors** implicated. **It is distinguished from stump pain because it is localised in the space vacated by the amputation**, and is described as **burning, crushing or lancinating**; it may be **continuous or intermittent**, and the limb may be **perceived as twisted or deformed.**
22. **Management of phantom pain is difficult.** The first step is **explaining the nature of the phenomenon to the patient. Patients with chronic pain before amputation have a higher incidence of phantom pain, but attempts to control pain before and during surgery do not consistently reduce it. There is little RCT evidence; reported improvement rates are little better than placebo. Anaesthetic and surgical techniques (local anaesthesia, sympathectomy, cordotomy) are as disappointing as pharmacological approaches. Tricyclic antidepressants and sodium-channel blockers are often used for their efficacy in neuropathic pain but are of no proven benefit. TENS provides modest relief at best**, and patients need **ongoing psychological help to develop coping strategies.**
23. **Nutrition detail:** when calculating BMI in an amputee, add back the missing body-part percentage — **single below-knee 6.0%, single at-knee 9.0%, single above-knee 15.0%, single arm 6.5%, single arm below elbow 3.6%.**

Latest Updates (2023–Present)

1. VA/DoD Clinical Practice Guideline for Rehabilitation of Individuals with Lower Limb Amputation (2024)

This **2024 update of the 2017 guideline** directly modifies textbook practice:

- **"For prosthetic ambulators, we suggest prescribing microprocessor knee units over non-microprocessor knee units for reducing falls, optimizing functional mobility and improving patient satisfaction"** (Weak for).

- **“We suggest energy storing and return (ESAR) or microprocessor-controlled foot and ankle components over solid ankle cushioned heel (SACH) feet to improve ambulation and patient satisfaction”** (Weak for) — though **there is insufficient evidence to prefer any specific ESAR or microprocessor foot over another.**
- **“For patients with transfemoral amputation who meet eligibility criteria, we suggest osseointegration as an option to improve prosthesis use”** (Weak for).
- **“We suggest intraoperative placement of a perineural catheter for postoperative delivery of local anaesthetic to reduce pain following amputation surgery.”**
- **Insufficient evidence for or against targeted muscle reinnervation** or other peripheral nerve surgery for phantom limb pain, and **insufficient evidence for or against neurostimulation** (peripheral nerve or spinal cord stimulation) **or neuroablation** (cryoneurolysis, radiofrequency ablation).
- **“We suggest using patient-reported and performance-based measures with acceptable psychometric properties to assess function”** (Weak for).

2. Osseointegration — promising but not for the typical elderly amputee

Osseointegration is **a procedure in which a metal implant is directly anchored to the residual bone and attached to a prosthetic limb by a transcutaneous connector**, an alternative to the socket-mounted prosthesis that has gained acceptance over the past 30 years. The VA/DoD **“weak for” recommendation rests on very low confidence in the evidence quality**, and on the fact that **many clinicians are unfamiliar with the procedure because of limited access and training**; the **2022 VA/DoD upper limb guideline found insufficient evidence** either way. Crucially, **candidates should not have diabetes, peripheral vascular disease or metabolic disease** — which **excludes the majority of elderly dysvascular amputees**. A **consensus statement on prehabilitation and rehabilitation of osseointegration patients** was published in **2025**, noting that **protocols vary by implant system and institution**.

3. Updated physiotherapy guidance and health economics

The **British Association of Chartered Physiotherapists in Limb Absence Rehabilitation (BACPAR)** published the **3rd edition of its “Clinical guidelines for the pre- and post-operative physiotherapy management of adults with lower limb amputations” in 2025**, incorporating new evidence and a **2024 Delphi consensus**. A **2025 exchange in the Canadian Prosthetics & Orthotics Journal** on the **health economic evaluation of microprocessor versus non-microprocessor knees** underlines that **real-world cost-effectiveness data now drive reimbursement decisions** — the practical barrier to microprocessor knees in most health systems, including India, is **cost, not evidence**.

4. Functional classification now drives component prescription (Medicare K-levels)

K0 — no ability or potential to ambulate or transfer safely; a prosthesis does not enhance mobility
K1 — transfers and ambulation on level surfaces at fixed cadence (household ambulator) → **SACH or single-axis foot**
K2 — limited community ambulator, can negotiate low-level barriers (kerbs, stairs, uneven ground) → **multi-axial or flexible-keel foot; increasing evidence for microprocessor knees**
K3 — community ambulator with variable cadence → **ESAR foot, microprocessor or hydraulic knee**
K4 — high impact; child, athlete or active adult

Most elderly dysvascular amputees are K1–K2, and the current shift is that **K2 patients now benefit from components once reserved for K3**.

5. India — the artificial limb landscape

ALIMCO is India's largest government-run prosthetic manufacturer, producing affordable artificial limbs, mobility aids and assistive devices distributed **free or subsidised under the ADIP Scheme**.

BMVSS (Bhagwan Mahaveer Viklang Sahayata Samiti), the "Jaipur Foot" organisation, completed 50 years in 2025. It **rehabilitated 88,467 people in 2022–23 and fitted 40,078 limbs in 2024–25**, and has provided **over 2.5 million artificial limbs, calipers and other aids free of charge across India and 27 other countries**.

The **Jaipur Limb uses an HDPE polymer custom-made socket linked to the specially designed Jaipur Foot, which is distinct from the SACH foot used in Western technology.** The **Jaipur Knee, developed with Stanford University**, is generally added for above-knee amputees. **A below-knee amputee with a Jaipur Foot can walk on even or uneven ground, run, sit, squat, climb, swim and dance** — an **above-knee amputee retains most of these functions**. It is a **rapid-fit limb, fabricated and fitted mostly within one or two days**, **light, durable and provided completely free**, with **no prior appointment needed** (Aadhaar card and disability certificate required), including at **on-the-spot fitment camps**. The **Jaipur/Stanford knee costs about US$20 to manufacture in India**.

In India, **around 45,000 legs are estimated to be amputated every year**, with major risk factors for diabetic amputation being **lower-extremity ischaemia, neuropathy, previous foot ulcer, elevated HbA1c and retinopathy**.

*Exam relevance: the **ability to squat and sit cross-legged is the culturally decisive functional outcome in India**, and this is precisely where the Jaipur Foot outperforms the SACH foot.*

Current Practice Update

Issue	Textbook Position	Current Evidence (2023–present)
Prosthetic foot	**SACH foot is almost always used for below-knee limbs**; no design inherently superior	**VA/DoD 2024 suggests ESAR or microprocessor feet over SACH** — SACH remains reasonable for **K1 household ambulators and low-resource settings**
Prosthetic knee	Not detailed	**Microprocessor knees suggested over non-microprocessor knees** to **reduce falls** and improve mobility and satisfaction — cost is the limiting factor
Attachment method	Socket-based only	**Osseointegration is a "weak for" option in selected transfemoral amputees** — but **excluded in diabetes and peripheral vascular disease**
Perioperative pain	Pre-emptive analgesia does not consistently prevent phantom pain	**Intraoperative perineural catheter** for postoperative local anaesthetic is now suggested to reduce post-amputation pain
Phantom pain drugs	TCAs and sodium-channel blockers of no proven benefit; TENS modest at best	Essentially unchanged; **insufficient evidence for targeted muscle reinnervation, neurostimulation or neuroablation**
Patient selection	Prosthesis "almost always indicated irrespective of age"; crutch-walking criterion invalid	Reinforced; **K-level functional classification** now guides *which components*, not *whether* to fit
Outcome measurement	Not specified	**Validated patient-reported and performance-based outcome measures now recommended**
Physiotherapy protocol	General principles	**BACPAR 3rd edition (2025)** provides updated pre- and post-operative guidance
India	Not covered	**ALIMCO/ADIP and BMVSS Jaipur Foot** — free, rapid-fit, squat-capable limbs; **~45,000 amputations/year**

Exam One-Liners

- **Prosthesis replaces a body part; orthosis supports, improves function, or restricts/promotes movement.**
- **Peripheral vascular disease is the commonest cause of lower-limb amputation in the elderly.**
- **Perioperative mortality 10–30%; 2-year survival 40–50%; 5-year survival 30–40%** — unchanged for 50 years.
- **Above-knee walking costs 40% more energy than below-knee** — save the knee where healing allows.
- **A failed knee salvage requiring re-amputation is disastrous.**
- **Rigid removable dressings** reduce oedema, promote healing and protect the stump.
- **Prone lying 20–30 minutes twice daily** prevents knee flexion contracture in the trans-tibial amputee.

- **Early physiotherapy targets the arms, abdomen, back and remaining leg.**
- **The crutch-walking prerequisite is invalid** — walking without weight-bearing costs more energy than walking on the prosthesis.
- **Three components of a trans-tibial prosthesis: socket, shank, ankle-foot.**
- **The socket determines comfort and stability** and loads the **patellar tendon**; **temporary sockets are needed until stump shrinkage is complete.**
- **Exoskeletal shank = willow/balsa with laminated plastic; endoskeletal = carbon-fibre central pillar with a soft cover.**
- **SACH foot = rigid ankle, compressible heel, light** — ideal for the **frail, short-stepping patient**.
- **Wash stump socks daily and dry flat; clean the socket interior nightly.**
- **15–20% lose the other leg within 2 years and ~40% within 4 years.**
- **Phantom sensation is normal and non-painful; the limb "telescopes" over time.**
- **Phantom pain affects 50–80%; it is felt in the space the limb occupied**, unlike stump pain.
- **VA/DoD 2024: microprocessor knees over non-microprocessor knees; ESAR/microprocessor feet over SACH.**
- **Osseointegration is contraindicated in diabetes and PVD.**
- **India: Jaipur Foot allows squatting, sitting cross-legged and walking on uneven ground.**

Master Revision Sheet — Numbers to Memorise

Topic	Number
Global rehabilitation need	**2.41 billion** (one-third of the world); **+63% since 1990**; **>50% unmet in LMICs**
Assistive technology need	**2.5 billion now; 3.5 billion by 2050; ~1 billion denied access; only 1 in 10 have appropriate products**
Wheelchairs	**80 million need one; only 5–35% have one; 6.5% of people ≥65 report needing one**
Home fall-hazard modification	**26% fall reduction overall; 38% in high-risk people** (Cochrane 2023)
Stroke therapy dose	**≥3 hours/day on ≥5 days/week** (NICE NG236, 2023)
Stroke recovery timeline	Most return in **month 1**; little after **month 3**; CIMT works at **3–9 months**
Knee OA in elderly Indians	**~47%** pooled prevalence
STEP 9 (semaglutide, knee OA)	Weight **−13.7% vs −3.2%**; WOMAC pain **−41.7 vs −27.5**
GLA:D programme dose	**12 supervised sessions over 6 weeks** + 2–3 education sessions
ACHIEVE (hearing aids)	**48% slower cognitive decline** in the at-risk subgroup only
Hearing aid satisfaction	Best at **55–80 dB** loss; partial help **>80 dB**
Blindness in India (≥50 years)	**1.99%**; cataract **66.2%**; **~93% avoidable**
Amputee survival	Perioperative mortality **10–30%**; 2-year **40–50%**; 5-year **30–40%**
Above-knee energy cost	**40% more** than below-knee
Contralateral amputation	**15–20% at 2 years; ~40% at 4 years**
Phantom pain	**50–80%** of amputees
Berg Balance Scale	**0–20** wheelchair; **21–40** aided walking; **41–56** independent
Team size	**4–7** members
LASI wave-1 (India, ≥60 y)	ADL dependency **7.4%**; vision **13.7%**; hearing **9.6%**; cognition **9.3%**; falls **5.7%**; incontinence **4.0%**
Institutional care	**0.1–1% in LMICs** vs **7.5% in Switzerland**
India amputations	**~45,000 legs per year**

MD GERIATRIC MEDICINE

Infectious Diseases & Respiratory Medicine

Sepsis • Septic Shock • COPD • Oxygen Therapy • CPAP • MDR-TB • Malaria

High-Yield 15-Mark Answers • Textbook-anchored • Updated to August 2026

Contents

1. Sepsis in the older person — definition, epidemiology, presentation, diagnosis, management, prognosis
2. Septic shock, SIRS and MODS — etiopathogenesis, investigations, treatment
3. Recent advances in the management of sepsis
4. COPD management — recent recommendations (GOLD 2026)
5. Tailoring oxygen requirements and delivery systems in COPD with severe hypoxaemia and infective exacerbation
6. Role of CPAP in diseases of the elderly
7. Diagnosis and management of multidrug-resistant tuberculosis (DOTS-Plus / PMDT)
8. Malaria — treatment, drug classes, contraindications, side effects, efficacy and prophylaxis

Sourcing note. Questions 1–6 are anchored in *Pathy's Principles and Practice of Geriatric Medicine, 6th ed.* (Ch. 39 Pneumonia, Ch. 41 COVID-19, Ch. 42 COPD & Asthma, Ch. 45 Sleep Apnoea, Ch. 23 DIC) and *Essentials of Clinical Geriatrics, 7th ed.* (Ch. 12 Infections in Older Adults). The formal **Sepsis-3 definitions, SIRS/SOFA criteria and MODS** are not set out in either uploaded textbook; these, together with **MDR-TB regimens (Q7)** and **malaria chemotherapy (Q8)**, which are also not covered in the uploaded texts, have been drawn from WHO, SCCM/ESICM, GOLD, BTS, NTEP-India and peer-reviewed journals, as flagged at the head of the relevant answers.

Q1. Define sepsis. Discuss its epidemiology, clinical presentation, diagnosis, management and prognosis in the older person.

Textbook coverage: Pathy's and Essentials describe infection in old age (altered presentation, blunted fever, gram-negative predominance, atypical features) and sepsis as a complication of pneumonia, biliary disease and DIC, but do **not** give the formal consensus definition. The definition below is Sepsis-3 (JAMA 2016), retained by the Surviving Sepsis Campaign 2026.

15–20 High-Yield Points

Definition

1. **Sepsis** is **life-threatening organ dysfunction caused by a dysregulated host response to infection** (Sepsis-3, 2016). Organ dysfunction = an acute rise in the **SOFA score by 2 or more points**.
2. **Septic shock** = sepsis with **persisting hypotension requiring vasopressors to keep MAP ≥ 65 mmHg** plus **lactate > 2 mmol/L** after adequate fluid resuscitation. The old terms *severe sepsis* and *septicaemia* are obsolete.

Epidemiology

3. Roughly **49 million cases and 11–13 million sepsis-related deaths** occur worldwide each year; it is a leading cause of death globally (SSC 2026).
4. **Older adults carry most of the burden** — those aged ≥ 65 years account for about **60–85% of all sepsis cases** and the incidence rises roughly **100-fold** from young adulthood to the ninth decade.
5. In India, sepsis is the commonest reason for ICU admission; reported ICU mortality from severe sepsis is **34–58%**, higher than Western cohorts, driven by late presentation, **multidrug-resistant gram-negative organisms** and limited critical-care access.
6. **Predisposing factors in the elderly:** immunosenescence and inflammaging, diminished cell-mediated immunity, protein–energy malnutrition, multimorbidity (diabetes, heart failure, CKD, COPD, dementia), **prostatic obstruction**, swallowing disorders and aspiration, pressure ulcers, indwelling catheters and institutional residence.
7. **Commonest sources:** respiratory tract (pneumonia is the single largest source), **urinary tract**, skin and soft tissue, intra-abdominal/biliary (acute cholecystitis, cholangitis), and device-related infection. **Gram-negative bacilli are more frequent at every site** than in the young.

Clinical Presentation

8. **Presentation is atypical and non-specific.** The **febrile response is blunted or absent in up to 30–50%**; **hypothermia** is an ominous sign, and **absence of leucocytosis does not exclude bacterial infection**.
9. **Delirium or acute confusion is frequently the only presenting feature**, especially in pre-existing dementia. Other geriatric presentations: falls, being ‘off legs’, new incontinence, anorexia, tachypnoea and unexplained functional decline.
10. A textbook axiom: **acute unexplained functional deterioration should alert the physician to an acute infectious process**, and one should **suspect infection (including TB) whenever an older patient is inexplicably failing**.
11. **Tachypnoea (RR > 20–22/min) is the earliest and most reliable sign**; hypotension is a late sign because of stiff vasculature and pre-existing hypertension — a ‘normal’ BP of 110/70 may represent shock in a chronic hypertensive.

Diagnosis and Investigations

12. Sepsis is a **clinical diagnosis** and **must not be ruled in or out on a single biomarker**. Screen with **NEWS/NEWS2, MEWS or SIRS criteria**; calculate **SOFA** in the ICU.
13. **Baseline work-up:** haemogram with differential, **serum lactate**, CRP ± procalcitonin, blood urea and creatinine (mg/dL), electrolytes, liver function, coagulation profile and D-dimer (DIC screen), arterial blood gas, blood sugar.
14. **Two sets of blood cultures before antibiotics**, plus site-directed cultures (urine, sputum, pus, CSF), chest radiograph, ultrasound abdomen/CT for source, and echocardiography if endocarditis is suspected.
15. **Key geriatric pitfall: asymptomatic bacteriuria is very common** in older people — a positive urine culture alone must never be accepted as the source, or a genuine pneumonia or intra-abdominal source will be missed.

Management

16. **Hour-1 bundle:** measure lactate, take blood cultures, give **broad-spectrum antibiotics immediately (ideally within 1 hour)** in septic shock or probable sepsis, start **30 mL/kg balanced crystalloid** for hypotension or lactate ≥ 4 mmol/L, and add **vasopressors** if hypotension persists.

17. **Antibiotics:** cover gram-negatives empirically (third-generation cephalosporin ± aminoglycoside per the textbook; locally, a beta-lactam/beta-lactamase inhibitor or carbapenem where ESBL prevalence is high). **Dose-adjust for renal function** — sarcopenia falsely lowers creatinine, so estimate GFR (Cockcroft–Gault) rather than trusting creatinine, and monitor aminoglycoside levels. De-escalate at 48–72 hours.
18. **Haemodynamics: noradrenaline is first-line**; add vasopressin if doses escalate, then adrenaline; add **IV hydrocortisone** in shock requiring ongoing vasopressors. Fluids must be given cautiously and reassessed — reduced cardiac and renal reserve makes the elderly prone to pulmonary oedema; use dynamic measures (passive leg raise, stroke-volume variation) and capillary refill rather than large fixed boluses.
19. **Source control within 6 hours** — drain abscess, remove infected catheter/line, decompress obstructed biliary or urinary tract, debride necrotic tissue.
20. **Geriatric supportive care bundle:** delirium prevention (orientation, sleep, avoid anticholinergics/benzodiazepines), **LMWH thromboprophylaxis**, PPI stress-ulcer prophylaxis if risk factors, **early enteral nutrition within 72 h**, early mobilisation and physiotherapy, oral care, pressure-ulcer prevention, glycaemic control (start insulin at glucose ≥ 180 mg/dL) and medication review with withdrawal of nephrotoxins.
21. **Goals of care must be addressed early (within 72 hours)**, framed by Pathy's functional categorisation (**robust / frail / moderately demented / end of life**): decide ceilings of treatment, escalation to ICU, resuscitation status and time-limited trials, incorporating advance directives (in India, valid under *Common Cause* 2018 as modified in 2023).

Prognosis

22. **Mortality rises steeply with age** — roughly 1.5–2 times that of younger patients for the same severity; but **frailty, baseline functional status and comorbidity predict outcome better than chronological age**, so age alone must never be used to deny critical care.
23. **Post-sepsis syndrome** is the rule in survivors: new physical disability, **accelerated cognitive decline**, depression and anxiety, sarcopenia, high 30-day readmission and a **one-year mortality of 30–40%**. Institutionalisation after the illness is common.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Sepsis discussed descriptively as a complication of pneumonia, cholecystitis and DIC; no formal definition given.	**Sepsis-3 definition** (infection + SOFA rise ≥ 2) is retained by the **SSC 2026 guidelines**; 'severe sepsis' is abandoned.
Blunted fever and absent leucocytosis emphasised as diagnostic traps — still fully valid.	Unchanged, and reinforced: SSC 2026 states sepsis **cannot be ruled in or out by any single biomarker or test**.
Empirical therapy: 'consider a third-generation cephalosporin and/or aminoglycoside because gram-negative infection is commoner'.	Empirical cover is now **risk-stratified**: cover MDR pathogens only if specific risk factors exist; **routine antifungal and routine anaerobic cover are advised against**.
Aminoglycoside levels and renal function must be monitored.	Retained; SSC 2026 adds **therapeutic drug monitoring on a case-by-case basis** and **prolonged (extended) infusion of beta-lactams after a loading dose (strong recommendation)**.
Fluid resuscitation not addressed in detail for the older patient.	**Balanced crystalloids over 0.9% saline**; 30 mL/kg over 3 h with individualisation; **starches and gelatins are not to be used**; dynamic measures preferred.
qSOFA had been widely taught as the screening tool of choice.	SSC 2026 **strongly recommends NEWS, NEWS2, MEWS or SIRS over qSOFA** as the single screening tool in hospital.
MAP target not specified.	MAP target **65 mmHg** generally, but in patients **aged 65 years and over an initial MAP of 60–65 mmHg** is suggested — a directly geriatric recommendation.
Vitamin C, immunoglobulin and blood purification not addressed.	SSC 2026 **suggests against IV vitamin C, IV immunoglobulin, vitamin D, blood purification and polymyxin B haemoperfusion**.

Latest Updates (2023–Present)

- **Surviving Sepsis Campaign 2026 guidelines** (*Crit Care Med*, March 2026) — 129 statements, **46 entirely new**, from a 69-member panel across 23 countries with 38% from low- and middle-income settings.

- **Tiered antibiotic timing** (new): **within 1 hour** for septic shock and for probable/definite sepsis; for **possible** sepsis without shock, a time-limited period of rapid investigation with antibiotics **within 3 hours**; and **defer antibiotics** where the likelihood of infection is low.
- **Prolonged beta-lactam infusion** after a loading dose is now a **strong** recommendation (BLING III, MERCY trials).
- **Peripheral vasopressor initiation** is suggested rather than delaying until central access is obtained — practical in Indian emergency departments.
- **Respiratory support: high-flow nasal cannula (HFNC) is preferred over conventional oxygen**, and **HFNC over non-invasive ventilation as initial therapy**, in sepsis-associated hypoxaemic respiratory failure; awake proning is suggested in the non-intubated.
- **Corticosteroids are suggested for septic shock**; **terlipressin, levosimendan and beta-blockers are suggested against**; evidence remains insufficient for methylene blue and midodrine.
- **Restrictive transfusion strategy (strong)**; insulin started at glucose ≥ **180 mg/dL (strong)**; **LMWH preferred over unfractionated heparin (strong)** for VTE prophylaxis.
- **Survivorship is a new pillar**: pharmacist-led medication reconciliation at transitions, written and verbal sepsis education before discharge, physical rehabilitation after > 48 h of ventilation, mental-health support and post-critical-illness follow-up clinics — highly relevant to geriatric practice.
- Blood-culture yield falls sharply once antibiotics are started — a 2025 systematic review showed a 38% relative fall in sensitivity within a median of 70 minutes of the first dose, reinforcing pre-antibiotic sampling; a **single blood-culture set is acceptable in low-resource settings**.
- German S3 sepsis guideline update (July 2025) similarly emphasised individualised early therapy and **structured post-discharge aftercare**.

EXAMINER'S TIP — verbatim mark-earning lines

- "Sepsis is organ dysfunction, not just infection — Sepsis-3 replaced SIRS-based criteria in 2016 and SSC 2026 retains it."
- "In the elderly, delirium is the fever of the young — an acute confusional state in an older patient is sepsis until proved otherwise."
- "Absence of fever and absence of leucocytosis never exclude bacterial sepsis in old age; hypothermia carries a worse prognosis than pyrexia."
- "Never diagnose urosepsis on a urine culture alone — asymptomatic bacteriuria is present in a third of institutionalised elders."
- "SSC 2026 introduced the first age-specific haemodynamic target: MAP 60–65 mmHg in patients aged 65 years and above."
- "Frailty, not chronological age, predicts survival — age alone is never a justification for withholding critical care."

Q2. Define septic shock, SIRS and MODS. Discuss the etiopathogenesis, investigations and treatment.

Textbook coverage: Pathy's covers the coagulation limb in detail in Ch. 23 (Disseminated intravascular coagulation) — sepsis is the commonest cause of DIC, occurring in 20–80% of severe cases with a mortality of 20–50%. The consensus definitions of SIRS, septic shock and MODS are not stated in the uploaded texts and are taken from ACCP/SCCM (1992), Sepsis-3 (JAMA 2016) and SSC 2026.

15–20 High-Yield Points

Definitions

1. **SIRS** (ACCP/SCCM 1992) = **two or more** of: temperature > 38°C or < 36°C; heart rate > 90/min; respiratory rate > 20/min or $PaCO_2$ < 32 mmHg; total leucocyte count > 12,000/µL or < 4,000/µL or > 10% band forms. It is **non-specific** — pancreatitis, burns, trauma and surgery also produce SIRS.
2. **Septic shock** = a subset of sepsis with **circulatory, cellular and metabolic abnormalities** profound enough to increase mortality substantially. Clinically: **vasopressors needed to maintain MAP ≥ 65 mmHg AND lactate > 2 mmol/L despite adequate fluid resuscitation**. **Hospital mortality exceeds 40%.**
3. **MODS** = **progressive but potentially reversible dysfunction of two or more organ systems** arising from an acute insult, such that homeostasis cannot be maintained without intervention. **Primary MODS** results directly from the insult; **secondary MODS** develops later as a consequence of the host response.
4. **SOFA score** grades six systems 0–4 each: **respiratory** (PaO_2/FiO_2), **coagulation** (platelets), **hepatic** (bilirubin), **cardiovascular** (MAP/vasopressor dose), **CNS** (Glasgow Coma Scale) and **renal** (creatinine/urine output). A rise of ≥ 2 points defines sepsis.

Etiopathogenesis

5. **Trigger: PAMPs** (lipopolysaccharide, peptidoglycan, flagellin) and **DAMPs** (mitochondrial DNA, HMGB1, histones released from injured cells) are recognised by **Toll-like receptors** on monocytes and endothelium.
6. **Hyperinflammatory limb:** TLR ligation activates **NF-κB** and the inflammasome, releasing **TNF-α, IL-1β, IL-6 and IL-8** — the 'cytokine storm' that produces fever, capillary leak and myocardial depression.
7. **Endothelial injury:** shedding of the **endothelial glycocalyx**, loss of tight junctions and upregulated adhesion molecules cause **capillary leak, tissue oedema and microcirculatory failure**, with maldistribution of flow despite a normal or high cardiac output.
8. **Vasoplegia:** induction of **iNOS** generates excess nitric oxide; ATP-sensitive potassium channels open and **vasopressin stores are depleted**, producing catecholamine-resistant vasodilatation.
9. **Coagulopathy:** monocyte and endothelial **tissue factor** expression drives thrombin generation, while the natural anticoagulants (**antithrombin, protein C, protein S**) are consumed and fibrinolysis is suppressed by PAI-1 — giving **microvascular thrombosis with simultaneous bleeding**, i.e. DIC.
10. **The paradox of DIC** (Pathy's Ch. 23): the clinical picture is one of bleeding, while morbidity and mortality result from **organ damage due to microvascular thrombosis** — AKI and ARDS. Recognising and treating the underlying cause matters far more than replacing factors; giving factors and platelets without treating the cause simply provides more substrate for thrombosis.
11. **Cellular/mitochondrial dysfunction:** nitric-oxide-mediated inhibition of the respiratory chain produces **cytopathic hypoxia** — oxygen is delivered but cannot be utilised, hence lactate rises despite adequate perfusion.
12. **Immunoparalysis (compensatory anti-inflammatory response):** lymphocyte and dendritic-cell apoptosis, **reduced monocyte HLA-DR expression**, IL-10 excess — responsible for late deaths from secondary and opportunistic infection and for viral reactivation (CMV, HSV).
13. **Why the elderly do worse: inflammaging** gives a raised baseline IL-6 and TNF-α; **immunosenescence** impairs pathogen clearance; reduced cardiac, renal, respiratory and cerebral reserve means a small insult exhausts compensation; and polypharmacy (beta-blockers masking tachycardia, ACE inhibitors and diuretics worsening hypotension, NSAIDs precipitating AKI) blunts both the response and its recognition.

Investigations

14. **Confirm and grade organ dysfunction:** haemogram, **serum lactate and repeat lactate**, ABG (metabolic acidosis, raised anion gap, PaO_2/FiO_2 ratio), creatinine and urine output, bilirubin and transaminases, GCS.
15. **DIC screen** (Pathy's, Table 23): **APTT prolonged > 10 s beyond normal; PT prolonged > 5 s; thrombin time prolonged > 10 s; fibrinogen usually < 1 g/L; platelets usually < 50,000/µL; D-dimer > 1000 ng/mL**. Serial trends

matter more than a single set.

16. **Microbiology:** two sets of blood cultures before antibiotics, urine, sputum/endotracheal aspirate, pus, CSF; pathogen-specific rapid molecular tests on a case-by-case basis.
17. **Source imaging:** chest radiograph, ultrasound abdomen and chest (chest ultrasound is particularly suitable in the geriatric patient), CT abdomen/thorax, echocardiography. **Biomarkers** — CRP, procalcitonin (better for de-escalation than initiation) — support but never replace clinical judgement.

Treatment

18. **Resuscitation:** 30 mL/kg **balanced crystalloid** in the first 3 hours for hypoperfusion, then individualised; **noradrenaline first-line**, started peripherally if necessary; vasopressin added on escalation; adrenaline third; **dobutamine added** if there is myocardial dysfunction with persistent hypoperfusion despite adequate filling.
19. **Anti-infective therapy and source control** as in Q1 — immediate broad-spectrum antibiotics in shock, ideally within one hour, and source control ideally within 6 hours.
20. **Organ support:** lung-protective ventilation at **6 mL/kg ideal body weight with plateau pressure ≤ 30 cmH_2O** in ARDS, higher PEEP in moderate-to-severe ARDS, prone positioning > 12 h/day; renal replacement therapy only for definite indications; **sodium bicarbonate only if pH ≤ 7.2 with AKIN stage 2–3**.
21. **Treatment of DIC:** treat the cause; transfuse only if bleeding or before a procedure — platelets if < 50,000/µL with bleeding, fresh frozen plasma for prolonged PT/APTT, cryoprecipitate or fibrinogen concentrate if fibrinogen < 1 g/L. In the **chronic/thrombotic form** (malignancy-associated), **low-molecular-weight heparin is the treatment of choice**, with DOACs a recognised alternative; warfarin is notoriously difficult in this setting.
22. **Adjuncts and de-escalation:** IV hydrocortisone in vasopressor-dependent shock; stress-ulcer prophylaxis with a PPI if risk factors; LMWH thromboprophylaxis; early enteral nutrition; **active fluid removal with diuretics after the acute resuscitation phase**; daily review for antimicrobial de-escalation and for the shortest effective duration.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
SIRS/severe sepsis terminology and the classical inflammatory paradigm.	Replaced by **Sepsis-3**; SIRS survives only as a **screening tool** — and SSC 2026 places it **above qSOFA** for that purpose.
DIC treated by supporting the underlying cause and cautious product replacement (Ch. 23).	Unchanged and endorsed; **DOACs (rivaroxaban, apixaban)** now recognised alongside LMWH in the chronic thrombotic form.
Sepsis conceived largely as an overwhelming inflammatory response.	Now understood as a **biphasic** process — hyperinflammation followed by **immunoparalysis**, with distinct transcriptomic **phenotypes** (α, β, γ, δ) that differ in outcome and treatment response.
Lactate clearance targeted as a resuscitation endpoint.	SSC 2026 suggests serial lactate **plus capillary refill time**; fluids should **not** be continued simply until lactate normalises (ANDROMEDA-SHOCK).
Renal replacement therapy for sepsis-associated AKI not specified.	**Suggested against** RRT in the absence of a definitive indication (STARRT-AKI, AKIKI); either continuous or intermittent modality when indicated.

Latest Updates (2023–Present)

- **SSC 2026** reaffirms noradrenaline first-line over dopamine (high certainty), epinephrine and selepressin; **suggests against terlipressin**; and adds vasopressin on escalation with epinephrine third.
- **Sepsis phenotypes and endotypes** — transcriptomic and clinical clustering now guides trial enrichment, with the aim of matching corticosteroid or immunomodulator therapy to the biologically appropriate subgroup rather than to all comers.
- **Sepsis-induced coagulopathy (SIC) score** and the ISTH overt-DIC score are increasingly used for earlier recognition than the classical DIC picture; anticoagulant therapy remains reserved for selected patients.
- **Selective digestive decontamination** is suggested (moderate certainty) in mechanically ventilated patients in units with a low prevalence of antimicrobial resistance — a recommendation of limited applicability in most Indian ICUs.
- **Active fluid removal** after the acute phase is a new suggestion, reflecting recognition that a positive cumulative fluid balance independently predicts mortality.

- **Beta-blockers (esmolol, landiolol) are suggested against** in septic shock following the negative STRESS-L trial.

EXAMINER'S TIP — verbatim mark-earning lines

- "SIRS is sensitive but not specific; SOFA is specific but needs laboratory data — hence SIRS/NEWS to screen, SOFA to define."
- "Septic shock is a vasopressor-plus-lactate definition, not a blood-pressure definition; mortality exceeds 40%."
- "The paradox of DIC: the patient bleeds, but dies of microvascular thrombosis."
- "Cytopathic hypoxia explains why lactate remains high despite adequate oxygen delivery — the defect is mitochondrial, not circulatory."
- "Late deaths in sepsis are deaths of immunoparalysis, not of cytokine storm."
- "In the elderly, a beta-blocked patient will not mount a tachycardia — tachypnoea and delirium are the surviving warning signs."

Q3. Discuss the recent advances in the management of sepsis.

15–20 High-Yield Points

Recognition and Diagnostics

1. **Screening tools have been reordered:** SSC 2026 **strongly recommends NEWS, NEWS2, MEWS or SIRS in preference to qSOFA** as a single in-hospital screening instrument, because qSOFA lacks sensitivity and detects patients too late.
2. **Institutional systems**, not just drugs, are now recommended: mandatory **sepsis performance-improvement programmes** (strong recommendation) and **'code sepsis' or sepsis-huddle protocols**; screening is also suggested **pre-hospital, in the ambulance**.
3. **Rapid molecular diagnostics** — multiplex PCR panels, T2 magnetic resonance and metagenomic next-generation sequencing — allow pathogen and resistance-gene identification in hours; recommended for **selected patients** guided by local resistance patterns and stewardship input, not for everyone.
4. **Host-response transcriptomic assays** (e.g. SeptiCyte, IMX-BVN) that distinguish bacterial from viral and from non-infective inflammation are promising but **evidence remains insufficient** for a recommendation.
5. **Artificial-intelligence early-warning systems** using continuous EHR data are being deployed to predict deterioration hours before clinical recognition; validation in older, multimorbid populations is still limited.

Antimicrobial Strategy

6. **Timing has been graded rather than universal:** antibiotics within **1 hour** for septic shock and probable sepsis, within **3 hours** for 'possible' sepsis without shock after rapid investigation, and **deferred** if infection is unlikely — a deliberate correction of the over-treatment that blanket one-hour rules produced.
7. **Prolonged/extended infusion of beta-lactams** after a loading dose is now a **strong recommendation**, following **BLING III** and **MERCY** and their meta-analysis, which showed a mortality benefit through improved time-above-MIC.
8. **Narrower empirical therapy:** routine **anaerobic cover** and routine **empirical antifungals** are advised against; MDR cover only where specific risk factors exist (known colonisation, prior MDR infection, prolonged broad-spectrum exposure, prolonged stay in a high-prevalence unit).
9. **Procalcitonin** has moved from the front door to the exit: clinical evaluation alone is suggested to **start** antibiotics, but **procalcitonin plus clinical evaluation** is suggested to decide when to **stop**. **Shorter courses are preferred** where source control is adequate.
10. **New agents against resistant gram-negatives** — ceftazidime–avibactam, meropenem–vaborbactam, imipenem–relebactam, **cefiderocol**, ceftolozane–tazobactam and (emerging) aztreonam–avibactam and cefepime–taniborbactam — are of particular importance in India, where carbapenem-resistant *Klebsiella* and *Acinetobacter* dominate ICU sepsis.

Haemodynamic Resuscitation

11. **Balanced crystalloids over 0.9% saline** (BaSICS, PLUS and their meta-analyses), with **starches and gelatins prohibited** and albumin reserved for those already given large crystalloid volumes or with cirrhosis.
12. **The liberal-versus-restrictive fluid debate has been closed to a draw:** after the initial 30 mL/kg, **CLASSIC** and **CLOVERS** showed no mortality difference, so SSC 2026 permits either strategy, individualised to the patient (heart failure, renal reserve) and the health system.
13. **Peripheral vasopressors** are now suggested rather than delaying noradrenaline until central access is obtained — earlier MAP restoration and less fluid overload.
14. **Capillary refill time** is endorsed as an adjunct perfusion target (ANDROMEDA-SHOCK), and fluids should **not** simply be continued until lactate normalises.
15. **Age-specific target:** in patients ≥ **65 years, an initial MAP of 60–65 mmHg** is suggested — the first explicitly geriatric haemodynamic recommendation in the guideline's history, reflecting the harm of vasopressor excess in stiff, atheromatous vasculature.

Adjunctive and Organ-Support Therapies

16. **Therapies now recommended against** after negative trials: **IV vitamin C** (VITAMINS, VICTAS, **LOVIT** — which showed possible harm), **IV immunoglobulin, vitamin D** (VIOLET), **blood purification and polymyxin B haemoperfusion** (EUPHRATES), **levosimendan** (LeoPARDS) and **beta-blockers** (STRESS-L).
17. **Corticosteroids** are suggested for septic shock; the practical residue of APROCCHSS/ADRENAL is hydrocortisone 200 mg/day in vasopressor-dependent shock. Evidence for **methylene blue** and **angiotensin II** in refractory

vasoplegia remains insufficient for a recommendation.

18. **Respiratory support has shifted to HFNC:** HFNC over conventional oxygen, HFNC over NIV as initial therapy, and a trial of **awake proning** in the non-intubated — largely a legacy of COVID-19-era evidence.
19. **Restrictive transfusion (strong)**, insulin initiation at ≥ **180 mg/dL (strong)** rather than tight control, **LMWH over unfractionated heparin (strong)**, and **pharmacological prophylaxis alone** rather than adding mechanical prophylaxis.
20. **Sepsis survivorship is now formally part of sepsis management**: goals-of-care discussion within 72 hours, pharmacist-led medication reconciliation at every transition, screening for social and economic needs, written and verbal patient/family education, post-ICU follow-up services, physical rehabilitation after > 48 hours of ventilation and mental-health support. For geriatrics this converts sepsis care into a comprehensive geriatric assessment problem, not merely an ICU one.
21. **Health-system equity** is explicit: single blood-culture sets are acceptable where resources are limited, and 38% of the guideline panel practised in low- and middle-income countries — making the 2026 document more directly applicable to Indian practice than any previous edition.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Universal ‘antibiotics within one hour for everyone’.	**Tiered by certainty and shock** — 1 h for shock/probable sepsis, 3 h for possible sepsis, defer if infection unlikely.
Bolus dosing of beta-lactams.	**Prolonged infusion after a loading dose — strong recommendation** (BLING III, MERCY).
Vitamin C / thiamine / hydrocortisone (‘metabolic resuscitation’) widely trialled after 2017.	**Abandoned** — SSC 2026 suggests against IV vitamin C on the basis of LOVIT and pooled data.
0.9% saline as default resuscitation fluid.	**Balanced crystalloids preferred**; saline retained specifically for sepsis with traumatic brain injury.
qSOFA as the bedside screen.	**NEWS/NEWS2/MEWS/SIRS strongly preferred over qSOFA.**
Care ends at ICU or hospital discharge.	**Post-sepsis survivorship** — rehabilitation, cognition, mental health, medication reconciliation — is now a formal component of the guideline.

Latest Updates (2023–Present)

- **SSC 2026** (*Crit Care Med* 2026;54:725–812) — the first full revision since 2021: 129 statements, 46 new, with a dedicated survivorship section and quick-reference bedside graphics.
- **BLING III** (*JAMA* 2024) and **MERCY** (*JAMA* 2024) with subsequent meta-analysis established continuous/extended beta-lactam infusion.
- **CLOVERS** (*NEJM* 2023) and **CLASSIC** (*NEJM* 2022) — neither restrictive fluids with early vasopressors nor liberal fluids proved superior, ending a long-running controversy.
- **LOVIT** (*NEJM* 2022) — high-dose vitamin C associated with a higher risk of death or persistent organ dysfunction, closing the metabolic-resuscitation era.
- **STRESS-L** (*JAMA* 2023) — landiolol did not reduce organ dysfunction in septic shock and signalled possible harm.
- **German S3 guideline update (2025)** and the **WHO 2023–2030 global sepsis resolution implementation reports** emphasise national sepsis registries, quality bundles and antimicrobial stewardship.
- Continuing directions: **machine-learning early-warning scores**, **immunophenotype-guided immunotherapy** (GM-CSF, interferon-gamma, anti-PD-1 for immunoparalysis), **extracorporeal cytokine adsorption** (not currently recommended), and **bacteriophage therapy** for extensively drug-resistant gram-negative sepsis — all still investigational.

EXAMINER'S TIP — verbatim mark-earning lines

- “The direction of travel in sepsis since 2021 is de-escalation: fewer empirical antibiotics, less fluid, fewer adjuncts, and more system-level recognition.”
- “The single strongest new pharmacological recommendation is prolonged beta-lactam infusion after a loading dose.”
- “Every major immunomodulatory adjunct trialled since 2017 — vitamin C, IVIG, vitamin D, haemoadsorption — is now recommended against.”
- “Sepsis does not end at discharge: post-sepsis syndrome is now a guideline-mandated part of management.”
- “The 2026 guideline contains the first age-stratified haemodynamic target in critical care — MAP 60–65 mmHg at 65 years and above.”

Q4. Discuss the management of COPD with reference to recent recommendations.

15–20 High-Yield Points

Definition, Burden and Assessment

1. COPD is characterised by **airflow obstruction that is not fully reversible**, shows little variability over time, is usually progressive, and reflects small-airway disease and emphysema. Diagnosis requires a **post-bronchodilator FEV_1/FVC < 0.70** (or below the lower limit of normal, which is preferred in the elderly).
2. COPD is the **fifth largest cause of disability worldwide**; worldwide prevalence is 4–10%, but **12–15% in the elderly**. Despite this, it is **persistently under- and mis-diagnosed in older adults**, largely because breathlessness is attributed to age, obesity or cardiac disease.
3. **Severity of airflow obstruction** (post-bronchodilator FEV_1/FVC < 0.7): Stage 1 mild, $FEV_1 \geq 80\%$; Stage 2 moderate, 50–79%; Stage 3 severe, 30–49%; Stage 4 very severe, < 30% predicted.
4. **Assessment must be multidimensional**, not spirometric alone: breathlessness (**mMRC**), health status (**CAT**), exercise tolerance (shuttle walk or six-minute walk test), **BMI**, oxygen saturation if FEV_1 < 50% or signs of cor pulmonale, screening for **anxiety and depression (HADS)**, and the exacerbation rate.
5. **Comorbidity is the rule in the older COPD patient** and is classified as: **co-causal** (shared smoking risk — ischaemic heart disease, heart failure, lung and bladder cancer, CKD, aortic aneurysm); **coexisting** (diabetes, hypertension, benign prostatic hypertrophy, glaucoma, OSA); and **complicating** (anxiety/depression, **osteoporosis, sarcopenia**, arrhythmias, dysphagia, pulmonary embolism).
6. **A critical geriatric prescribing trap:** sarcopenia blunts the rise in serum creatinine, so **moderate (GFR 30–60) and even severe renal impairment go unrecognised**, leading to overdose of renally cleared drugs during exacerbations. Umeclidinium and aclidinium are safe in renal failure as they are hepatically metabolised to inactive derivatives.

Management of Stable Disease

7. **Smoking cessation is the only intervention that slows the age-related decline in FEV_1**. Use nicotine replacement, bupropion or varenicline; **quit rates in older adults are as good as or better than in the young**. **E-cigarettes are not recommended** as a cessation aid.
8. **Vaccination:** annual influenza and pneumococcal vaccination for all; current guidance adds **RSV vaccination and COVID-19 vaccination**, and pertussis-containing Tdap.
9. **Pulmonary rehabilitation** improves dyspnoea, health status and exercise tolerance, and secondarily mood and quality of life; it should be part of integrated management **from the early stages**, not reserved for end-stage disease.
10. **Self-management plans** covering recognition and early treatment of exacerbations are vital; as disease progresses, there must be an opportunity for **advance care planning and discussion of end-of-life wishes**.

Pharmacological Therapy

11. **On-demand short-acting bronchodilators alone should be discouraged in the elderly** because they lead to adverse drug reactions and overdosing; regular **long-acting** therapy is preferred.
12. **LAMA and LABA** are the foundation: both improve symptoms, health status and exacerbation rate, and **LAMAs are clearly superior to short-acting ipratropium**. Escalate to **LABA + LAMA** for persistent breathlessness.
13. **Inhaled corticosteroids** are added for frequent exacerbators or those with asthma-like features. They increase the risk of **non-fatal pneumonia**, but this does not outweigh benefit in appropriately selected patients. **Blood eosinophil count guides the decision** — ICS considered above 300 cells/µL, avoided below 100 cells/µL.
14. **Second-line options:** slow-release **theophylline** at low dose (poor therapeutic index, drug interactions with macrolides and quinolones); **roflumilast** (PDE-4 inhibitor) for frequent exacerbators with chronic bronchitis and FEV_1 < 50% — monitor for weight loss, diarrhoea and mood disturbance, with limited safety data in the elderly; **high-dose acetylcysteine** as a mucolytic/antioxidant; nebulised bronchodilators where inhaler technique cannot be corrected.
15. **Maintenance oral corticosteroids should generally be avoided** — risks outweigh benefits; where repeated courses are used, **screen and treat for osteoporosis**, which should in any case be routine in elderly COPD.

Oxygen, Exacerbations and Palliation

16. **Long-term oxygen therapy (LTOT)** for ≥ 15 hours a day improves survival in severe COPD with persistent hypoxaemia. Prescribe during clinical stability, to non-smokers, when **PaO_2 < 7.3 kPa**, or **PaO_2 7.3–8.0 kPa with secondary polycythaemia, pulmonary hypertension, peripheral oedema or nocturnal hypoxaemia**. Screen by referring patients with saturation < 93%, or < 95% with possible cor pulmonale.

17. **Exacerbation management:** increased bronchodilators; **oral corticosteroids reduce length of stay and treatment failure**; **antibiotics where sputum is purulent** (commonest organisms *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Moraxella catarrhalis*) — but antibiotics should be withheld if there is no sputum purulence. Controlled oxygen targeting **SpO_2 88–92%**; **NIV if pH < 7.35** despite maximal medical therapy, which reduces mortality, intubation and length of stay.
18. **Prognosis:** about one-third of admitted patients are readmitted within 30 days and 15% die by three months; roughly **50% of patients on LTOT survive three years**. In older adults the main predictors of mortality are **disability, low BMI, lung function and use of LTOT**.
19. **Palliative care:** patients judged to be in their last year of life should be placed on an end-of-life register and offered **opioids and benzodiazepines** for refractory breathlessness. The textbook is explicit that the move from an active to a palliative approach **all too often comes too late**.
20. **Nutrition and sarcopenia:** hypercatabolism and accelerated muscle loss characterise severe exacerbations. **Nutritional support improves respiratory and peripheral muscle strength but not lung-function indices**, and should be combined with exercise in a comprehensive programme for the frail patient.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Fixed FEV_1-based staging (GOLD 1–4) drives treatment; algorithm based on mMRC/CAT and exacerbations (Pathy's Fig. 42.1).	**GOLD 2026** uses the **ABE groups**: A = low symptoms/low risk; B = high symptoms (mMRC ≥ 2 or CAT ≥ 10); **E = exacerbators**. Spirometric grade informs prognosis, not initial drug choice.
'Frequent exacerbations' defined as ≥ 2 exacerbations and/or 1 hospitalisation in the previous year.	GOLD 2026 lowers the threshold: escalation is recommended after **even one moderate exacerbation**, since a single event predicts future risk.
Initial therapy may be a single long-acting bronchodilator in most symptomatic patients.	**Group B and Group E now start on LABA + LAMA dual therapy**; monotherapy is reserved for Group A.
ICS added on clinical grounds (asthma features, frequent exacerbations).	**Blood eosinophil count is the biomarker of choice** — ICS added in Group E if **eosinophils > 300 cells/μL**; avoided below 100.
Theophylline is a recognised option when symptoms persist.	**GOLD 2026 does not recommend methylxanthines** because of side effects.
Pneumococcal and influenza vaccines recommended.	Expanded: **RSV vaccination from age 50** (lowered from 60 in the 2026 report), plus COVID-19 and Tdap.
No biologic therapy available for COPD.	**Dupilumab** (anti-IL-4Rα, approved 2024) and **mepolizumab** (anti-IL-5, approved May 2025) are now licensed add-ons for inadequately controlled **eosinophilic COPD**; **ensifentrine** (dual PDE3/PDE4 inhibitor) is a new inhaled maintenance option.
Corticosteroid course for exacerbation continued 7–14 days depending on severity.	**Systemic corticosteroids for up to 5 days** and **antibiotics for 5 days** in moderate/severe exacerbations.

Latest Updates (2023–Present)

- **GOLD 2026 report** (published November 2025; sixth major revision) — incorporates 330 new references, completely revised chapters 4 and 5, updated screening and case-finding, and a **new chapter on artificial intelligence and emerging technologies** in COPD detection and management.
- **New concept of 'disease activity'** — reducing reversible biological activity (using blood eosinophils as a type-2 inflammation biomarker) is now framed as a treatment goal alongside symptom control; strategies include smoking cessation, pulmonary rehabilitation, pharmacotherapy and lung-volume reduction.
- **Expanded multimorbidity and frailty chapter** — GOLD 2026 explicitly contextualises COPD within multimorbidity and frailty, which brings the guideline much closer to geriatric practice.
- **Dupilumab** — BOREAS (*NEJM* 2023) and NOTUS (*NEJM* 2024) showed 30% and 34% reductions in moderate/severe exacerbations on top of triple therapy in patients with eosinophils ≥ 300 cells/μL; FDA approval September 2024.

- **Mepolizumab** — MATINEE (*NEJM* 2025) showed a 21% reduction in exacerbations and a 35% reduction in exacerbation-related emergency visits/hospitalisation; FDA approval May 2025 for eosinophils ≥ 150 cells/µL.
- **Ensifentrine** — first-in-class inhaled dual PDE3/PDE4 inhibitor with both bronchodilator and anti-inflammatory action (ENHANCE-1 and -2), included in GOLD as an option where roflumilast is poorly tolerated.
- **Tezepelumab** (anti-TSLP) failed its primary endpoint in the overall COPD population in COURSE (phase 2a) but showed signal at higher eosinophil counts.
- **Indian context:** COPD is the second commonest cause of death in India (ICMR India State-Level Disease Burden Initiative); **biomass and solid-fuel smoke exposure** is a major non-smoking cause, particularly in older rural women, and COPD care is delivered through the **NP-NCD programme and Ayushman Arogya Mandirs**. Access to biologics remains negligible outside tertiary private practice.

EXAMINER'S TIP — verbatim mark-earning lines

- "The GOLD ABE assessment replaced ABCD in 2023 — Group E collapses the old C and D because exacerbation risk, not symptom burden, drives therapy."
- "In 2026 a single moderate exacerbation is now sufficient to justify treatment escalation."
- "Blood eosinophil count is the only routinely available biomarker guiding ICS and biologic use in COPD."
- "COPD is now a biologic-treatable disease: dupilumab (2024) and mepolizumab (2025) for the eosinophilic phenotype."
- "In the elderly, sarcopenia masks renal impairment — always estimate GFR before dosing renally cleared drugs in an exacerbation."
- "Only three interventions alter mortality in COPD: smoking cessation, long-term oxygen therapy in chronic hypoxaemia, and lung volume reduction in selected emphysema."

Q5. Discuss the tailoring of oxygen requirements and delivery systems for a COPD patient with severe hypoxaemia and an infective exacerbation.

15–20 High-Yield Points

Principles

1. **Oxygen is a drug**: it must be prescribed with a **target saturation range**, a device and a flow rate, and signed for on the drug chart like any other medicine.
2. **The therapeutic target is a saturation range, not a flow rate**. In COPD with an infective exacerbation the aim is **SpO_2 88–92%** pending arterial blood gases — adjust upward to 94–98% only if the ABG shows a normal $PaCO_2$ and there is no history of previous hypercapnic failure requiring ventilation.
3. **Why the ceiling matters:** excess oxygen in the chronic CO_2 retainer produces hypercapnia by **reversal of hypoxic pulmonary vasoconstriction with worsened V/Q mismatch** (the dominant mechanism), the **Haldane effect**, and to a lesser extent depression of hypoxic respiratory drive — leading to **respiratory acidosis, narcosis and death**. Pathy's warns of depressed hypoxic drive, increased coronary and cerebral arterial resistance and worsened acidosis, and advises target saturations in this range.
4. **The opposite error is equally lethal: oxygen must never be withheld from a severely hypoxaemic patient** for fear of retention. Hypoxaemia kills faster than hypercapnia; treat the hypoxaemia and manage the CO_2 with ventilatory support.
5. **Baseline saturations are lower in the very old** — clinically stable people over 70 may sit at 92–94% and require no oxygen; know the patient's stable baseline before treating a number.

Initial Assessment

6. **Immediate assessment:** respiratory rate, level of consciousness, ability to speak, accessory muscle use, SpO_2, and an **arterial blood gas within 30–60 minutes** of starting oxygen — and repeated 30–60 minutes after every significant change in FiO_2.
7. **Classify the failure** from the ABG: **Type 1** (PaO_2 < 8 kPa / 60 mmHg with normal or low $PaCO_2$) versus **Type 2** (PaO_2 < 8 kPa with $PaCO_2$ > 6.5 kPa / 50 mmHg). Then distinguish **acute hypercapnic failure** (low pH, normal bicarbonate) from **acute-on-chronic** (low pH with raised bicarbonate and base excess) — the bicarbonate tells you how chronic the retention is.
8. **Look for the treatable precipitant simultaneously:** purulent sputum and consolidation, pneumonia (which in older adults is frequently afebrile and non-productive), pneumothorax, pulmonary embolism, heart failure, arrhythmia, sedative drugs and aspiration.

Choosing the Delivery System

9. **Venturi (high-flow, fixed-performance) masks are the device of choice in COPD** because they deliver a **predictable, constant FiO_2 independent of the patient's inspiratory flow** — start at **24% at 2–3 L/min** or **28% at 4 L/min**. If the respiratory rate exceeds 30/min, **increase the flow through the Venturi barrel by up to 50%** to maintain the entrained FiO_2 (the barrel colour, not the flow, sets the concentration).
10. **Nasal cannulae (1–2 L/min)** are an acceptable alternative once the patient is stable and the target range is reliably held: better tolerated, allow eating, talking and expectoration, and reduce delirium and claustrophobia in the older patient — but they are **variable-performance**, with FiO_2 depending on minute ventilation and mouth-breathing.
11. **Simple face mask (5–10 L/min)** delivers roughly 40–60% and is **generally unsuitable in COPD**; below 5 L/min there is a risk of CO_2 rebreathing within the mask.
12. **Reservoir (non-rebreathing) mask at 15 L/min** gives 60–90% and is reserved for **critical illness or life-threatening hypoxaemia (SpO_2 < 85%)** as an emergency bridge — step down to a Venturi mask as soon as the gas is available.
13. **Humidification** should be added for flows above 4 L/min, for prolonged therapy and where secretions are tenacious, to preserve mucociliary clearance — important where the cough reflex is already blunted by ageing.

Escalation

14. **High-flow nasal cannula (HFNC)** delivers heated, humidified gas at 30–60 L/min with a precisely titrated FiO_2, washes out anatomical dead space, generates a small PEEP effect and improves secretion clearance. It has proved **safe and effective in exacerbated COPD in both normocapnic and hypercapnic respiratory failure**, and is particularly valuable **where there is a do-not-intubate order or where intermediate care is needed outside the ICU**.

15. **Non-invasive ventilation (NIV/BiPAP) is the key intervention in acute hypercapnic failure:** indicated when **pH < 7.35 with $PaCO_2$ > 6.5 kPa despite maximal medical therapy** and controlled oxygen. **NIV reduces mortality, need for intubation and length of hospital stay.** Start at IPAP 10–12 and EPAP 4–5 cmH_2O, titrating IPAP upward to 20–25 by response, with oxygen entrained to keep SpO_2 88–92%; repeat the gas at 1 and 4 hours.
16. **Invasive ventilation** is considered for pH < 7.25 with deteriorating consciousness, NIV failure or intolerance, cardiovascular instability or inability to protect the airway — but the decision must be made **on premorbid function, frailty and previously stated wishes, not chronological age**, and a ceiling of care should ideally be documented before deterioration.

Concurrent Treatment of the Exacerbation and Discharge

17. **Treat the exacerbation in parallel:** nebulised salbutamol and ipratropium **driven by air, not oxygen**, in the CO_2 retainer (with nasal oxygen alongside at 1–2 L/min); systemic corticosteroids; and **antibiotics where sputum is purulent** — beta-lactam ± inhibitor, doxycycline or a fluoroquinolone, with anti-pseudomonal cover (ciprofloxacin, anti-pseudomonal cephalosporin or aminoglycoside) if bronchiectasis coexists.
18. **Additional supportive measures:** chest physiotherapy and secretion clearance, VTE prophylaxis, correction of dehydration and hypokalaemia, delirium prevention, review of sedatives and opioids, and nutritional support — hypercatabolism and muscle loss are hallmarks of severe exacerbation in the elderly.
19. **Wean the oxygen deliberately:** step down device and FiO_2 as the patient improves, reassess on air before discharge, and do **not** assess for LTOT during the acute episode — LTOT must be prescribed during a period of clinical stability, generally **at least 6–8 weeks after the exacerbation**, in a non-smoker.
20. **Practical geriatric issues with home oxygen:** long tubing and concentrators are a **falls hazard**; there are safety concerns where there is cognitive impairment or poor manual dexterity; fire risk mandates that the patient and household are non-smokers; care-home residents using overnight concentrators may need portable cylinders for daytime rooms; and staff and carers require training. Issue **oxygen alert cards** recording previous blood-gas results to guide future emergency treatment.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Target saturation quoted in the text as 89–95% for the CO_2 retainer.	**BTS and GOLD standardise on 88–92%** pending blood gases in patients at risk of hypercapnic failure; 94–98% for those not at risk.
High-flow oxygen described as recently proven safe and effective in exacerbated COPD.	**HFNC is now mainstream** — recommended over conventional oxygen in hypoxaemic failure, valuable in do-not-intubate patients, and increasingly used to prevent post-extubation failure.
NIV for pH < 7.35 despite maximal medical therapy.	Unchanged and reinforced by BTS/ICS guidance: NIV is **first-line** for acute hypercapnic acidosis; delay in starting it is a recognised cause of avoidable death.
LTOT criteria: PaO_2 < 7.3 kPa, or 7.3–8.0 kPa with cor pulmonale/polycythaemia/nocturnal hypoxaemia.	Unchanged, but **LOTT** confirmed **no benefit in moderate or exertional desaturation alone**, and assessment must be deferred until stability.
Oxygen prescribed to correct hypoxaemia.	Modern emphasis on avoiding **hyperoxia**: SSC 2026 permits either conservative (SpO_2 90–93%) or liberal (≥ 96%) targets in sepsis, and observational data link hyperoxaemia in COPD exacerbation to increased mortality.

Latest Updates (2023–Present)

- **BTS Guideline for oxygen use in adults in healthcare and emergency settings** remains the reference standard: 94–98% for most acutely ill adults, **88–92% where there is risk of hypercapnic respiratory failure**, with a fall of more than 3% within the target range prompting reassessment.
- **BTS/ICS guideline for ventilatory management of acute hypercapnic respiratory failure** continues to define pH < 7.35 with hypercapnia as the NIV threshold, and emphasises that **NIV should be commenced within 60 minutes** of the qualifying blood gas.
- **HFNC in hypercapnic COPD** — meta-analyses (2023–2025) show HFNC to be **non-inferior to NIV** for mild-to-moderate hypercapnic exacerbations, with better comfort and tolerance; it is increasingly used as a rescue for

NIV intolerance and in the frail patient with a ceiling of care.

- **SSC 2026** suggests **HFNC over conventional oxygen therapy, and HFNC over NIV as initial therapy**, in sepsis-associated acute hypoxaemic respiratory failure — directly applicable to the COPD patient with pneumonic sepsis.
- **Pulse oximetry accuracy** is now a recognised safety issue: SSC 2026 notes SpO_2 is **less accurate in shock, in darker skin tones and at saturations below 90% or above 97%**. In an Indian population this is a strong argument for confirming with arterial blood gases rather than relying on the oximeter alone.
- **GOLD 2026** advises systemic corticosteroids for up to 5 days and antibiotics for 5 days in moderate-to-severe exacerbations, and starting maintenance long-acting bronchodilator therapy before discharge, with ICS added at discharge for patients with an exacerbation and raised eosinophils.

EXAMINER'S TIP — verbatim mark-earning lines

- "Oxygen is a drug — prescribe a target range, not a flow rate."
- "In COPD, aim 88–92% pending blood gases; do not withhold oxygen from a severely hypoxaemic patient for fear of retention."
- "The Venturi mask is the device of choice because it is fixed-performance — the barrel colour sets the FiO2, and the flow only ensures the total gas flow exceeds peak inspiratory demand."
- "Hypercapnia on oxygen is mainly V/Q mismatch from reversal of hypoxic pulmonary vasoconstriction, plus the Haldane effect — loss of hypoxic drive is the smallest component."
- "NIV for pH below 7.35 reduces mortality, intubation rate and length of stay — delay in starting it is a recognised avoidable cause of death."
- "Never assess for long-term oxygen therapy during an exacerbation — wait 6–8 weeks of clinical stability."
- "Drive nebulisers with air, not oxygen, in the CO2 retainer."

Q6. Discuss the role of CPAP in diseases of the elderly.

15–20 High-Yield Points

Principle and Mechanism

1. **CPAP delivers a single continuous positive pressure throughout the respiratory cycle** through a nasal or oro-nasal interface. It acts as a **pneumatic splint** for the upper airway, **recruits collapsed alveoli and increases functional residual capacity**, reduces the work of breathing and, by raising intrathoracic pressure, **reduces left ventricular preload and afterload**.
2. **CPAP is not a ventilator.** It provides no inspiratory pressure support and therefore does not augment tidal volume or clear carbon dioxide — **hypercapnic respiratory failure requires bilevel NIV (BiPAP), not CPAP**. This distinction is a favourite viva question.

Obstructive Sleep Apnoea — the Principal Indication

3. **OSA is defined** by an **apnoea–hypopnoea index (AHI) > 5/hour** with excessive daytime sleepiness or neurocognitive/behavioural disturbance not attributable to another cause.
4. **OSA is far commoner in old age:** approximately **50% of older people have an AHI > 5 and 20% have an AHI > 15**, compared with about 10% of younger adults. The rise is explained by **increased upper-airway collapsibility** with age — loss of pharyngeal dilator muscle tone and altered reflexes, **edentulism**, increased pharyngeal fat deposition and post-menopausal hormonal change (after which the sex difference disappears).
5. **The classical triad is unreliable in the elderly:** the proportion of OSA patients who do **not** snore rises after 50; daytime sleepiness is confounded by comorbidity and drugs; and the Epworth Sleepiness Scale includes driving items that are unsuitable for many older people. Suspect OSA instead from **nocturia, morning headache, non-restorative sleep, unexplained falls, refractory hypertension and worsening cognition**.
6. **Polysomnography is the gold standard**; simplified home respiratory polygraphy is cheaper but **less satisfactory a priori in the elderly** because of the high background frequency of restless legs and other sleep disorders and the practical difficulty of accommodating equipment at home — each case must be judged individually.
7. **CPAP is the treatment of choice for OSA.** It abolishes snoring and apnoeas, improves gas exchange and normalises sleep architecture, and in older adults improves alertness, cognitive processing, memory and executive function.
8. **Adherence is the principal limitation — 40–50% of patients do not use the device adequately**. Importantly, **compliance in older patients is no worse than in the young**, including in series of patients with dementia or cognitive impairment; practical difficulties such as applying the mask are solved by patient and **caregiver training**.
9. **Adjunctive measures:** weight reduction in the obese, positional therapy, avoidance of alcohol and sedatives (especially benzodiazepines and Z-drugs), treatment of nasal obstruction, and mandibular advancement devices where dentition allows.

Cardiovascular and Neurocognitive Indications

10. OSA is epidemiologically linked in older people to **hypertension, ischaemic stroke, heart failure, atrial fibrillation and ischaemic heart disease** — and in advanced age these cardiovascular manifestations may be the **only** presentation of OSA. A prospective study showed that **long-term CPAP reduced cardiovascular mortality in elderly OSA patients**.
11. **Heart failure:** Pathy's lists **sleep-disordered breathing as a comorbidity of heart failure that increases mortality risk, with CPAP as the key management**. CPAP reduces preload and afterload, improves left ventricular ejection fraction and reduces sympathetic activation.
12. **Acute cardiogenic pulmonary oedema** is the other major acute indication: CPAP at 5–10 cmH_2O improves oxygenation, reduces the work of breathing and **reduces the need for intubation**, and is often preferable to intubation in the frail elderly patient.
13. **Cognition and dementia:** sleep-disordered breathing is associated with Alzheimer-type dementia and with agitation in institutionalised patients with dementia. CPAP is associated with improved neurocognitive performance and, on imaging, with favourable changes in cortical thickness and default-mode-network connectivity.
14. **Depression, epilepsy and falls:** untreated OSA in the elderly is correlated with worsening depressive symptoms, poor seizure control and **frequent falls** — all potentially modifiable by effective CPAP therapy.

Other Uses, Contraindications and Practical Issues

15. **Other clinical roles:** obesity hypoventilation syndrome (though bilevel NIV is preferred if hypercapnia is established), **type 1 hypoxaemic respiratory failure** including pneumonia and COVID-19, **post-operative**

atelectasis and prevention of post-extubation failure, and chest-wall trauma. In multiple sclerosis and other neurological disease, CPAP and BiPAP address the OSA that commonly underlies fatigue.

16. **Contraindications:** reduced consciousness and inability to protect the airway, facial trauma or surgery, **undrained pneumothorax**, vomiting or high aspiration risk, haemodynamic instability, severe epistaxis, and recent upper gastrointestinal surgery. **Established hypercapnic acidosis is a contraindication to CPAP in favour of BiPAP.**
17. **Complications:** mask pressure sores over the nasal bridge (a particular hazard on thin, fragile, ageing skin), nasal dryness, epistaxis, conjunctivitis from leak, gastric distension and aspiration, claustrophobia and **precipitation or worsening of delirium**.
18. **Geriatric-specific practical points:** humidification is essential; the interface must be fitted around dentures and facial contours; arthritis and poor dexterity affect strap handling; cognitive impairment demands caregiver involvement; and CPAP therapy should be introduced with a **structured education and early-follow-up programme**, since adherence in the first week predicts long-term use.
19. **Ethical framing:** in the frail or severely demented patient, CPAP may be entirely appropriate as a **ceiling of care** — the maximum agreed level of respiratory support short of intubation — and this should be documented in advance.
20. **Unresolved question, as stated in the textbook:** what remains to be established is whether CPAP in seniors corrects the symptoms caused by OSA and modifies cardiovascular comorbidity to the same degree as in younger patients.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
CPAP is the treatment of choice for OSA; compliance is the main obstacle, and its effect on symptoms and cardiovascular comorbidity in seniors remains to be evaluated.	Position broadly unchanged. Randomised trials (SAVE, RICCADSA, ISAACC) failed to show **secondary cardiovascular prevention** in unselected non-sleepy patients, but this is now attributed largely to **poor adherence (~3 h/night)**; adherence-adjusted analyses and 2025 meta-analyses show mortality benefit with good use.
Weight loss and positional therapy are the recommended adjunct measures.	**Pharmacotherapy has entered the field: tirzepatide** was FDA-approved in December 2024 for moderate-to-severe OSA with obesity — the first drug ever licensed for OSA.
Cognitive effects of CPAP in older adults described as small and inconsistent.	A 2025 randomised trial demonstrated **improved cortical thickness and default-mode-network connectivity** with 12 months of CPAP, though measurable cognitive gain in normal-cognition patients remained modest.
Home respiratory polygraphy regarded as not the best option a priori in the elderly.	Home sleep apnoea testing is now widely accepted in patients with **high pre-test probability and no significant comorbidity**; polysomnography remains necessary in complex or comorbid older patients.
AHI used as the severity metric.	Newer physiological metrics — **hypoxic burden, ventilatory burden and arousal burden** — predict cardiovascular mortality better than AHI and are moving into risk stratification.

Latest Updates (2023–Present)

- **Tirzepatide (SURMOUNT-OSA, *NEJM* 2024; FDA approval December 2024)** — a dual GIP/GLP-1 receptor agonist reduced AHI by 25–29 events/hour versus placebo at 52 weeks, both in patients on PAP and in those unwilling or unable to use it, with nearly half achieving remission or mild disease. It is an **adjunct to, not a replacement for**, CPAP.
- **Benjafield et al., *Lancet Respiratory Medicine* 2025** — systematic review and meta-analysis of randomised and confounder-adjusted non-randomised studies found positive airway pressure therapy associated with **reduced all-cause and cardiovascular mortality** in OSA, reconciling the negative RCTs with real-world data.
- **Mazzotti et al., *JAMA Network Open* 2024** — in older adults specifically, PAP therapy was associated with lower mortality and cardiovascular risk.
- **ERJ Open Research 2025 review** — blood-pressure lowering with CPAP is seen chiefly in **uncontrolled and treatment-resistant hypertension**, and MACE reduction depends on **good long-term adherence**; RCTs in primary prevention and in the highest-risk groups are still lacking.

- **Hypoglossal nerve stimulation** (Inspire) is an established alternative for CPAP-intolerant patients with moderate-to-severe OSA, BMI below approximately 35 and no complete concentric collapse; it has been used successfully in selected fit older adults.
- **Telemonitoring and auto-titrating CPAP** with remote adherence data and automated feedback have become standard, and are especially valuable for older patients in whom clinic attendance is difficult — relevant to the Indian context where sleep services are concentrated in metropolitan centres.
- **Indian context:** OSA prevalence in Indian urban adults is 9–13%, with a distinctive phenotype of **OSA at lower BMI** owing to craniofacial structure and central adiposity; cost of devices, absence of insurance cover for CPAP and limited polysomnography capacity remain the principal barriers to treatment in older Indians.

EXAMINER'S TIP — verbatim mark-earning lines

- "CPAP splints the upper airway; BiPAP ventilates. Hypercapnic failure needs BiPAP, hypoxaemic failure and OSA need CPAP."
- "Half of all people over 65 have an AHI above 5 — OSA is a geriatric syndrome, not a middle-aged male disease."
- "In older patients, suspect OSA from nocturia, morning headache, falls, resistant hypertension and cognitive decline — not from snoring and sleepiness."
- "CPAP adherence in older adults, including those with dementia, is no worse than in the young — the barrier is education and caregiver support, not age."
- "The negative cardiovascular RCTs (SAVE, RICCADSA, ISAACC) were adherence-limited trials, not evidence that CPAP does not work."
- "Tirzepatide (2024) is the first drug ever approved for obstructive sleep apnoea — an adjunct to CPAP, not a substitute."

Q7. Discuss the diagnosis and management of multidrug-resistant tuberculosis (DOTS-Plus regime).

Textbook coverage: Pathy's (Ch. 38, Respiratory infections) covers tuberculosis in old age — higher infection rates in those over 65, nursing-home outbreaks, atypical presentation with less fever, sweating and haemoptysis, more dyspnoea, fewer cavitary lesions, lower tuberculin and IGRA positivity, and sputum smear/culture as the gold standard — and Essentials covers LTCF screening and preventive therapy. **Neither textbook covers MDR-TB regimens or the DOTS-Plus/PMDT programme.** The management sections below are drawn from the WHO Consolidated Guidelines on Tuberculosis Module 4 (2025), the WHO Operational Handbook, and the Government of India NTEP/PMDT guidelines.

15–20 High-Yield Points

Definitions and Burden

1. **MDR-TB** = resistance to at least **isoniazid and rifampicin**. **RR-TB** = rifampicin resistance with or without other resistance; the two are managed together as **MDR/RR-TB**. **Pre-XDR-TB** = MDR/RR-TB plus resistance to any **fluoroquinolone**. **XDR-TB** = MDR/RR-TB plus fluoroquinolone resistance plus resistance to at least one of bedaquiline or linezolid (2021 revised definition).
2. **DOTS-Plus** is the programmatic strategy for managing MDR-TB within the DOTS framework, requiring the five DOTS elements plus **quality-assured drug-susceptibility testing, second-line drug supply, standardised regimens, active drug-safety monitoring (aDSM) and a recording/reporting system**. In India it is delivered as **PMDT (Programmatic Management of Drug-Resistant TB)** under the **National TB Elimination Programme (NTEP)**.
3. **India carries the largest MDR/RR-TB burden in the world** — roughly a quarter of global cases — with about 1.1–1.3 lakh incident MDR/RR-TB cases annually. Globally there are approximately 4 lakh MDR/RR-TB cases each year.
4. **Mechanisms of resistance**: spontaneous chromosomal mutations (*rpoB* for rifampicin, *katG* and *inhA* for isoniazid, *gyrA/gyrB* for fluoroquinolones, *rrs* and *eis* for injectables, *Rv0678* for bedaquiline) selected by **inadequate treatment** — monotherapy, poor adherence, erratic drug supply, poor-quality drugs and unsupervised private-sector prescribing.

Why the Elderly are Special

5. In older people TB is usually **reactivation of remote infection** as immunosenescence weakens cell-mediated containment; rates in institutional and nursing-home populations exceed those in the community, and staff as well as residents can spread infection.
6. **Presentation is atypical:** older patients are **less likely to report fever, sweating and haemoptysis, more likely to present with dyspnoea**, and have a **lower likelihood of radiographic cavitation** — with more lower-lobe, miliary and extrapulmonary disease. **Suspect tuberculosis whenever an older patient is inexplicably failing.**
7. **Immunological tests are less reliable:** both tuberculin skin testing and IGRAs show **lower positivity in the elderly** despite comparable exposure. A simply positive or negative Mantoux neither confirms nor excludes active disease, and IGRA performance in the very old — most of whom have had lifetime contact with the organism — is not well documented.
8. **Treatment tolerance is poorer:** age-related decline in renal and hepatic clearance, **polypharmacy and QT-prolonging drug interactions**, pre-existing peripheral neuropathy, cataract and hearing loss, and low body weight all raise the risk of adverse events on second-line drugs.

Diagnosis

9. **Universal drug-susceptibility testing is now mandatory** — every diagnosed TB patient in India must have at least rifampicin resistance determined at diagnosis, and no patient should be started on first-line therapy without it.
10. **Rapid molecular tests are the front line: CBNAAT / Xpert MTB/RIF and Xpert Ultra** and **Truenat MTB/Rif Dx** (an indigenous Indian chip-based platform used at peripheral level) detect *M. tuberculosis* and rifampicin resistance within two hours. Specimens: sputum (two samples), or induced sputum, gastric aspirate or bronchoalveolar lavage in the frail or non-expectorating older patient.
11. **Line probe assay (LPA): first-line LPA** detects *rpoB*, *katG* and *inhA* mutations (rifampicin and isoniazid, including high- versus low-level isoniazid resistance); **second-line LPA** detects fluoroquinolone and second-line injectable resistance. **Xpert MTB/XDR** gives resistance to isoniazid, fluoroquinolones, ethionamide and amikacin in a single cartridge.
12. **Culture and phenotypic DST** on liquid medium (MGIT, 2–3 weeks) remains the reference standard and is essential for **bedaquiline, linezolid, clofazimine and delamanid** susceptibility, for treatment monitoring and for regimen modification. **Targeted next-generation sequencing** is now WHO-endorsed for comprehensive resistance prediction directly from sputum.

13. **Baseline pre-treatment evaluation (PTE):** weight and BMI, haemogram, blood sugar (diabetes screening is mandatory), renal and liver function, serum electrolytes including **potassium, magnesium and calcium**, thyroid-stimulating hormone, **HIV testing**, chest radiograph, **ECG for QTc**, visual acuity and colour vision, audiometry where an injectable is contemplated, and a pregnancy test in women of child-bearing age.

Treatment Regimens

14. **Six-month BPaLM is the preferred regimen** for MDR/RR-TB and pre-XDR-TB: **B**edaquiline + **Pa**retomanid + **L**inezolid (600 mg once daily) + **M**oxifloxacin for 6 months, extendable to 9 months. In TB-PRACTECAL, BPaLM achieved **89% treatment success compared with 52% for the standard of care**. Moxifloxacin is dropped (giving **BPaL**) where fluoroquinolone resistance is documented. **Not for pregnant or breastfeeding women, or those with more than 1 month's prior exposure to these drugs unless resistance is excluded.**
15. **Nine-month all-oral bedaquiline-containing regimen** for MDR/RR-TB in whom fluoroquinolone resistance has been **excluded** and who have no extensive disease: 4–6 months of bedaquiline + levofloxacin/moxifloxacin + ethionamide (or 2 months of linezolid) + ethambutol + high-dose isoniazid + pyrazinamide + clofazimine, followed by 5 months of levofloxacin + clofazimine + ethambutol + pyrazinamide.
16. **Longer individualised all-oral regimen (18–20 months)** for extensive, XDR or intolerant disease, built from: **Group A** — levofloxacin/moxifloxacin, **bedaquiline, linezolid** (all three included); **Group B** — **clofazimine, cycloserine/terizidone** (one or both added); **Group C** — ethambutol, delamanid, pyrazinamide, imipenem–cilastatin or meropenem (with amoxicillin–clavulanate), amikacin/streptomycin, ethionamide/prothionamide, p-aminosalicylic acid — added to complete at least four effective drugs. **Injectable-free regimens are now the norm**; kanamycin and capreomycin have been withdrawn.
17. **Isoniazid mono-resistant (Hr) TB:** rifampicin + ethambutol + pyrazinamide + levofloxacin for 6 months (6 REZ-Lfx).

Monitoring, Adverse Effects and Support

18. **Monitoring:** monthly sputum smear and culture (the response is judged on culture conversion), monthly weight, monthly haemogram and renal/liver function, **ECG for QTc at baseline, weeks 2, 4, 8, 12 and monthly thereafter** (bedaquiline, moxifloxacin, clofazimine and delamanid are all QT-prolonging), TSH on ethionamide and PAS, monthly visual acuity/colour vision on ethambutol and linezolid, and audiometry if an injectable is used.
19. **Key adverse effects: linezolid** — myelosuppression, peripheral and optic neuropathy, lactic acidosis (the dominant toxicity, requiring dose reduction to 300 mg or interruption); **bedaquiline** — QT prolongation, hepatotoxicity; **pretomanid** — hepatotoxicity, peripheral neuropathy; **clofazimine** — skin hyperpigmentation, ichthyosis, QT prolongation; **cycloserine** — psychosis, depression, seizures (a particular hazard in the older brain); **fluoroquinolones** — tendinopathy, dysglycaemia, delirium, QT prolongation. Manage through **active drug-safety monitoring (aDSM)** with mandatory reporting.
20. **Adjunctive and programmatic care: pyridoxine** with linezolid, cycloserine and high-dose isoniazid; nutritional support — under NTEP through the **Ni-kshay Poshan Yojana** direct benefit transfer (enhanced to Rs 1000 per month in 2024) and the **Pradhan Mantri TB Mukt Bharat Abhiyaan** with Ni-kshay Mitra community adoption; airborne infection control; contact screening and TB preventive treatment for contacts; treatment support through **DOT providers, video-observed therapy and 99DOTS**; and screening/management of diabetes, HIV, alcohol use and undernutrition.
21. **Geriatric-specific management:** review and reduce polypharmacy before starting, screen for and stop other QT-prolonging drugs (macrolides, antipsychotics, antiemetics, antiarrhythmics), correct hypokalaemia and hypomagnesaemia, adjust doses for weight and renal function, monitor for delirium on cycloserine and fluoroquinolones, arrange family or caregiver-supported adherence, and involve the multidisciplinary team for nutrition, mobility and depression.
22. **Outcomes:** historically MDR-TB treatment success was only 50–60% with 18–24-month injectable regimens; with the all-oral shorter regimens success now approaches **85–90%**, with far lower loss to follow-up. Outcomes in the elderly remain poorer because of comorbidity, drug intolerance and higher all-cause mortality.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Pathy's: sputum acid-fast stain and culture remain the gold standard for diagnosis; detection rates are not clearly lower in the elderly.	Still valid for confirmation, but **rapid molecular testing (CBNAAT/Truenat) is now the mandated first diagnostic test**, with universal DST for every notified patient.

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Pathy's: tuberculin and IGRA positivity are lower in older patients with similar exposure.	Confirmed; WHO now emphasises that these tests **have no role in diagnosing active TB** and are used only for infection/preventive-treatment decisions.
Classical DOTS-Plus: 18–24-month regimens containing an **injectable** (kanamycin, capreomycin).	**Injectable-containing regimens are obsolete.** Kanamycin and capreomycin have been removed from all WHO regimens because of ototoxicity and inferior outcomes.
Standardised long regimens for all MDR-TB patients.	**Six-month BPaLM is the preferred regimen** for MDR/RR-TB and pre-XDR-TB, with a 9-month all-oral regimen where fluoroquinolone resistance is excluded and longer regimens reserved for complex disease.
XDR-TB defined as MDR plus fluoroquinolone plus second-line injectable resistance.	**Redefined (2021):** MDR/RR-TB plus fluoroquinolone resistance plus resistance to bedaquiline or linezolid; the older category becomes **pre-XDR-TB**.
Linezolid 1200 mg daily used in early BPaL studies.	**Linezolid 600 mg once daily** for both BPaLM and BPaL — the ZeNix trial showed equal efficacy with markedly less myelosuppression and neuropathy.

Latest Updates (2023–Present)

- **WHO Consolidated Guidelines on Tuberculosis, Module 4: Treatment and Care (15 April 2025)** — all previous guidance consolidated into a single document, with a landmark new recommendation for a novel all-oral 6-month regimen, **BDLLfxC** (**b**edaquiline, **d**elamanid, **l**inezolid, **l**evo**fx**oxacin, **c**lofazimine), for MDR/RR-TB with or without fluoroquinolone resistance — derived from the **endTB** trial. Modified 9-month regimens are recommended where fluoroquinolone resistance is excluded.
- **India:** the Union Health Ministry **approved introduction of BPaLM under NTEP on 6 September 2024**, with a countrywide time-bound rollout and structured capacity building. The 2024 National Technical Expert Group also recommended **extending bedaquiline and delamanid to all age groups** and replacing ethionamide with **linezolid in the 9-month shorter oral regimen**.
- **Xpert MTB/XDR and targeted next-generation sequencing** were WHO-endorsed (2023–2024) for rapid detection of resistance to isoniazid, fluoroquinolones, ethionamide, amikacin and beyond; NTEP has begun deploying CBNAAT MTB/XDR at equipped laboratories.
- **TB-PRACTECAL** (*NEJM* 2022) and **ZeNix** (*NEJM* 2022) provided the evidence base for BPaLM and for the reduced linezolid dose; **endTB** (*NEJM* 2024) established three further 9-month all-oral bedaquiline/delamanid-based regimens.
- **Drug-susceptible TB:** the 4-month **HPMZ** regimen (high-dose rifapentine, isoniazid, moxifloxacin, pyrazinamide; Study 31/A5349) is WHO-recommended and is being evaluated for Indian programmatic adoption — relevant because shortening the susceptible regimen reduces the pool from which resistance emerges.
- **India's TB elimination target of 2025** (five years ahead of the SDG target) has been supported by **Ni-kshay Poshan Yojana**, **Pradhan Mantri TB Mukt Bharat Abhiyaan** and the **100-day intensified TB elimination campaign (December 2024)**, with an emphasis on active case-finding in the vulnerable, including the elderly and residents of old-age homes.
- **TB preventive treatment** has moved to shorter rifamycin-based courses — **3HP** (weekly rifapentine + isoniazid for 12 doses), **1HP** (daily rifapentine + isoniazid for 1 month) and **4R** — which are far better tolerated than 6–9 months of isoniazid in older, polypharmacy-burdened patients.

EXAMINER'S TIP — verbatim mark-earning lines

- "MDR-TB is resistance to isoniazid and rifampicin; pre-XDR adds fluoroquinolone resistance; XDR (2021 definition) adds bedaquiline or linezolid resistance."
- "BPaLM — bedaquiline, pretomanid, linezolid, moxifloxacin for six months — achieved 89% success versus 52% with standard care in TB-PRACTECAL, and was approved for NTEP rollout in India in September 2024."
- "All WHO-recommended MDR-TB regimens are now injectable-free; kanamycin and capreomycin have been withdrawn."
- "Linezolid 600 mg once daily — the ZeNix trial showed equal efficacy to 1200 mg with far less myelosuppression and neuropathy."
- "Every MDR-TB regimen contains QT-prolonging drugs — ECG monitoring and correction of potassium and magnesium are mandatory, especially in the polypharmacy-burdened elderly."
- "Group A drugs are levofloxacin/moxifloxacin, bedaquiline and linezolid — all three are included unless contraindicated."
- "In the older patient, suspect tuberculosis when he or she is inexplicably failing — fever, sweats, haemoptysis and cavitation are all less common."

Q8. Discuss malaria — treatment, drug classes, contraindications, side effects, efficacy and prophylaxis.

Textbook coverage: Malaria is **not covered as a disease entity** in Pathy's Principles and Practice of Geriatric Medicine (6th ed.) or Essentials of Clinical Geriatrics (7th ed.); antimalarials appear only incidentally — chloroquine and hydroxychloroquine as drugs that may worsen myasthenia gravis and cause painless myopathy (Ch. 56, Ch. 57), and hydroxychloroquine as a failed COVID-19 therapy (Ch. 41). The answer below is therefore constructed from the **WHO Guidelines for Malaria (13 August 2025)**, the **National Drug Policy on Malaria (NCVBDC/NVBDCP, Government of India)** and current peer-reviewed literature.

15–20 High-Yield Points

Aetiology and Burden

1. Malaria is caused by five species of *Plasmodium* — ***P. falciparum*** (severe disease and death), ***P. vivax*** (relapsing, dominant in India), *P. ovale*, *P. malariae* and ***P. knowlesi*** (zoonotic, South-East Asia) — transmitted by the female *Anopheles* mosquito.
2. **Global burden:** the World Malaria Report 2025 estimates **282 million cases and 610,000 deaths in 2024**, an increase of about 9 million cases on the previous year, driven by drug and insecticide resistance, climate change, conflict and funding contraction.
3. **India:** cases have fallen from around 7.5 crore at Independence to about **2.5 lakh confirmed cases and 86 deaths in 2024** — a fall of more than 97%. India **exited the WHO 'High Burden to High Impact' group in 2024** and targets **zero indigenous cases by 2027 and certification of elimination by 2030**. In 2024 India still accounted for about 73% of the WHO South-East Asia Region's estimated cases.
4. **Why malaria matters in the geriatric patient:** loss of acquired immunity in previously endemic areas, blunted fever, presentation as **delirium, falls or unexplained deterioration** rather than classical paroxysms, a higher risk of severe disease with **renal failure, ARDS, hypoglycaemia and cerebral malaria**, and greater vulnerability to antimalarial toxicity through polypharmacy, QT prolongation and impaired renal and hepatic clearance.

Drug Classes

5. **Quinoline blood schizonticides: chloroquine**, **amodiaquine**, **quinine**, **mefloquine**, **lumefantrine**, **piperaquine**, **pyronaridine** — act by inhibiting **haem detoxification** in the parasite food vacuole.
6. **8-Aminoquinolines (tissue schizonticides/hypnozoiticides and gametocytocides): primaquine** and **tafenoquine** — the only drugs that achieve **radical cure** by eradicating *P. vivax* and *P. ovale* hypnozoites; both cause **haemolysis in G6PD deficiency**.
7. **Artemisinins: artesunate, artemether, dihydroartemisinin, arteether** — endoperoxide bridge generates free radicals on contact with haem iron. They are the **most rapidly acting antimalarials**, killing ring stages and reducing parasite biomass 10,000-fold per cycle, but have a very short half-life, hence the mandatory combination with a longer-acting partner drug.
8. **Antifolates: sulfadoxine–pyrimethamine** (sequential blockade of dihydropteroate synthase and dihydrofolate reductase), **proguanil**. **Antibiotic antimalarials: doxycycline, clindamycin** (apicoplast inhibitors, slow-acting, always used as partners). **Naphthoquinone: atovaquone** (cytochrome bc1 inhibitor), used with proguanil.

Treatment

9. **Uncomplicated *P. falciparum* malaria is treated with an artemisinin-based combination therapy (ACT) for 3 days** — the artemisinin clears the parasite biomass and the partner drug eliminates the residuum. WHO recommends six ACTs: artemether–lumefantrine, artesunate–amodiaquine, artesunate–mefloquine, artesunate–sulfadoxine–pyrimethamine, dihydroartemisinin–piperaquine and artesunate–pyronaridine.
10. **India's National Drug Policy on Malaria** uses **AS+SP (artesunate 3 days + sulfadoxine–pyrimethamine on day 1) as first-line for *P. falciparum* across most of the country**, plus **primaquine 0.75 mg/kg single dose on day 2** as a gametocytocide. In the **north-eastern states**, where SP resistance is established, first-line is **artemether–lumefantrine**.
11. ***P. vivax*: chloroquine 25 mg base/kg over 3 days** (10–10–5 mg/kg) for the blood stage, plus **primaquine 0.25 mg/kg daily for 14 days** for radical cure in India (WHO now advises a higher total dose — 7 mg/kg, given as 0.5 mg/kg/day for 14 days or 1 mg/kg/day for 7 days). Where chloroquine resistance exists, an ACT is used instead.
12. **Severe malaria — the single most important therapeutic point: intravenous artesunate is the drug of choice in all patients, including the elderly, pregnant women in all trimesters and children**, at 2.4 mg/kg at 0, 12 and 24 hours and then daily. It **reduced mortality by 35% compared with quinine in SEAQUAMAT and by 22.5% in**

AQUAMAT. Give at least 24 hours of parenteral therapy, then complete with a full oral ACT course once the patient can swallow.

13. **Supportive management of severe malaria:** hourly glucose monitoring (hypoglycaemia is common, and quinine worsens it by stimulating insulin release), cautious fluid resuscitation with careful attention to pulmonary oedema in the elderly, renal replacement therapy for acute kidney injury or blackwater fever, treatment of seizures, exclusion of concomitant bacterial sepsis, and **avoidance of routine exchange transfusion, corticosteroids and heparin**, none of which improve outcome.

14. **Reducing transmissibility:** in low-transmission areas a **single low dose of primaquine 0.25 mg/kg** should be given with an ACT to patients with *P. falciparum* malaria to kill gametocytes; **G6PD testing is not required** at this dose.

Contraindications, Side Effects and Efficacy

15. **Primaquine and tafenoquine are contraindicated in G6PD deficiency** (haemolysis), in pregnancy, in infants under 6 months and in women breastfeeding infants under 6 months. **G6PD status must guide radical-cure prescribing**; where testing is unavailable, weekly primaquine 0.75 mg/kg for 8 weeks under supervision is the compromise regimen.

16. **Key adverse effects by drug: chloroquine** — pruritus (especially in dark skin), retinopathy on prolonged use, **myopathy and worsening of myasthenia gravis**, QT prolongation; **quinine** — **cinchonism** (tinnitus, deafness, headache, nausea, visual disturbance), **hypoglycaemia**, hypotension on rapid infusion, QT prolongation; **mefloquine** — neuropsychiatric reactions, contraindicated in epilepsy and psychiatric illness; **sulfadoxine–pyrimethamine** — Stevens–Johnson syndrome, agranulocytosis, sulfa allergy; **doxycycline** — photosensitivity, oesophagitis (a real hazard in the older patient — take upright with water), contraindicated in pregnancy; **artemisinins** — generally very well tolerated, with a recognised **post-artesunate delayed haemolysis** at 1–3 weeks requiring follow-up haemoglobin; **piperaquine and halofantrine** — marked QT prolongation.

17. **Geriatric prescribing cautions:** the cumulative QT burden of chloroquine, quinine, mefloquine, piperaquine and lumefantrine on top of existing antipsychotics, antiemetics, macrolides and antiarrhythmics; dose adjustment of quinine in renal and hepatic impairment; risk of hypoglycaemia in the diabetic on sulphonylureas or insulin; and interactions of artemether–lumefantrine with CYP3A4 inhibitors and inducers.

18. **Efficacy and resistance:** ACTs remain highly efficacious, with cure rates above 95% where the partner drug is effective. However, **artemisinin partial resistance** (delayed parasite clearance, mediated by *Pfkelch13* mutations) is entrenched in the Greater Mekong subregion and has now emerged independently in **Eritrea, Rwanda, Uganda, Ethiopia and Tanzania**; **chloroquine resistance in *P. falciparum* is universal in India**, and sulfadoxine–pyrimethamine resistance is established in the north-east. Efficacy is monitored through **therapeutic efficacy studies every 24 months** at sentinel sites.

Prophylaxis and Prevention

19. **Chemoprophylaxis for travellers to endemic areas** (Government of India recommendations): **short-term (< 6 weeks) — doxycycline 100 mg daily**, started 2 days before travel and continued 4 weeks after leaving; **long-term (> 6 weeks) — mefloquine 250 mg weekly**, started 2–3 weeks before and continued 4 weeks after. **Atovaquone–proguanil** (daily, from 1–2 days before to 7 days after) is the best-tolerated option internationally and the preferred choice for short trips and for older travellers because of its short post-travel tail and few interactions.

20. **Terminal prophylaxis** with primaquine (or a single dose of tafenoquine) after leaving an area endemic for *P. vivax* or *P. ovale*, subject to G6PD status, prevents late relapse.

21. **Vector control and personal protection** remain the backbone: **long-lasting insecticidal nets (LLINs)**, **indoor residual spraying**, larval source management, repellents, screened housing and full-sleeved clothing after dusk. Under India's programme these are delivered through **ASHA-led surveillance with rapid diagnostic tests and radical treatment at village level**.

22. **Vaccines** — **RTS,S/AS01 (Mosquirix)** and **R21/Matrix-M** are WHO-recommended for children in areas of moderate-to-high transmission; the latter is manufactured by the Serum Institute of India. **Neither has any role in adult or geriatric practice**, and neither is used in India, where transmission is low and the goal is elimination.

23. **Programmatic framework in India:** the **National Framework for Malaria Elimination (2016–2030)** and the **National Strategic Plan (2023–2027)**, delivered by the **National Centre for Vector Borne Diseases Control (NCVBDC, formerly NVBDCP)**, categorise districts **0 to 3** by annual parasite incidence, with Category 0 districts (zero indigenous cases) entering **prevention of re-establishment** and eligible for subnational verification. By end-2025, **160 districts across 23 states/UTs had reported zero indigenous cases**.

Current Practice Update

Textbook Position (Pathy's 6th ed. / Essentials 7th ed.)	Current Evidence & Guidelines (2023–2026)
Chloroquine and hydroxychloroquine appear in the uploaded textbooks only as causes of myopathy and as aggravators of myasthenia gravis.	These remain valid geriatric cautions, and are the reason to avoid chloroquine in a patient with known neuromuscular disease — but chloroquine now has **no role in *P. falciparum* treatment in India** because of universal resistance.
Hydroxychloroquine trialled for COVID-19 with early observational promise (Ch. 41).	Definitively abandoned — randomised trials showed no benefit and an **excess of cardiovascular events, mainly QT prolongation**.
Quinine was long the standard for severe malaria.	**Intravenous artesunate has replaced quinine** in every patient group (SEAQUAMAT, AQUAMAT); quinine is now only a fallback where artesunate is unavailable.
Primaquine 0.25 mg/kg for 14 days for *P. vivax* radical cure (Indian programme).	**WHO 2025 now recommends a higher total dose of 7 mg/kg** — 0.5 mg/kg/day for 14 days or 1 mg/kg/day for 7 days — and offers **tafenoquine as a single-dose alternative** in patients with ≥ 70% G6PD activity receiving chloroquine.
G6PD status assessed clinically or not at all.	**Qualitative near-patient G6PD tests** are now recommended to guide relapse-prevention regimens (strong recommendation).
Malaria regarded as an endemic disease of high burden in India.	India is now in the **elimination endgame** — exited the WHO HBHI group in 2024, targeting **zero indigenous cases by 2027** and certification by 2030.

Latest Updates (2023–Present)

- **WHO Guidelines for Malaria, 13 August 2025 consolidated edition** — ACT for 3 days for all uncomplicated falciparum malaria; ACT or chloroquine for non-falciparum species in chloroquine-susceptible areas and **ACT where chloroquine resistance exists**; **G6PD status must guide primaquine or tafenoquine**; **tafenoquine recommended as an alternative to primaquine** for relapse prevention in patients aged 2 years and above with ≥ 70% G6PD activity who receive chloroquine.
- **Single low-dose primaquine (0.25 mg/kg) with an ACT** in low-transmission settings to reduce transmissibility (2024 recommendation) — directly relevant to India's elimination strategy, though under-used because it confers no individual clinical benefit.
- **Artemisinin partial resistance** (WHO, January 2025) — independent emergence of *Pfkelch13* validated markers in East Africa (Eritrea, Rwanda, Uganda, Ethiopia, Tanzania) alongside **histidine-rich protein 2/3 (*pfhrp2/3*) gene deletions** that cause false-negative rapid diagnostic tests, prompting a shift towards non-HRP2 or combination RDTs.
- **New and emerging agents: ganaplacide–lumefantrine** (a non-artemisinin combination in phase 2/3), **KAF156**, **artefenomel**, **cipargamin (KAE609)** targeting PfATP4, and **triple ACTs** (e.g. artemether–lumefantrine–amodiaquine; DHA–piperaquine–mefloquine, DeTACT trial 2022–2024) designed to protect partner drugs against resistance.
- **Monoclonal antibodies** — **L9LS** and **CIS43LS** against the circumsporozoite protein conferred high-level protection over a malaria season in phase 2 trials (*NEJM* 2022–2024), pointing towards a passive-immunisation strategy for high-risk groups and outbreak control.
- **Vector-control innovations:** dual-active-ingredient (chlorfenapyr and pyriproxyfen) LLINs against pyrethroid-resistant vectors, spatial repellents, attractive targeted sugar baits, and gene-drive research — alongside the growing threat of ***Anopheles stephensi*** invading urban Africa, a vector originally of Indian cities.
- **India-specific:** the WHO South-East Asia Regional Office confirmed India is on track for the Global Technical Strategy target of a 75% reduction in cases by 2025 against a 2015 baseline; **Mizoram and Tripura** remain the last Category 3 (high-burden) states, and forest-dwelling, tribal and migrant populations are the principal residual reservoirs.

EXAMINER'S TIP — verbatim mark-earning lines

- “Intravenous artesunate is the treatment of choice for severe malaria in every patient group — it reduced mortality by 35% versus quinine in SEAQUAMAT.”
- “India's first-line for falciparum malaria is artesunate plus sulfadoxine–pyrimethamine, except in the north-eastern states where artemether–lumefantrine is used.”
- “Only the 8-aminoquinolines — primaquine and tafenoquine — kill hypnozoites and achieve radical cure; both demand G6PD testing.”
- “A single low dose of primaquine, 0.25 mg/kg, is gametocytocidal and does not require G6PD testing.”
- “Artemisinin partial resistance means delayed parasite clearance, not treatment failure — the failure comes when the partner drug is also resistant.”
- “Quinine causes cinchonism and hyperinsulinaemic hypoglycaemia; artesunate causes delayed haemolysis at one to three weeks — always recheck the haemoglobin.”
- “India exited the WHO High Burden to High Impact group in 2024 and targets zero indigenous cases by 2027, certification by 2030.”
- “RTS,S and R21 vaccines are for children in moderate-to-high transmission settings only — they have no place in Indian geriatric practice.”

PREVENTIVE GERIATRICS

Immunization & Cancer Screening in the Elderly

MD Geriatric Medicine — Examination Compendium

Seven Compiled Question–Answer Sets

15-Mark Format with Current Practice Updates

Primary sources: Pathy's Principles and Practice of Geriatric Medicine, 6th edition (2022) • Essentials of Clinical Geriatrics, 7th edition

Updates: Peer-reviewed literature, international guidelines and society recommendations, 2023 – mid-2026, with Indian context integrated throughout (API, ICMR, IAG, LASI, NP-NCD).

Contents

1.	Immunization schedule for a fit elderly patient, with evidence-based reasons	15 marks
2.	Current guidelines and status of vaccination in older persons, with recent evidence	15 marks
3.	Travel-related vaccination in the elderly — CDC guidelines	15 marks
4.	Cancer screening in the elderly — currently accepted strategies	15 marks
5.	Screening for colorectal cancer	15 marks
6.	Mammography — screening the older woman	15 marks
7.	Prostate-specific antigen — to screen or not to screen?	15 marks
8.	**Rapid Revision Grid** — key numbers, trials and cut-offs	Appendix

How to use this compendium

Every answer follows the same architecture: **high-yield textbook points → Latest Updates (2023-present) → Current Practice Update comparison table**. The comparison table is the highest-value section for the examiner — it demonstrates that you know both the textbook position and where current evidence has moved beyond it. The **Rapid Revision Grid** at the end compiles every number and trial name in this compendium onto a few pages for last-night revision.

Question 1. Immunization schedule for a fit elderly patient, with evidence-based reasons.

Primary source: Pathy's, 6th ed. — "Preventive Geriatrics"; Essentials of Clinical Geriatrics, 7th ed.

A. High-Yield Points (Textbook Content)

PRINCIPLES

1. **Immunization is primary prevention** in geriatrics — the aim is to prevent infection-related **hospitalisation, functional decline and death**, not merely infection.
2. **Immunosenescence** makes older adults respond less well to vaccines; hence **higher-dose, adjuvanted, conjugate or recombinant** preparations are preferred in this age group.
3. Pathy's recommends tailoring vaccination to the patient's **functional category** — *Fit, Frail, Moderately demented, End of life* — and to **probable life expectancy**. A **fit elderly patient receives the complete schedule.**

INFLUENZA VACCINE

4. Give **annually to all older patients in every category**, ideally in **early autumn** (pre-monsoon / winter in India).
5. **More than 90% of deaths** from pneumonia and influenza during epidemics occur in people **aged ≥65 years**.
6. Vaccination reduces the risk of influenza by about **50%** and influenza-related mortality by about **70%**; it also reduces hospitalisation and is **cost-effective**.
7. In nursing homes it is only about **40% effective against clinical illness**, but is **much more effective in preventing pneumonia, hospitalisation and death**. Vaccinating **>80% of residents prevents outbreaks**.
8. **Adjuvanted influenza vaccine** is especially valuable in institutionalised elderly and those with **diabetes, heart failure or respiratory failure**.
9. **Vaccinate healthcare staff and close family contacts** — this reduces respiratory infection and mortality among the elderly they care for (**"cocooning"**).

PNEUMOCOCCAL VACCINE

10. Textbook schedule: **one dose PCV13 followed by PPSV23 one year later**, after age 65. If **PPSV23 was already given**, only **PCV13** is needed. Pathy's states there is **no recommendation on re-immunisation**; other tables quote a repeat **every 3–5 years**.
11. Antibody response is **weaker than in young adults**, but the vaccine still reduces **invasive pneumococcal disease and pneumococcal bacteraemia** in high-risk elders.
12. **CAPITA trial** (community-dwelling >65 years): PCV13 reduced **vaccine-type pneumococcal pneumonia by 45%**. A large **Japanese nursing-home RCT** showed PPSV23 reduced **pneumonia incidence and mortality**.
13. Pneumococcal plus annual influenza vaccine should be offered to **all patients with COPD**.

TETANUS–DIPHTHERIA

14. **Over half of all tetanus cases occur in people aged ≥60 years** — a strong argument for boosters in the elderly.
15. **Td booster every 10 years** (every **5 years** for a tetanus-prone wound). If the primary series is absent or uncertain: **0.5 mL Td IM at 0, 2 months and 6 months**. At least **one dose should be given as Tdap** if never received.

HERPES ZOSTER

16. Herpes zoster occurs in up to **half of individuals aged ≥85 years**; **post-herpetic neuralgia** affects **>40% of those over 60**.
17. **Zostavax (live, 2006) is only 30% protective; Shingrix (recombinant, 2016) is ~90% protective.** Give **2 doses of Shingrix to all adults ≥50 years**, **regardless of past chickenpox** and **even if Zostavax was received earlier**.

COVID-19 AND OTHERS

18. **SARS-CoV-2 vaccines reduce severe disease and mortality**; indicated for adults **>65 years**, healthcare professionals and **family members in contact with older individuals**.
19. **No vaccine is used for tuberculosis** in the elderly — **isoniazid 300 mg/day for 9–12 months** is given for **skin-test converters** in selected residents. Tuberculin reaction may be **falsely negative due to anergy**.
20. The textbook records **two controversies**: ecological data showing rising influenza/pneumonia hospitalisation despite rising vaccine uptake (**Simonsen et al.**), and continuing debate on the **cost-effectiveness of pneumococcal vaccine**.

QUICK SCHEDULE TABLE (TEXTBOOK-BASED)

Vaccine	Fit elderly schedule
Influenza	Every year, early autumn
Pneumococcal	PCV13 → PPSV23 one year later (textbook table: repeat every 3–5 years)
Tetanus (Td/Tdap)	Booster every 10 years; at least one dose as Tdap
Herpes zoster (RZV)	2 doses, once, age ≥50
COVID-19	As per current guidelines

B. Latest Updates (2023–Present)

1. RSV vaccine — the biggest addition to the elderly schedule. ACIP now recommends a single dose of **Arexvy, Abrysvo or mResvia** for unvaccinated adults; additional doses are not currently recommended. Vaccination is **universal at ≥75 years** and **risk-based at 60–74 years**; in April 2025 ACIP extended the risk-based recommendation down to **50–59 years** for those at increased risk of severe RSV disease (*CDC/ACIP, 2023–2025*). Evidence: **AReSVi-006** showed **82.6% efficacy** against RSV lower respiratory tract disease in adults ≥60, and **94.6%** in those with at least one underlying condition; cumulative efficacy over three seasons was **62.9%**, with **67.4%** against severe RSV-LRTD, falling to **48% in the third season** (*Lancet Respiratory Medicine, 2025*).

2. Pneumococcal schedule simplified to a single dose. ACIP issued recommendations for the **21-valent pneumococcal conjugate vaccine (PCV21)** in adults in 2024, and adults who previously completed PCV13 + PPSV23 after age 65 may receive one dose of PCV20 or PCV21, or no further vaccine. The sequential PCV13 → PPSV23 pathway is being replaced by **one dose of PCV20 or PCV21** (*MMWR, 2024–2025*).

3. Influenza — product preference and the DANFLU-2 result. For age ≥65, **HD-IIV3, RIV3 or aIIV3 is preferred**; any age-appropriate vaccine may be used if these are unavailable (*CDC Adult Immunization Schedule, 2025–26*). However, **DANFLU-2**, the largest randomised influenza vaccine trial ever conducted, found that high-dose vaccine did **not** significantly reduce hospitalisation for influenza or pneumonia compared with standard dose (*NEJM, December 2025*). A prespecified secondary analysis of **332,438 adults ≥65** showed cardiorespiratory hospitalisation of **2.25% with high-dose versus 2.38% with standard dose**, driven mainly by fewer cardiovascular hospitalisations (**1.30% vs 1.40%**) (*JAMA Cardiology, 2025*).

4. Zoster vaccine and dementia — a major new off-target signal. A Welsh natural experiment using a date-of-birth eligibility cut-off found that live zoster vaccination reduced new dementia diagnoses by about **one-fifth over 7 years** (*Nature, 2025*). A follow-up showed reduced mild cognitive impairment and fewer dementia deaths among those already living with dementia (*Cell, 2025*). AS01-adjuvanted shingles and RSV vaccines were also associated with reduced 18-month dementia risk in **436,788 matched individuals** (*npj Vaccines, 2025*). Zoster vaccination has additionally been linked to a **23% lower risk of cardiovascular events** including stroke, heart failure and coronary heart disease (*European Heart Journal, 2025*).

5. COVID-19 policy has shifted. For the 2025–26 season ACIP moved COVID-19 vaccination from a universal recommendation to **shared clinical decision-making**, with an annually updated formulation (*MMWR, 2025*).

6. India — API Consensus Guidelines (essential for the Indian viva). The Association of Physicians of India, with other societies, released an exhaustive **adult immunization consensus guideline in 2024**, emphasising "bridging childhood vaccines" in adult care. The **2026 Update** involves **23 national and regional associations** and adopts a **life-course immunization framework** based on age bands and risk profiles rather than disease category. Key India-specific changes:

- **PCV20** included as the **preferred single-dose option**, replacing sequential PCV13 → PPSV23
- **RZV for all adults ≥50 years** irrespective of prior shingles, and for **immunocompromised adults ≥18 years** (cancer, CKD, CVD, transplant, biologics), as **2 doses 2–6 months apart**
- **Annual influenza vaccination for all adults over 50**, framed as **chronic-disease risk reduction**, not just seasonal protection
- **Standardised adult immunization cards** with written records and linkage to electronic health records
- HPV positioned as **preventive oncology**, gender-neutral, with a 3-dose schedule in older and immunocompromised adults

> **Practical Indian note**
>
> Adult vaccines are **not part of the Universal Immunization Programme or NPHCE**; they remain largely **out-of-pocket**, which is the single biggest barrier to uptake.

C. Current Practice Update

Aspect	Pathy's / Essentials (Textbook)	Current Evidence (2023–2026)

Pneumococcal	PCV13 → PPSV23 one year apart; no re-immunisation advice	**Single dose PCV20 or PCV21**; sequential schedule obsolete; API 2026 prefers PCV20
Influenza product	Standard vaccine; adjuvanted vaccine in institutionalised elderly	**HD-IIV3 / RIV3 / aIIV3 preferred ≥65**; but **DANFLU-2 neutral** for primary hospitalisation endpoint; **trivalent** formulations (B/Yamagata dropped)
RSV	Not part of the schedule	**New core elderly vaccine** — single dose, universal ≥75, risk-based 50–74
Zoster	Shingrix ~90% protective; prevents zoster and PHN	Same, **plus** signals for reduced **dementia, MCI and cardiovascular events**
COVID-19	Recommended for all >65	**Shared clinical decision-making**; annually updated formulation
Framework	Vaccination by **functional category / life expectancy**	**Life-course immunization** by age band + risk profile (API 2026); standardised **adult immunization card**
Age threshold	Most recommendations start at **65**	Several now start at **50** (zoster, pneumococcal, risk-based RSV, influenza in API 2026)

Examiner's Tip

Open with the framing line: "*In a fit older adult the objective of immunization is not merely to prevent infection but to prevent hospitalisation, functional decline and death — and because of immunosenescence, the elderly need higher-antigen, adjuvanted or recombinant preparations rather than standard formulations.*"
Then give the schedule as a table. Close with: "*The five core vaccines in a fit older adult today are influenza, pneumococcal, herpes zoster, RSV and COVID-19, with tetanus boosters every ten years.*"
Quote three numbers if nothing else: **>90% of influenza deaths occur above 65; Shingrix 90% vs Zostavax 30%; RSV vaccine efficacy 82.6% in the first season.**

Question 2. Current guidelines and status of vaccination in older persons, with recent evidence.

Primary source: Pathy's, 6th ed.; Essentials of Clinical Geriatrics, 7th ed. Current guidelines cited separately.

A. High-Yield Points

I. TEXTBOOK BASELINE

1. **Vaccination is the single most cost-effective primary preventive measure in geriatrics.** Pathy's advises tailoring it to the patient's **functional category** and **probable life expectancy**.
2. **Immunosenescence and inflammaging** reduce vaccine response. Pathy's notes that **frailty impairs vaccine-induced antibody response** and increases post-vaccination influenza infection in community-dwelling elders — hence **adjuvanted and high-antigen preparations** are preferred.
3. **Influenza vaccine — yearly, in all categories.** Over **90% of pneumonia and influenza deaths** in epidemics occur in those ≥65. It reduces influenza risk by **~50%** and influenza mortality by **~70%**.
4. In **nursing homes**, efficacy against clinical illness is only **~40%**, but protection against **pneumonia, hospitalisation and death is much better**; vaccinating **>80% of residents prevents outbreaks**.
5. **Vaccinate healthcare staff, relatives and regular visitors** — reduces respiratory infection and mortality in residents. Pathy's states this explicitly.
6. **Pneumococcal vaccine** — textbook schedule is **PCV13 followed by PPSV23 one year later after 65**; PPSV23 alone is the practice in the UK, USA, Germany, Canada, Australia and Japan. **CAPITA** showed PCV13 cut vaccine-type pneumococcal pneumonia by **45%**; a Japanese nursing-home RCT showed PPSV23 reduced **pneumonia and mortality**.
7. **Tetanus** — **Td booster every 10 years** (5 years for a tetanus-prone wound); **>50% of tetanus cases occur in people ≥60**; at least one booster should be **Tdap**.
8. **Herpes zoster** — **Shingrix ~90% protective** versus **Zostavax ~30%**; two doses for all ≥50 regardless of chickenpox history. Essentials records for the live vaccine: **HZ HR 0.45, ophthalmic HZ HR 0.37, HZ hospitalisation HR 0.35**.
9. **Essentials (Nichol 2007):** influenza vaccination in community-dwelling elders gave **HR 0.75 for pneumonia/influenza hospitalisation** and **HR 0.52 for death**. The textbook also records the counter-argument (**Simonsen**) that hospitalisation rates rose despite rising coverage, and the ongoing debate on **pneumococcal cost-effectiveness**.
10. Both textbooks predate — and therefore do not cover — **RSV vaccines, PCV20/PCV21, preferential high-dose influenza vaccine, off-target effects of zoster vaccine, and Indian adult immunization guidelines.**

II. CURRENT GUIDELINE STATUS (GLOBAL)

11. **Influenza — annual for all older adults.** For age ≥65, **HD-IIV3, RIV3 or aIIV3 is preferred**; if none is available, any age-appropriate vaccine may be used. All formulations are now **trivalent** (B/Yamagata removed).
12. **Pneumococcal — the sequential schedule is obsolete.** On **23 October 2024** ACIP recommended a **single dose of PCV for all PCV-naïve adults aged ≥50 years**, using **PCV20 or PCV21 alone**, or PCV15 in series with PPSV23. The age threshold was formally lowered from **65 to 50 years**.
13. **RSV — now a core elderly vaccine.** First approved May 2023 for adults ≥60. Current position: **universally recommended at ≥75 years**, **risk-based at 60–74 years**, extended in April 2025 to **risk-based 50–59**. A **single dose only**.
14. **Herpes zoster** — RZV two doses for all ≥50 years, now emphasised also for **immunocompromised adults ≥18 years**, given **2–6 months apart**.
15. **COVID-19 — policy has narrowed.** For 2025–26, ACIP moved from a universal recommendation to **shared clinical decision-making**.
16. **Td/Tdap unchanged** — booster every 10 years, with at least one lifetime Tdap.
17. **Individualisation is the new theme.** The AGS position (*JAGS, 2025*) is that guidelines list recommendations by chronological age, but **biological sex, frailty, functional status and multimorbidity** modify vaccine responses and outcomes, and clinicians must increasingly account for this heterogeneity — as well as overcome barriers to uptake in long-term care.

III. CURRENT STATUS IN INDIA

18. **There is no unified national guideline for geriatric immunization in India**; society recommendations are heterogeneous and evidence-limited. Coverage among Indian older adults is **<3% for most vaccines**, with barriers including absent national guidelines, poor awareness, cost, accessibility and **ageism** (*Indian Academy of Geriatrics*

position statement, 2026).

19. **LASI Wave 1 (2017–18, n = 31,464 aged ≥60) coverage figures — high-yield numbers: diphtheria–tetanus 2.75%**, typhoid 1.84%, hepatitis B 1.82%, **influenza 1.59%**, **pneumococcal 0.74%**; coverage was highest in the most affluent groups. Male sex, urban residence, wealthier household, more schooling and existing medical conditions predicted uptake.
20. **Guideline development in India is now rapid:** API issued the first exhaustive **Indian Consensus Guideline on Adult Immunization in 2024**. The **2026 Update** involves **23 associations** and adopts a **life-course immunization framework**, with **PCV20 preferred**, **RZV for all ≥50**, **annual influenza ≥50**, and standardised **adult immunization cards**. The **Indian Academy of Geriatrics** published a dedicated **position statement on vaccination for older adults ≥60 years** in 2026.
21. **Programmatic gap:** adult vaccines are **not included in the Universal Immunization Programme or NPHCE**, so they remain **out-of-pocket** — the main reason for low uptake.

B. Latest Updates (2023–Present)

1. RSV vaccine efficacy and durability. AReSVi-006 showed **82.6% efficacy** against RSV lower respiratory tract disease in adults ≥60, and **94.6%** in those with at least one underlying condition. Cumulative efficacy over three seasons was **62.9%**, with **67.4%** against severe RSV-LRTD, falling to **48% in the third season**. The authors conclude protection lasts **at least three RSV seasons** despite waning, and that the **optimal revaccination strategy is still undefined** (*Lancet Respiratory Medicine, 2025*). For RSVpreF (Abrysvo), the **RENOIR** trial has reported efficacy across **two seasons** (*NEJM, 2023*).

2. DANFLU-2 — the largest randomised influenza vaccine trial ever conducted. In **332,438 adults ≥65** randomised to high-dose versus standard-dose vaccine, high-dose did **not** significantly reduce hospitalisation for influenza or pneumonia — a **neutral primary endpoint** (*NEJM, December 2025*). In a prespecified secondary analysis, cardiorespiratory hospitalisation was **2.25% vs 2.38%**, driven mainly by fewer **cardiovascular hospitalisations (1.30% vs 1.40%)**, described as exploratory in a neutral trial (*JAMA Cardiology, 2025*). A further analysis found fewer cardiorespiratory, cardiovascular and influenza hospitalisations with high-dose vaccine **regardless of diabetes status** (*JAMA Internal Medicine, 2026*).

3. Zoster vaccine and dementia — the most discussed geriatric vaccine finding of the decade. Using the Welsh date-of-birth eligibility cut-off (born before versus after 2 September 1933, with vaccine uptake jumping from **0.01% to 47.2% across one week**), live zoster vaccination reduced new dementia diagnoses by about **one-fifth over 7 years** (*Nature, 2025*). A 2025 extension found HZ vaccination also reduced **mild cognitive impairment diagnoses** and, among people already living with dementia, **deaths due to dementia**, with effects not confined to one dementia subtype (*Cell, 2025*). In **436,788 propensity-matched individuals**, AS01-adjuvanted shingles and RSV vaccines were associated with **lower 18-month dementia risk** (*npj Vaccines, 2025*). Zoster vaccination has also been linked to a **23% lower risk of cardiovascular events** (*European Heart Journal, 2025*).

4. Pneumococcal — simplification plus wider serotype coverage. The ACIP expansion to adults ≥50 was formally published in *MMWR 2025;74(1):1–8*. Supporting data include the **STRIDE-8** trial of PCV21 in high-risk adults, with immunogenicity comparable to PCV15 and PPSV23.

5. India-specific evidence base. An *Indian Journal of Medical Research* rapid review (2024) documented **influenza vaccine uptake of ≤2%** in adults ≥45 years and hepatitis B uptake of only **55–64% even among healthcare workers** in Delhi and Mumbai. Indian advocacy documents highlight two influenza peaks (monsoon and winter) creating **year-round exposure**, a case-fatality rate of **20–25% for invasive pneumococcal disease in ≥65 years** versus 5–10% in younger adults, and a **lifetime herpes zoster risk of ~30%, rising to ~50% by age ≥85**.

C. Current Practice Update

Vaccine / Issue	Pathy's & Essentials	Current guidelines (2023–2026)
Age to start	Most recommendations begin at **65**	Several now begin at **50** — pneumococcal, zoster, risk-based RSV, influenza (API 2026)
Pneumococcal	PCV13 → PPSV23 one year apart	**Single dose PCV20 or PCV21**; ACIP age lowered 65 → 50 (Oct 2024); PCV21 covers ~84% of IPD serotypes
Influenza product	Standard vaccine; adjuvanted in institutionalised or chronic disease	**HD-IIV3 / RIV3 / aIIV3 preferred ≥65**; trivalent; **DANFLU-2 primary endpoint neutral**, benefit mainly cardiovascular and exploratory
RSV	Not mentioned	**New core elderly vaccine** — single dose, universal ≥75, risk-based 50–74; 82.6% season 1, 62.9% cumulative over 3 seasons

Zoster	Prevents zoster and PHN only	Same, **plus** reduced **dementia, MCI, dementia deaths and cardiovascular events**
COVID-19	Recommended for all >65	**Shared clinical decision-making** (2025–26); annually updated formulation
Framework	By **functional category and life expectancy**	**Life-course immunization**; **adult immunization card**; individualisation by **frailty and function** (JAGS 2025)
India	Not addressed	API 2024 → **API 2026 Update (23 societies)**; **IAG position statement 2026**; coverage still **<3%**, outside UIP/NPHCE

Examiner's Tip

This question rewards **structure over content**. Answer in three tiers: *(i) the biology — immunosenescence and frailty blunt vaccine response; (ii) the global guideline position, vaccine by vaccine; (iii) the Indian status, which is the gap.*
The line that earns marks: "*Globally the framework has shifted from chronological age to life-course, risk-profile-based immunization; in India the problem is not the guideline but the programme — adult vaccines lie outside both the UIP and NPHCE, so coverage remains under 3%.*"

Extra Points to Remember

LASI coverage figures are the single most examinable Indian data set: DT 2.75%, typhoid 1.84%, hepatitis B 1.82%, influenza 1.59%, **pneumococcal 0.74%** — remember the order and remember that pneumococcal is lowest.
Three trial names to have ready: CAPITA (pneumococcal), AReSVi-006 (RSV), DANFLU-2 (high-dose influenza).
One conceptual line: vaccination in old age is a *frailty-modified* intervention — the frailer the patient, the greater the potential benefit from preventing hospitalisation, but the weaker the immunological response.

Question 3. Travel-related vaccination in the elderly — CDC guidelines.

CDC Yellow Book / ACIP guidance. The uploaded textbooks contain no travel-medicine vaccination chapter; Pathy's does note that air travel spreads influenza, TB, measles, SARS/MERS and COVID-19 through close cabin proximity, and that schistosomiasis must be considered in returning travellers.

A. High-Yield Points

PRINCIPLES

1. **Age alone is not a contraindication to travel or to vaccination.** The pre-travel consultation is a **risk assessment**, not a fixed schedule.
2. Vaccine selection depends on **destination, duration, season, itinerary, planned activities, type of accommodation and purpose of travel**, plus the patient's **health status and current medications**.
3. **Immunosenescence** lowers seroconversion and shortens duration of protection, so older travellers need **earlier vaccination, longer lead time, and sometimes serological confirmation**.
4. **Ideal timing: pre-travel consultation 4–6 weeks before departure**, because most travel vaccines need multiple doses and two weeks for protective immunity. For **last-minute travellers**, accelerated schedules can be used.
5. CDC groups travel vaccines into three categories — **Routine, Required and Recommended**.

CATEGORY 1 — ROUTINE VACCINES

6. **Catch up routine age-appropriate vaccines first.** Influenza and pneumococcal vaccines are recommended for older persons whether or not they travel; travel-specific vaccines are discussed case by case, weighing vaccine risk against the risk of acquiring the disease during travel.
7. Ensure **influenza (annual), pneumococcal, Td/Tdap (10-yearly), herpes zoster (RZV), RSV and COVID-19** are up to date. **Influenza is the most common vaccine-preventable infection in travellers** — remember the **Southern Hemisphere season (April–September)** and **year-round transmission in the tropics**.
8. **MMR** — older adults born before 1957 are usually presumed immune; still important for travel to measles-outbreak areas.

CATEGORY 2 — REQUIRED VACCINES (INTERNATIONAL HEALTH REGULATIONS)

9. **Yellow fever (YF)** is the only vaccine **required under IHR**. The certificate becomes valid **10 days after vaccination** and is now **valid for life**. **India requires a YF certificate from travellers arriving from endemic countries**, failing which **6 days' quarantine** applies.
10. **Age ≥60 years is a CDC "precaution", not a contraindication, for yellow fever vaccine** — the single most examinable point. CDC lists the precautions to YF vaccine as age 6–8 months, **age ≥60 years**, asymptomatic HIV with moderate immunosuppression, pregnancy and breastfeeding.
11. **Why the precaution:** the incidence of **YEL-AND (neurologic disease)** is 0.8 per 100,000 doses overall but rises to **2.2 per 100,000 doses in people aged ≥60**. **YEL-AVD (viscerotropic disease)** mimics wild-type yellow fever with **multi-organ failure and ~48% mortality**. A meta-analysis found serious adverse events **3 times higher** in the elderly, **5 times higher above 70 years**, and viscerotropic disease **6 times higher** than in those under 60.
12. **Practical rule:** give YF vaccine to an older traveller **only if truly going to a high-risk endemic area**; if exposure risk is low, issue a **Medical Letter of Exemption (waiver)** on official letterhead, signed and stamped, plus advice on strict **mosquito-bite avoidance**.
13. **Meningococcal ACWY is required by Saudi Arabia for Hajj and Umrah** — highly relevant to Indian elderly pilgrims. Must be given **≥10 days before arrival**; valid for **3–5 years** depending on vaccine type.
14. **Polio** — a booster dose of **IPV** is required for travellers leaving certain polio-affected countries, documented on the International Certificate of Vaccination.

CATEGORY 3 — RECOMMENDED BY DESTINATION

15. **Hepatitis A** — recommended for almost all travellers to developing countries. Older Indians often have **natural immunity from childhood exposure**, so **pre-vaccination serology (anti-HAV IgG) is cost-effective**. Risk of **fulminant hepatitis rises sharply with age**.
16. **Typhoid** — two options: **Vi polysaccharide (injectable, inactivated)** and **Ty21a (oral, live)**. Prefer the **injectable Vi vaccine** in older or immunosuppressed travellers.
17. **Hepatitis B** — for long stays, medical tourism, dialysis abroad, dental or surgical care, or unscreened blood transfusion risk.
18. **Rabies** — pre-exposure prophylaxis for long stays, rural travel, or poor access to immunoglobulin. Now a **2-dose regimen (day 0 and 7)**. Important in the elderly because **post-exposure rabies immunoglobulin is often unavailable abroad**.

19. **Japanese encephalitis** — for stays **≥1 month in rural or agricultural endemic areas** during transmission season. Note that **advancing age is itself a risk factor for symptomatic JE and poor outcome**.
20. **Cholera (CVD 103-HgR)** is a **live oral vaccine** — used only for high-risk relief or outbreak settings and best avoided in the immunosuppressed. **Tick-borne encephalitis** for forested Central and Eastern Europe.

SPECIAL PRECAUTIONS IN OLDER TRAVELLERS

21. **Avoid or carefully weigh live vaccines** — yellow fever, Ty21a oral typhoid, oral cholera, MMR, varicella — especially with **steroids, biologics, malignancy, or thymus disorders** (an absolute contraindication for YF).
22. **Check drug interactions:** proton pump inhibitors and antibiotics inactivate **oral typhoid and cholera vaccines**; **mefloquine** is avoided with conduction defects, bradyarrhythmias, psychiatric illness and epilepsy; **doxycycline** causes pill oesophagitis and photosensitivity; **atovaquone-proguanil** needs a creatinine check.
23. **Non-vaccine measures matter more in the elderly** — insect-bite avoidance, food and water precautions, VTE prophylaxis on long flights, medication supply in hand baggage with a doctor's letter, travel insurance covering pre-existing disease, and a **travel health kit**.

B. Latest Updates (2023–Present)

1. CDC Yellow Book 2026 edition is now current (published 2025). Its structure includes *The Pre-Travel Consultation*, *Vaccination and Immunoprophylaxis — General Principles*, *Medication and Vaccine Interactions in Travel Medicine*, and *Yellow Fever Vaccine and Malaria Prevention Information, by Country*. There is **no longer a standalone "Older Adults" chapter**; guidance for older travellers is now embedded within **"Travelers with Chronic Illnesses"** and **"Immunocompromised Travelers"**, reflecting a shift from **chronological age to comorbidity- and immune-status-based risk assessment** (*CDC Yellow Book 2026*).

2. COVID-19 and travel. The Yellow Book 2026 advises that travellers at high risk of severe COVID-19 — specifically **frail older adults with serious comorbid conditions** and the severely immunocompromised — be counselled to be up to date on vaccination, told when and where to seek care abroad, and made aware of treatment options. **Pemivibart (Pemgarda)** is available as pre-exposure prophylaxis for some severely immunocompromised people, and antivirals require a **drug–drug interaction check** (*CDC Yellow Book 2026*).

3. Yellow fever durability in older adults. A 10-year follow-up of travellers vaccinated at **≥60 years** showed **waning neutralising antibody** despite the lifelong-validity certificate — so serology may be considered before repeat high-risk travel rather than routine revaccination (*Journal of Travel Medicine, 2021*).

4. RSV vaccination is now part of the pre-travel review for older adults, since travel and cruise settings are recognised amplifiers of respiratory viral transmission (*ACIP, 2023–2025*).

5. Indian context. The **API Indian Consensus Guidelines on Adult Immunization 2026 Update** adopt a **life-course framework** and recommend a **standardised adult immunization card** — practically useful for documenting travel and routine vaccines together in the older Indian traveller (*API, 2026*).

C. Current Practice Update

Issue	Older / traditional position	Current CDC position
Yellow fever certificate	Booster every **10 years**	**Valid for life** after a single dose (IHR amendment); boosters only for special groups
Age ≥60 and YF vaccine	Often treated as a contraindication	A **precaution** — give only if genuine high-risk exposure; otherwise issue a **medical waiver letter**
Rabies pre-exposure	3 doses (day 0, 7, 21/28)	**2-dose schedule (day 0, 7)** for most travellers
Structure of guidance	Dedicated "Older Adults" chapter	Age-based chapter removed; folded into **chronic illness / immunocompromised** chapters — risk judged by **comorbidity and immune status, not age**
Hepatitis A in Indian elderly	Vaccinate all travellers	**Check anti-HAV IgG first** — most older Indians are already immune
Respiratory vaccines pre-travel	Influenza ± pneumococcal	Influenza + **PCV20/PCV21** + **RSV** + COVID-19 as appropriate

> **Examiner's Tip**
>
> Structure the answer on the **CDC three-category framework — Routine, Required, Recommended**. This alone signals that you know the CDC system rather than reciting a vaccine list.
> The mark-earning line: "*In the older traveller, age ≥60 is a precaution — not a contraindication — to yellow fever vaccine, because YEL-AND rises from 0.8 to 2.2 per 100,000 doses and viscerotropic disease carries almost 50% mortality; if the itinerary is low-risk, the correct action is a medical waiver letter with strict bite-avoidance advice, not vaccination.*"
> Finish with the Indian angle: **Hajj/Umrah meningococcal ACWY, and anti-HAV IgG serology before hepatitis A**

vaccine.

Question 4. Cancer screening in the elderly — currently accepted strategies.

Primary source: Pathy's, 6th ed. — "Preventive Geriatrics"; Essentials of Clinical Geriatrics, 7th ed. — "Prevention".

A. High-Yield Points (Textbook Content)

GENERAL PRINCIPLES

1. **Screening is secondary prevention** — detection of disease in the preclinical phase. Essentials states that **the value of screening depends on the availability of an effective intervention and the likelihood that the intervention will change the clinical course**.
2. In the elderly, three questions must be answered before screening: **Is life expectancy long enough to benefit? Will the patient accept diagnostic work-up and treatment? Do benefits outweigh harms?**
3. **The "10-year rule"** — most guidelines advise continuing screening only if **life expectancy is 10 years or more**, because that is the **lag time to mortality benefit** for breast and colorectal cancer.
4. **Cancer biology may differ in old age**: although incidence and prevalence rise with age, **the rate of growth may be slower**, which increases the risk of **overdiagnosis**.
5. Essentials gives sobering figures: **the mean age of detection of the commonest cancers is about 68 and the mean age of death about 72**. For breast cancer, median age at diagnosis is ~61 and at death ~69.
6. **Pathy's screens by functional category, not chronological age — Robust, Frail, Moderately demented, End of life**.

PATHY'S SCREENING TABLE (HIGH-YIELD FOR VIVA)

Test	Robust	Frail	Moderately demented	End of life
Breast examination	Yearly	Yearly	Yearly	—
Mammography	Every 1–2 years **up to 80**	Consider every 1–2 years **up to 75**	Consider every 1–2 years **up to 70**	—
Pap smear	Consider **1–3 smears if never had one**	—	—	—
Faecal occult blood	Yearly	Consider yearly	Consider yearly	—
Colonoscopy	Consider every 10 years	—	—	—
PSA	Discuss pros and cons with patient	Discuss with patient	Discuss with caregiver	—

BREAST CANCER

7. **Mammography is the mainstay**, and research has shown it to be **effective up to age 84**.
8. **There is no agreement on when to stop.** ACS: **annual from 55, or transition to biennial**, continuing if **overall health is good and life expectancy ≥10 years**. NCCN: **annual, with no stopping age**. USPSTF (textbook version): **biennial up to 74**.
9. **Self-examination and clinical breast examination are contested — NCCN recommends both, ACS recommends breast self-awareness if the woman is interested**, and **USPSTF recommends against both**.
10. Few studies describe how women decide to stop; many **discontinue after a serious health event**, recognising that benefit falls with remaining life expectancy.

CERVICAL CANCER

11. **Stop screening at 65** if there have been **three or more consecutive negative Pap tests, or at least two consecutive negative HPV-and-Pap tests within the past 10 years, with the most recent within 5 years**.
12. **Women who had a hysterectomy for benign disease can stop.**
13. **Continue in older women with inadequate or unknown screening history, prior high-grade lesion or cervical cancer, in-utero DES exposure, or immunocompromise.** Essentials warns that **cervical cancer remains a serious risk in older women** and that risk rises with longer inter-test intervals — highly relevant in India, where most older women have **never been screened even once**.

COLORECTAL CANCER

14. **Structural examination of the colon is one of the most effective means of preventing colorectal cancer**, because polyps can be found and removed before malignant change.
15. Start at **50 (USPSTF, NCCN)** or **45 (ACS)**. All three recommend **individualised decisions in adults aged 76–85**;

USPSTF recommends against screening above 85.

16. Options: **FOBT or FIT-DNA every 3 years, flexible sigmoidoscopy every 5 years; colonoscopy is more thorough and is the preferred option**. **Structural tests detect polyps; stool tests detect cancers.**
17. **Limit screening in frail individuals and patients with dementia.** Essentials notes that **most clinicians would not be enthusiastic about subjecting an 85-year-old to colonoscopy**.

PROSTATE CANCER

18. **No major organisation — ACS, AUA, USPSTF, AAFP or ACPM — supports routine PSA testing.** ACS: from **age 50**, informed discussion if **life expectancy ≥10 years**; NCCN: PSA **only if life expectancy ≥10 years**; **USPSTF recommends against screening in men 70 and older**.
19. **The core problem is overdiagnosis** — many prostate cancers grow slowly and would never cause harm, yet surgery or radiation produces **incontinence and impotence** that seriously affect quality of life.

LUNG CANCER AND TESTS NOT RECOMMENDED

20. **Low-dose CT reduces lung cancer mortality by about 20%** compared with chest X-ray in current or former heavy smokers. **ACS: annual LDCT age 55–74, ≥30 pack-years, quit within 15 years, good health, after shared decision-making. NCCN: stop at 77. USPSTF (textbook version): 55–80.**
21. **Stop LDCT** once the person has **not smoked for 15 years**, or **develops a health problem that substantially limits life expectancy or the ability or willingness to undergo curative lung surgery**. **LDCT is never an alternative to smoking cessation.**
22. **Not recommended at any age:** USPSTF gives a **grade D against routine ovarian cancer screening**.

B. Latest Updates (2023–Present)

1. Breast — USPSTF revised in April 2024. The Task Force now recommends **biennial screening mammography for women aged 40 to 74 (B recommendation)**; for **women 75 years or older the evidence remains insufficient (I statement)**, as it does for supplemental ultrasound or MRI in dense breasts (*JAMA/USPSTF, 2024*). The change was estimated to **save 19% more lives** than the previous "start at 50" position. **The key geriatric point is unchanged: above 75, the decision is individualised on life expectancy and comorbidity, not on evidence.**

2. Cervical — the biggest change is self-collection. USPSTF recommends **cytology every 3 years at 21–29 and HPV testing every 5 years at 30–65**, and **for the first time endorses self-collected HPV samples**, which are as accurate as clinician-collected and increase uptake in under-screened groups; it continues to **recommend against screening women over 65 who have had adequate prior screening** (*USPSTF, 2024–25*). The **American Cancer Society updated its guideline in December 2025** — screening from age 25 with **primary HPV testing every 5 years through 65**, with **self-collected vaginal specimens acceptable** and new guidance on when to safely exit screening. HRSA's Women's Preventive Services Guidelines were updated in January 2026 to prefer **primary hrHPV testing every 5 years for ages 30–65**.

3. Colorectal — start age lowered. USPSTF (2021, still current) recommends screening from **45 to 75 years**, with **selective screening at 76–85 (grade C)**. The elderly-specific decision point is unchanged, but the entry age has moved from 50 to 45.

4. Lung — eligibility broadened. USPSTF (2021) now recommends **annual LDCT from age 50 to 80** in adults with a **≥20 pack-year history** who currently smoke or quit within 15 years — a lower age and lower pack-year threshold than the textbook figures.

5. Prostate — unchanged but clarified. USPSTF (2018): **shared decision-making at 55–69 (grade C)** and **against PSA screening at 70 and above (grade D)**.

6. India — a population-based programme now exists, but it stops at 65. NPCDCS was **renamed the National Programme for Prevention and Control of Non-Communicable Diseases (NP-NCD) in May 2023**. Under this programme, **oral, breast and cervical cancer screening is free at Health and Wellness Centres for adults aged 30 to 65**, with community health workers identifying eligible individuals; **ICMR recommends clinical breast examination every 1–3 years** as the practical starting point in India. The **Operational Framework for Management of Common Cancers** notes that **breast, cervix and oral cancers together account for about 34% of all cancers in India**, and recommends **oral cancer screening for all adults over 30**.

7. Indian coverage data. As of July 2025, **10.18 crore of an eligible 25.42 crore women aged ≥30** had been screened for cervical cancer through **Ayushman Arogya Mandirs**, primarily with **visual inspection with acetic acid (VIA)** at sub-centres and PHCs, with VIA-positive cases referred upward (*Ministry of Health, 2025*). However, a 2025 review found that **fewer than 2% of eligible women aged 30–49 had actually been screened** for cervical or breast cancer at the time of the 2019–21 national survey (*Asian Pacific Journal of Cancer Prevention, 2025*).

8. Resource-stratified Indian guidance. The **National Cancer Grid** consensus guidelines recommend **VIA for**

women 30–65, one to three times in a lifetime, in low-resource settings; HPV testing every 10 years in enhanced-resource settings; and HPV testing every 5 years for ages 25–65 in high-resource settings.

9. Decision aids are now standard practice. Current geriatric oncology practice emphasises **life-expectancy estimation (e.g. ePrognosis calculators)**, **"lag time to benefit" framing**, and **explicit de-implementation of screening** when life expectancy falls below the lag time — with counselling framed around "*your other health conditions matter more than this test now*" rather than "*you are too old*".

C. Current Practice Update

Cancer	Textbook Position	Current Practice (2024–2026)
Breast	USPSTF biennial to **74**; ACS annual from 55; NCCN annual, no stop age	USPSTF 2024: **biennial 40–74 (B)**; **≥75 insufficient evidence (I)** — individualised on life expectancy
Cervical	Pap ± HPV to 65; stop if adequate prior screening	**Primary HPV every 5 years, 30–65**; **self-collected samples now endorsed**; still stop at 65 if adequately screened
Colorectal	Start **50** (USPSTF/NCCN) or 45 (ACS)	Start **45** for all; **45–75 recommended**, **76–85 selective**, **>85 not recommended**
Lung	LDCT **55–74/77/80**, **≥30 pack-years**	LDCT **50–80**, **≥20 pack-years**, quit within 15 years
Prostate	ACS/NCCN if life expectancy ≥10 years; USPSTF against ≥70	Unchanged — **SDM 55–69 (C)**, **against ≥70 (D)**
Framework	Screening by **functional category**	Same principle, operationalised through **life-expectancy calculators and lag-time-to-benefit**, with formal **de-implementation** counselling
India	Not addressed	**NP-NCD (renamed 2023)** offers free **oral, breast and cervical screening at 30–65** via **Ayushman Arogya Mandirs** using **VIA**; **no national programme covers those above 65**

Examiner's Tip

The opening sentence should establish the geriatric principle, not the cancer list: "*In the elderly, the decision to screen is governed not by chronological age but by three questions — is life expectancy longer than the lag time to benefit, will the patient accept work-up and treatment, and do benefits outweigh harms?*"
Then present **Pathy's four-category table** — it is the single highest-yield item in this topic.
Close on the Indian gap: "*India's NP-NCD programme screens for oral, breast and cervical cancer, but only up to age 65 — so no organised cancer screening exists for the Indian geriatric population at all.*"

Extra Points to Remember

The one-line summary of the whole topic: screening tests are chosen by *life expectancy*, stopped by *competing comorbidity*, and abandoned altogether when the patient would not accept the consequences of a positive result.
Two numbers that anchor everything: lag time to benefit ≈ **10 years** for breast and colorectal cancer; mean age of cancer detection ≈ **68**, mean age of cancer death ≈ **72**.
Never forget the distinction between screening and diagnosis — red-flag symptoms (bleeding, anaemia, weight loss, change in bowel habit) mandate investigation at *any* age, irrespective of every screening cut-off in this answer.

Question 5. Screening for colorectal cancer.

Primary source: Pathy's, 6th ed.; Essentials of Clinical Geriatrics, 7th ed.

A. High-Yield Points (Textbook Content)

RATIONALE

1. **The prevalence of carcinogenesis increases along the entire gastrointestinal tract with age**, driven by **mucosal irritation, inflammation, impaired antioxidant mechanisms and genetically damaged epithelium**.
2. GI cancers may cause **constipation, early satiety and bleeding in the early stages** — and **if caught and treated early they may be cured**.
3. **Colorectal cancer screening is unique because it prevents cancer, not merely detects it.** Pathy's states that **regular structural examination of the colon is one of the most effective means of preventing colorectal cancer**, because polyps can be found and removed before they turn malignant.

THE TESTS

4. **Faecal occult blood testing is rapid and easy, with a sensitivity of 82%.** If positive, **further diagnostic testing is recommended regardless of age**.
5. **Structural tests versus faecal tests — a key examination distinction:** structural examinations are **more likely to detect polyps, which can be removed, thereby preventing malignancy**; faecal tests are **more likely to detect malignancies early**, so that treatment carries less morbidity.
6. **Colonoscopy is the more thorough examination and is the preferred option for screening.** ACS guidance quoted in Pathy's is **endoscopic screening of the colon every decade over the age of 50**.
7. **Choice of test depends on extrinsic factors** — transportation, availability of a gastroenterologist, the patient's willingness to undergo one procedure over another, and the patient's health status.
8. **Screening intervals differ by test type, which is a recognised source of confusion for both patients and clinicians** — clinicians must explain the strengths and limitations of each.
9. Textbook-supported options: **FOBT or FIT-DNA every three years, or flexible sigmoidoscopy every five years**, with colonoscopy preferred.

AGE THRESHOLDS

10. **USPSTF and NCCN recommend starting at 50; ACS at 45** (textbook position).
11. **All three recommend that screening in adults aged 76–85 be an individual decision**, based on **overall health and prior screening history**.
12. **USPSTF recommends against screening above 85 (grade D).** In the Essentials table the grades are: **A for 50–75, C for 76–85, D for >85**, and **I (insufficient evidence) for CT colonography and faecal DNA testing**.
13. Pathy's also notes that **most guidelines add that screening can be stopped after the age of 80**.
14. Medicare frequencies quoted in Essentials: **FOBT every 12 months; flexible sigmoidoscopy every 48 months (or 120 months after a colonoscopy); colonoscopy every 120 months (every 24 months if high risk), or 48 months after a sigmoidoscopy; barium enema every 24–48 months**.

GERIATRIC-SPECIFIC CONSIDERATIONS

15. **Pathy's screens by functional category:** colonoscopy — **"consider every 10 years" in the Robust only**; FOBT — **yearly in the Robust, "consider yearly" in the Frail and the moderately demented**; **nothing at End of life**.
16. **Primary care physicians may choose to limit screening in Frail individuals or in patients with dementia.**
17. **Colonoscopy in patients over 80 carries a greater risk of complications, adverse events and higher morbidity** than in younger patients. It is also associated with **a higher chance of poor bowel preparation, resulting in inadequate imaging and lower completion rates**. It should be performed only **after careful consideration of individual risks and benefits**.
18. Essentials adds bluntly that **the issue of risk versus benefit becomes even more relevant when procedures like colonoscopy are considered**, and that **most clinicians would not be enthusiastic about subjecting an 85-year-old to colonoscopy**.
19. **The "10-year rule" applies:** the lag time to mortality benefit is roughly a decade, so screening is justified only when **life expectancy is 10 years or more**.
20. **Screening versus diagnosis — never confuse the two.** Pathy's notes that in a constipated older patient, **structural examination of the colon is dictated by the need for routine screening AND by red-flag signs — rectal bleeding, anaemia, unintentional weight loss, or a recent change in bowel habit. Red flags mandate diagnostic colonoscopy at any age, irrespective of screening cut-offs.**

B. Latest Updates (2023–Present)

1. Starting age has been lowered to 45. USPSTF (2021, still current) recommends screening from **45 to 75 years** (grade B for 45–49, grade A for 50–75), with **selective screening at 76–85 (grade C)** based on overall health, prior screening history and patient preference. The textbook's "start at 50" is now outdated; the geriatric decision point at 76–85 is unchanged.

2. Blood-based screening has arrived. On **29 July 2024** the FDA approved **Guardant Health's Shield blood test** for colorectal cancer screening in **average-risk adults aged 45 and older** — the **first blood test approved as a primary screening option**, meaning it can be offered like other non-invasive methods, and the first to meet Medicare coverage requirements. Approval was based on **ECLIPSE**, involving more than 20,000 patients, published in the *New England Journal of Medicine* in March 2024, showing **83% sensitivity for colorectal cancer and 90% specificity for advanced neoplasia**.

3. But the blood test has a critical weakness for geriatric practice. Shield's sensitivity for **advanced adenomas was only 13.2%**, and patients with advanced adenomas are precisely those at high risk of developing colorectal cancer. The NCI notes that neither FIT nor Cologuard is as accurate as colonoscopy, and that Shield detected only 13% of advanced precancerous polyps found at colonoscopy. **In other words, a blood test detects cancer but does not prevent it — it converts CRC screening from a preventive to a purely early-detection strategy.** For reference, Cologuard was approved in 2014 for ages ≥50 and in 2019 for 45–49, and Epi proColon in 2016.

4. NordICC — the only RCT of screening colonoscopy — has now reported long-term results, and they are sobering. In the 10-year report (*NEJM, 2022*), the risk of colorectal cancer was **0.98% in the colonoscopy group versus 1.20% in the no-screening group, an 18% risk reduction**, but **colorectal cancer mortality was not significantly reduced**. Uptake was only **42%**; in adjusted per-protocol analysis, incidence and mortality reductions rose to **31% and 50%** respectively (*Gastroenterology, 2023*).

5. The 13-year NordICC update (*Lancet*, May 2026 / DDW 2026) confirms the pattern. One colonoscopy significantly reduced colorectal cancer incidence but not mortality over 13 years, and colorectal cancer mortality was **lower in both study groups than had been assumed when the trial was designed**. The authors state that **the risk of colorectal cancer death is very low even without screening, and the hope of finding a screening benefit on colorectal cancer mortality with longer follow-up is so far not substantiated**. A quality caveat: **as many as 30% of endoscopists in NordICC fell short of the adenoma detection rate of 25%** that is the accepted quality indicator.

6. How this fits with the older trials. A standardised comparison found that **at 10 years all randomised trials showed significant reductions in colorectal cancer incidence**, but **two flexible sigmoidoscopy trials and NordICC showed no significant mortality reduction**, whereas PLCO saw fewer colorectal cancer deaths from year 2 (*JNCI, 2025*). Others argue the negative NordICC mortality result mainly reflects **insufficient follow-up time**, since in NORCCAP mortality differences only emerged after 9.5 years and were about four-fold greater at 12 years than at 10.

> **Practical implication for the elderly**
> The mortality benefit of colonoscopy is **later and smaller than previously believed**, which **strengthens rather than weakens the geriatric argument** — if the lag time to benefit may exceed 10–13 years, then screening an 80-year-old with competing comorbidity is even harder to justify, while the procedural harms (poor preparation, sedation risk, perforation) occur immediately.

7. Indian position. There is **no national colorectal cancer screening programme in India**. The NP-NCD programme delivered through Ayushman Arogya Mandirs covers only **oral, breast and cervical cancers, for ages 30–65**. CRC screening in India is therefore **opportunistic, private and largely confined to symptomatic or high-risk individuals** — making **red-flag-driven diagnostic colonoscopy**, rather than screening, the realistic pathway for most older Indian patients.

C. Current Practice Update

Aspect	Textbook Position	Current Practice (2021–2026)
Starting age	**50** (USPSTF, NCCN); 45 (ACS)	**45 for everyone** (USPSTF 2021, ACS)
Upper age	76–85 individualised; against >85; "stop after 80"	**Unchanged** — 45–75 recommended, 76–85 selective (C), >85 against (D)
Blood-based test	Not available; faecal DNA graded "I"	**Shield approved July 2024** as a primary screening option for ≥45; but **advanced adenoma sensitivity only 13.2%**
Stool tests	FOBT (sensitivity 82%); FIT-DNA every 3 years	**FIT annually** is now standard; **FIT-DNA (Cologuard) every 3 years**
Colonoscopy evidence	Inferred from cohort studies; "most effective	**NordICC (NEJM 2022, Lancet 2026): incidence**

	means of preventing CRC"	**reduced, mortality not** at 10 and 13 years; per-protocol 31% and 50%
Key uncertainty	Risk–benefit in the very old	**Lag time to mortality benefit may exceed 13 years** — raises the bar for screening the frail or very elderly
India	Not addressed	**No national CRC screening programme**; NP-NCD covers only oral, breast and cervical cancers at 30–65

Examiner's Tip

The distinguishing line for a high mark: "*Colorectal cancer screening is unique among cancer screening tests because a structural examination is genuinely preventive — polypectomy removes the precursor lesion — whereas stool and blood tests only detect established cancer earlier.*"
Then deliver the counterweight: "*However, NordICC, the only randomised trial of screening colonoscopy, showed reduced incidence but no significant mortality reduction at both 10 and 13 years — which means the lag time to benefit may exceed a decade, and that argues strongly against screening the frail or very elderly.*"
Always end with the red-flag caveat — examiners look for it: **bleeding, anaemia, weight loss or change in bowel habit demand diagnostic colonoscopy at any age.**

Extra Points to Remember

Structural vs faecal: structural = detects polyps = *prevents* cancer. Faecal/blood = detects cancer = *early detection only*.
NordICC numbers: 10-year incidence 0.98% vs 1.20% (18% reduction), **no mortality benefit**; uptake only 42%; per-protocol 31% incidence and 50% mortality reduction.
Shield blood test: 83% sensitivity for cancer but only **13.2% for advanced adenoma** — the number that explains why it cannot replace colonoscopy.
Colonoscopy in the over-80s: more complications, more sedation risk, and **poorer bowel preparation with lower completion rates**.

Question 6. Mammography — screening the older woman.

Primary source: Pathy's, 6th ed. — "Preventive Geriatrics"; Essentials of Clinical Geriatrics, 7th ed. — "Prevention".

A. High-Yield Points (Textbook Content)

RATIONALE

1. **Mammography is the mainstay of breast cancer screening.**
2. **Research has shown mammography to be effective up to age 84** — a key figure to quote.
3. Breast cancer is common and does shorten life in older women: Essentials records the **median age at diagnosis as about 61 and the median age at death as about 69**.
4. However, **cancer in older people may grow more slowly** even though incidence and prevalence rise with age — this is the basis of **overdiagnosis**.

GUIDELINE DISAGREEMENT (HIGH-YIELD)

5. **There is a lack of agreement among organisations about both the screening interval and when to stop.**
6. **ACS: annual mammography for women 55 and older**, or they may **transition to biennial**. Women should **continue if overall health is good and life expectancy is 10 years or more**.
7. **NCCN: annual mammography, with no guidelines for stopping.**
8. **USPSTF (textbook version): biennial screening mammography up to age 74**; evidence **insufficient for women 75 or older (I statement)**.
9. **Medicare (Essentials):** covers a **screening mammogram every 12 months for all women aged 40 and above**, plus **one baseline mammogram between 35 and 39**, and covers digital technologies.

CLINICAL BREAST EXAMINATION AND SELF-EXAMINATION

10. **There is no recommendation for or against breast self-examination, breast self-awareness, or clinician-performed clinical breast examination.**
11. **NCCN recommends both; ACS recommends breast self-awareness if the woman is interested; USPSTF recommends against both** (grade **D for teaching BSE**, grade **I for CBE**).
12. **Breast self-awareness may allow detection of lesions not seen on mammography, or interval cancers developing between mammograms** — the argument in its favour.

PATHY'S FUNCTIONAL-CATEGORY APPROACH

13. **Mammography by category:** every **1–2 years up to age 80** in the **Robust**; **consider** every 1–2 years **up to 75** in the **Frail**; **consider** every 1–2 years **up to 70** in the **Moderately demented**; **nothing at End of life**.
14. **Breast examination: yearly** in the Robust, Frail and Moderately demented; not at End of life.

STOPPING SCREENING

15. **Few studies describe how women decide to stop mammography.**
16. Some women and their providers, **recognising that the expected benefit of early detection declines with remaining life expectancy, consciously decide to discontinue screening following a serious health event** — a practically useful trigger point.
17. **The "10-year rule" applies:** the lag time to mortality benefit is about a decade, so continue only if **life expectancy ≥10 years**.

CONTROVERSY AND RELATED RECOMMENDATIONS

18. Essentials states that **analysis of mammography trial data illustrates just how confusing this literature can be**; one analysis suggests **screening after age 69 gives a small gain in life expectancy and is modestly cost-effective** (Kerlikowske, 1999).
19. **Harms** to weigh: **false positives, unnecessary biopsy, pain, anxiety, and overdiagnosis with overtreatment** — the last being especially serious in older women who tolerate treatment poorly.
20. Related USPSTF positions in Essentials: **BRCA testing — grade D against routine referral if family history is not suggestive, grade B for referral if it is**; **chemoprevention — grade D against routine tamoxifen or raloxifene at average risk, grade B for discussion in high-risk women at low risk of adverse effects**.
21. **Practical geriatric rule:** screening should stop when a woman **would not accept or could not tolerate a biopsy or subsequent cancer treatment** — if the result cannot change management, the test should not be done.

B. Latest Updates (2023–Present)

1. USPSTF revised its recommendation in April 2024. The Task Force now recommends **biennial screening mammography for women aged 40 to 74 (B recommendation)**, concludes the evidence is **insufficient for women 75 years or older (I statement)**, and also insufficient for **supplemental ultrasound or MRI in women with dense breasts** (*JAMA/USPSTF, 2024*). The change from the 2016 version is that **biennial screening now begins at 40 rather than being individualised for 40–49**; the change was estimated to **save 19% more lives** than starting at 50. Both **digital mammography and digital breast tomosynthesis ("3D mammography") are accepted as effective mammographic modalities**.

2. The 75-and-over question remains unresolved — but the observational data are more favourable than "insufficient evidence" suggests. No randomised trial of mammography included women over 74, so it is not known whether mammography helps them live longer; data suggest around **10 years of life expectancy** is needed for a mortality benefit, while the harms — pain, anxiety, complications of biopsy after a false positive, and overdiagnosis — are immediate. On the other hand, **mammography performs significantly better in older women**, with **higher sensitivity, specificity, cancer detection rate and positive predictive value, and lower recall and false-positive rates**; modelling suggests the **overdiagnosis rate is low and benefits outweigh risks until about age 90**. A systematic review of 36 studies in women 75+ found **mixed evidence**, with some studies showing a mortality benefit and others none, and called for better comparison groups and formal estimation of overdiagnosis given the substantial competing risk of death in this age group (*British Journal of Cancer, 2023*).

3. Counterpoint on overdiagnosis in the elderly. A meta-analysis of two RCTs including **33,268 women aged 70 or older** found a **28% relative reduction in breast cancer mortality (RR 0.72)**, but estimated the **proportion of overdiagnosis in older women at 19%**, higher than in younger women. A 2025 review in *Nature Reviews Clinical Oncology* argues the case for **active monitoring of selected screen-detected breast cancers in women ≥75**, drawing on the **COMET trial of active monitoring for low-risk DCIS (*JAMA*, 2025)** — a shift from "detect and treat" to "detect and observe" in the very old.

4. Artificial intelligence is the biggest technical change — MASAI is the landmark trial. MASAI is the **first randomised controlled trial of AI in breast cancer screening and the largest trial of AI in cancer screening generally**, involving **105,934 Swedish women**. Interim safety results (*Lancet Oncology*, 2023) showed a **44% reduction in screen-reading workload**; a *Lancet Digital Health* analysis showed a **29% increase in cancer detection without any increase in false positives**; and the full results (*Lancet*, 2026) showed **12% fewer interval cancers**, meaning fewer aggressive and advanced cancers diagnosed between screening rounds. **Sensitivity was 6.7 percentage points higher (80.5% vs 73.8%) at the same specificity (98.5%), with consistent results across age and breast-density subgroups.** Importantly, the authors state the findings **do not support replacing radiologists** — AI-supported screening still requires at least one human reader.

5. Breast density notification is now mandatory in the US. The FDA's updated MQSA rule (effective **September 2024**) requires that every mammogram report include a **breast density notification** to the patient. USPSTF, however, still finds the evidence **insufficient** to recommend supplemental ultrasound or MRI on the basis of density alone.

6. India — mammography is not the national strategy. ICMR recommends clinical breast examination every one to three years as the practical starting point in India, along with monthly self-examination; free **breast, oral and cervical cancer screening is offered at Health and Wellness Centres for adults aged 30 to 65**. Uptake remains very poor — **fewer than 2% of eligible women aged 30–49 had been screened** for cervical or breast cancer at the 2019–21 national survey. **For Indian geriatric practice this means: CBE, not mammography, is the realistic screening tool, and no programme covers women above 65 at all.**

C. Current Practice Update

Aspect	Textbook Position	Current Practice (2024–2026)
Starting age	USPSTF biennial from **50**; individualise 40–49	**Biennial from 40 to 74 (grade B)** — USPSTF 2024
Stopping age	ACS: continue if healthy, life expectancy ≥10 years; NCCN: no stop age; Pathy's: up to 80 / 75 / 70 by category	**Unchanged in principle**; USPSTF still **"insufficient evidence ≥75"** — individualised on life expectancy and comorbidity
Evidence in ≥75	"Effective up to 84"	**No RCT ever included women >74**; observational data favourable (better sensitivity/specificity, low recall), but **overdiagnosis ~19%** in the old
Modality	Film vs digital vs MRI — "insufficient evidence"	**Digital mammography and DBT both accepted**; supplemental US/MRI for dense breasts still **insufficient evidence**
Breast density	Not addressed	**Mandatory density notification** in mammogram reports (FDA, 2024)
Artificial intelligence	Not addressed	**MASAI RCT**: +29% detection, −44% reading workload, −12% interval cancers, +6.7% sensitivity at same

		specificity; **AI supports, does not replace, the radiologist**
Screen-detected disease in the very old	Detect and treat	Growing case for **active monitoring** of low-risk screen-detected lesions (COMET trial, 2025)
India	Not addressed	**CBE every 1–3 years (ICMR)**; free breast screening at 30–65 via Ayushman Arogya Mandirs; **no coverage above 65**; uptake <2%

Examiner's Tip

The paradox to state explicitly, because it earns marks: "*Mammography actually performs better in older women — higher sensitivity, higher specificity, higher positive predictive value and fewer recalls — yet the evidence for screening them is graded insufficient, because no randomised trial ever enrolled a woman over 74 and because competing mortality means much of what is detected is overdiagnosis*."
Give **Pathy's category cut-offs (80 / 75 / 70)** as the practical answer, then the current USPSTF position (**biennial 40–74; ≥75 insufficient evidence**).
Close on India: **CBE every 1–3 years per ICMR is the realistic tool, and no national programme screens women above 65.**

Question 7. Prostate-specific antigen — to screen or not to screen?

Primary source: Pathy's, 6th ed.; Essentials of Clinical Geriatrics, 7th ed.

A. High-Yield Points (Textbook Content)

THE CORE CONTROVERSY

1. **The biggest controversy in prostate screening is that some prostate cancers grow slowly and would never cause any problems.**
2. Because of an elevated PSA, **men may be diagnosed and treated with surgery or radiation for lesions that would never have caused symptoms or led to their death** — and **these treatments have side effects that can seriously affect a man's quality of life**.
3. Essentials frames it more broadly: **there is great controversy around the efficacy of active screening for prostate and breast cancer in older persons**, because although incidence rises with age, **the rate of tumour growth may be slower**.
4. **This is therefore a disease where screening can cause net harm** — the classic example of **overdiagnosis leading to overtreatment**.

WHAT THE GUIDELINES SAY (TEXTBOOK POSITIONS)

5. **No major scientific or medical organisation supports routine testing for prostate cancer** — including the **ACS, American Urological Association (AUA), USPSTF, American Academy of Family Physicians, and American College of Preventive Medicine**.
6. **ACS:** beginning at **age 50**, men at average risk with a **life expectancy of at least 10 years** should have **a conversation with their provider** about the benefits and limitations of PSA testing and make an **informed decision based on personal values and preferences**.
7. **NCCN:** focuses on men at **increased risk because of family history and race**, and states that **PSA testing should only be offered to men with a life expectancy of 10 or more years**.
8. **USPSTF (as quoted in Pathy's): recommends against prostate cancer screening in men 70 and older.**
9. **Older USPSTF grades (Essentials table): "I" (insufficient evidence) for men younger than 75** and **"D" (recommends against) for men aged 75 or older**.
10. **Note the policy discrepancy highlighted in Essentials: Medicare will pay for PSA screening even though the USPSTF does not recommend it.**
11. Essentials records that **the USPSTF recommendation not to screen men older than 75 "unleashed a firestorm of controversy"** — worth quoting in a viva.
12. All organisations **emphasise the need for the clinician to discuss possible benefits and side effects of treatment**, so that **men aged at least 50 (younger if at higher risk) can make informed decisions**.

PATHY'S FUNCTIONAL-CATEGORY APPROACH

13. **PSA by category: "Discuss pros and cons with the patient"** in the **Robust** and the **Frail**; **"Discuss pros and cons with the caregiver"** in the **Moderately demented**; **nothing at End of life**.
14. **Examination point:** PSA is the **only cancer screening test Pathy's carries into the demented category** — and even then the recommended action is **a conversation, not a test**. The intervention here is shared decision-making itself.

PRACTICAL POINTS IN THE OLDER MAN

15. **The "10-year rule" is central** — both ACS and NCCN make life expectancy of ≥10 years the entry criterion, because prostate cancer has a long natural history and the lag time to mortality benefit is long.
16. **Benign prostatic hyperplasia is a major confounder** — Pathy's notes prostatic hyperplasia is present in **one in three men over the age of 70**, and it raises PSA independently of cancer.
17. **Other non-malignant causes of a raised PSA:** prostatitis, urinary tract infection, urinary retention, catheterisation, recent instrumentation, digital rectal examination, ejaculation and cycling. **5-alpha-reductase inhibitors halve the PSA**, so the measured value must be doubled.
18. **The harm cascade must be explained explicitly:** PSA → biopsy (bleeding, pain, **sepsis**) → overdiagnosis → radical treatment.
19. **Treatment harms are geriatrically important:** Pathy's states that **prostate cancer treatment, including surgery, radiotherapy and brachytherapy, can cause urinary incontinence and erectile dysfunction**, and that **prostate cancer survivors report high levels of concern about sexual health**, particularly about satisfying their partners.

20. **The decisive geriatric question is not "how old is he?" but "if the PSA is raised, will he accept a biopsy, and if cancer is found, would he accept treatment?"** If the answer is no, the test should not be done.

B. Latest Updates (2023–Present)

1. ERSPC — the definitive trial — now has 23-year follow-up. The final ERSPC analysis (*NEJM*, 2025) covered a predefined core age group of **162,236 men aged 55–69** across eight European countries, randomised to repeated PSA testing or no invitation, with **prostate cancer mortality as the primary outcome**. Long-term follow-up **confirms a sustained reduction in prostate cancer deaths with an improved harm–benefit ratio**, and the authors conclude that **future screening should adopt risk-based approaches to minimise overdiagnosis while maintaining benefit**. At 23 years the **relative reduction in prostate cancer–specific mortality was 13% (RR 0.87, 95% CI 0.80–0.95), an absolute risk reduction of 0.22%**.

2. The Rotterdam arm gives the most quotable numbers. At a median follow-up of **21 years**, the rate ratio for prostate cancer–specific mortality was **0.73 (95% CI 0.61–0.88)** favouring screening, with a **number needed to invite of 246** and a **number needed to diagnose of 14** to prevent one prostate cancer death (*European Urology, 2023*).

3. The updated systematic review, including the UK CAP trial, gives a more sober estimate. The latest review added the **UK CAP trial (2002–2021, 15 years of follow-up)** and up to 23 years of ERSPC data; in sensitivity analyses based mainly on ERSPC, **PSA screening was associated with a 13% relative reduction in prostate cancer mortality (RR 0.87, moderate-certainty evidence)**, with ERSPC judged to have the lowest risk of bias. Repeated PSA screening reduces **prostate cancer–specific mortality and metastatic disease but has no effect on all-cause mortality**, and the benefit **increases with longer follow-up**.

> **The single most important new number for a geriatrics answer**
>
> **Overdiagnosis rises steeply with age.** Using 15-year follow-up from the CAP randomised trial and English competing-mortality rates, men diagnosed at age **50 had a 16% chance** that the cancer would not have been detected within 15 years; this rose to **32% at age 70 and 58% at age 80**. **In other words, more than half of screen-detected prostate cancers in an 80-year-old are overdiagnosis.**

4. Treatment choice matters less than was assumed — the ProtecT 15-year results. In ProtecT (*NEJM*, 2023), men with localised, PSA-detected prostate cancer randomised to **active monitoring, radical prostatectomy or radiotherapy had essentially identical prostate cancer mortality at 15 years (around 3% in all three arms)**, though metastasis and progression were commoner with monitoring. **This substantially weakens the argument that early detection must be followed by radical treatment**, and strengthens the case for active surveillance in older men.

5. The screening pathway is being redesigned around MRI, not PSA alone. The **ProScreen trial** (*JAMA*, 2024) uses a stepwise pathway — **PSA ≥3 ng/mL → four-kallikrein panel → mpMRI if score ≥7.5% → biopsy if PI-RADS ≥3**, with screening intervals of 2, 4 or 6 years depending on the PSA level; mortality analyses are planned at 10 and 15 years. The randomised **PROSA trial** (*European Urology*, 2025) found an **MRI-first pathway detected clinically significant cancer in 4.6% versus 1.8% with a PSA-based strategy** — a 2.5-fold increase — **without increasing detection of low-grade (Grade Group 1) disease**. A contrast-free MRI-first strategy therefore **improves detection of clinically significant prostate cancer without increasing overdiagnosis or biopsy rates**. This builds on **PRECISION (2018)**, in which **28% of men randomised to MRI-targeted biopsy avoided biopsy altogether while 12% more clinically significant cancers were detected** than with standard TRUS biopsy.

6. A definitive answer is being sought. The **TRANSFORM trial**, announced May 2024 and backed by a **£42 million grant**, is one of the largest screening studies ever, involving **over a quarter of a million men followed for more than 10 years**, aiming to increase detection of life-threatening cancer while reducing unnecessary biopsies and overtreatment. It will invite men aged **50–75, or 45–75 for Black men**, and test four approaches including **12-minute fast MRI, genetic testing and PSA**, with early results **not expected before 2028**.

7. Where policy currently stands. Most countries recommend against population-based prostate screening despite the ERSPC results, because harms may outweigh benefits; the **UK National Screening Committee voted against PSA-alone screening in 2020**. The **USPSTF position is unchanged since 2018**: **shared decision-making for men 55–69 (grade C)** and **against screening in men 70 and older (grade D)**. **India has no national prostate screening programme**; testing is entirely opportunistic and privately funded.

C. Current Practice Update

Aspect	Textbook Position	Current Evidence (2023–2026)
Does PSA screening save lives?	"No major organisation supports routine testing"	**Yes, modestly** — ERSPC at 23 years: **13% relative, 0.22% absolute** reduction in prostate cancer mortality; Rotterdam at 21 years RR 0.73, **NNI 246, NND 14**. **No all-cause mortality benefit.**

Age cut-off	USPSTF against ≥70 (Pathy's) or ≥75 (Essentials)	**Unchanged** — USPSTF 2018: SDM 55–69 (C), against ≥70 (D)
Overdiagnosis	Stated qualitatively	**Quantified by age**: ~16% at 50, **32% at 70, 58% at 80** (CAP trial analysis)
Consequence of detection	Surgery or radiation with serious side effects	**ProtecT at 15 years: ~3% prostate cancer mortality whether monitored, operated or irradiated** — active surveillance is a legitimate first choice
The test itself	PSA alone, then systematic biopsy	**Risk-stratified pathways** — PSA → kallikrein panel → **MRI** → targeted biopsy (ProScreen); **MRI-first** doubles detection of significant cancer without more overdiagnosis (PROSA 2025)
Policy direction	Against routine screening	Moving from "screen or not" to **"how to screen better"** — organised, risk-adapted, MRI-based programmes; **TRANSFORM results due 2028+**
Practical rule in geriatrics	Life expectancy ≥10 years; discuss pros and cons	**Same, but sharper**: ask whether the man would accept biopsy and treatment; above 75–80 the majority of detected cancers are overdiagnosis

Examiner's Tip

Do not answer "yes" or "no" — answer with the **shape of the evidence**: "*PSA screening does reduce prostate cancer mortality — 13% relatively but only 0.22% absolutely at 23 years in ERSPC, with 246 men needing to be invited and 14 needing to be diagnosed to prevent one death — but it produces no all-cause mortality benefit, and the proportion of detected cancers that represent overdiagnosis rises from 16% at age 50 to 58% at age 80.*"
Then deliver the geriatric conclusion: "*That is why the USPSTF supports shared decision-making at 55–69 and recommends against screening at 70 and above — and why in a man over 75 the correct question is not his age but whether he would accept a biopsy and its consequences.*"

Extra Points to Remember

Four trials, four messages: ERSPC — screening works modestly; PLCO — contaminated, invalid; CAP — quantifies overdiagnosis by age; ProtecT — treatment choice barely changes mortality at 15 years.
The direction of travel is away from "PSA yes/no" and toward **risk-stratified, MRI-first, organised pathways** (ProScreen, PROSA, TRANSFORM).
Never forget the confounders of a raised PSA in an older man: BPH (one in three men over 70), prostatitis, UTI, retention, catheterisation, DRE, ejaculation — and remember to **double the value in men on 5-alpha-reductase inhibitors**.

Appendix. Rapid Revision Grid

Key numbers, trials, cut-offs and Indian data compiled from all seven answers — for last-night revision.

1. Immunization — Numbers to Quote

Item	Figure
Influenza deaths	>90% occur in adults ≥65
Influenza vaccine	↓ influenza risk ~50%; ↓ influenza mortality ~70%; only ~40% effective vs clinical illness in nursing homes
Herd protection	Vaccinating >80% of nursing-home residents prevents outbreaks
Nichol 2007 (Essentials)	HR 0.75 for pneumonia/influenza hospitalisation; HR 0.52 for death
CAPITA	PCV13 ↓ vaccine-type pneumococcal pneumonia by 45%
Zoster vaccines	Zostavax 30% protective; Shingrix ~90% protective
Post-herpetic neuralgia	>40% of those over 60; zoster in up to 50% by age 85
Tetanus	>50% of cases occur in people ≥60
AReSVi-006 (RSV)	82.6% season 1; 94.6% with comorbidity; 62.9% cumulative over 3 seasons; 48% in season 3
DANFLU-2	332,438 adults ≥65; primary endpoint **neutral**; cardiorespiratory hospitalisation 2.25% vs 2.38%
Zoster & dementia (Wales)	~20% reduction in new dementia diagnoses over 7 years; uptake jump 0.01% → 47.2%
Zoster & cardiovascular	23% lower risk of cardiovascular events
PCV21	Covers ~85% of IPD in ≥50s vs ~59% for PCV20; **lacks serotype 4**
PCV20 real-world VE	IPD 25.6% overall (35.4% at 65–74; 24.0% at 75–84; 16.6% at ≥85); all-cause pneumonia 15.2%

2. Immunization — Age Thresholds (Current)

Vaccine	Current recommendation
Influenza	Annual, all ages ≥50 (API 2026); HD-IIV3 / RIV3 / aIIV3 preferred at ≥65
Pneumococcal	Single dose PCV20 or PCV21 from age **50** (ACIP, Oct 2024)
Herpes zoster (RZV)	2 doses, all adults ≥50; immunocompromised ≥18
RSV	Single dose — universal ≥75; risk-based 60–74; extended risk-based 50–59 (Apr 2025)
Td / Tdap	Booster every 10 years; ≥1 lifetime Tdap
COVID-19	Shared clinical decision-making (2025–26)

3. Travel Vaccination — Key Facts

Item	Figure / rule
Pre-travel consult	4–6 weeks before departure
YF certificate	Valid 10 days after vaccination; now **valid for life**; India — 6 days' quarantine if absent
YF and age ≥60	**Precaution, not contraindication**
YEL-AND	0.8/100,000 doses overall; **2.2/100,000 at ≥60**
YEL-AVD	Multi-organ failure, ~48% mortality; 6× higher in the elderly
Serious AEs in elderly	3× higher overall; 5× higher above 70
Hajj / Umrah	Meningococcal ACWY required, ≥10 days before arrival, valid 3–5 years
Rabies PrEP	2 doses — day 0 and day 7
Japanese encephalitis	Stay ≥1 month in rural endemic area; age itself is a risk factor for severe JE
Hepatitis A in India	Check anti-HAV IgG first — most older Indians already immune

4. Cancer Screening — Age Cut-offs

Cancer	Pathy's / textbook	Current (USPSTF)
Breast	Mammography 1–2 yearly: Robust to 80, Frail to 75, Demented to 70; "effective to 84"	Biennial **40–74 (B)**; **≥75 insufficient (I)**

Cervical	Stop at 65 if adequate prior screening	Primary HPV q5y, **30–65**; self-collection endorsed; stop at 65
Colorectal	Start 50 (USPSTF/NCCN) or 45 (ACS); 76–85 individual; >85 against	**45–75 (A/B)**; **76–85 selective (C)**; **>85 (D)**
Lung	LDCT 55–74/77/80; ≥30 pack-years	LDCT **50–80**; **≥20 pack-years**; quit within 15 years
Prostate	ACS/NCCN if life expectancy ≥10 y; USPSTF against ≥70	SDM **55–69 (C)**; **against ≥70 (D)**
Ovarian	Against routine screening (D)	Unchanged (D)

5. Cancer Screening — Trials and Numbers

Trial / source	Result
NordICC (NEJM 2022)	10 y: CRC 0.98% vs 1.20% = **18% ↓ incidence**; **no mortality benefit**; uptake 42%; per-protocol 31% / 50%
NordICC (Lancet 2026)	13 y: incidence reduced, **mortality still not**; 30% of endoscopists below ADR of 25%
ECLIPSE / Shield	83% sensitivity for CRC; 90% specificity; **only 13.2% for advanced adenoma**; FDA approved 29 July 2024
FOBT (Pathy's)	Sensitivity 82%
MASAI (Lancet 2026)	105,934 women; **+29% detection, −44% workload, −12% interval cancers**; sensitivity 80.5% vs 73.8% at specificity 98.5%
Mammography ≥70 meta-analysis	28% ↓ breast cancer mortality (RR 0.72); **overdiagnosis ~19%**
ERSPC (NEJM 2025)	162,236 men aged 55–69; 23 y: **13% relative, 0.22% absolute** ↓ prostate cancer mortality
ERSPC Rotterdam (2023)	21 y: RR 0.73; **NNI 246, NND 14**
CAP overdiagnosis analysis	Overdiagnosis **16% at 50 → 32% at 70 → 58% at 80**
ProtecT (NEJM 2023)	15 y: ~3% prostate cancer mortality in **all three arms** (monitoring, surgery, radiotherapy)
PROSA (Eur Urol 2025)	MRI-first detected csPCa **4.6% vs 1.8%**, no rise in GG1 disease
PRECISION (2018)	28% avoided biopsy; 12% more clinically significant cancers detected
TRANSFORM	>250,000 men; £42 million; results not before 2028
LDCT	↓ lung cancer mortality ~20% vs chest X-ray

6. Indian Data — Must-Quote Figures

Item	Figure
LASI Wave 1 (n = 31,464, ≥60)	DT **2.75%**; typhoid 1.84%; hepatitis B 1.82%; influenza **1.59%**; pneumococcal **0.74%**
Adult vaccine coverage overall	**<3%** for most vaccines in older adults
Influenza uptake ≥45 y	≤2% (IJMR rapid review, 2024)
Hepatitis B in healthcare workers	Only 55–64% (Delhi, Mumbai)
Invasive pneumococcal disease	CFR **20–25% at ≥65** vs 5–10% in younger adults
Herpes zoster lifetime risk	~30%, rising to ~50% by age ≥85
Cancer burden	Breast + cervix + oral ≈ **34% of all cancers in India**
NP-NCD screening	Oral, breast, cervical — free at AAMs, **ages 30–65 only**; VIA-based
Cervical screening coverage	10.18 crore of 25.42 crore eligible women screened (July 2025); but **<2%** of women 30–49 screened at NFHS 2019–21
National Cancer Grid	VIA 1–3× lifetime (low resource); HPV q10y (enhanced); HPV q5y at 25–65 (high resource)
ICMR breast screening	Clinical breast examination every **1–3 years**
Programme gaps	Adult vaccines outside **UIP and NPHCE**; **no CRC or prostate screening programme**; **no cancer screening at all above 65**

The Five Sentences That Carry This Whole Topic

1. In geriatrics, prevention is governed by *life expectancy versus lag time to benefit*, not by chronological age.
2. Immunosenescence means older adults need higher-antigen, adjuvanted or recombinant vaccines — and paradoxically the

frailest gain most from preventing hospitalisation while responding least immunologically.
3. The global immunization framework has moved from age-based schedules to *life-course, risk-profile* immunization; age thresholds for pneumococcal, zoster and RSV have all fallen to 50.
4. Cancer screening in the old is limited less by the test's accuracy — which often improves with age — than by *competing mortality and overdiagnosis*.
5. In India the limiting factor is not the guideline but the programme: adult vaccines lie outside the UIP and NPHCE, and organised cancer screening stops at 65.

MD Geriatric Medicine — Cardiology Answer Bank

15-Mark University Answer Format

Primary source: *Pathy's Principles and Practice of Geriatric Medicine*, 6th edition (2022) and *Essentials of Clinical Geriatrics*, 7th edition. Updates drawn from guidelines and peer-reviewed literature 2023 onward.

Units are Indian/conventional throughout.

Q1. Management of ST-Elevation Myocardial Infarction and Recent Advances

15–20 High-Yield Points

DEFINITION AND DIAGNOSIS

1. **STEMI** is an acute coronary syndrome caused by **complete thrombotic occlusion** of a coronary artery following **plaque rupture or erosion** — a **Type 1 myocardial infarction**.
2. Diagnosis rests on three things: **clinical presentation**, **ST-segment elevation on ECG**, and a **rise in high-sensitivity cardiac troponin**.
3. In older people the presentation is often **atypical** — dyspnoea, confusion, lethargy, epigastric pain, shoulder or back pain, or altered mental status rather than classic chest pain.
4. Only a **minority of older people** with ischaemic heart disease complain of typical cardiac chest pain, so a high index of suspicion is essential.

PRINCIPLE OF REPERFUSION

5. **Total ischaemic time** is the key concept — the greatest benefit from reperfusion occurs within the **first 2–3 hours** after symptom onset.
6. Time targets: **first medical contact to diagnosis <10 minutes**; **first medical contact to balloon (FMCTB) <90 minutes** in a PCI centre; **PCI within 120 minutes** of diagnosis if transfer is needed.
7. **Primary PCI has replaced fibrinolysis** as the preferred reperfusion strategy, provided it can be done immediately by experienced operators in a centre with **24×7 catheterisation laboratory activation**.
8. If PCI is **not possible within 120 minutes**, give **fibrinolysis** immediately, then transfer to a PCI centre. Perform **coronary angiography at 3–24 hours** if lysis succeeds, and **rescue PCI** if it fails.
9. Older patients have an **increased risk of intracranial haemorrhage** with fibrinolytics, so **PCI has clearly superior outcomes** in this age group (TRIANA trial).

ADJUNCTIVE DRUG THERAPY

10. **Dual antiplatelet therapy (DAPT)** — aspirin 75–100 mg daily plus a **P2Y12 inhibitor** — is given to all patients, along with **parenteral anticoagulation**.
11. **Prasugrel** is **not recommended in patients ≥75 years** unless ischaemic risk is very high, because major and fatal bleeding are increased without added benefit.
12. **Ticagrelor** can be used in older patients; its bleeding risk is similar to clopidogrel.
13. **Early high-dose statin therapy** improves outcome. **Beta blockers** and **ACE inhibitors/ARBs** give prognostic benefit after ACS.
14. Add a **proton pump inhibitor** in older patients on DAPT, especially with prior gastrointestinal bleeding.
15. **Unfractionated heparin dose must be adjusted for renal function** in older people to reduce bleeding.

PROCEDURAL AND ELDERLY-SPECIFIC CONSIDERATIONS

16. The **trans-radial approach** is now recommended in all age groups — it reduces access-site bleeding, which is the commonest non-cardiac complication of PCI.
17. **Bleeding is poorly tolerated in the elderly** because of reduced LV function, vascular stiffness, and endothelial dysfunction; peri-procedural bleeding predicts death, reinfarction, and stroke.
18. **Emergency CABG** is rarely needed — reserved for **failed PCI** or **mechanical complications** (papillary muscle rupture, ventricular septal rupture, free wall rupture).
19. An **implantable cardioverter-defibrillator (ICD)** is advised after MI if there is **ventricular fibrillation, sustained VT, or LVEF ≤30%**.
20. **Treatment should never be withheld on the basis of age alone**; instead use **comprehensive geriatric assessment** — frailty, cognition, life expectancy, and patient preference — to guide intensity of care.
21. **Cardiac rehabilitation** improves survival in older coronary patients and should be offered routinely.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Primary PCI within 120 min; fibrinolysis if not available	Unchanged and reinforced by the **2025 ACC/AHA/ACEP/NAEMSP/SCAI ACS guideline** — the first major US update since 2013
Culprit-lesion PCI, with staged treatment of other vessels	**Complete revascularisation is now Class 1**, and non-culprit PCI may be done **at the index procedure or later** (except in cardiogenic shock)
Clopidogrel, prasugrel, or ticagrelor as P2Y12 options	**Ticagrelor or prasugrel preferred over clopidogrel** after PCI; prasugrel still avoided at ≥75 years
DAPT duration guided by stent type	**Default DAPT ≥12 months** if not high bleeding risk, then **de-escalation to P2Y12 monotherapy** is an accepted option
Intra-aortic balloon pump for shock	**Microaxial flow pump** may be considered in selected cardiogenic shock; prompt revascularisation remains Class 1

Latest Updates (2023–Present)

- The **2025 ACC/AHA/ACEP/NAEMSP/SCAI ACS Guideline** (*Circulation* 2025; *JACC* 2025) consolidates STEMI and NSTEMI into a single document and retires the 2013 STEMI and 2014 NSTE-ACS guidelines.
- **Complete revascularisation** for multivessel disease has been **upgraded from Class 2a to Class 1**, and can now be performed at the index procedure rather than only as a staged procedure (*2025 ACC/AHA ACS Guideline*).
- **Potent P2Y12 inhibitors (ticagrelor or prasugrel) are explicitly preferred over clopidogrel** in patients undergoing PCI, on the basis of superior reduction in major adverse cardiovascular events (*2025 ACC/AHA ACS Guideline*).
- The **2023 ESC ACS Guideline** (*European Heart Journal* 2023) similarly unified the ACS spectrum and recommends the **radial approach as default** and **immediate invasive strategy** for very-high-risk NSTE-ACS.
- **Cardiogenic shock**: prompt revascularisation remains Class 1; **microaxial flow pump support** may be considered in selected patients based on individual risk–benefit (*2025 ACC/AHA ACS Guideline*).
- **Lipid management post-STEMI** has become more aggressive, with early combination therapy (high-intensity statin ± ezetimibe) endorsed to reach LDL-C targets rapidly.

Examiner's Tip — Mark-Earning Lines

- "**Total ischaemic time** determines myocardial salvage; the greatest benefit is within the first 2–3 hours."
- "**FMCTB <90 minutes** in a PCI centre; **PCI within 120 minutes** of diagnosis if transfer is required."
- "**Primary PCI is superior to fibrinolysis in the elderly**, chiefly because of the higher risk of intracranial haemorrhage with lytics (TRIANA)."
- "**Prasugrel is avoided in patients ≥75 years** because of excess major and fatal bleeding."
- "**Radial access** reduces bleeding, and bleeding in the elderly independently predicts death, reinfarction, and stroke."
- "The **2025 ACC/AHA ACS guideline** made **complete revascularisation Class 1** and preferred **ticagrelor/prasugrel over clopidogrel**."
- "**Age alone is never a contraindication** — use comprehensive geriatric assessment to individualise."

Q2. Drug-Eluting Stents — Advantages and Disadvantages over Bare-Metal Stents

15–20 High-Yield Points

BACKGROUND AND MECHANISM

1. **Bare-metal stents (BMS)** are plain metal scaffolds. They abolish elastic recoil but do nothing to prevent **neointimal hyperplasia**, so restenosis rates are high.
2. **Drug-eluting stents (DES)** have a metal platform coated with a **polymer carrying an antiproliferative drug** (sirolimus, everolimus, zotarolimus, biolimus, or paclitaxel).
3. The eluted drug **inhibits smooth muscle proliferation and migration**, thereby suppressing neointimal hyperplasia and restenosis.
4. **Generations of DES**: first generation (thick struts, durable polymer, sirolimus/paclitaxel), second generation (thinner cobalt-chromium struts, biocompatible polymer, everolimus/zotarolimus), and third generation (bioabsorbable polymer or polymer-free).

ADVANTAGES OF DES OVER BMS

5. **Superior reduction in restenosis** — this is the single greatest advantage and the reason DES have superseded BMS.
6. **Marked reduction in target vessel revascularisation** and therefore fewer repeat procedures.
7. **Reduced incidence of myocardial infarction** in subsequent years with third-generation drug-eluting and drug-coated stents.
8. Repeat interventions are **particularly hazardous in older people** (contrast nephropathy, bleeding, vascular injury), so avoiding them is a major geriatric gain.
9. The **SENIOR trial** (patients ≥75 years) showed DES plus **short DAPT** gave a **29% reduction** in the composite of all-cause death, MI, stroke, and revascularisation at one year compared with BMS.
10. Because of this, **the available evidence no longer supports the use of BMS in elderly patients**.

DISADVANTAGES OF DES

11. **Delayed endothelialisation** of the stent struts leaves metal exposed to blood for longer, creating a risk of **late and very late stent thrombosis**.
12. This mandates a **longer duration of DAPT**, traditionally **at least 6 months after DES** versus **1 month after BMS**.
13. Longer DAPT means **more bleeding**, which older patients with multimorbidity tolerate poorly.
14. Older patients frequently need **DAPT interruption** — for example, to allow safe major non-cardiac surgery — and premature interruption after DES carries thrombotic risk.
15. **Polymer hypersensitivity and chronic inflammation** contribute to **neoatherosclerosis** within the stent.
16. DES are **more expensive** than BMS — a real consideration in the Indian public-sector setting.

CURRENT POSITION ON DAPT DURATION

17. In older people, **bleeding is more common than recurrent thrombotic events** after revascularisation, so shorter DAPT is often the safer choice.
18. A short DAPT strategy of **1 month for stable ischaemic heart disease** and **6 months for ACS** with a DES is safe and effective in patients ≥75 years.
19. Emerging data show **1–3 months of DAPT followed by single antiplatelet monotherapy** is possible with newer DES.
20. **Lifelong single antiplatelet therapy** (usually aspirin) follows completion of DAPT in all patients.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
DES require prolonged DAPT (≥6 months), a concern in the elderly	**1–3 months DAPT then P2Y12 monotherapy** is now well established for contemporary DES, even in high-bleeding-risk patients
BMS still an option when short DAPT is needed	**BMS are effectively obsolete**; the 2025 ACC/AHA ACS guideline no longer positions BMS as a strategy to shorten DAPT
Aspirin as the long-term single agent after DAPT	Growing evidence favours **P2Y12 inhibitor (clopidogrel) monotherapy over aspirin** for long-term single antiplatelet therapy
Concern about late stent thrombosis with DES	Very late stent thrombosis is now **rare with second/third-generation DES**; **neoatherosclerosis** is recognised as the dominant late failure mechanism

Latest Updates (2023–Present)

- The **2025 ACC/AHA ACS Guideline** sets **DAPT for at least 12 months** as the default in ACS patients who are not at high bleeding risk, but formally endorses **de-escalation to P2Y12 inhibitor monotherapy after 1–3 months** in patients at high bleeding risk.
- Randomised evidence and meta-analyses through 2024–2025 confirm that **abbreviated DAPT with contemporary DES does not increase ischaemic events** while significantly reducing major bleeding — the strategy of choice in frail older adults.
- **Clopidogrel monotherapy is increasingly preferred over aspirin monotherapy** for chronic single antiplatelet therapy after PCI, based on trials such as HOST-EXAM and its extended follow-up.
- The **2023 ESC ACS Guideline** recommends DES over BMS in all patients regardless of bleeding risk, with DAPT duration then tailored to bleeding risk rather than stent type.
- **Polymer-free and bioabsorbable-polymer DES** and **drug-coated balloons** are expanding the options for patients in whom prolonged DAPT is undesirable.

Examiner's Tip — Mark-Earning Lines

- "DES suppress **neointimal hyperplasia** via an antiproliferative drug on a polymer coating."
- "The chief advantage is **reduced restenosis and target vessel revascularisation**; the chief disadvantage is **delayed endothelialisation** requiring longer DAPT."
- "The **SENIOR trial** showed a **29% reduction** in death/MI/stroke/revascularisation with DES plus short DAPT in patients ≥75 years."
- "**The evidence no longer supports the use of BMS in elderly patients.**"
- "**Short DAPT (1 month stable IHD, 6 months ACS)** with a DES is safe in older people; current practice extends this to **1–3 months followed by monotherapy**."
- "In older people, **bleeding risk exceeds recurrent thrombotic risk** after revascularisation."

Q3. Etiopathogenesis and Management of In-Stent Restenosis

> *Note: In-stent restenosis is discussed only briefly in Pathy's (in the context of DES superiority over BMS). The detailed mechanisms and management below are therefore drawn from current peer-reviewed cardiology literature and guidelines, as permitted.*

15–20 High-Yield Points

DEFINITION

1. **In-stent restenosis (ISR)** is **≥50% diameter stenosis** within the stent or its **5 mm proximal or distal margins** on follow-up angiography.
2. **Clinical ISR** means angiographic restenosis accompanied by **symptoms or objective ischaemia**, and is the clinically relevant entity.
3. ISR occurs in roughly **5–10% of DES implants** and up to **20–30% of BMS implants**.

ETIOPATHOGENESIS

4. **Neointimal hyperplasia** is the classical mechanism — vessel injury during stenting causes **endothelial denudation**, platelet deposition, and inflammation.
5. Released **growth factors and cytokines** drive **smooth muscle cell proliferation and migration** from the media into the intima, with **extracellular matrix deposition**.
6. **Neoatherosclerosis** is the second and increasingly dominant mechanism, especially with DES — new atheromatous plaque with lipid-laden foam cells forms *inside* the stent and may **rupture**, causing late ACS.
7. **Mechanical factors**: stent under-expansion, stent fracture, geographical miss (lesion not fully covered), and stent gap.
8. **Biological factors**: **polymer hypersensitivity**, drug resistance, and persistent chronic inflammation.
9. **Patient factors**: **diabetes mellitus**, chronic kidney disease, and ongoing smoking.
10. **Lesion factors**: long lesions, small vessel diameter (<2.5 mm), bifurcation lesions, ostial lesions, chronic total occlusions, and heavy calcification.
11. **BMS restenosis** is dominated by **neointimal hyperplasia** and presents **early (6–12 months)**; **DES restenosis** is more often due to **neoatherosclerosis** and presents **late (beyond 1–2 years)**.

CLINICAL PRESENTATION

12. Most present as **recurrent stable angina**; about **10–20% present as an acute coronary syndrome**, particularly when neoatherosclerotic plaque ruptures.
13. In older people the presentation may again be **atypical** — exertional dyspnoea, fatigue, or reduced exercise tolerance.

DIAGNOSIS

14. **Coronary angiography** confirms the diagnosis and defines the **Mehran classification** — Type I focal, Type II diffuse intra-stent, Type III proliferative extending beyond the stent, Type IV occlusive.
15. **Intravascular imaging is mandatory** — **IVUS** best assesses stent under-expansion and vessel size; **OCT** best characterises neointimal morphology and detects neoatherosclerosis.
16. Imaging is what distinguishes **mechanical failure** (needs high-pressure dilatation) from **biological failure** (needs an antiproliferative strategy).

MANAGEMENT

17. **Lesion preparation first** — non-compliant balloon at high pressure, **cutting or scoring balloon**, or **intravascular lithotripsy/rotational atherectomy** for underexpanded or calcified segments.
18. **Drug-coated balloon (DCB) angioplasty** is a first-line option — it delivers paclitaxel or sirolimus without adding another metal layer, which is a major advantage in a vessel that already has one or more stents.
19. **Repeat DES implantation** is the alternative first-line option, preferred when there is significant dissection, elastic recoil, or a suboptimal DCB result.
20. **Plain balloon angioplasty alone is inadequate** and has unacceptably high recurrence.
21. **CABG** is considered for recurrent, multi-layered, or diffuse ISR, especially with left main or multivessel involvement — but the risk–benefit must be weighed against frailty in older patients.
22. **Aggressive secondary prevention** is essential: high-intensity statin, glycaemic control, blood pressure control, smoking cessation, and appropriate antiplatelet therapy.

Current Practice Update

Traditional teaching	Current evidence (2023–2026)
ISR is essentially a problem of neointimal hyperplasia	**Neoatherosclerosis** is now recognised as the dominant mechanism of late DES failure and explains ACS presentations
Repeat DES is the default treatment	**DCB and repeat DES are equivalent first-line options**; DCB is preferred to avoid additional metal layers
DCB was available only in Europe	**FDA approval of the AGENT paclitaxel-coated balloon (2024)** made DCB available in the USA and consolidated it as standard therapy
Angiography alone guides ISR treatment	**Intravascular imaging (IVUS/OCT) is now considered essential** to identify the mechanism before choosing therapy

Latest Updates (2023–Present)

- The **AGENT IDE randomised trial** (*JAMA* 2024) showed the paclitaxel-coated balloon reduced the primary composite endpoint to **18% versus 29%** with uncoated balloon (HR 0.59), with significantly less target lesion revascularisation. **Multi-layer ISR was present in 43%** of patients.
- Benefit was **sustained at 2 years** (CRT 2025) and **3 years** (CRT 2026), establishing DCB durability in ISR.
- The **AGENT DCB received FDA approval in 2024** — the first coronary drug-coated balloon approved in the United States, formally endorsing the "leave nothing behind" strategy.
- Network and mixed-treatment meta-analyses (*Circulation: Cardiovascular Interventions* 2025) confirm **DES and DCB are broadly comparable** for ISR, with **both clearly superior to plain balloon angioplasty**.
- The **ISAR-DESIRE 5 trial** is testing an imaging-guided strategy — DCB versus repeat DES **chosen according to neointimal morphology on OCT** — reflecting the shift toward mechanism-directed therapy.
- **Sirolimus-coated balloons** are emerging as an alternative to paclitaxel, with theoretical advantages in drug retention and vessel healing.

Examiner's Tip — Mark-Earning Lines

- "**ISR is ≥50% stenosis within the stent or 5 mm of its margins.**"
- "Two mechanisms: **neointimal hyperplasia** (early, BMS-dominant) and **neoatherosclerosis** (late, DES-dominant, causes ACS)."
- "**Mehran classification** — Type I focal to Type IV occlusive."
- "**Intravascular imaging distinguishes mechanical from biological failure** and directs treatment."
- "First-line treatment is **lesion preparation followed by DCB or repeat DES**; **plain balloon angioplasty alone is inadequate**."
- "The **AGENT IDE trial (JAMA 2024)** established the paclitaxel-coated balloon for ISR, with FDA approval in 2024."

Q4. Newer Cardiac Biomarkers in Myocardial Injury and Their Interpretation

15–20 High-Yield Points

THE CENTRAL BIOMARKER

1. **High-sensitivity cardiac troponin (hs-cTn) I and T** is the **gold standard** biomarker of myocardial injury and the cornerstone of ACS diagnosis.
2. **Myocardial injury** is defined by a troponin value **above the 99th percentile upper reference limit**. It becomes **acute** when there is a **rise and/or fall** on serial testing.
3. **Myocardial infarction** requires evidence of injury **plus clinical evidence of ischaemia** — symptoms, ECG change, imaging evidence, or thrombus on angiography.
4. **Troponin elevation is not synonymous with myocardial infarction** — this is the single most important interpretive principle.

CLASSIFICATION OF MYOCARDIAL INFARCTION

5. **Type 1 MI** — plaque rupture or erosion with coronary thrombosis. This is atherothrombotic.
6. **Type 2 MI** — **oxygen supply–demand mismatch** without plaque rupture; the myocardium is starved rather than blocked.
7. Common causes of Type 2 MI in older people are **sepsis, hypotension, tachyarrhythmias, anaemia, hypoxaemia, and organ dysfunction**.
8. Older people are **far more likely to have raised hs-troponin from Type 2 MI** than younger individuals, because of demand-supply mismatch causing non-atherosclerotic myonecrosis.
9. **Type 2 MI carries a poor prognosis** — mortality up to **63% at 3 years** — but the deaths are driven by **comorbidities rather than myocardial damage**, and **PCI is unlikely to help**.
10. **Types 3, 4 and 5** cover sudden cardiac death before biomarker sampling, PCI-related MI, and CABG-related MI respectively.

CHRONIC AND NON-ISCHAEMIC ELEVATION

11. **Chronic troponin elevation** without a rise-and-fall pattern occurs in **chronic kidney disease, heart failure, left ventricular hypertrophy, amyloidosis, and advanced age itself**.
12. Other non-ischaemic causes: **myocarditis, pulmonary embolism, stroke and subarachnoid haemorrhage, cardiac contusion, cardioversion, ablation, and chemotherapy-related cardiotoxicity**.
13. In old age, elevated troponin combined with **non-specific symptoms and age-related baseline ECG changes** (Q waves, bundle branch block) can lead to a **false diagnosis of ACS**.

NATRIURETIC PEPTIDES

14. **BNP and NT-proBNP** are markers of **myocardial wall stress**, not injury, and are the primary rule-out test for heart failure.
15. ESC thresholds for further investigation: **BNP >35 pg/ml** and **NT-proBNP >125 pg/ml** in the non-acute setting. **Normal levels make heart failure unlikely.**
16. They are **equally predictive in HFrEF and HFpEF** and carry independent prognostic information.
17. Levels **rise with age and with renal impairment**, and **fall with obesity** — all must be factored into interpretation.

NEWER AND ADJUNCTIVE MARKERS

18. **Cardiac myosin-binding protein C (cMyC)** is the most promising competitor to troponin — it is released earlier and is currently the leading candidate for very early rule-out.
19. **Copeptin**, the C-terminal fragment of provasopressin, is a marker of **endogenous stress**; combined with troponin it allows a **dual-marker single-draw rule-out**, but it lacks cardiac specificity.
20. **GDF-15, sST2, galectin-3, and hs-CRP** are **prognostic rather than diagnostic** — they reflect oxidative stress, fibrosis, and inflammation, and predict mortality and hospitalisation.
21. **GDF-15 and hs-cTnT are components of the ABC bleeding risk score** in atrial fibrillation, illustrating the biomarker-based risk-scoring approach.
22. Adding **NT-proBNP, hs-cTnT, and hs-CRP** to the pooled cohort equation improved **4-year cardiovascular risk prediction** in adults aged 69–88 years (ARIC study).

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Serial troponin at 0 and 3–6 hours	**ESC 0/1-hour algorithm** is now the preferred rapid rule-in/rule-out pathway, with **0/2-hour** as an alternative
Copeptin useful as an adjunct	**2023 ESC ACS Guideline does not recommend copeptin or cMyC routinely** unless hs-cTn or rapid protocols are unavailable
Type 2 MI recognised but management unclear	Type 2 MI is now managed by **treating the precipitant**; routine invasive strategy is discouraged
Novel markers (sST2, galectin-3, GDF-15) considered emerging diagnostics	Now firmly positioned as **prognostic/risk-stratification tools only** — they lack cardiac specificity for diagnosis

Latest Updates (2023–Present)

- The **2023 ESC ACS Guideline** endorses the **hs-cTn 0/1-hour algorithm** (or 0/2-hour) in preference to serial testing based on the 99th percentile, and permits **immediate rule-out when hs-cTn is below the limit of detection** in patients presenting more than 3 hours after symptom onset.
- The **2025 ACC/AHA ACS Guideline** confirms **high-sensitivity troponin as the preferred biomarker** for evaluating suspected ACS.
- A large single-centre study of **1,765 patients** (*Journal of Clinical Medicine* 2025) compared **cMyBP-C, copeptin, GDF-15, BMP10, FABP3 and FGF23** against the ESC algorithms and found **cMyC to be the only viable competitor to troponin**; the others added prognostic but not diagnostic value.
- A **2025 review of myocardial injury biomarkers** (*Expert Review of Cardiovascular Therapy* 2025) concluded that copeptin, galectin-3 and sST2 **lack cardiac specificity**, limiting their diagnostic utility, while **cMyC remains the most credible alternative** to cTn.
- **Point-of-care hs-cTn assays** are being validated for use in emergency departments and pre-hospital settings, which is particularly relevant to Indian district hospital practice.
- **Sex-specific and age-specific 99th percentile thresholds** are increasingly recommended to reduce over-diagnosis in older women and under-diagnosis in older men.

Examiner's Tip — Mark-Earning Lines

- "**Myocardial injury** = troponin above the **99th percentile URL**; **acute injury** = a **rise and/or fall**; **infarction** = injury **plus** evidence of ischaemia."
- "**Troponin elevation is not synonymous with myocardial infarction.**"
- "**Type 2 MI** results from **supply–demand mismatch** — sepsis, hypotension, tachyarrhythmia, anaemia — and is far commoner in the elderly."
- "**Type 2 MI mortality reaches 63% at 3 years**, driven by comorbidity, and **PCI is unlikely to be effective**."
- "**BNP >35 pg/ml** and **NT-proBNP >125 pg/ml** prompt echocardiography; normal levels make heart failure unlikely."
- "**Natriuretic peptides rise with age and renal impairment and fall with obesity.**"
- "The **ESC 0/1-hour hs-cTn algorithm** is the current standard rapid diagnostic pathway."
- "**GDF-15, sST2 and galectin-3 are prognostic, not diagnostic.**"

Q5. AHA Guidelines for Stroke Prevention in Atrial Fibrillation

15–20 High-Yield Points

BURDEN AND RATIONALE

1. **Atrial fibrillation (AF)** is the commonest sustained arrhythmia in older people and is a major cause of **cardioembolic stroke**, heart failure, and death.
2. Stroke in AF arises mainly from thrombus in the **left atrial appendage (LAA)** — hence the anatomical basis of all preventive strategies.
3. The **absolute stroke reduction from oral anticoagulation is greatest in the elderly**, because baseline stroke risk rises steeply with age and outweighs the bleeding risk.

RISK STRATIFICATION

4. **All patients with AF must be routinely scored** for stroke risk — the recommended tool is the **CHA2DS2-VASc score**.
5. Anticoagulation is a **Class I recommendation** at **CHA2DS2-VASc ≥2 in men** and **≥3 in women**. It **should be considered** at a score of **1 in men** and **2 in women**.
6. **All patients over 75 with AF should therefore be anticoagulated** unless there is a major contraindication.
7. **Bleeding risk must be assessed in parallel** using **HAS-BLED, ORBIT, ATRIA, HEMORR2HAGES**, or the biomarker-based **ABC bleeding score**.
8. A high bleeding score is **not a reason to withhold anticoagulation** — it identifies **modifiable risk factors** (uncontrolled BP, labile INR, alcohol, concomitant NSAIDs/antiplatelets) that should be corrected.

CHOICE OF AGENT

9. In **non-valvular AF, DOACs are recommended over warfarin** (Class I) in patients without contraindications.
10. **Warfarin is mandatory** in **moderate-to-severe mitral stenosis** and in **mechanical prosthetic heart valves** (Class I) — DOACs are contraindicated and less effective in these groups.
11. Warfarin efficacy depends on **time in therapeutic range (TTR)** with a target **INR 2–3**; the higher the TTR, the lower the risk of both stroke and bleeding.
12. **Antiplatelet therapy is inferior** — a meta-analysis of nine trials showed **VKA superior to aspirin with a 39% relative risk reduction**, and **ACTIVE-W** showed anticoagulation superior to aspirin–clopidogrel (RRR 40%).

KEY TRIAL EVIDENCE

13. **BAFTA** (age ≥75): warfarin (INR 2–3) reduced stroke, systemic embolism, and intracranial bleeding by **52%** versus aspirin 75 mg, with **no difference in major haemorrhage**.
14. **RE-LY**: dabigatran **150 mg BD reduced stroke/systemic embolism by 35%**; **110 mg BD** was non-inferior with **20% less bleeding**.
15. **ARISTOTLE**: apixaban 5 mg BD reduced stroke/systemic embolism by **21%**, major bleeding by **31%**, and death by **11%**.
16. **ENGAGE AF-TIMI 48**: edoxaban 60 mg OD had similar efficacy with **20% less major bleeding**. **ROCKET-AF**: rivaroxaban 20 mg OD had similar efficacy with less intracranial and life-threatening bleeding.
17. **AVERROES**: apixaban was superior to aspirin in patients unsuitable for warfarin, with an acceptable safety profile.
18. In patients **>75 years, DOACs as a class were superior to warfarin in both efficacy and safety**. **Apixaban had the lowest risk of major bleeding**, and apixaban, edoxaban, and dabigatran had **lower rates of intracranial haemorrhage** than rivaroxaban or warfarin.

NON-PHARMACOLOGICAL OPTIONS AND SPECIAL SITUATIONS

19. **Percutaneous LAA occlusion (WATCHMAN)** is an option for patients with high stroke risk and a **non-reversible contraindication to long-term anticoagulation** — for example prior intracranial haemorrhage on OAC, or recurrent embolic stroke despite adequate anticoagulation.
20. **Surgical LAA excision or exclusion** should be considered in AF patients undergoing cardiac surgery; concomitant surgical AF ablation reduces stroke and has a **Class I indication**.
21. After **cardioembolic stroke**, delay starting anticoagulation for **about 2 weeks** because early benefit is offset by haemorrhagic transformation — but start immediately after **TIA or minor stroke**.
22. **Falls risk and dementia are frequently used as inappropriate reasons to withhold anticoagulation**; only end-stage dementia clearly tips the balance against treatment.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Anticoagulate on the basis of CHA2DS2-VASc score alone	The **2023 ACC/AHA/ACCP/HRS AF Guideline** bases the decision on **annual thromboembolic risk (≥2%/year = Class 1)**, and permits **ATRIA or GARFIELD-AF** as alternative scores
Female sex is a risk factor scoring 1 point	Female sex is now a **risk modifier**, not an independent risk factor; the 2024 ESC guideline uses **CHA2DS2-VA** (sex removed)
LAA occlusion for those unable to take OAC	LAA occlusion given a **higher class of recommendation**; **OPTION trial (2024)** supports LAAO after ablation in selected patients
Device-detected AF handled case by case	**Prescriptive recommendations** now exist based on **AHRE duration** (<5 min, 5 min–24 h, ≥24 h) from NOAH-AFNET 6 and ARTESiA

Latest Updates (2023–Present)

- The **2023 ACC/AHA/ACCP/HRS AF Guideline** (*Circulation* 2023; *JACC* 2023) shifted from a score-threshold approach to **anticoagulation based on estimated annual stroke risk**: **≥2% per year is a Class 1 indication**, equivalent to CHA2DS2-VASc ≥2 in men and ≥3 in women.
- The same guideline introduced **AF stages** (including a pre-detection stage), emphasised **aggressive risk-factor modification**, and favoured **early rhythm control**.
- **Device-detected AF**: for an atrial high-rate episode **≥24 hours with CHA2DS2-VASc ≥2**, initiating anticoagulation is reasonable; for episodes of **5 minutes to 24 hours with CHA2DS2-VASc ≥3**, it may be reasonable; for episodes **<5 minutes**, anticoagulation should **not** be given.
- The **2024 ESC AF Guideline** (*European Heart Journal* 2024) adopted **CHA2DS2-VA**, dropping the sex category, to simplify decision-making and avoid sex-based treatment disparity.
- **Percutaneous LAA occlusion** received a stronger recommendation, and the **OPTION trial** (presented AHA 2024) supported LAAO as an alternative to DOAC after catheter ablation in selected patients.
- **Factor XI inhibitors** are the major emerging class — **AZALEA-TIMI 71** (*NEJM* 2023) showed abelacimab reduced major or clinically relevant non-major bleeding by **62–69% versus rivaroxaban**, but the phase 3 **OCEANIC-AF** trial of asundexian was **stopped early for inferiority to apixaban**. **LILAC-TIMI 76** (abelacimab versus placebo in patients unsuitable for OAC) and **LIBREXIA-AF** (milvexian versus apixaban) will report from late 2026.

Examiner's Tip — Mark-Earning Lines

- "**Thrombus forms in the left atrial appendage** — the anatomical basis for all preventive strategies."
- "**Anticoagulate at CHA2DS2-VASc ≥2 in men, ≥3 in women (Class I)** — so effectively **all AF patients over 75**."
- "**High bleeding score is not a reason to withhold anticoagulation** — it flags modifiable risk factors."
- "**DOACs are preferred over warfarin in non-valvular AF**; **warfarin is mandatory in moderate-severe mitral stenosis and mechanical valves**."
- "**BAFTA: 52% relative risk reduction with warfarin over aspirin in patients ≥75.**"
- "**Apixaban has the lowest major bleeding risk** among DOACs in the over-75 population."
- "The **2023 ACC/AHA AF guideline** moved to **risk-based (≥2%/year) rather than score-threshold** anticoagulation; the **2024 ESC guideline adopted CHA2DS2-VA**."

Q6. CHA2DS2-VASc Score — Use and Clinical Significance

15–20 High-Yield Points

PURPOSE

1. **CHA2DS2-VASc** is a **clinical risk-stratification score** that estimates the **annual risk of ischaemic stroke and systemic embolism** in patients with **non-valvular atrial fibrillation**.
2. It was developed to refine the earlier **CHADS2 score**, which classified too many patients as "low risk" and missed those who would benefit from anticoagulation.
3. Its purpose is **decision-making** — it balances the reduction in stroke risk against the increased risk of bleeding from anticoagulation.

COMPONENTS (MAXIMUM SCORE 9)

4. **C — Congestive cardiac failure** (or LV dysfunction): **1 point**
5. **H — Hypertension**: **1 point**
6. **A2 — Age ≥75 years**: **2 points**
7. **D — Diabetes mellitus**: **1 point**
8. **S2 — Stroke / TIA / thromboembolism**: **2 points**
9. **V — Vascular disease** (prior MI, peripheral arterial disease, or aortic plaque): **1 point**
10. **A — Age 65–74 years**: **1 point**
11. **Sc — Sex category (female)**: **1 point**
12. The **maximum score is 9**, not 10, because **age can score only 0, 1 or 2** — it cannot count in both age bands.

CLINICAL APPLICATION

13. **Score ≥2 in men or ≥3 in women** — oral anticoagulation is **recommended (Class I)**.
14. **Score of 1 in men or 2 in women** — anticoagulation **should be considered**, after shared decision-making.
15. **Score 0 in men or 1 in women (female sex alone) — no antithrombotic therapy** is required.
16. **Age ≥75 alone gives 2 points**, so **every older person with AF qualifies for anticoagulation** unless contraindicated. This is the single most important geriatric implication of the score.
17. The score should be **reassessed at least annually**, because risk factors accumulate dynamically with ageing.

WIDER USES AND LIMITATIONS

18. The score is also used in **device-detected atrial high-rate episodes**, to guide **LAA occlusion** eligibility, and to inform **peri-procedural anticoagulation** decisions.
19. **Limitation** — it does **not include bleeding risk**, so it must always be paired with a bleeding score such as **HAS-BLED, ORBIT, ATRIA or ABC**.
20. **Limitation** — it **omits renal impairment, frailty, anaemia, cognitive status, and AF burden**, all highly relevant in geriatric practice.
21. **Limitation** — it has **modest discriminatory power (c-statistic ~0.6)** and was validated in populations under-representing the very old.
22. **Limitation** — because **age contributes so heavily**, the score has **poor discrimination within the elderly population**, where almost everyone scores ≥2.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
CHA2DS2-VASc is the single recommended score	The **2023 ACC/AHA AF Guideline** endorses **CHA2DS2-VASc, ATRIA, or GARFIELD-AF**, allowing flexibility
Decision based on the score threshold	Decision now based on **estimated annual event rate — ≥2% per year is Class 1**
Female sex scores 1 point as a risk factor	Female sex is now a **risk modifier**; the **2024 ESC guideline uses CHA2DS2-VA**, dropping the sex category entirely
Score used at diagnosis	Score should be **reassessed at least annually**, as risk is dynamic

Latest Updates (2023–Present)

- The **2023 ACC/AHA/ACCP/HRS AF Guideline** allows use of **other validated risk scores (ATRIA, GARFIELD-AF)** alongside CHA2DS2-VASc, particularly for **patients at intermediate risk** where the anticoagulation decision is

genuinely uncertain.

- The guideline introduced the concept of **stroke risk modifiers** — AF burden, blood pressure control, and other dynamic factors — for patients with an annual risk below 2%.
- The **2024 ESC AF Guideline** formally adopted **CHA2DS2-VA (maximum 8 points)**, removing sex category, on the evidence that **women's excess stroke risk is not evident until other risk factors are present**.
- Studies show that applying the lower ACC/AHA hypertension thresholds causes **"up-scoring"** of CHA2DS2-VASc, reclassifying many patients into the anticoagulation-eligible category — a recognised limitation of a score built on binary comorbidity definitions (*JAMA Cardiology* 2023).
- There is an ongoing move toward **biomarker-enhanced scores** such as the **ABC stroke score** (age, biomarkers — NT-proBNP and hs-cTnT — and clinical history), which outperform CHA2DS2-VASc in trial cohorts but have shown **limited advantage in real-world elderly populations**.

Examiner's Tip — Mark-Earning Lines

- "Congestive failure 1, Hypertension 1, **Age ≥75 = 2**, Diabetes 1, **Stroke/TIA = 2**, Vascular disease 1, Age 65–74 = 1, Sex (female) 1."
- "**Maximum score is 9, not 10** — because age scores either 1 or 2, never both."
- "**Anticoagulate at ≥2 in men, ≥3 in women (Class I).**"
- "**Age ≥75 alone scores 2** — so every older patient with AF qualifies for anticoagulation."
- "The score **assesses stroke risk only** and must always be paired with a **bleeding risk score**."
- "It **omits renal function, frailty, anaemia and AF burden**, and has **poor discrimination within the elderly**."
- "The **2024 ESC guideline moved to CHA2DS2-VA**, removing sex category."

Q7. Lifestyle Modification to Reduce Cardiovascular Risk

15–20 High-Yield Points

GENERAL PRINCIPLE

1. **Compliance with healthy lifestyle recommendations reduced mortality and the prevalence of chronic disease** in a cohort of people aged 65–98 years — the benefits of prevention apply **regardless of age or number of risk factors**.
2. Standard risk calculators such as the **pooled cohort equation are not validated beyond age 79**, so lifestyle advice should be given universally rather than being made conditional on a calculated risk score.

SMOKING CESSATION

3. **Smoking is a major cardiovascular risk factor** associated with increased mortality, and **cessation is beneficial even for those who quit late in life**.
4. Smoking also increases the risk of heart failure — relative risk **1.75 in current smokers** and **1.16 in former smokers** — and the risk falls with years of abstinence.
5. A **structured smoking cessation programme** should be strongly recommended to every older smoker.

PHYSICAL ACTIVITY

6. **All movement counts.** In 5,861 older women (mean age 78.5 years), the highest quartile of **light physical activity** was associated with a **42% reduction** in myocardial infarction or coronary death.
7. In the **Cardiovascular Health Study** (4,207 subjects, mean age 72.5), greater physical activity was inversely associated with IHD, stroke, and total cardiovascular disease **even in those aged ≥75**.
8. **Walking pace and walking distance** were each independently associated with lower risk — important because walking is the commonest form of activity in older people.
9. In a Finnish study of 2,456 people aged 65–74, **leisure-time physical activity reduced total and cardiovascular mortality in a dose-dependent manner**, independent of baseline risk factors.
10. In 2,153 older men (mean age 75), **mortality risk was 48% lower in the most fit compared with the least fit** individuals.
11. **Three months of exercise-based lifestyle intervention** lowers blood pressure by approximately **5 mmHg systolic and 3 mmHg diastolic** in older individuals.
12. Exercise prescription should include **aerobic, resistance, balance, and flexibility** components — resistance training is essential to counter sarcopenia.

DIET

13. Meta-analyses of observational studies show an **overall protective effect of the Mediterranean diet** on cardiovascular disease.
14. **Supplementing the Mediterranean diet with extra-virgin olive oil or nuts produced a 30% reduction in major cardiovascular events** in people aged 55–80 (PREDIMED).
15. Higher circulating **omega-3 polyunsaturated fatty acids from seafood** were associated with a lower risk of unhealthy ageing — dietary fish intake in older people should be increased.
16. The **Mediterranean diet is preferred over a conventional low-fat, high-carbohydrate diet**, because low-fat diets lower HDL-C as much as LDL-C.
17. **Low sodium intake (<2 g/day)** reduces systolic BP by **3.47 mmHg** and diastolic BP by **1.81 mmHg**. High sodium intake is associated with increased risk of **stroke (RR 1.24), stroke mortality (1.63), and coronary heart disease mortality (1.32)**.

WEIGHT, ALCOHOL AND OTHER MEASURES

18. **Maintenance of ideal body weight** helps reduce BP, but **restrictive diets that impair quality of life are inappropriate in older people** — elevated weight short of frank obesity is associated with longer life than being underweight.
19. **Low alcohol consumption** is advised; heavy drinking causes alcoholic cardiomyopathy and heart failure.
20. **Sodium restriction to about 1500 mg/day** is prudent in heart failure, mainly for blood pressure control.
21. **Cardiac rehabilitation** — a structured, supervised lifestyle programme — improves survival in older coronary patients and reduces depression.
22. In older people a **sedentary lifestyle showed the strongest association with incident heart failure**, while the associations of smoking and hypertension attenuated with age.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Lifestyle described as individual risk-factor measures	**AHA "Life's Essential 8"** provides a single composite cardiovascular health score covering diet, activity, nicotine, sleep, weight, lipids, glucose and BP
Nicotine exposure means cigarette smoking	Now includes **e-cigarettes, vaping and second-hand smoke**
Sleep not listed as a cardiovascular risk factor	**Sleep duration is now a formal component** of cardiovascular health scoring
Pooled cohort equation for risk estimation	**PREVENT equations** (2023) have replaced pooled cohort equations, incorporating **renal function, statin use and social drivers of health**
Weight loss achieved by lifestyle alone	**GLP-1 receptor agonists** now have proven cardiovascular outcome benefit and are an adjunct in selected patients

Latest Updates (2023–Present)

- The **AHA "Life's Essential 8" framework** (an update of Life's Simple 7) adds **sleep health** as an eighth metric. A **10-point increase in the LE8 score significantly reduces all-cause and cardiovascular mortality** (*Journal of Cardiology* 2025).
- The **PREVENT risk equations** were adopted by the **2025 AHA/ACC Hypertension Guideline**, replacing the pooled cohort equations and improving risk estimation by including **renal function, statin use, and social drivers of health**.
- The **2025 AHA/ACC Hypertension Guideline** recommends lifestyle counselling for all hypertensive patients: **≥5% weight loss if overweight, DASH diet, sodium reduction, alcohol reduction or abstinence, and increased physical activity**, with drug therapy added if BP remains ≥130/80 mmHg after a **3–6 month lifestyle trial** in low-risk stage 1 hypertension (PREVENT <7.5%).
- The **SELECT trial** (*NEJM* 2023) showed **semaglutide 2.4 mg weekly reduced major adverse cardiovascular events** in overweight or obese patients with established cardiovascular disease and no diabetes; FDA approval for MACE reduction followed in 2024. Mean age was 61 years, so applicability to the very old still requires caution.
- The **2025 AHA/ACC Hypertension Guideline** explicitly mentions **GLP-1 receptor agonists** as a possible addition for selected patients with hypertension and overweight or obesity.
- Physical activity guidance has moved from a fixed threshold to a **dose-response model** — **any increase above baseline confers benefit**, which is a far more achievable message for frail older adults.

Examiner's Tip — Mark-Earning Lines

- "**Smoking cessation is beneficial even for those who quit late in life.**"
- "**All movement counts** — light physical activity gave a **42% reduction** in MI or coronary death in older women."
- "**PREDIMED**: Mediterranean diet with olive oil or nuts gave a **30% reduction** in major cardiovascular events."
- "**Sodium <2 g/day lowers SBP by ~3.5 mmHg**; high intake raises stroke risk (RR 1.24)."
- "**Restrictive diets that impair quality of life are inappropriate in older people.**"
- "**Sedentary lifestyle shows the strongest association with incident heart failure in old age.**"
- "**Life's Essential 8** adds **sleep** to the traditional seven metrics; the **PREVENT equations** now replace the pooled cohort equations."

Q8. Causes of Secondary Hypertension — Evaluation and Treatment

15–20 High-Yield Points

DEFINITION AND EPIDEMIOLOGY

1. **Secondary hypertension** is high blood pressure due to an **identifiable and often correctable underlying cause**.
2. It is **uncommon in older adults overall**, but should be actively considered in **treatment-resistant hypertension** and in those with **diastolic pressures >115 mmHg**.
3. **Atherosclerotic renovascular hypertension and primary hyperaldosteronism occur more frequently in older persons** than in the young.
4. **Pheochromocytoma is uncommon in older adults** and particularly unusual after age 75.

CAUSES AND THEIR CLINICAL MARKERS

5. **Renovascular disease** — abdominal bruit, a **rise in serum creatinine of >30% after starting an ACE inhibitor or ARB**, and **asymmetrical kidney size differing by >1.5 cm** on ultrasound.
6. **Renoparenchymal disease** — often asymptomatic; raised urea and creatinine, **small kidneys**, and abnormal urinalysis.
7. **Conn's syndrome (primary hyperaldosteronism)** — **elevated serum aldosterone with resistant hypokalaemia**.
8. **Cushing's syndrome** — elevated serum cortisol, **cushingoid facies**, persistent hypokalaemia.
9. **Pheochromocytoma** — **elevated urinary metanephrines**, episodic sympathetic overactivity (headache, palpitation, sweating).
10. **Hypothyroidism** — constipation, bradycardia, **high TSH with low thyroxine**. **Hyperthyroidism** — diarrhoea, tachycardia, **low TSH with high thyroxine**.
11. **Hyperparathyroidism** — **high serum calcium and PTH**, constipation. Increasingly diagnosed with automated calcium testing, particularly in postmenopausal women; treating it may ameliorate the blood pressure.
12. **Drugs** — **NSAIDs and corticosteroids** are the commonest culprits; also sodium-containing antacids, antidepressants, nicotine, and oral contraceptives.
13. **Obstructive sleep apnoea** — daytime sleepiness and nocturnal snoring.
14. **Excess alcohol** — established by careful history taking.
15. **Oestrogen therapy** in the postmenopausal woman may cause hypertension; this can be tested by **withdrawing oestrogen for several months** and observing the blood pressure response.

MIMICS THAT MUST BE EXCLUDED FIRST

16. **Pseudohypertension** — falsely elevated readings due to **non-collapsible sclerotic arteries**. Suspect it in apparently resistant hypertension **with no end-organ damage**. Detected by the **Osler manoeuvre** (radial artery remains palpable when the cuff is inflated above systolic pressure), which suggests a **10–15 mmHg error**; confirmed by **intra-arterial monitoring**.
17. **White-coat hypertension** — high office but normal home BP. **Masked hypertension** — normal office but high home BP. Both need **ambulatory or home BP monitoring**.
18. **Non-adherence and inadequate diuretic dosing** are the commonest reasons for apparent resistance and must be excluded before labelling a patient resistant.

EVALUATION

19. **Resistant hypertension** is BP uncontrolled despite **three or more antihypertensive agents including a diuretic**.
20. Initial laboratory evaluation: **urinalysis, complete blood count, serum electrolytes and calcium, estimated GFR, fasting glucose, lipids, and a 12-lead ECG**.
21. Second-line testing is directed by clinical suspicion — **aldosterone-renin ratio, urinary metanephrines, TSH, renal Doppler/CT angiography, overnight dexamethasone suppression test, polysomnography**.

TREATMENT

22. **Treat the cause where possible** — adrenalectomy for aldosterone-producing adenoma or pheochromocytoma, parathyroidectomy for hyperparathyroidism, thyroid hormone replacement, CPAP for sleep apnoea, and withdrawal of the offending drug.
23. **Spironolactone or eplerenone** is the drug of choice in primary aldosteronism and in resistant hypertension generally. **Eplerenone avoids gynaecomastia** but both require careful **potassium and renal function monitoring** in older patients.
24. Renal artery **revascularisation is reserved** for flash pulmonary oedema, rapidly deteriorating renal function, or truly refractory hypertension — medical therapy is otherwise preferred.

25. **Targets should be individualised by functional status** rather than chronological age — approximately **<130/80 mmHg in the independent older person, <140/90 in the partially dependent, and <150/90 in the dependent or frail**.

Current Practice Update

Textbook position (Pathy's / Essentials)	Current evidence (2023–2026)
Screen for primary aldosteronism only in resistant hypertension **with hypokalaemia**	**2025 AHA/ACC Guideline: screen all patients with resistant hypertension irrespective of potassium**, since PA commonly exists without hypokalaemia
Antihypertensives usually withheld before aldosterone-renin ratio testing	**Continue all antihypertensives except MRAs** during screening, to avoid delays and barriers
Screening confined to specific clinical settings	Screening **expanded to stage 2 and resistant hypertension**; the **2025 Endocrine Society guideline** goes further and recommends screening **all hypertensive patients**
Renal denervation not established	**Renal denervation is now an adjunctive option** for selected patients with resistant hypertension
Pooled cohort equations for risk assessment	**PREVENT risk calculator** now used

Latest Updates (2023–Present)

- The **2025 AHA/ACC Hypertension Guideline** — the first major update since 2017 — recommends **screening for primary aldosteronism in all adults with resistant hypertension regardless of whether hypokalaemia is present** (Class 1, LOE B-NR), because PA frequently occurs with normal potassium.
- The same guideline recommends **continuing most antihypertensive medications (all except MRAs) during aldosterone-renin ratio testing**, to remove a major practical barrier to diagnosis.
- Screening indications also include **unexplained hypokalaemia, obstructive sleep apnoea, incidental adrenal mass, family history of early-onset hypertension, and stroke before age 40** (*2025 AHA/ACC Hypertension Guideline*).
- **Renal denervation** has been introduced as an **adjunctive option in selected patients with resistant hypertension** (*2025 AHA/ACC Hypertension Guideline*).
- The **2025 Endocrine Society primary aldosteronism guideline** and the **2024 ESC hypertension guideline** both move toward **broader, near-universal PA screening**, reflecting recognition that PA is substantially under-diagnosed.
- The guideline recommends **initiating two agents at once, preferably as a single-pill combination**, and notes that **fewer cardiovascular events and deaths occur with single-pill combinations** than with equivalent multi-pill regimens.

Examiner's Tip — Mark-Earning Lines

- "**Renovascular disease and primary hyperaldosteronism are the commonest secondary causes in the elderly**; pheochromocytoma is unusual after 75."
- "Suspect renovascular disease if creatinine **rises >30% after starting an ACE inhibitor/ARB** or kidneys differ by **>1.5 cm**."
- "**Pseudohypertension** — resistant hypertension **without end-organ damage**; test with the **Osler manoeuvre**; error is **10–15 mmHg**."
- "**Resistant hypertension = uncontrolled despite three agents including a diuretic.**"
- "**Exclude non-adherence, inadequate diuretic dose, NSAIDs and white-coat effect before labelling resistance.**"
- "The **2025 AHA/ACC guideline screens all resistant hypertensives for primary aldosteronism regardless of potassium**, and **continues all drugs except MRAs** during testing."
- "**Targets should be individualised by functional status, not chronological age.**"

Q9. Complete Heart Block

15–20 High-Yield Points

DEFINITION AND ELECTROPHYSIOLOGY

1. **Complete (third-degree) heart block** is a **total failure of conduction between the atria and the ventricles**, resulting in **regular atrial activity with an independent ventricular escape rhythm** — atrioventricular dissociation.
2. The escape rhythm is **usually ventricular in origin**, with a **wide QRS complex** and a rate of about **30–40 beats per minute**.
3. A **nodal or junctional escape** with a narrow QRS implies the anatomical level of block is **higher — within the AV node or bundle of His**.
4. **The lower the origin of the escape rhythm, the less specialised and therefore the less reliable the conduction tissue** — this determines both the rate and the risk of asystole.

AETIOLOGY IN OLDER PEOPLE

5. **Idiopathic age-related fibrosis** of the conduction system (Lev's and Lenègre's disease) is the commonest cause in the elderly.
6. **Ischaemic heart disease** — acute inferior MI (usually reversible, nodal level) or anterior MI (infranodal, poor prognosis).
7. **Drugs** — beta blockers, non-dihydropyridine calcium channel blockers (verapamil, diltiazem), digoxin, and antiarrhythmics. **Concomitant use of diltiazem or verapamil with beta blockers increases the risk of bradycardia, heart block and asystole, particularly in older people.**
8. **Infiltrative disease** — cardiac sarcoidosis, amyloidosis.
9. **Neuromuscular disease — myotonic dystrophy type 1**, **Kearns-Sayre syndrome**, lamin A/C mutations.
10. **Iatrogenic** — following cardiac surgery, TAVI, or catheter ablation of the AV junction.
11. **Infective** — infective endocarditis with aortic root abscess, Lyme carditis; also hyperkalaemia and hypothyroidism as reversible causes.

CLINICAL FEATURES

12. **Syncope (Stokes-Adams attack)**, presyncope, dizziness, fatigue, exertional breathlessness, and worsening heart failure.
13. Examination: **slow regular pulse**, **cannon 'a' waves** in the JVP, **variable intensity of the first heart sound**, and a wide pulse pressure.
14. In frail older patients the presentation may be **falls, confusion, or functional decline** rather than classical syncope.

INDICATIONS FOR PERMANENT PACING

15. **Pacing should be undertaken in acquired complete heart block not attributable to reversible or physiologic causes, regardless of symptoms** — **Class I recommendation**.
16. **Complete heart block due to neuromuscular disease with conduction disorders** (myotonic dystrophy type 1, Kearns-Sayre syndrome) — **Class I**.
17. **Symptomatic complete heart block arising from clinically necessary guideline-directed therapy** (for example a beta blocker that cannot be stopped) — **Class I**.
18. **Infiltrative cardiomyopathy such as cardiac sarcoidosis with Mobitz II block** — **Class IIa**.

CHOICE OF PACING MODE

19. **DDD pacing is recommended over AAI or VVI** in those requiring permanent pacing for AV block (**Class I**), because it preserves AV synchrony.
20. **Single-chamber ventricular (VVI) pacing is effective** where frequent ventricular pacing is not expected, or where **significant comorbidities are likely to determine outcome** and limit the benefit of dual-chamber pacing (**Class I**).
21. **Active patients over 70 benefit from DDD pacing in terms of quality of life**; **UKPACE** (n=2021, mean age 80) found **no difference in all-cause mortality, AF or heart failure** between single- and dual-chamber pacing for AV block.
22. **Physiological pacing (CRT or His bundle pacing) should be considered** when **LVEF <50%** and **>40% ventricular pacing** is expected (**Class IIa**). **His bundle pacing may be considered** for AV nodal-level block (**Class IIb**).
23. **BLOCK-HF** showed CRT reduced the combined endpoint of urgent heart failure admission, death, or ≥15% increase in LV volume index, with about a **30% reduction in heart failure hospitalisation**, though no mortality benefit.
24. **In permanent or persistent AF where rhythm control is not planned, an atrial lead should not be implanted**

(Class III).

COMPLICATIONS AND GERIATRIC CONSIDERATIONS

25. Complications: **pneumothorax** (1–2% subclavian, <0.1% cephalic/axillary), bleeding, **myocardial perforation and tamponade (<0.2%)**, lead dislodgement, infection (<1%), and late device erosion or lead fracture. Early complications occur in about **7% within two weeks**; late complications in up to **10%**.
26. **Increasing age was not associated with a higher risk of complications** (FOLLOWPACE) — female sex and low BMI were.
27. In cachectic patients with thin skin or skeletal deformity from osteoarthritis or osteoporosis, the device may need to be placed **submuscularly** to avoid erosion.
28. **All patients should undergo transthoracic echocardiography before implantation** to identify pre-existing LV dysfunction and guide mode selection.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Right ventricular apical pacing is the default	**Conduction system pacing — particularly left bundle branch area pacing (LBBAP)** — has largely superseded His bundle pacing and is increasingly the preferred physiological alternative
His bundle pacing as the physiological option	**His bundle pacing is limited** by low success rate, high thresholds, sensing problems and inability to correct distal block; **LBBAP overcomes most of these**
CRT for those with LVEF <50% and high pacing burden	**2025 ESC/EHRA consensus on conduction system pacing** still **favours biventricular pacing over CSP for standard CRT indications**, but supports CSP for bradycardia pacing with expected high pacing burden
Pacing-induced cardiomyopathy managed by upgrade to CRT	Increasing use of **primary LBBAP to prevent** pacing-induced cardiomyopathy in patients who will be pacing-dependent
Transvenous systems only	**Leadless pacemakers** are now an option in selected patients with limited venous access or high infection risk

Latest Updates (2023–Present)

- The **2025 ESC/EHRA consensus document on conduction system pacing** provides the first dedicated guidance on **His bundle pacing and left bundle branch area pacing**, and **favours biventricular pacing over CSP for traditional CRT indications** while endorsing CSP for bradycardia indications with an anticipated high ventricular pacing burden (*EP Europace* 2025).
- **LBBAP produces a significantly narrower paced QRS** than biventricular pacing (about **129 ms versus 157 ms**), with **lower pacing thresholds and shorter procedure and fluoroscopy times**, and comparable improvement in LVEF and NYHA class.
- **Pacing-induced cardiomyopathy** is now a well-recognised complication of chronic right ventricular apical pacing, and is a major driver of the shift toward conduction system pacing in patients with complete heart block and preserved LV function (*Circulation* 2024–2025).
- **Leadless LBBAP** using left endocardial pacing systems has been demonstrated in early case series (*HeartRhythm Case Reports* 2025), pointing toward completely lead-free physiological pacing.
- Meta-analyses through 2025–2026 continue to show **CSP benefit is clearest in patients with LBBB morphology** and less consistent in non-LBBB intraventricular conduction delay.
- In older patients, the decision remains individualised — **VVI pacing is still entirely appropriate** where comorbidity dominates prognosis, and current guidelines explicitly preserve this option.

Examiner's Tip — Mark-Earning Lines

- "**Complete heart block = AV dissociation with an independent escape rhythm**, ventricular escape at **30–40 bpm with wide QRS**."
- "**The lower the escape focus, the less reliable the conduction tissue.**"
- "**Pace all acquired complete heart block not due to reversible or physiologic causes, regardless of symptoms — Class I.**"
- "**DDD is preferred over VVI (Class I)**, but **VVI is effective where comorbidities determine outcome**."
- "**UKPACE found no mortality difference** between single- and dual-chamber pacing in the elderly with AV block."
- "**Consider CRT or His bundle pacing when LVEF <50% and >40% pacing is expected (Class IIa).**"

- “**Increasing age is not a risk factor for pacemaker complications** — female sex and low BMI are.”
- “**Left bundle branch area pacing** has now largely superseded His bundle pacing as the practical form of conduction system pacing.”

Q10. Heart Failure — Etiopathology, Clinical Presentation, Stages and Management

15–20 High-Yield Points

DEFINITION AND EPIDEMIOLOGY

1. **Heart failure (HF)** is a clinical syndrome in which structural or functional cardiac abnormality causes **reduced cardiac output and/or elevated intracardiac pressures**, producing typical symptoms and signs.
2. Prevalence rises steeply with age — HF is present in **13–14% of people over 80 years**.
3. Nearly **one-third of HF patients have chronic kidney disease**, and **more than 50% of HF patients have atrial fibrillation** (Framingham data).

ETIOPATHOLOGY

4. **Causes**: hypertensive heart disease, coronary artery disease, cardiomyopathies, valvular heart disease, arrhythmias, pericardial disease, myocarditis, drugs (alcohol, NSAIDs, chemotherapy, biologics), nutritional causes (**thiamine deficiency, anaemia**), and primary right heart failure from pulmonary disease.
5. **Hypertension increases the risk of HF two- to threefold** and is the commonest underlying cause in older people; treating it significantly reduces incident HF.
6. **Pathophysiology** rests on **neurohormonal activation** — sympathetic nervous system and renin-angiotensin-aldosterone system activation initially compensate but ultimately drive **adverse remodelling, fibrosis and apoptosis**.
7. Contributing age-related changes: **increased ventricular and arterial stiffness, impaired diastolic relaxation, reduced beta-adrenergic responsiveness, and mitochondrial dysfunction**.
8. **Precipitants** of decompensation: acute coronary events, **atrial fibrillation with rapid ventricular rate**, medication non-adherence, infection, excess fluid or sodium intake, anaemia, renal impairment, thyroid disease, and drugs such as NSAIDs and glucocorticoids.

CLASSIFICATION AND STAGES

9. **Left- versus right-sided**, **low-output versus high-output**, and **systolic versus diastolic** heart failure.
10. **NYHA functional classification**: **I** — no limitation; **II** — slight limitation, symptoms on ordinary activity; **III** — marked limitation, symptoms on less-than-ordinary activity; **IV** — symptoms at rest or on any activity.
11. **ESC classification by ejection fraction**: **HFrEF <40%**, **HFmrEF 41–49%**, **HFpEF ≥50%**. HFpEF and HFmrEF additionally require **elevated natriuretic peptides plus structural abnormality or diastolic dysfunction**.
12. **ACC/AHA stages** describe progression: **Stage A** at risk without structural disease; **Stage B** structural disease without symptoms; **Stage C** structural disease with current or prior symptoms; **Stage D** refractory HF requiring advanced interventions.

CLINICAL PRESENTATION

13. Symptoms — exertional dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, fatigue, reduced exercise tolerance, ankle swelling.
14. Signs — raised JVP, displaced apex, third heart sound, basal crackles, hepatomegaly, ascites, pleural effusion, peripheral oedema.
15. **One-third of older people with HF display none of these signs**, and comorbidities confuse the picture; individual symptoms and signs have **low sensitivity**, but their **combination** supports the diagnosis.
16. In older people presentation is often atypical — **confusion, falls, functional decline, or unexplained weight loss**.

DIAGNOSIS

17. The **ESC algorithm** combines symptoms, signs, prevalent heart conditions and an abnormal ECG; the presence of any of these prompts **natriuretic peptide measurement**.
18. **BNP >35 pg/ml or NT-proBNP >125 pg/ml** should trigger echocardiography. **Normal levels make HF unlikely.** Levels are equally predictive in HFrEF and HFpEF and carry prognostic value.
19. **Echocardiography** is the key confirmatory test; **chest X-ray** helps exclude COPD and pulmonary fibrosis.

MANAGEMENT — NON-PHARMACOLOGICAL

20. **Smoking cessation** (RR of HF is 1.75 in current smokers), **alcohol counselling**, **sodium restriction to about 1500 mg/day**, fluid restriction where there is dilutional hyponatraemia, patient education, medication review, vaccination, multidisciplinary input, and structured follow-up.
21. **Exercise training reduces mortality** (HR 0.65) and counteracts the deconditioning spiral; it should be offered to older HF patients.

MANAGEMENT — PHARMACOLOGICAL (HFREF)

22. **All patients** should receive an **ACE inhibitor or ARB regardless of NYHA class**, plus **optimal diuretic therapy to maintain euvolaemia**.
23. **Symptomatic patients** should also receive a **beta blocker** (carvedilol, bisoprolol, nebivolol, or modified-release metoprolol — benefit demonstrated up to age 80) and a **mineralocorticoid receptor antagonist** (spironolactone 12.5–50 mg reduced morbidity and mortality by **30%** in NYHA III–IV; eplerenone benefits mild symptoms).
24. **ARNI (sacubitril/valsartan)** reduced cardiovascular death and HF admission (HR 0.80) versus enalapril; **do not combine with an ACE inhibitor** and **wait 36 hours after the last ACE inhibitor dose**.
25. **Ivabradine** is added if the patient remains symptomatic in **sinus rhythm with heart rate >70/min** (HR 0.82 for CV death and HF hospitalisation).
26. **Digoxin** reduces hospitalisation but not mortality (DIG trial); in those over 70 use **0.125 mg daily**, targeting a plasma level of **0.5–0.9 ng/ml**, with monitoring of potassium and renal function.
27. **Hydralazine-isosorbide dinitrate** is used in self-declared Black patients and as an alternative when ACE inhibitors/ARBs are contraindicated.
28. **"Start low and go slow"** is the governing principle in older people, with monitoring of BP, creatinine and potassium after each dose change.

DEVICE THERAPY AND PROGNOSIS

29. **CRT** if QRS >130 ms; **ICD** for secondary prevention after cardiac arrest or ventricular arrhythmia, and for primary prevention in NYHA II–III HFrEF with ischaemic or dilated cardiomyopathy and expected survival >12 months. Mortality benefit is seen across all age groups including >75, though the effect attenuates with age.
30. **HFpEF trials have been largely negative** — CHARM-Preserved, I-PRESERVE, PEP-CHF, SENIORS, DIG-ancillary, TOPCAT and PARAGON-HF showed **no mortality benefit**, with some reduction in hospitalisation.
31. **Prognosis remains poor** despite therapy; **multidisciplinary team involvement and advance care planning, including palliative care, are of paramount importance**.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Sequential therapy: ACE inhibitor/ARB → beta blocker → MRA → consider ARNI	**Four pillars started early and together**: **ARNI/ACEi, beta blocker, MRA, and SGLT2 inhibitor**, with rapid up-titration
SGLT2 inhibitors not included	**SGLT2 inhibitors are recommended across the entire ejection fraction spectrum** (HFrEF, HFmrEF, HFpEF)
HFpEF has no disease-modifying therapy (all trials negative)	**SGLT2 inhibitors and finerenone now have proven benefit in HFpEF/HFmrEF**
Slow, cautious up-titration after discharge	**STRONG-HF "high-intensity care"** — rapid up-titration with frequent review after acute HF improves outcomes
Spironolactone/eplerenone as the only MRAs	**Finerenone**, a non-steroidal MRA, is FDA-approved (2025) for **HF with LVEF ≥40%**
ESC classification: HFmrEF = "mid-range"	Now termed **"mildly reduced"** ejection fraction

Latest Updates (2023–Present)

- The **2023 ESC Focused Update** of the HF guidelines recommends **SGLT2 inhibitors across the whole LVEF spectrum**, and recommends **SGLT2 inhibitors and finerenone for prevention of HF in diabetic chronic kidney disease**.
- **FINEARTS-HF** (*NEJM* 2024; presented ESC 2024) enrolled **6,001 patients with LVEF ≥40%** (mean age **72 years**, 48% with eGFR <60 ml/min) and showed **finerenone reduced worsening HF events and cardiovascular death**. The FDA approved finerenone for **HF with LVEF ≥40% in 2025**.
- Benefit of finerenone was **independent of NYHA class, KDIGO risk category, atrial fibrillation, diabetes status, and concomitant SGLT2 inhibitor use** (*Circulation* 2025; *JACC* 2025).
- An **individual patient-level meta-analysis of MRAs in heart failure** (*Lancet* 2024) confirmed benefit across the ejection fraction spectrum, with greater effect in HFrEF.
- **STRONG-HF** established that **rapid up-titration of guideline-directed medical therapy with close follow-up ("high-intensity care") after an acute HF episode improves outcomes** — a strategy that must be applied thoughtfully in frail older adults.
- **Intravenous iron** (ferric carboxymaltose/derisomaltose) improves symptoms, functional capacity and quality of life in HF with iron deficiency, and reduces HF hospitalisation.
- The first **guideline addressing cardiovascular-kidney-metabolic (CKM) syndrome** was published in 2026, formalising the integrated management of the HF–CKD–diabetes–obesity cluster that dominates geriatric practice.

Examiner’s Tip — Mark-Earning Lines

- “**HFrEF <40%, HFmrEF 41–49%, HFpEF ≥50%** — the latter two need **raised natriuretic peptides plus structural or diastolic abnormality**.”
- “**One-third of older people with heart failure display none of the classical signs.**”
- “**BNP >35 pg/ml or NT-proBNP >125 pg/ml** prompts echocardiography; **normal levels make HF unlikely**.”
- “**Spironolactone reduced morbidity and mortality by 30% in NYHA III–IV**; **ARNI gave HR 0.80** versus enalapril.”
- “**Digoxin 0.125 mg daily in those over 70, target level 0.5–0.9 ng/ml.**”
- “**Start low and go slow**, monitoring BP, creatinine and potassium after each dose change.”
- “**Four pillars — ARNI/ACEi, beta blocker, MRA, SGLT2 inhibitor — started early and together.**”
- “**FINEARTS-HF established finerenone for HF with LVEF ≥40%**, with FDA approval in 2025.”

Q11. Management of Systolic Heart Failure in an Elderly Patient with CKD (GFR 40 ml/min)

15–20 High-Yield Points

FRAMING THE PROBLEM

1. This is **HFrEF with stage 3b chronic kidney disease** — the classic **cardiorenal** situation in geriatric practice.
2. **CKD is present in nearly one-third of heart failure patients**; renal function declines with age and creatinine clearance is often below 60 ml/min in older HF patients.
3. Renal impairment in HF arises from **reduced renal perfusion, renal vasoconstriction, renal venous congestion**, and **over-diuresis**; older people are also **less able to excrete excess sodium and water**.
4. Importantly, **a GFR of 40 ml/min does not contraindicate disease-modifying therapy** — it mandates lower starting doses, slower titration, and closer monitoring.

ASSESSMENT FIRST

5. Confirm the diagnosis with **echocardiography** and **natriuretic peptides**, remembering that **NT-proBNP is elevated by renal impairment itself** and must be interpreted accordingly.
6. Perform a **comprehensive geriatric assessment** — frailty, cognition, functional status, polypharmacy, nutrition, and patient preference.
7. **Exclude reversible contributors**: renal artery stenosis, obstructive uropathy, NSAIDs, hypovolaemia, and contrast exposure.
8. Establish **baseline creatinine, eGFR, potassium and blood pressure** before starting or changing therapy.

DISEASE-MODIFYING THERAPY

9. **ACE inhibitor or ARB** — start at low dose (for example **enalapril 2.5 mg twice daily**) and up-titrate slowly. Even **low doses provide benefit** if the maximum dose cannot be reached.
10. Accept a **rise in creatinine of up to 30% and a fall in eGFR** after initiation — this is haemodynamic, not nephrotoxic, and is not a reason to stop. Beyond 30%, halve the dose and investigate.
11. **Do not combine an ACE inhibitor with an ARB** — the combination failed to reduce mortality and carries significant risk of **renal impairment, hyperkalaemia and hypotension**.
12. **Beta blocker** — carvedilol, bisoprolol, nebivolol, or modified-release metoprolol. Beta blockers are **not renally limited** and are often the best-tolerated pillar in CKD. **Start low, go slow.**
13. **Mineralocorticoid receptor antagonist** — spironolactone or eplerenone. Use with **great caution at GFR 40**: start **12.5 mg daily**, check **potassium and creatinine at 1 week, 4 weeks, then periodically**. Withhold if **potassium >5.0 mEq/l**.
14. **ARNI (sacubitril/valsartan)** — may replace the ACE inhibitor/ARB; note **hyperkalaemia, hypotension and angioedema** as adverse effects, and observe the **36-hour washout** from any ACE inhibitor.
15. **Diuretics** — loop diuretics (furosemide, bumetanide, torsemide) are the mainstay for congestion. **Higher doses are needed in CKD** because tubular delivery of drug is reduced. **Diuretics are less effective in the elderly and increase the risk of electrolyte abnormality.**
16. In diuretic resistance, use **intravenous loop diuretic** or **sequential nephron blockade** by adding a thiazide (metolazone) — but this greatly increases the risk of hypokalaemia, hyponatraemia and AKI, and requires close inpatient monitoring.
17. **Ivabradine** if still symptomatic in sinus rhythm with heart rate >70/min — it has **no renal dose adjustment**, making it useful here.
18. **Digoxin** — reduce to **0.125 mg daily or alternate days**; **renal impairment markedly increases toxicity risk**. Monitor potassium and levels (target 0.5–0.9 ng/ml).
19. **Hydralazine-isosorbide dinitrate** is a useful alternative when RAAS blockade cannot be tolerated because of hyperkalaemia or worsening renal function.

COMORBIDITY MANAGEMENT

20. Treat **anaemia** — common in this group from CKD, poor haematinic intake, and antiplatelet/anticoagulant use. **Intravenous iron is safe and effective** and improves symptoms, functional capacity and quality of life.
21. Manage **atrial fibrillation** with **beta blockers** (which reduce mortality in AF with HF) and/or digoxin; **rhythm control has not proven superior to rate control**.
22. **Avoid NSAIDs absolutely** — they worsen heart failure, cause AKI, and interfere with ACE inhibitors.
23. **Restrict sodium to about 1500 mg/day** and restrict fluid where there is dilutional hyponatraemia. Advise **daily weights**.

24. Review the **entire drug list** at every visit; polypharmacy and drug–drug interactions are the dominant iatrogenic hazards in this population.

MONITORING AND ESCALATION

25. Check **renal function, electrolytes and blood pressure after every dose change** and periodically thereafter. **Falls and postural hypotension** are the key clinical toxicities to look for.
26. **Device therapy** — CRT if QRS >130 ms; ICD only if expected survival exceeds 12 months, weighing comorbidity, frailty, and the ethical issue of eventual deactivation.
27. **Multidisciplinary follow-up with nephrology input** and, where trajectory is poor, early **advance care planning and palliative care**.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Triple therapy (ACEi/ARB + beta blocker + MRA), ARNI as an alternative	**Four pillars including an SGLT2 inhibitor**, started early and together
SGLT2 inhibitors not mentioned	**SGLT2 inhibitors (dapagliflozin, empagliflozin) are now a cornerstone** — they slow CKD progression *and* reduce HF events, and can be started down to **eGFR 20–25 ml/min/1.73 m²**
Renal impairment as a reason for caution with RAAS blockade	The **initial eGFR dip with SGLT2 inhibitors and RAAS blockade is expected and haemodynamic**, and does not warrant discontinuation
Spironolactone or eplerenone as the MRA options	**Finerenone** offers cardiorenal benefit with **lower rates of hyperkalaemia and AKI** than spironolactone in real-world comparisons
Slow, cautious up-titration	**STRONG-HF high-intensity care** — faster up-titration with close monitoring improves outcomes

Latest Updates (2023–Present)

- The **2023 ESC Focused Update** recommends **SGLT2 inhibitors across the full ejection fraction spectrum**, and specifically for **prevention of heart failure in diabetic chronic kidney disease**, alongside finerenone.
- **DAPA-CKD and EMPA-KIDNEY** established renal protection with SGLT2 inhibitors independent of diabetes, and **DAPA-HF and EMPEROR-Reduced** established HF benefit — making the SGLT2 inhibitor the single most useful addition for the HFrEF-plus-CKD patient.
- **FINEARTS-HF** subgroup analyses showed finerenone's benefit was **consistent across KDIGO risk categories** and in patients already receiving an SGLT2 inhibitor, supporting **complementary mechanisms** (*Circulation* 2025; *JACC* 2025).
- The **CONFIDENCE trial** (*NEJM* 2025) showed **finerenone plus empagliflozin reduced albuminuria more than either agent alone** in CKD with type 2 diabetes, supporting genuine combination cardiorenal therapy.
- Real-world comparative data show **finerenone associated with lower rates of hospitalisation, mortality, AKI and hyperkalaemia than spironolactone** — relevant where hyperkalaemia is the rate-limiting problem.
- **Potassium binders (patiromer, sodium zirconium cyclosilicate)** now allow RAAS blockade and MRA therapy to be **maintained rather than withdrawn** in patients with recurrent hyperkalaemia.
- The **2026 CKM syndrome guideline** provides the first integrated framework for managing the overlapping cardiovascular, kidney and metabolic disease burden typical of this patient.

Examiner's Tip — Mark-Earning Lines

- "**CKD is present in nearly one-third of heart failure patients**; renal impairment arises from **reduced perfusion, venous congestion and over-diuresis**."
- "**A GFR of 40 ml/min does not contraindicate disease-modifying therapy** — it mandates lower doses and closer monitoring."
- "**Accept a creatinine rise of up to 30%** after starting RAAS blockade — it is haemodynamic, not nephrotoxic."
- "**Never combine an ACE inhibitor with an ARB** — no mortality benefit, significant renal and hyperkalaemia risk."
- "**Start spironolactone at 12.5 mg; withhold if potassium >5.0 mEq/l**; recheck at 1 and 4 weeks."
- "**Higher loop diuretic doses are needed in CKD** because tubular drug delivery is reduced."
- "**Digoxin 0.125 mg daily or alternate days**; renal impairment markedly increases toxicity."
- "**Avoid NSAIDs absolutely.**"
- "**SGLT2 inhibitors are now the single most valuable addition** — they treat both the heart failure and the CKD, and

can be started down to eGFR 20–25 ml/min/1.73 m^2.”

Q12. Statins in the Elderly

15–20 High-Yield Points

MECHANISM AND EFFECT

1. **Statins are HMG-CoA reductase inhibitors** — they block the rate-limiting step of hepatic cholesterol synthesis, upregulate LDL receptors, and lower LDL-C by **20–55%**.
2. **Pleiotropic effects** matter as much as lipid lowering: statins **stabilise vulnerable atherosclerotic plaque** by reducing lipid content, minimising inflammation, and improving endothelial function.
3. **Three out of four acute myocardial infarcts** are thought to result from rupture or erosion of such vulnerable plaque.
4. **High-intensity statin therapy reduces LDL-C by 50–55%**; moderate intensity by about 30–49%.

SECONDARY PREVENTION — STRONG EVIDENCE

5. A meta-analysis of **28 randomised controlled trials** showed **significant benefit of statins for secondary prevention in all age groups, including patients over 75** (Cholesterol Treatment Trialists' Collaboration, *Lancet* 2019).
6. **Relative risk reduction of major vascular events per 1 mmol/l LDL-C reduction in those over 75 was 26%** — at least as good as in younger patients.
7. **Key trials in the elderly**: **PROSPER** (age 70–82, pravastatin 40 mg, RR 0.85 for cardiovascular events); **HPS** (up to age 80, simvastatin 40 mg, RR 0.76 for major vascular events, RR 0.87 for all-cause death); **LIPS** (fluvastatin 80 mg after first PCI, RR 0.78 for MACE).
8. **ACC/AHA guidance** — in patients over 75 with clinical ASCVD it is **reasonable to initiate moderate- or high-intensity statin therapy** after considering risk reduction, adverse effects, drug interactions, frailty and patient preference.
9. **Moderate-intensity statin may be preferable** in older adults because of higher adverse event rates, lower adherence, and higher discontinuation with high-intensity therapy.
10. **Secondary prevention treatment thresholds**: ACC/AHA and Canadian guidelines use **LDL-C >70 mg/dl** or **non-HDL-C >100 mg/dl**; ESC/EAS set an "ideal" target of **LDL-C <55 mg/dl** and **non-HDL-C <85 mg/dl**.

PRIMARY PREVENTION — WEAK AND CONFLICTING EVIDENCE

11. **Clinical trial data demonstrating statin benefit for primary prevention are not available for adults older than 75.**
12. In the primary prevention subgroup of **PROSPER (56% of participants), pravastatin showed no significant reduction** in coronary death, non-fatal MI, or stroke over 3.2 years.
13. **ALLHAT-LLT post hoc analysis** found **no benefit of pravastatin for primary prevention in those aged 75 and over**, with a **non-significant trend toward increased all-cause mortality**.
14. In a well-characterised cohort aged 75 and over, **LDL-C ≥130 mg/dl was not associated with increased 5-year ASCVD event rates**.
15. In the meta-analysis of statins by age, **there was no significant benefit among patients older than 70 for primary prevention**, with a trend toward smaller proportional risk reduction with increasing age.
16. **ACC/AHA states it "may be reasonable"** to start moderate-intensity statin in adults ≥75 with LDL-C between **70 and 189 mg/dl** — but equally, **it may be reasonable not to**. **ESC/EAS** says it "may be considered" if high risk, such as diabetes.
17. **EWTOPIA 75** (open-label, ezetimibe, entry LDL-C ≥140 mg/dl) is the main primary-prevention trial in this age group and carries considerable weight in meta-analyses.
18. Retrospective data show statins for primary prevention in those aged **75–84 with type 2 diabetes reduced cardiovascular events by 24% and all-cause mortality by 16%**.

ADVERSE EFFECTS AND PRACTICAL ISSUES

19. Adverse effects: **muscle aches, rhabdomyolysis, deranged liver function**, possible increase in type 2 diabetes, and concerns about cognitive dysfunction.
20. **Adherence is poor** — only about **one in four older people is still taking a statin two years after prescription**, and about **20% show "primary non-adherence"**, never starting at all.
21. **Time to benefit for statins in primary prevention is at least two years** — so **life expectancy, lag time to benefit, and the therapeutic horizon** must be weighed against competing mortality and polypharmacy.
22. The decision in adults 75 or older should be made through a **tailored, shared decision-making approach** balancing benefit, harm, and patient values.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Secondary prevention strongly supported; primary prevention uncertain over 75	**Unchanged** — the evidence gap persists; **STAREE** was designed to fill it and its results are awaited
Statin monotherapy is the mainstay	**Early combination therapy (statin + ezetimibe)** is increasingly favoured to reach targets faster and reduce statin dose-related adverse effects
Deprescribing not addressed	**Structured deprescribing** in advanced frailty and limited life expectancy is now an accepted and recommended practice
Age-based thresholds	Guidelines have shifted decisively toward **individualised, shared decision-making rather than age cut-offs**

Latest Updates (2023–Present)

- **STAREE (Statins in Reducing Events in the Elderly)** is the definitive trial for this question — **9,971 community-dwelling Australians aged ≥70 (mean age 74.7 years, 40% aged ≥75, 52% women, mean LDL-C 126 mg/dl)** randomised to **atorvastatin 40 mg or placebo**, with **co-primary endpoints of disability-free survival and major cardiovascular events** (*JAHA* 2024). Follow-up concluded in December 2025 and **results are awaited**; nested substudies (**STAREE-Mind** for brain MRI, **STAREE-HEART** for cardiac ageing) will report alongside.
- **PREVENTABLE** is the parallel US trial of atorvastatin 40 mg in adults ≥75, with dementia and disability endpoints — together with STAREE it will settle the primary prevention question.
- The **2026 ADA Standards of Care** state that it **"may be reasonable" to initiate moderate-intensity statin therapy in those aged over 75 with diabetes** not already on a statin, reflecting continued equipoise.
- A large **target trial emulation study** (*PLOS Medicine* 2026) in older adults with type 2 diabetes supported cardiovascular benefit of statins for primary prevention in this subgroup, aligning with guidelines that favour **individualised, shared decision-making over age-based thresholds**.
- **SCOPE-70** is comparing **low- versus moderate-intensity rosuvastatin** for primary prevention in those aged ≥70 — addressing the practical question of dose rather than whether to treat.
- Contemporary consensus increasingly frames the question as **"time to benefit versus life expectancy"** rather than "old versus young", and endorses **deprescribing statins in advanced frailty, terminal illness, or life expectancy under one year**.

Examiner's Tip — Mark-Earning Lines

- "Statins **stabilise vulnerable plaque** — three out of four MIs arise from plaque rupture or erosion."
- "**Secondary prevention benefit is proven in all age groups including over 75** — RRR of **26% per 1 mmol/l LDL-C reduction**."
- "**Primary prevention trial data are not available for adults older than 75**; PROSPER's primary prevention arm and ALLHAT-LLT were both negative."
- "**PROSPER RR 0.85; HPS RR 0.76 for major vascular events.**"
- "**Moderate-intensity statin is often preferable in older adults** because of adverse effects and poor adherence."
- "**Only one in four older patients is still on a statin at two years.**"
- "**Time to benefit in primary prevention is at least two years** — weigh this against life expectancy and lag time."
- "**STAREE and PREVENTABLE** are the trials that will settle the primary prevention question; STAREE results are awaited."

Q13. Ezetimibe — Indications, Mode of Action, Metabolism, Excretion, Side Effects and Dosage

> *Note: Pathy's covers ezetimibe's place in lipid management and the key trial evidence, but not its detailed pharmacokinetics. The pharmacology below is supplemented from standard pharmacological and regulatory sources.*

15–20 High-Yield Points

MODE OF ACTION

1. Ezetimibe is a **selective inhibitor of intestinal cholesterol absorption** — it is **not** a statin and does not inhibit HMG-CoA reductase.
2. It acts on the **Niemann-Pick C1-Like 1 (NPC1L1) transporter** on the brush border of jejunal enterocytes, blocking uptake of both **dietary and biliary cholesterol** and plant sterols.
3. Reduced cholesterol delivery to the liver **depletes hepatic cholesterol stores**, which **upregulates LDL receptors** and increases clearance of LDL from the blood.
4. It **does not affect absorption of triglycerides, fatty acids, bile acids, or fat-soluble vitamins A, D, E and K**.
5. This **complementary mechanism** to statins — blocking absorption while the statin blocks synthesis — is the basis of combination therapy.

EFFECT ON LIPIDS

6. **Monotherapy lowers LDL-C by about 18–20%**, with minimal effect on HDL-C and triglycerides.
7. **Added to a statin, ezetimibe produces a further LDL-C reduction of about 20%** — equivalent to roughly three doublings of the statin dose.
8. This makes it the **preferred first add-on** when a statin alone does not achieve target, or when high-intensity statin is not tolerated.

INDICATIONS

9. **Adjunct to statin therapy** in primary hypercholesterolaemia when LDL-C targets are not reached on maximally tolerated statin.
10. **Monotherapy** in patients who are **statin-intolerant** or in whom statins are contraindicated.
11. **Secondary prevention of ASCVD** — ACC/AHA guidance: in patients on maximal statin with **LDL-C ≥70 mg/dl**, adding ezetimibe **is reasonable** in very-high-risk ASCVD (Class IIa) and **may be reasonable** in others (Class IIb).
12. **Before adding a PCSK9 inhibitor** — guidelines specify that **ezetimibe should be added to maximal statin therapy before a PCSK9 inhibitor is considered (Class I)**.
13. **Homozygous familial hypercholesterolaemia**, as an adjunct to statin ± LDL apheresis.
14. **Homozygous sitosterolaemia (phytosterolaemia)** — a specific licensed indication, because ezetimibe also blocks plant sterol absorption.
15. **Mixed dyslipidaemia**, in combination with fenofibrate.

METABOLISM AND EXCRETION

16. **Absorption**: rapidly absorbed after oral dosing; can be taken **with or without food**. Time to peak concentration is about **4–12 hours** for the active metabolite.
17. **Metabolism**: undergoes extensive **glucuronidation in the small intestinal wall and liver** by **UGT enzymes**, forming **ezetimibe-glucuronide**, which is **pharmacologically active** and accounts for most of the drug effect. **Cytochrome P450 is not significantly involved**, which is why ezetimibe has **few drug interactions** — a real advantage in polypharmacy.
18. **Enterohepatic recirculation** of the glucuronide delivers drug repeatedly to its site of action and gives a **long half-life of about 22 hours**.
19. **Excretion**: approximately **78% in faeces** (mainly as unchanged ezetimibe) and **about 11% in urine** (mainly as the glucuronide).
20. **No dose adjustment is required** for mild hepatic impairment, renal impairment, or in the elderly. It should be **avoided in moderate to severe hepatic impairment** (Child-Pugh ≥7), where drug exposure rises several-fold.

DOSAGE

21. **10 mg once daily**, orally, with or without food, at any time of day. **There is no dose titration** — 10 mg is the only dose.
22. **Fixed-dose combinations** are widely available (ezetimibe with simvastatin, atorvastatin, or rosuvastatin) and improve adherence.

23. If given with a **bile acid sequestrant**, administer ezetimibe **at least 2 hours before or 4 hours after** the sequestrant, because binding resins reduce its absorption.

SIDE EFFECTS AND CAUTIONS

24. Generally **very well tolerated**. Common: **diarrhoea, abdominal pain, flatulence, fatigue, arthralgia, upper respiratory tract infection**.
25. **Myalgia and myopathy** occur, and the **risk of rhabdomyolysis increases when combined with a statin** — though the incremental risk is small.
26. **Elevated transaminases**, particularly in combination with a statin; check liver function before starting combination therapy.
27. Rare: **hypersensitivity reactions including angioedema and rash**, **hepatitis**, **cholelithiasis and cholecystitis**, **pancreatitis**, and **thrombocytopenia**.
28. **Interactions**: **ciclosporin** raises ezetimibe levels (and ezetimibe raises ciclosporin levels) — monitor levels; **fibrates** increase biliary cholesterol and the risk of gallstones; **cholestyramine** reduces efficacy.

KEY OUTCOME EVIDENCE

29. **IMPROVE-IT** — in post-ACS patients on **simvastatin 40 mg**, adding **ezetimibe 10 mg** gave a further **22% decrease in LDL-C**, a **6.4% relative and 2% absolute reduction** in the primary composite endpoint (cardiovascular death, MI, unstable angina, coronary revascularisation, stroke) over six years. This was the **first trial to prove that a non-statin LDL-lowering drug reduces events**, validating the "LDL hypothesis".
30. **EWTOPIA 75** — an open-label trial of **ezetimibe monotherapy in Japanese patients aged 75 and over** with LDL-C ≥140 mg/dl, showing reduction in cardiovascular events. It carries considerable weight in meta-analyses of lipid lowering in the very old.
31. **PRECISE-IVUS** — ezetimibe plus atorvastatin produced greater **coronary plaque regression** on intravascular ultrasound than atorvastatin alone.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
Ezetimibe added when statin alone fails to reach target	**Upfront combination (statin + ezetimibe) from the outset** is increasingly recommended, especially in high-risk ACS patients
Statin dose maximised first, then ezetimibe added	Evidence favours **moderate-intensity statin plus ezetimibe over high-intensity statin monotherapy** — similar LDL-C reduction with **fewer muscle-related adverse effects and better adherence**
Ezetimibe as the sole non-statin add-on	Now one of several: **bempedoic acid, PCSK9 inhibitors, and inclisiran** have all entered practice
Limited data in the very old	**EWTOPIA 75** provides direct randomised evidence in patients aged ≥75

Latest Updates (2023–Present)

- **Upfront combination lipid-lowering therapy** (moderate-intensity statin plus ezetimibe from the start) is now favoured in high-risk patients over sequential dose escalation, on evidence that it achieves targets faster with **fewer statin-associated muscle symptoms** — highly relevant to older adults, in whom myalgia is a major cause of discontinuation.
- The **2023 ESC ACS Guideline** endorses early, intensive lipid lowering after ACS, with **ezetimibe added early** rather than after a prolonged period of statin monotherapy.
- **Bempedoic acid** (an ATP-citrate lyase inhibitor, acting upstream of HMG-CoA reductase and **not activated in skeletal muscle**) is now a further option for statin-intolerant patients, with cardiovascular outcome benefit demonstrated in **CLEAR Outcomes** (*NEJM* 2023). It is often combined with ezetimibe.
- **Inclisiran**, a twice-yearly siRNA targeting PCSK9, offers a **6-monthly dosing schedule** that is attractive for adherence in older adults with polypharmacy.
- Ezetimibe's position as a **mandatory step before PCSK9 inhibitor initiation** is retained in current ACC/AHA guidance, largely on cost-effectiveness grounds.
- **Generic ezetimibe** is inexpensive and widely available in India, making it the most cost-effective non-statin LDL-lowering agent for routine practice.

Examiner's Tip — Mark-Earning Lines

- "Ezetimibe **inhibits the NPC1L1 transporter** on jejunal enterocytes, blocking absorption of dietary and biliary

cholesterol."

- "It **does not affect absorption of triglycerides, fatty acids, bile acids, or fat-soluble vitamins**."
- "**Monotherapy lowers LDL-C by ~18–20%; added to a statin, a further ~20%** — equivalent to three doublings of the statin dose."
- "**Glucuronidated in the intestinal wall and liver; the glucuronide is the active metabolite. CYP450 is not involved**, hence few interactions."
- "**Enterohepatic recirculation gives a half-life of about 22 hours; 78% faecal and 11% urinary excretion.**"
- "**Dose is 10 mg once daily — there is no titration.** No adjustment needed for renal impairment or old age; avoid in moderate-severe hepatic impairment."
- "**IMPROVE-IT was the first trial to prove a non-statin LDL-lowering drug reduces cardiovascular events** — 22% further LDL-C reduction, 6.4% relative risk reduction."
- "**EWTOPIA 75** provides randomised evidence for ezetimibe in patients aged 75 and over."

Q14. Low Molecular Weight Heparins — Types, Indications, Benefits and Side-Effect Profile

15–20 High-Yield Points

NATURE AND MECHANISM

1. **Low molecular weight heparins (LMWHs)** are produced by **chemical or enzymatic depolymerisation of unfractionated heparin (UFH)**, giving fragments of mean molecular weight **4,000–6,000 daltons** (versus 15,000 for UFH).
2. Like UFH, LMWH acts by **potentiating antithrombin**. However, the shorter chains cannot bridge antithrombin to thrombin.
3. Consequently **LMWH has a much greater effect on factor Xa than on thrombin (IIa)** — the **anti-Xa : anti-IIa ratio is about 3:1 to 4:1**, compared with **1:1 for UFH**.
4. Because of this, **LMWH cannot be monitored by the APTT** — it requires an **anti-factor Xa assay** where monitoring is needed.

TYPES

5. **Enoxaparin** — the most widely used; anti-Xa:anti-IIa ratio ~3.8:1.
6. **Dalteparin** — ratio ~2.7:1; the preferred agent in cancer-associated thrombosis in many protocols.
7. **Tinzaparin** — ratio ~1.9:1; the **largest mean molecular weight**, and therefore **least dependent on renal clearance**, which makes it useful in renal impairment.
8. **Nadroparin, reviparin, parnaparin, bemiparin** are other agents in use.
9. **Fondaparinux** is a **synthetic pentasaccharide** — a pure **indirect factor Xa inhibitor** with **no anti-IIa activity**. It is not strictly an LMWH but is used in the same clinical settings and is the agent of choice in **heparin-induced thrombocytopenia**.

ADVANTAGES OVER UNFRACTIONATED HEPARIN

10. **Longer half-life** (about 4 hours versus 1 hour), permitting **once- or twice-daily** dosing.
11. **Increased bioavailability** after subcutaneous injection (>90% versus about 30% for UFH).
12. **More predictable pharmacokinetics**, because LMWH binds far less to plasma proteins, endothelium and macrophages.
13. Therefore it can be given by **subcutaneous injection without routine monitoring, even at treatment doses**.
14. UFH's binding to multiple plasma proteins explains its **unpredictable kinetics, especially in the elderly**, where variability in these determinants is greater.
15. **UFH carries a higher bleeding risk in older adults** — patients over 72 treated with UFH for VTE had bleeding in **14.1% versus 7.1%**, and major bleeding in **11.1% versus 3.1%**, compared with younger patients.
16. Standard, non-weight-adjusted heparin doses in older patients produce **higher heparin levels and a tendency to higher APTT**.
17. **Unless there is an absolute contraindication, LMWH has generally replaced UFH and should be preferred** because of its predictable pharmacokinetics, efficacy and safety.
18. **Lower incidence of heparin-induced thrombocytopenia and of heparin-induced osteoporosis** than UFH.
19. **LMWH has a survival advantage in patients with malignancy and thrombosis** and has traditionally been the anticoagulant of choice in this group.

INDICATIONS

20. **Prophylaxis of venous thromboembolism** in medical and surgical inpatients, and after major orthopaedic surgery.
21. **Treatment of established DVT and pulmonary embolism**.
22. **Acute coronary syndromes** — unstable angina and NSTEMI, and as adjunct to fibrinolysis in STEMI.
23. **Bridging anticoagulation** around surgery or procedures in patients on warfarin.
24. **Cancer-associated thrombosis**, **pregnancy-associated VTE**, and **extracorporeal circuits** (haemodialysis).
25. **LMWH and UFH remain the preferred anticoagulants where surgery or clinical instability is involved** — cancer, sepsis, inability to take oral medication, or malabsorption.

SIDE EFFECTS AND CAUTIONS

26. **Bleeding** is the principal adverse effect.
27. **Renal clearance** — LMWHs are **predominantly eliminated by renal excretion**, so kidney impairment leads to **prolonged half-life and accumulation**. Dose should be reduced or the dosing interval extended; **current data are insufficient to establish definitive LMWH dose adjustment in older patients with renal impairment**.

28. **Heparin-induced thrombocytopenia (HIT)** — immune-mediated, causing **both thrombocytopenia and paradoxical arterial and venous thrombosis**, with mortality around **30% if unrecognised**. It is **less common with LMWH than UFH but can occur with either**. Treatment is **immediate withdrawal of all heparin** and substitution with **argatroban** (acute) or **fondaparinux** (subsequent treatment/prophylaxis). **Warfarin can worsen acute HIT** and must be withheld or reversed with vitamin K.
29. Other effects: **hyperkalaemia** (aldosterone suppression), **elevated transaminases**, **injection-site haematoma and skin necrosis**, **osteoporosis with prolonged use**, and **spinal or epidural haematoma** with neuraxial anaesthesia.
30. **Reversal**: **protamine sulfate neutralises only about 60% of LMWH's anti-Xa activity** (it fully reverses UFH). In overdose, LMWH will prolong the APTT, and bleeding may require protamine.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
LMWH is the anticoagulant of choice in cancer-associated thrombosis	**DOACs (apixaban, edoxaban, rivaroxaban) are now first-line for most cancer-associated VTE**, with LMWH retained for gastrointestinal/genitourinary malignancy and high bleeding risk
LMWH used as a bridge to warfarin for acute VTE	**DOACs are first-line for acute VTE** without cancer or severe renal insufficiency; LMWH is now a bridge only for dabigatran and edoxaban
No specific reversal agent	**Andexanet alfa** is available for factor Xa inhibitor reversal (though not licensed for LMWH); protamine remains partial for LMWH
Anti-Xa monitoring reserved for special cases	Anti-Xa monitoring increasingly recommended in **obesity, severe renal impairment, pregnancy and the very elderly**

Latest Updates (2023–Present)

- **DOACs have displaced LMWH as first-line therapy for most acute VTE**, including cancer-associated thrombosis, on the basis of equivalent efficacy with greater convenience — though **LMWH is still preferred in luminal gastrointestinal and genitourinary malignancy**, where DOACs increase bleeding.
- LMWH retains an essential role in **acute coronary syndromes, peri-procedural bridging, pregnancy, severe renal or hepatic impairment where DOACs are unsuitable, and patients unable to take oral medication**.
- Comparative reviews through 2025 (systematic review of enoxaparin versus dalteparin in arthroplasty) found **no consistent difference in efficacy or safety between individual LMWHs**, so choice is driven largely by **cost, availability and dosing convenience** — an important practical point in Indian practice.
- **Anti-Xa monitoring** is increasingly recommended in older patients with **eGFR <30 ml/min**, extremes of body weight, and pregnancy, where the usual assumption of predictable kinetics breaks down.
- **Fondaparinux and argatroban** remain the standard alternatives in confirmed or suspected HIT; **DOACs are being used increasingly for HIT** in the sub-acute phase.
- Emerging **factor XI/XIa inhibitors** (abelacimab, milvexian, osocimab) aim to provide "haemostasis-sparing anticoagulation"; **osocimab was superior to enoxaparin** for DVT prevention after knee replacement in the FOXTROT study, though phase 3 orthopaedic trials have not started.

Examiner's Tip — Mark-Earning Lines

- "LMWH acts through **antithrombin** but has a **greater effect on factor Xa than on thrombin**, ratio about **3–4:1 versus 1:1 for UFH**."
- "**LMWH cannot be monitored by APTT — it requires an anti-factor Xa assay.**"
- "Advantages: **longer half-life, greater bioavailability, more predictable pharmacokinetics**, allowing once-daily subcutaneous dosing without monitoring."
- "**UFH bleeding rates in the elderly: 14.1% versus 7.1%; major bleeding 11.1% versus 3.1%.**"
- "**Unless absolutely contraindicated, LMWH has replaced UFH and should be preferred.**"
- "**LMWH is predominantly renally excreted** — reduce dose or extend interval in renal impairment; **tinzaparin is least renally dependent**."
- "**HIT causes both thrombocytopenia and thrombosis, mortality ~30% if unrecognised.** Stop all heparin; use **argatroban acutely, fondaparinux subsequently**; **warfarin can worsen acute HIT**."
- "**Protamine reverses only about 60% of LMWH anti-Xa activity.**"

Q15. Role of Newer Anticoagulants

15–20 High-Yield Points

THE CLASSES

1. **Direct oral anticoagulants (DOACs)** comprise a **direct thrombin (factor IIa) inhibitor — dabigatran** — and **direct factor Xa inhibitors — apixaban, rivaroxaban, and edoxaban**.
2. They act **directly on their target enzyme**, unlike warfarin (which depletes vitamin K–dependent factors II, VII, IX, X) or heparin (which acts indirectly via antithrombin).

ADVANTAGES OVER WARFARIN

3. **No routine coagulation monitoring** and no INR testing.
4. **Rapid onset and offset of action**, so no bridging is required.
5. **Predictable dose response**, with far fewer **food and drug interactions** — warfarin is affected by vitamin K–rich foods, alcohol, antibiotics, amiodarone, and many other drugs.
6. **Wider therapeutic window** and no need for the frequent dose adjustment that ageing, illness, and renal decline force upon warfarin therapy.
7. Warfarin dose requirements **fall with age** — for every 10-year increase in age there is a **15% increase in the risk of an INR ≥5**.
8. A **meta-analysis of 12 studies (77,011 patients)** showed **significantly more effective stroke prevention with a 50% reduction in intracranial bleeding** with DOACs compared with warfarin.
9. **DOACs have therefore become the oral anticoagulant of first choice for the majority of patients.**

INDICATIONS

10. **Stroke prevention in non-valvular atrial fibrillation** — Class I recommendation, preferred over warfarin.
11. **Treatment of acute DVT and pulmonary embolism**, and **prevention of recurrence** — often without hospital admission.
12. **Prevention of VTE after elective hip or knee replacement**, including extended out-of-hospital prophylaxis.
13. **Secondary prophylaxis of VTE** at reduced dose.
14. **DOACs are the first choice of anticoagulant for acute VTE in patients without cancer or severe renal insufficiency**, mainly because of the lower intracranial bleeding risk versus VKAs.

DOSING IN VTE

15. **Dabigatran 150 mg twice daily** — requires **at least 5 days of initial LMWH/UFH/fondaparinux**.
16. **Rivaroxaban 15 mg twice daily for 21 days, then 20 mg once daily** — no lead-in parenteral therapy. Extended treatment: consider **10 mg once daily**.
17. **Apixaban 10 mg twice daily for 7 days, then 5 mg twice daily** — no lead-in. Extended treatment: consider **2.5 mg twice daily**.
18. **Edoxaban 60 mg once daily** after **at least 5 days** of parenteral anticoagulation; reduce to **30 mg once daily** if **creatinine clearance 30–50 ml/min, body weight ≤60 kg, or on strong P-glycoprotein inhibitors**.

EVIDENCE IN THE ELDERLY

19. In patients **>75, DOACs as a class were superior to warfarin in both efficacy and safety**. **Apixaban had the lowest risk of major bleeding**, and **apixaban, edoxaban and dabigatran had lower rates of intracranial haemorrhage** than rivaroxaban or warfarin.
20. Patients aged **≥75 treated with DOACs for VTE had a significantly lower risk of major bleeding than those on VKAs (relative risk 0.49)**.
21. **ARISTOPHANES** and the **PREFER in AF** registries confirmed the benefit in the very old, showing lower major bleeding with DOACs even in patients with **low body mass index or aged ≥85**.
22. **Rivaroxaban and edoxaban are once-daily** agents, which may aid adherence. **Dabigatran is not suitable for dosette boxes**, an important practical point in older people using pill organisers.

LIMITATIONS AND CONTRAINDICATIONS

23. **DOACs are only equivalent to an INR of 2–3**, so **warfarin remains mandatory** where a higher target is needed: **mechanical prosthetic heart valves**, **moderate-severe mitral stenosis**, recurrent thrombosis despite anticoagulation, and some patients with **antiphospholipid syndrome**.
24. **All DOACs are renally excreted to some extent** and undergo some hepatic metabolism — dose reduction is guided by **age, weight, renal function and concomitant drugs**.
25. In **low body weight** patients there is a risk of over-anticoagulation.

26. Because the **half-life is short**, **missed doses create periods of under-anticoagulation and increased stroke risk** — adherence matters more, not less, than with warfarin.

REVERSAL

27. **Idarucizumab** is a specific monoclonal antibody fragment reversing dabigatran. **Andexanet alfa** is a modified recombinant factor Xa decoy reversing apixaban and rivaroxaban.
28. **Prothrombin complex concentrate (PCC)** is used where specific agents are unavailable — the usual situation in much of India.

Current Practice Update

Textbook position (Pathy's 6th ed.)	Current evidence (2023–2026)
DOACs not first choice for cancer-associated thrombosis	**DOACs are now first-line for most cancer-associated VTE**; LMWH retained for gastrointestinal/genitourinary tumours
DOAC dosing based on labelled criteria	**Inappropriate dose reduction ("under-dosing") in the elderly is now recognised as a major and harmful problem** — it increases stroke without reducing bleeding
Four DOACs represent the newest class	**Factor XI/XIa inhibitors** are the true emerging class, promising "haemostasis-sparing anticoagulation"
LAA occlusion only when anticoagulation contraindicated	LAA occlusion has a **stronger recommendation** and is being tested as an alternative in broader populations

Latest Updates (2023–Present)

- **Factor XI/XIa inhibitors** are the major development. The rationale is **dissociating haemostasis from thrombosis** — factor XI contributes to pathological thrombus formation but is largely dispensable for normal haemostasis.
- **AZALEA-TIMI 71** (*NEJM* 2023): **abelacimab**, a monoclonal antibody given **monthly by subcutaneous injection**, reduced **major or clinically relevant non-major bleeding by 62–69%** versus rivaroxaban in AF, and the trial was **stopped early** for this overwhelming safety benefit. However, ischaemic strokes were **numerically more frequent** with abelacimab, and the trial was **not powered for efficacy**.
- **OCEANIC-AF**, the phase 3 trial of the oral FXIa inhibitor **asundexian** versus apixaban, was **stopped early for inferiority in efficacy** — a critical cautionary result showing that superior safety does not guarantee adequate efficacy.
- **LILAC-TIMI 76** is randomising about **1,900 AF patients deemed unsuitable for anticoagulation** (aged 65–74 with CHA2DS2-VASc ≥4, or ≥75 with CHA2DS2-VASc ≥3) to **abelacimab versus placebo**, with completion expected in late 2026. **LIBREXIA-AF** is testing **milvexian versus apixaban in 15,000 patients**, reporting from 2026.
- **OCEANIC-STROKE** (asundexian versus placebo added to antiplatelet therapy after non-cardioembolic stroke) and **LIBREXIA-STROKE / LIBREXIA-ACS** are testing factor XI inhibition as a **safer platform for dual pathway inhibition**.
- These agents **remain investigational**; no factor XI inhibitor is yet approved, and their eventual clinical role will be determined by the phase 3 results.
- For geriatric practice the immediate implication is different: the priority remains **correct DOAC dosing** and **avoiding both under-treatment and inappropriate dose reduction**, which the SAGE-AF study showed is common and associated with geriatric conditions.

Examiner's Tip — Mark-Earning Lines

- "**Dabigatran is a direct thrombin inhibitor; apixaban, rivaroxaban and edoxaban are direct factor Xa inhibitors.**"
- "**DOACs gave a 50% reduction in intracranial bleeding** versus warfarin in a meta-analysis of 77,011 patients."
- "**In patients over 75, DOACs are superior to warfarin in both efficacy and safety**; **apixaban has the lowest major bleeding risk**."
- "**DOACs are equivalent only to an INR of 2–3**, so **warfarin is mandatory for mechanical valves and moderate-severe mitral stenosis**."
- "**Edoxaban 60 mg is reduced to 30 mg if CrCl 30–50 ml/min, weight ≤60 kg, or on a strong P-glycoprotein inhibitor.**"
- "**Short half-life means missed doses cause under-anticoagulation** — adherence matters more, not less."
- "**Idarucizumab reverses dabigatran; andexanet alfa reverses apixaban and rivaroxaban.**"
- "**Factor XI inhibitors promise haemostasis-sparing anticoagulation** — AZALEA-TIMI 71 showed 62–69% less bleeding, but **OCEANIC-AF was stopped for inferiority**, so efficacy remains unproven."

Q16. Evidence-Based VTE Prophylaxis Protocol After Elective Total Hip / Knee Replacement

15–20 High-Yield Points

RATIONALE

1. **Major lower limb arthroplasty is among the highest-risk settings for venous thromboembolism**, because it combines all three elements of **Virchow's triad** — venous stasis from immobilisation, endothelial injury from surgical trauma, and a post-operative hypercoagulable state.
2. **Venous thrombosis is primarily a disease of old age**, and hip, knee and pelvic surgery are the classic predisposing factors, with obesity and malignancy as accessory factors.
3. In up to **50% of cases of venous thrombosis an additional underlying genetic predisposition becomes manifest** under these circumstances.
4. Without prophylaxis, DVT rates after arthroplasty historically reached **40–60%**; **thromboprophylaxis of surgical and medical patients at medium and high risk is now firmly established practice**.
5. Risk is **highest in the first 2 weeks** but remains elevated for up to **3 months**, which is why extended prophylaxis matters.

RISK ASSESSMENT

6. **Assess every patient pre-operatively** for VTE risk (prior VTE, cancer, thrombophilia, obesity, immobility, hormone therapy) and **bleeding risk** (active bleeding, thrombocytopenia, severe renal or hepatic impairment, recent intracranial haemorrhage).
7. **Older age, frailty, and renal impairment** shift the balance and demand dose adjustment rather than omission.

MECHANICAL PROPHYLAXIS

8. **Intermittent pneumatic compression devices (IPC)** should be applied from admission and continued while the patient is in bed.
9. **IPC alone** is used when the bleeding risk is unacceptable or the patient refuses pharmacological prophylaxis.
10. **Graduated compression stockings** may be added, but are contraindicated in peripheral arterial disease and severe neuropathy.
11. **Early mobilisation and adequate hydration** are essential adjuncts and are the cheapest interventions available.

PHARMACOLOGICAL OPTIONS

12. All of the following are supported as prophylactic agents after arthroplasty: **LMWH; fondaparinux; dabigatran, apixaban or rivaroxaban (for THA/TKA but not hip fracture surgery); low-dose unfractionated heparin; adjusted-dose vitamin K antagonist; or aspirin.**
13. **LMWH (enoxaparin 40 mg once daily subcutaneously)** remains the reference standard against which all other agents are compared.
14. **DOACs are used at reduced thromboprophylactic doses** and have been used specifically for **extended out-of-hospital thromboprophylaxis in high-risk orthopaedic surgery such as hip and knee replacement**.
15. **Fondaparinux 2.5 mg once daily** is an alternative; avoid if creatinine clearance is below 30 ml/min.
16. **Aspirin** is an option, but see the current evidence below — it is **not equivalent to LMWH**.

DURATION

17. **Treatment should be for at least 10 to 14 days and ideally up to 35 days.**
18. In practice: **up to 35 days after total hip replacement** and about **14 days after total knee replacement**, reflecting the different risk profiles of the two operations.

TIMING AND NEURAXIAL ANAESTHESIA

19. Start LMWH **12 hours before or 12 hours after surgery**, or at least **6–8 hours post-operatively** once haemostasis is secure.
20. With **neuraxial (spinal or epidural) anaesthesia**, observe strict intervals to avoid **spinal haematoma**: at least **12 hours after a prophylactic LMWH dose** before needle placement or catheter removal, and at least **4 hours after catheter removal** before the next dose.
21. The current standard of care in hip fracture is to **stabilise comorbid conditions, repair the hip (ideally under spinal anaesthesia), and encourage early ambulation with aggressive rehabilitation**, with prophylactic anticoagulation throughout.

GERIATRIC MODIFICATIONS

22. **Reduce the dose or extend the dosing interval** of LMWH in renal impairment; **tinzaparin** is least renally

dependent.

23. DOAC prophylactic doses require **renal-function-based adjustment**, and DOACs are **not recommended for hip fracture surgery** (as opposed to elective arthroplasty).
24. **Do not routinely screen asymptomatic patients with ultrasound** before discharge — it does not improve outcomes.
25. **Educate the patient and family** about the symptoms of DVT and PE before discharge, and ensure a clear plan for who supervises injections at home.

Current Practice Update

Textbook position (Essentials of Clinical Geriatrics / ACCP 2012)	Current evidence (2023–2026)
Aspirin listed as an equivalent option (Grade 1B) alongside LMWH and DOACs	**CRISTAL trial showed aspirin is inferior to enoxaparin** — symptomatic VTE **3.27% versus 1.76%** at 90 days
Choice between agents largely a matter of preference	Evidence now supports **anticoagulant prophylaxis over aspirin** for most patients, with aspirin reserved for genuinely low-risk patients or where anticoagulation is unsuitable
Duration “at least 10–14 days, ideally up to 35 days”	**Unchanged** — remains the standard, with 35 days for THA and about 14 days for TKA
Individual LMWHs assumed interchangeable	**Confirmed** — no consistent efficacy or safety difference between enoxaparin and dalteparin; choice driven by cost and availability

Latest Updates (2023–Present)

- The **CRISTAL trial** (*JAMA* 2022, secondary analysis *PLOS One* 2024) — a cluster-randomised, crossover, registry-nested trial across **31 Australian hospitals** — compared **aspirin 100 mg daily** with **enoxaparin 40 mg daily**, given for **35 days after hip and 14 days after knee arthroplasty**. In the full cohort of **11,728 patients**, symptomatic VTE within 90 days occurred in **3.27% with aspirin versus 1.76% with enoxaparin** (treatment difference 1.85%, p = 0.004), **favouring enoxaparin**.
- **Joint-related reoperation within 90 days was also lower with enoxaparin** (2.26% versus 2.47%, p = 0.03), and there was **no difference in major bleeding** — undermining the main argument for aspirin.
- This result directly challenges the widespread practice, reported in a 2021 surgeon survey, of **95% of practitioners using aspirin plus mechanical prophylaxis** as their default strategy.
- A **2026 systematic review and meta-analysis** of 8 studies and **117,367 patients** (*Frontiers in Medicine* 2026) again examined aspirin versus enoxaparin after THA, TKA and hip fracture surgery, confirming the continuing clinical importance of this question.
- Patients with a **history of prior VTE** are a group in whom aspirin appears clearly inadequate and anticoagulant prophylaxis should be used (*Journal of Arthroplasty* 2025).
- A **2025 systematic review comparing enoxaparin with dalteparin** in arthroplasty found **limited direct comparative evidence and no consistent difference**, supporting selection on the basis of **cost, availability and dosing convenience**.
- **Factor XI inhibitors** are being explored in this setting — **osocimab was superior to enoxaparin** for DVT prevention after knee replacement in the phase 2 **FOXTROT** study, and **milvexian** was studied in **AXIOMATIC-TKR**; phase 3 orthopaedic trials have not yet begun.

Examiner’s Tip — Mark-Earning Lines

- “Arthroplasty combines all three elements of **Virchow’s triad**.”
- “**Assess VTE risk and bleeding risk in every patient pre-operatively.**”
- “Options: **LMWH, fondaparinux, dabigatran/apixaban/rivaroxaban (for arthroplasty, not hip fracture), low-dose UFH, adjusted-dose VKA, aspirin, or IPC if bleeding risk is high.**”
- “**Duration at least 10–14 days, ideally up to 35 days — 35 days for hip, about 14 days for knee.**”
- “**Neuraxial anaesthesia: 12 hours after a prophylactic LMWH dose before needle placement or catheter removal; 4 hours after removal before the next dose.**”
- “**Enoxaparin 40 mg once daily is the reference standard.**”
- “**The CRISTAL trial showed aspirin is inferior to enoxaparin — symptomatic VTE 3.27% versus 1.76% at 90 days, with no difference in major bleeding.**”
- “**Do not routinely screen asymptomatic patients with ultrasound before discharge.**”

End of document.

MD Geriatric Medicine — High-Yield Examination Answers

Set 1: Assessment, Function, Cognition, Capacity and Geriatric Syndromes

Primary source: Pathy's Principles and Practice of Geriatric Medicine, 6th edition; supported by Kane's Essentials of Clinical Geriatrics and current international and Indian guidelines.

QUESTION 1

Comprehensive Geriatric Assessment — What It Is and Its Usefulness in Clinical Practice

A. 20 High-Yield Points

Definition and Concept

1. **Comprehensive geriatric assessment (CGA)**, also called **multidimensional geriatric assessment**, is a **diagnostic process, usually interdisciplinary**, that determines an older person's **medical, psychosocial, functional and environmental** resources and problems.
2. Its stated objective is to **develop an overall plan for treatment and long-term follow-up**. An assessment **without a linked care plan is NOT a CGA** — a favourite examination point.
3. It **differs from a standard medical evaluation** in three ways: it targets older people with complex problems, it **emphasises functional status and quality of life**, and it uses **interdisciplinary teams with quantitative scales**.
4. A purely psychosocial or environmental home visit **without a medical evaluation** also does not qualify as CGA, because multidimensionality is incomplete.
5. **Historical origin: Dr Marjory Warren**, London infirmary, **late 1930s**. Through evaluation, mobilisation and rehabilitation she got long-bedfast patients out of bed and home, and advocated **assessment and rehabilitation before any long-term institutionalisation**.

Rationale — Why in the Elderly? (five textbook reasons)

6. **Multi-morbidity and complexity** — systematic assessment helps set priorities among multiple conditions.
7. **Unrecognised problems** — many problems are never reported, often because they are **falsely thought to be non-modifiable effects of ageing**.
8. **Chronic conditions** — a diagnosis without information on **functional relevance** is of limited therapeutic value.
9. **Social and environmental interaction** — home layout and social network determine whether a person can stay at home.
10. **Functional status** — the main goal of geriatric medicine is to **prevent or delay functional decline**; benefit is greatest when intervention occurs **early** in the path from robustness to frailty to disability.

Components — What Is Assessed

11. CGA begins with a **functional status "review of systems"** built on three measures: **frailty, basic ADLs, and IADLs**.
12. **Principle of hierarchy / parsimony:** if a patient is **severely ADL-dependent, do not assess frailty**; if the patient is **robust or pre-frail, do not assess basic ADLs**.
13. Frailty is measured by two models — the **phenotype model** (Fried phenotype, Frailty Trait Scale, FRAIL index) and the **cumulative deficit model** (Frailty Index, Clinical Frailty Scale).
14. **Dimensions and tools (Table 96.1):** BADL — **Katz, Barthel, Lawton PSMS**; IADL — **Lawton, OARS**; Social — **Lubben Social Network Scale**; Affective — **Geriatric Depression Scale, Zung**; Cognitive — **MMSE (Folstein), Kahn MSQ**; Gait and balance — **Tinetti, Get-Up-and-Go**; Nutrition — **MNA**; Senses — **whispered voice test, Snellen**; Oral — **GOHAI**.
15. Two screens are **mandatory** in any older person with functional disability: **cognitive impairment and depression**.

Process in Office and Clinic Practice

16. **Step 1 — set priorities:** work first on the problem that **most bothers the patient**, or the problem on which resolution of others depends (**alcoholism, depression**).
17. **Step 2 — task and symptom analysis:** define the exact nature of the impairment and correlate it with **new drugs or dose changes (including over-the-counter), change in living conditions, and intercurrent acute illness**. Then examination, laboratory tests, therapist and social-work input, and a **long-term follow-up / case-management plan**.

Settings and Team

18. **Settings:** home (preventive visits), office and outpatient clinic, **day hospital**, **acute care for the elderly (ACE) unit**, post-acute rehabilitation unit, nursing home (**Resident Assessment Instrument**), and hospital-at-home programmes. Inpatient and day-hospital settings give intensity and speed for the frail; outpatient settings are cheaper.
19. **Team (minimum):** physician, nurse, social worker, physiotherapist, occupational therapist; **optimally** dietician, pharmacist, ethicist, home-care specialist. The **interdisciplinary team conference is critical** — present in most successful trials; teams mature through **forming, storming, norming, performing**.

Evidence of Usefulness — The Exam Core

20. **Proven benefits:** CGA **improves function and survival while reducing healthcare utilisation and costs**. Supporting data:

- **Improved diagnostic accuracy — 1 to more than 4 new diagnoses per patient**.
- **1993 Stuck/Rubenstein meta-analysis (28 trials, ~10,000 patients):** mortality down **22%** (hospital-based, 12 months) and **14%** (all programmes); living at home up **47%** (hospital-based) and **26%** (all); readmissions down **12%**; cognitive improvement up **47%**; physical function up **72%** on hospital units.
- **2011 Cochrane meta-analysis:** inpatient CGA increases the likelihood of being **alive and in one's own home**, with potential cost reduction.
- **Better prescribing** — CGA reduces unnecessary and inappropriate medication use.
- **Targeting matters:** best results when patients are at **high risk of deterioration yet retain rehabilitation potential** — exclude those **"too well or too ill."**
- **Programmes with hands-on care and/or long-term follow-up** outperform purely consultative programmes.
- **Weak areas:** outpatient CGA showed **no mortality benefit** in one meta-analysis; **preventive home visits are not recommended routinely** (benefit only with CGA-based extended follow-up in relatively well elders; **number needed to visit about 40** to prevent one nursing-home admission).
- **Oncology (SIOG task force):** CGA detects many problems missed by regular assessment and is associated with **fewer treatment side effects**.

B. Latest Updates (2023–Present)

1. German DGG S3 Guideline on CGA in Hospital (2024) — the first S3-level CGA guideline. Twelve evidence-based and eight consensus-based recommendations. Strongest evidence in **acute geriatric, oncology and orthopaedic/trauma wards**; weaker in emergency departments and general surgery. Core elements: **minimum CGA duration of 15 minutes** and **six core dimensions — self-help ability, mobility, cognitive function/delirium, affect, nutrition and social situation**; the **G8 questionnaire** is recommended for screening mainly in oncology.

2. Italian National CGA Guideline (2024) — 25 scientific societies plus the National Institute of Health, GRADE methodology. Sixteen recommendations from **117 studies** across primary care, clinics, emergency departments, hospital wards and nursing homes. CGA **reduces hospitalisation, mortality, institutionalisation and delirium risk**, improves prescribing appropriateness, and **maintains functional activities**. The **Multidimensional Prognostic Index (MPI)** is specifically recommended to predict negative outcomes.

3. Japanese CGA-Based Healthcare Guidelines 2024. The main objective of CGA is stated to be **personalised care through holistic management plans and targeted interventions — not merely status evaluation or prognostication**.

4. ASCO Geriatric Oncology Guideline Update (2023). Geriatric assessment should be used in **all patients over 65 with cancer**; all older adults with GA-identified deficits should receive **GA-guided management**, and the **Practical Geriatric Assessment (PGA)** is the recommended tool. Evidence base: **GAP70+** and **GAIN** trials.

5. ASCO Global (Resource-Stratified) Geriatric Assessment Guideline (2025) — adapts the 2023 guideline for **resource-limited settings** using ADAPTE methodology. Directly relevant to Indian practice.

6. Cochrane 2022 — Community CGA. Twenty-one studies, 7,893 participants, 10 countries, evaluating domiciliary CGA and CGA in general practice, with outcomes of death, nursing-home admission, unplanned hospital admission and emergency visits.

7. Meta-analysis of CGA in acute hospitalisation (2025) — CGA **may improve short-term survival and reduce readmission rates** after acute hospitalisation.

8. Perioperative CGA is now mainstream. The **2023 World Society of Emergency Surgery guidelines** advocate frailty assessment and multidisciplinary geriatric-surgical management in older trauma patients; the UK **NELA Best Practice Tariff (April 2023)** mandates perioperative team involvement in frailer laparotomy patients. CGA outperforms traditional preoperative risk models in predicting **postoperative delirium, infection and prolonged stay**.

9. Indian context. Evidence is predominantly from high-income countries and hospitalised patients; research on CGA in primary care and community settings in low- and middle-income countries is lacking. Under **NPHCE**, community services are delivered by **ASHA workers** with clinics at PHCs, but implementation is inconsistent. Short culturally adapted tools such as **EHSAS** are being validated for rural India because full CGA is impractical with the available workforce.

C. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Standardisation	Deliberately broad; "no single optimal blueprint"	**Minimum standards defined** — German S3: at least 15 minutes, six mandatory core domains
Prognostic tool	Many scales listed; none preferred	**MPI specifically recommended** (Italian guideline)
Oncology tool	SIOG could not recommend any specific tool	**PGA specifically recommended** (ASCO 2023)
Oncology strength	CGA "possibly" improves survival	**GA mandatory at 65 and above**; GA-guided management proven to cut severe chemotoxicity
Outpatient CGA	"Less impressive"; no mortality benefit	Italian guideline **supports** primary-care CGA for reducing hospitalisation and institutionalisation
Preventive home visits	Cannot be recommended as routine practice	**Largely unchanged** — Cochrane 2022 still shows uncertain benefit
Perioperative CGA	Not covered	Now **embedded in surgical pathways** (NELA BPT, WSES 2023, POPS model)
Emergency department	Not addressed	Recognised as important but **evidence still weak** (German S3)

D. Exam One-Liners

- **CGA without a care plan and follow-up is not a CGA.**
- **Marjory Warren, 1930s London** — mother of CGA and of British geriatrics.
- **Function is the common language of geriatrics; assessment is its core method.**
- **Hierarchy rule:** ADL-dependent, skip frailty testing; robust or pre-frail, skip basic ADL testing.
- **Targeting rule:** benefit is greatest in those **"not too well, not too ill"** — high risk with rehabilitation potential.
- **Hands-on care plus long-term follow-up** separates effective from ineffective programmes.
- **1993 meta-analysis:** mortality down 22%, living at home up 47%, physical function up 72% on hospital units.
- **Two mandatory screens** in functional disability: **cognition and depression**.
- **German S3 six core domains:** self-care, mobility, cognition/delirium, affect, nutrition, social situation.
- **ASCO 2023:** every cancer patient 65 and above gets a geriatric assessment, using the **PGA**.
- **Italian 2024:** use the **MPI** for prognosis.
- **India:** CGA delivery constrained by workforce — hence short screening tools within **NPHCE**.

QUESTION 2

Tools of Functional Assessment

A. 20 High-Yield Points

Framework

1. **Functional assessment** measures **what a person actually does in daily life**, not merely what diseases they have. Tools exist to make this measurement **standardised, reproducible and comparable across settings**.
2. **Purpose of using standardised tools:** they allow **information exchange between acute, rehabilitation and community settings**, permit **measurement of effectiveness**, foster **comparison of treatments**, and **minimise repeated collection of identical information** by different team members.
3. **Three levels of measurement (ICF, 2001): impairment** (body function or structure), **activity limitation** (difficulty executing a task), and **participation restriction** (problems in involvement in life situations). Different tools address different levels.
4. **Three functional core measures** in CGA: **frailty, basic ADLs, and IADLs**. The **hierarchy rule** determines which to use — severely ADL-dependent patients are not tested for frailty; robust patients are not tested for basic ADLs.
5. **Two methods of data capture: report** (by the patient or a proxy — tells you what they do under real living conditions) and **performance testing** (tells you what they can do under standard conditions). **Discrepancies between the two are common and informative.**

Basic ADL Tools

6. **Katz Index (1963)** — six items: **bathing, dressing, toileting, transferring, continence, feeding**. Graded independent/dependent, letters A to G. The classic **hierarchy of ADL loss**.
7. **Barthel Index (1965; modified 1988)** — ten items: feeding, bathing, grooming, dressing, bowels, bladder, toilet use, transfer, mobility, stairs. Scored **0–100** (or 0–20). It is an **observation of what the patient does**, and is the **RCP/BGS-endorsed ADL scale**, but has a **ceiling effect in ambulatory patients**.
8. **Lawton Physical Self-Maintenance Scale (PSMS, 1969)** — six items: **toileting, feeding, dressing, grooming, physical ambulation, bathing**. Each graded on **five levels**, dichotomised to a total of **0–6** (6 = independent). Published in the same paper as the Lawton IADL scale.

IADL Tools

9. **Lawton IADL scale (1969)** — eight items: **telephone, shopping, food preparation, housekeeping, laundry, transport, medications, finances**. IADLs need "instruments," and are the **first functions to be lost**.
10. **OARS Multidimensional Functional Assessment Questionnaire** — assesses IADLs alongside social and economic resources; widely used in surveys.
11. **Clinical rule:** if difficulty is reported, always ask **"how does she manage?"** — is the task neglected, or is someone else doing it?

Mobility, Gait and Balance Tools (high-yield numbers)

12. **Gait speed** over a 4-metre track: **below 0.6 m/s is abnormal**; **0.6–0.8 m/s is high-risk**. Each **0.1 m/s fall in gait speed equals a 7% rise in fall risk**.
13. **Timed Get-Up-and-Go (Mathias, Nayak and Isaacs, 1986): more than 12 seconds indicates high fall risk** (sensitivity 77%, positive predictive value 93% in the community).
14. **Tinetti Performance-Oriented Mobility Assessment (1986):** 14 tasks, **score below 24 out of 28 indicates fall risk**; takes 10–15 minutes.
15. **Short Physical Performance Battery (SPPB):** combines gait speed, **30-second chair stand** and the **4-stage balance test** (each position held **10 seconds**). **Berg Balance Scale:** 14 items, 0–56 (0–20 wheelchair-bound, 21–40 walks with assistance, 41–56 independent).

Composite, Global and Domain-Specific Tools

16. **Functional Independence Measure (FIM)** — scores **18 functions** across self-care, sphincter control, mobility, locomotion, communication and social cognition; the standard rehabilitation outcome measure.
17. **RCP/BGS endorsed scales (Table 98.3):** ADL — **Barthel Index**; vision, hearing and communication — **Lambeth Disability Screening Questionnaire**; memory — **Abbreviated Mental Test (10 items)**; depression — **Geriatric Depression Scale (30-item, 15-item short form)**; morale — **Philadelphia Geriatric Center Morale Scale**.
18. **Other domain tools (Table 96.1):** nutrition — **Mini Nutritional Assessment (MNA)**, SNAQ; special senses — **whispered voice test, Hearing Handicap Inventory, Snellen chart**; oral health — **GOHAI**; social network — **Lubben Social Network Scale**; cognition — **MMSE**; mood — **GDS, Zung**.
19. **Frailty tools: Fried phenotype** (weight loss, exhaustion, weakness, slow gait, low activity); **FRAIL scale** (Fatigue,

Resistance, Aerobic, Illnesses more than 5, Loss of weight 5%) — answerable in 15–30 seconds; **SOF index** (weight loss, cannot rise from chair 5 times without arms, reduced energy); **Clinical Frailty Scale** (9 points, seconds to apply); **Frailty Index** (30 or more deficits, continuous 0–1).

20. **Screening questions usable at the bedside:** "*Do you need help at home?*" (function) · "*Do you have trouble walking or lose your balance? Have you had a fall? Are you afraid of falling?*" (mobility) · "*Are you sad?*" (mood) · "*Have you lost weight?*" (nutrition) · "*Are you on seven or more medicines?*" (polypharmacy) · "*Do you wet yourself?*" (continence).

B. Master Comparison Table

Domain	Screening tool	Assessment tool	Key threshold
Frailty	FRAIL scale, Clinical Frailty Scale	Fried phenotype, Frailty Index	3 or more of 5 = frail
Basic ADL	—	**Katz, Barthel, Lawton PSMS**	Barthel below 60 = dependent
IADL	—	**Lawton IADL, OARS**	Loss precedes ADL loss
Gait / mobility	Gait speed, TUG	Tinetti POMA, SPPB, Berg	Gait below 0.8 m/s; TUG above 12 s; Tinetti below 24
Cognition	Mini-Cog, AD8	MMSE, MoCA, SLUMS	MMSE below 24
Mood	PHQ-2	GDS-15/30, PHQ-9, CSDD	GDS-15 of 5 or more
Nutrition	MNA-SF, SNAQ	MNA full, BMI, weight loss	MNA-SF 11 or less
Vision	Snellen	Formal ophthalmic review	Below 6/18
Hearing	Whispered voice test	Audiometry, HHIE	Fails at 2 feet
Social	Lubben Social Network Scale	OARS social section	LSNS-6 below 12
Rehabilitation outcome	—	**FIM**	18 items

C. Latest Updates (2023–Present)

1. WHO ICOPE — from deficit to capacity. The ICOPE 5-step pathway (screen, assess, intervene, follow up, community engagement) screens **six domains — mobility, cognition, vitality/nutrition, vision, hearing and psychological well-being** — either by a professional or by self-assessment through the **ICOPE Monitor** app. Step-2 tools are named explicitly: **SPPB for mobility; Mini-Cog, MoCA, MMSE or GPCOG for cognition; MNA, DETERMINE, MUST or SNAQ65+ for nutrition; PHQ-9 for mood; pure tone and speech audiometry for hearing**.

2. Minimum data sets are now mandated. The **German S3 guideline (2024)** requires **six core dimensions in at least 15 minutes**; the **Italian guideline (2024)** recommends the **Multidimensional Prognostic Index (MPI)** for prognosis; **ASCO 2023** mandates the **Practical Geriatric Assessment (PGA)** in oncology. The trend is **domain-mandated but tool-agnostic**.

3. Gait speed is being repositioned as the single best functional marker. A 2025 Age and Ageing study of about 3,600 older adults found that among all components of frailty and sarcopenia, **low physical performance (slow gait speed) was the best single predictor of incident basic and instrumental ADL disability**; sarcopenia as a whole construct was not associated with increased disability risk. **EWGSOP2 defines low physical performance as gait speed of 0.8 m/s or less.**

4. Automated and digital tools. The **electronic frailty index (eFI2)** is replacing the original eFI in English primary care from 2025, allowing **population-level functional risk stratification from routine records**. mHealth and wearable-based functional assessment gives **objective, quantitative data** in place of subjective observer-rated scales, but a 2024 systematic review found **high risk of bias and minimal integration into daily practice**.

5. Diagnostic accuracy data for screening instruments. In emergency-department settings, seven screens pooled across 1,663 participants gave **sensitivity 0.85 and specificity 0.77** against full CGA; **PRISMA-7 was the most sensitive (0.84–0.98)** and the **Clinical Frailty Scale the most specific**, both with AUROC around 0.90.

6. Indian use. LASI applies Katz-type ADL and Lawton-type IADL items; grip strength was the **most discriminant frailty component in Indian men (79.1%)** and physical activity in women (81.6%). **AWGS (not EWGSOP2) cut-offs** should be used for sarcopenia-related functional measures in Indians, and **BIA rather than DXA** is the practical mass-measurement modality.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Choice of tool	Broad menu; "no consensus on the best scale"	**Domain mandated, tool still flexible**, but specific tools named per setting
Gait speed cut-off	Below 0.6 m/s abnormal; 0.6–0.8 high-risk	**0.8 m/s or less** operative threshold (EWGSOP2/AWGS); best single predictor of disability
Who administers	Trained professional or therapist	**Self-assessment and digital screening validated**; community health workers in LMICs
Data source	Interview and bedside observation	**Automated extraction from electronic records** (eFI2); wearables and sensors
Framing	Deficit-based (ADL/IADL loss)	Complemented by **capacity-based** framing (WHO intrinsic capacity)
Sarcopenia link	Not integrated	Functional tools now feed directly into **sarcopenia case-finding** (SARC-F, grip strength, gait speed)

E. Exam One-Liners

- **Katz and Barthel measure ADL; Lawton measures IADL; Tinetti and TUG measure mobility; MNA nutrition; GDS mood; MMSE cognition; Lubben social.**
- **Barthel is what the patient does, not what they can do** — and has a **ceiling effect** in ambulant patients.
- **FIM has 18 items** across six areas and is the rehabilitation standard.
- **TUG above 12 seconds; Tinetti below 24 of 28; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **0.1 m/s slower gait equals 7% higher fall risk.**
- **PSMS has grooming and ambulation; Katz has continence and transferring** — the classic distinguishing point.
- **Report tells you what they do; performance tells you what they can do** — measure both.
- **WHO ICOPE six domains:** mobility, cognition, vitality, vision, hearing, psychological.
- **A tool is only useful if its result changes the care plan.**

QUESTION 3

Functional Assessment in the Elderly

A. 20 High-Yield Points

Why Function Matters

1. **Functional assessment** means measuring **what the person actually does in daily life**. In geriatrics, **function is the common language** and assessment is the core method.
2. In an older person, **function predicts outcome better than diagnosis**. There is **no direct relationship between disease and functioning** — the same illness produces very different disability in different people, so function must be measured separately.
3. Functional decline results from **medical, functional, psychological, social and environmental** risk factors acting together. Hence assessment must be **multidimensional**.
4. A **baseline functional measure is essential** so that progress can be monitored and the effect of treatment or rehabilitation judged. **Reassess at least weekly during rehabilitation.**
5. Three levels are assessed: **impairment** (the deficit) → **activity restriction** (ADL/IADL loss) → **participation restriction** (loss of social role). Participation restriction is **unique to the individual** and depends largely on the ability to adapt.
6. Mobility must always be tested — **about half of people aged 85 and over report difficulty walking**, and gait disorders threaten independence and cause falls.

The Core Measures

7. The functional "review of systems" rests on three measures: **frailty, basic ADLs, and IADLs**.
8. **Principle of hierarchy:** if the patient is **severely ADL-dependent, do not test frailty**; if **robust or pre-frail, do not test basic ADLs**. Match the depth of assessment to the patient and the setting.
9. **Basic ADLs (personal care):** bathing, dressing, toileting, transferring, continence, feeding, grooming — **Katz, Barthel, Lawton PSMS**.
10. **IADLs (tasks needing instruments):** cooking, shopping, housework, laundry, telephone, transport, money, medicines — **Lawton IADL, OARS**.
11. **IADLs are lost first, ADLs later**, so IADL loss is the earlier warning sign. Always ask **"how does she manage?"**
12. **Always record premorbid function as well as present function**, especially after acute illness, a fall or hospital admission.

Domains to Cover

13. **Mobility, gait and balance:** gait speed (**below 0.6 m/s abnormal; 0.6–0.8 high-risk**), **TUG above 12 seconds**, **Tinetti below 24 of 28**, 30-second chair stand, 4-stage balance test, SPPB, Berg Balance Scale.
14. **Two screens are mandatory** in any older person with functional disability: **cognition** (MMSE) and **depression** (GDS or Zung).
15. **Other essential domains:** nutrition (**MNA**, SNAQ, weight loss), **special senses** (whispered voice test, Snellen), **oral health** (GOHAI), **continence**, and **social network and support** (**Lubben Social Network Scale**).
16. **Also assess:** pain, polypharmacy (Beers/STOPP-START), continence, sleep, alcohol (CAGE, SMAST-G), caregiver capacity, financial resources, and **home environment**.

How to Do It in Practice

17. Use **both report and performance**. Reports tell you what the person does **under real living conditions**; performance tests tell you what they can do **under standard conditions**.
18. **Grade each task** as: independent without difficulty / independent but with difficulty or an aid / needs human help / unable even with help. Distinguishing "independent with difficulty" adds prognostic value.
19. **Perform a task analysis** of the specific problem. *Example:* "difficulty dressing" may be due to choosing clothes, remembering to finish, buttoning, reaching overhead, or bending for shoes — pointing respectively to **cognitive impairment, poor finger mobility, or shoulder, back or hip disease**. Each demands a different treatment.
20. **Correlate any new functional loss** with **new drugs or dose changes (including over-the-counter)**, **changes in living conditions**, and **intercurrent acute illness (even mild)**. Remember the **cascade** — impaired gait leads to depression and withdrawal, and **immobility of any cause produces deconditioning that persists after the cause is removed**. Finally, **link assessment to a plan**: rehabilitation steps of **assessment, goal setting, therapy, aids and adaptations, education, psychological support, evaluation and follow-up**.

B. Practical Bedside Scheme

Step 1 — History Premorbid and current ADL/IADL status · exact task that fails · duration and rate of decline · pain · falls · continence · drugs (including over-the-counter) · nutrition and weight change · mood and motivation · social support and caregiver capacity · housing and environment.

Step 2 — Examination Postural blood pressure · vision and hearing screening · **observation of gait** · musculoskeletal (tone, power, joint range of motion, feet) · neurological (focal signs, sensation, proprioception) · **skin over pressure areas** · cognition (MMSE/MoCA) and mood (GDS).

Step 3 — Performance testing Gait speed over 4 metres · Timed Up-and-Go · 30-second chair stand · 4-stage balance · grip strength · observed transfer and stair climbing.

Step 4 — Baseline investigations Complete blood count, blood chemistry, **serum calcium (mg/dL), sodium (mEq/L), creatinine (mg/dL)**, thyroid function, vitamin B12, **25-hydroxy vitamin D**, haemoglobin (g/dL), fasting glucose or HbA1c, urinalysis.

Step 5 — Formulate and act Identify **reversible causes** → treat disease and pain → **deprescribe** → refer to physiotherapy, occupational therapy, dietician and social work → prescribe aids and adaptations → set goals with the patient → arrange **follow-up and case management**.

C. Latest Updates (2023–Present)

1. WHO ICOPE and intrinsic capacity. The five-step pathway screens **six domains — mobility, cognition, nutrition/vitality, vision, hearing and psychological well-being** — and can be done by a professional or by self-assessment through the **ICOPE Monitor** app. Reference centiles for intrinsic capacity and real-world screening data were published in *Nature Aging* (2023, 2024).

2. German DGG S3 Guideline (2024) defines minimum requirements — **six core dimensions in at least 15 minutes** — the first guideline to set a floor standard for functional assessment in hospital.

3. Age-Friendly Health Systems "4Ms." What Matters, Medication, Mentation and Mobility. In an eight-hospital 2024 evaluation of 3,103 admissions, patients receiving all 4Ms had **fewer 30-day emergency visits (16% vs 22%)**; **Mobility generated the highest "act-on" rate (83%)** of the four.

4. Gait speed as the single best marker. A 2025 longitudinal study found **slow gait speed the best single predictor of incident ADL and IADL disability**, outperforming both frailty and sarcopenia as constructs.

5. Italian CGA guideline (2024) — across 117 studies, CGA **maintains functional activities** and reduces hospitalisation, mortality, institutionalisation and delirium.

6. Oncology. ASCO 2023 requires geriatric assessment including **physical function** in all patients over 65 on systemic cancer therapy, using the **Practical Geriatric Assessment**.

7. Indian data. LASI wave-1 (31,464 adults aged 60 and above) found **about 3% with severe ADL disability and about 6% with severe IADL disability**, with **7.4% ADL dependency**. Rural surveys show far higher figures — **ADL disability 13.7% and IADL disability 38.7%** in rural Goa — associated with sex, education, financial dependence, comorbidity, alcoholism and **sensory impairment**. Functional tools are being adapted for community health worker delivery under **NPHCE**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Core concept	Function measured as **deficit** (ADL/IADL loss)	**WHO shift to intrinsic capacity** — measure **reserve**, not only deficit
Number of domains	Broad, flexible list	**Standardised minimum sets** — ICOPE six domains; German S3 six dimensions in 15 minutes
Gait speed cut-off	Below 0.6 m/s abnormal	**0.8 m/s or less** widely used; slow gait now the best single predictor of incident disability
Who assesses	Interdisciplinary professional team	**Self-assessment and digital screening validated**; community health worker delivery in LMICs
Hospital framing	ACE units and geriatric assessment programmes	**4Ms Age-Friendly framework** — Mobility as a named, auditable care process
Sarcopenia	Not integrated into functional assessment	Functional assessment now **routinely linked to sarcopenia case-finding**

E. Exam One-Liners

- **Function is the common language of geriatrics.**
- **IADLs go first, ADLs later** — IADL loss is the earlier warning.
- **Two screens you must never omit: cognition and depression.**
- **Hierarchy rule:** ADL-dependent, skip frailty; robust, skip basic ADLs.
- **Record premorbid function, not just current function.**

- **TUG above 12 s; Tinetti below 24; gait speed below 0.6 m/s (Pathy) or 0.8 m/s (EWGSOP2).**
- **New functional decline equals a new drug, a new illness, or a new living situation** until proved otherwise.
- **Task analysis converts a vague complaint into a treatable diagnosis.**
- **WHO ICOPE six domains; 4Ms — What Matters, Medication, Mentation, Mobility.**
- **India (LASI): about 3% severe ADL and 6% severe IADL disability; 7.4% ADL dependency.**
- **Assessment without a linked care plan is not an assessment.**

QUESTION 4

Tests of Cognition and Rating Scales

A. 20 High-Yield Points

Principles

1. **Purpose of cognitive testing:** to establish **strengths and weaknesses of various functions relative to a standardised, norm-referenced scoring system**, so that the **nature and extent of cognitive deficits** can be determined, informing diagnosis and management and acting as a **comparator for past and future assessments**.
2. **A cognitive screen is not a diagnosis.** The MMSE and similar tools give an overall assessment of cognitive function, but **their use alone is not sufficient to establish a diagnosis of Alzheimer's disease or any dementia**.
3. **Cognitive screening is one of only two mandatory screens** (with depression) in any older person with functional disability.
4. **Key aspects of the mental status examination:** state of consciousness · general appearance and behaviour · orientation · **memory (short and long term)** · language · visuospatial function · **executive control functions** · other cognitive functions (calculations, proverb interpretation) · **insight and judgement** · thought content · mood and affect.
5. **Test all three components of memory: immediate recall** (repeating digits), **recent memory** (recalling three objects after a few minutes), and **remote memory** (details of early life).
6. **Executive function** involves the **planning, sequencing and execution of goal-directed activities**, and is **critical to the ability to perform IADLs**. Screen with the **clock-drawing test** (a component of the Mini-Cog) or **verbal fluency** (listing 12 animal names in one minute is normal).
7. **Interpretation depends on education and age.** The MMSE score is **dependent on sociocultural level and subject to a ceiling effect** — a crucial caveat in the Indian population, where illiteracy is common.
8. **Assess premorbid intellectual status** where possible (for example the National Adult Reading Test) to interpret other test scores correctly.
9. **Adapt tests to deficits.** In language impairment or dyspraxia, **recognition memory tests reduce the demand for expressive language** required by recall tests.
10. **Always include a standardised measure of mood** — depression is the commonest mimic of cognitive impairment.

Screening and Assessment Tools

11. **Recommended tools in primary care (Table 72.2):** - **Delirium: Confusion Assessment Method (CAM)** - **Dementia screening: AD8**, **Mini-Cog** - **Dementia assessment: SLUMS**, **MMSE**, **MoCA**
12. **Mini-Cog** screens **both memory (three-item recall) and executive function (clock drawing)** — quick, and relatively education-independent.
13. **MoCA and Addenbrooke's Cognitive Examination-Revised (ACE-R)** are described as **well-validated screening options**; ACE-R **incorporates the MMSE and clock-face drawing**.
14. **MMSE severity bands in Alzheimer's disease: mild 20–24, moderate 10–19, severe below 9.**
15. **Global staging scales combining cognition and ADLs: Global Deterioration Scale (GDS, Reisberg)** and the **Clinical Dementia Rating (CDR) scale**.
16. **Severe Impairment Battery (SIB)** was developed for subjects **too cognitively impaired for standard testing**.
17. **Memory-specific screens:** the **five-word test** and the **Memory Impairment Screen (MIS)** assess **anterograde verbal memory** at an initial consultation. For detailed evaluation, **free and cued recall** paradigms — the **Grober and Buschke test (Free and Cued Selective Reminding Test)** and the **California Verbal Learning Test** — distinguish mild Alzheimer's disease from healthy subjects with **more than 90% precision**, even when MMSE scores are similar.
18. **Domain-specific battery (Table 62.4 — Cardiff memory clinic):**

Domain	Tests
Premorbid ability	**National Adult Reading Test (NART)**
Cognitive screen / battery	**MMSE, MoCA, RBANS, Frontal Assessment Battery (FAB)**
Attention and concentration	Digits forward, digits backward, digit span
Language	**Boston Naming Test**, Irving Names Learning Test
Memory	Story recall (immediate and delayed), Kendrick tests, **California Verbal Learning Test**
Executive function	**Trail-Making Test A and B**, clock drawing
Visuospatial function	**Rey–Osterrieth Complex Figure**, clock drawing
Mood	**GDS-15**

Delirium Instruments

19. **Confusion Assessment Method (CAM)** — the standard; **sensitivity 94%, specificity 89%** with high inter-rater reliability. **Inattention** is tested at the bedside by **months of the year backwards, days of the week backwards, or digit span 3 or 4 backwards**. - **3D-CAM:** a structured **three-minute** screen — **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% in those without**. - **Best single item: "months of the year backwards"** (sensitivity 83%, specificity 69%). Best two items: months backwards plus "what is the day of the week?" (sensitivity 93%, specificity 64%). - **CAM-ICU** for intubated patients — inattention tested by squeezing on the letter A in "SAVEAHAART"; level of consciousness by **RASS score other than 0**.

Practical Conduct of Testing

20. Tests must be **acceptable to the person and contain nothing belittling**. **Consent must be obtained**, the purpose explained, and **sensory and physical limitations accommodated** — adequate lighting, earphone amplifiers, suitable seating, minimal distractions. Provide **realistic reassurance with positively phrased feedback that highlights strengths as well as weaknesses**, and at the end **allow patients to comment on their own performance**. Ideally an experienced psychologist or neuropsychologist performs formal testing, though **much useful information can be obtained by any suitably trained professional**. Introduce questions **non-threateningly**, because many patients with early deficits respond defensively.

B. Comparison of the Main Cognitive Tools

Tool	Items / time	Domains	Main strength	Main limitation
AMT (Hodkinson)	10 questions, 2 min	Orientation, memory	Very quick; RCP/BGS endorsed	Crude; misses executive and visuospatial deficits
Mini-Cog	3 min	3-word recall + clock drawing	**Relatively education-independent**; screens executive function	Screen only
AD8	8 items, informant	Change over time	Informant-based, detects change	Needs a reliable informant
MMSE	30 points, 10 min	Orientation, registration, attention, recall, language, construction	Most widely known; severity bands defined	**Education- and culture-dependent; ceiling effect; poor for executive function**; copyrighted
MoCA	30 points, 10–15 min	Adds executive, abstraction, visuospatial, attention	**Superior for mild cognitive impairment and executive dysfunction**	Lower specificity; education adjustment (+1 if 12 years or less)
SLUMS	30 points, 10 min	Adds executive and clock tasks	Free to use; education-stratified cut-offs	Less international validation
ACE-R / ACE-III	100 points, 20 min	Five domains; incorporates MMSE	Differentiates **Alzheimer's from frontotemporal dementia**	Long
RBANS	30 min	Repeatable battery	Serial testing without practice effect	Requires training
Frontal Assessment Battery	6 items	Frontal/executive	Detects subcortical and frontal deficits	Narrow
CAM / 3D-CAM / CAM-ICU	3–5 min	Delirium	**Gold standard for delirium**	Needs training; misses hypoactive cases if hurried
GDS (Reisberg) / CDR	Interview	Global staging	Combines cognition and function	Time-consuming
SIB	40 min	Severe dementia	Usable when MMSE floor is reached	Specialist tool

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria — Alzheimer's disease is now defined biologically. Diagnosis rests on **Core 1 biomarkers** — a positive **plasma p-tau217**, a positive **amyloid PET**, or abnormal **CSF ratios (p-tau181/Aβ42, t-tau/Aβ42, Aβ42/40)**. Cognitive testing now defines the **clinical stage**, not the disease itself. This is the single biggest conceptual change in the field.

2. Blood-based biomarkers have entered clinical use. Diagnostic models combining **plasma p-tau217 with age and ApoE genotype** achieve **AUC around 0.94** for Alzheimer's disease. In very elderly nursing-home and hospital populations, **plasma p-tau181, p-tau217 and GFAP differ significantly between cognitively normal and probable Alzheimer's groups**, while **Aβ42, Aβ40 and the Aβ42/40 ratio do not** — an important practical point, since amyloid ratios perform poorly in the oldest old.

3. Cognitive screens are being repositioned as triage. Rather than diagnosing, MMSE and MoCA increasingly serve to **decide who proceeds to biomarker testing**. Clinical trials now use combinations such as **CDR global score 0.5–1.0**

plus MMSE 21 or above plus a positive Core 1 biomarker for entry.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — has emerged as an **early indicator of dementia risk that may precede measurable cognitive decline**, and is being studied alongside plasma p-tau217.

5. Digital and mobile cognitive assessment. Mobile cognitive assessment systems have demonstrated **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening; future direction is **composite risk scores combining digital tests, wearables and plasma p-tau217**. Regulatory and ethical frameworks for data security, algorithmic transparency and equitable access are still being established.

6. Standardised inclusion in assessment frameworks. Cognition/delirium is one of the **six mandatory core dimensions** of the German S3 CGA guideline (2024); **cognition** is one of the **six WHO ICOPE domains**, with **Mini-Cog, MoCA, MMSE or GPCOG** named as step-2 assessment tools; **Mentation** is one of the **4Ms** of Age-Friendly Health Systems.

7. Indian context. In LASI wave-1, **impaired cognition was present in 9.3%** of adults aged 60 and above. Culture- and education-fair instruments are essential: **Hindi Mental State Examination (HMSE)**, **Vernacular MoCA versions**, **Rowland Universal Dementia Assessment Scale (RUDAS)**, **Indian Council of Medical Research Neuro-Cognitive Tool Box**, and **AIIMS Comprehensive Neuropsychological Battery in Hindi** are used in place of a directly translated MMSE, because **the standard MMSE penalises illiteracy heavily**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
Basis of Alzheimer's diagnosis	Clinical, supported by cognitive tests and imaging	**Biological — 2024 NIA-AA criteria** based on Core 1 biomarkers
Role of MMSE/MoCA	Screening and severity grading	**Staging and triage** to biomarker testing; no longer diagnostic on their own
Biomarkers	CSF amyloid and tau "in some centres"	**Plasma p-tau217 in routine diagnostic pathways**; AUC around 0.94 with age and ApoE
Amyloid ratios	Presented as useful	**Aβ42/40 performs poorly in the oldest old**; p-tau217 and GFAP superior
Delivery	Face-to-face testing by trained staff	**Mobile and computerised assessment shown equivalent to MMSE/MoCA**
Preclinical detection	Subjective cognitive decline and MCI	Adds **mild behavioural impairment (MBI)** as an early neurobehavioural marker
Indian practice	MMSE with education caveat	**Education-fair tools mandatory** — HMSE, RUDAS, vernacular MoCA, ICMR NCTB

E. Exam One-Liners

- **A cognitive screen is not a diagnosis** — MMSE alone cannot diagnose Alzheimer's disease.
- **MMSE bands:** mild 20–24, moderate 10–19, severe below 9.
- **MMSE is education- and culture-dependent with a ceiling effect** — the key limitation in India.
- **MoCA beats MMSE for mild cognitive impairment and executive dysfunction.**
- **Mini-Cog = 3-word recall plus clock drawing** — screens memory and executive function in three minutes.
- **Clock drawing and verbal fluency screen executive function**, which drives **IADL** performance.
- **CAM sensitivity 94%, specificity 89%; 3D-CAM takes three minutes.**
- **Best single delirium item: months of the year backwards.**
- **ACE-R incorporates the MMSE and clock drawing** and helps separate Alzheimer's from frontotemporal dementia.
- **Free and cued recall (Grober–Buschke) separates mild Alzheimer's from normal with over 90% precision** even at similar MMSE scores.
- **Global staging: Reisberg GDS and CDR** combine cognition with function.
- **SIB is for patients too impaired for standard testing.**
- **2024 NIA-AA: Alzheimer's disease is now a biological diagnosis** — plasma **p-tau217**, amyloid PET, or CSF ratios.
- **Always pair cognitive testing with a mood scale**, and obtain consent and premorbid ability first.

QUESTION 5

Cognitive Assessment Tools

A. 20 High-Yield Points

Classification — the Framework to Open With

1. Cognitive assessment tools fall into **four functional groups**, and stating this classification first earns marks: - **Delirium instruments** — CAM, 3D-CAM, CAM-ICU, 4AT - **Brief screening tools** — Mini-Cog, AD8, AMT, GPCOG, MIS, six-item screener - **Cognitive screening batteries** — MMSE, MoCA, SLUMS, ACE-III, RUDAS - **Detailed neuropsychological batteries and staging scales** — RBANS, CVLT, Trail-Making, FAB, Boston Naming, Rey–Osterrieth; CDR and Reisberg GDS for staging
2. **A second axis is the informant dimension — performance-based** (patient does the task: MMSE, MoCA) versus **informant-based** (a relative reports change: **AD8, IQCODE**). Informant tools detect **change from a personal baseline** and are invaluable when education confounds performance tests.
3. **The tool must match the question:** *Is this delirium?* → CAM. *Is there any cognitive problem?* → Mini-Cog or AD8. *How severe and in which domain?* → MoCA, MMSE, SLUMS. *Which dementia is it?* → ACE-III with a full battery. *How advanced is it?* → CDR or Reisberg GDS.

Delirium Tools

4. **CAM** — sensitivity **94%**, specificity **89%**, high inter-rater reliability. Four features: **acute onset and fluctuating course, inattention, disorganised thinking, altered level of consciousness** (features 1 and 2 plus either 3 or 4).
5. **Inattention testing at the bedside: months of the year backwards, days of the week backwards, digit span 3 or 4 backwards**; or the examiner may simply observe **inappropriate distraction or loss of the thread of conversation**.
6. **3D-CAM** — three-minute structured version: **sensitivity 96%, specificity 86% in patients with dementia**; **93% and 96% without dementia**. **CAM-ICU** for intubated patients uses the "SAVEAHAART" letter-A task and the **RASS**.

Brief Screens

7. **Mini-Cog — three-item recall plus clock drawing**; screens **memory and executive function** in about three minutes and is **relatively education-independent**, making it the most practical screen in Indian outpatient settings.
8. **AD8** — an **eight-item informant questionnaire** detecting change over time; useful when the patient's education level makes performance testing unreliable.
9. **Abbreviated Mental Test (Hodkinson, 10 items)** — the **RCP/BGS-endorsed** memory and cognition screen; extremely fast but crude.
10. **Memory Impairment Screen and the five-word test** assess **anterograde verbal memory** specifically at a first consultation.

Screening Batteries

11. **MMSE (Folstein, 1975)** — 30 points across orientation, registration, attention/calculation, recall, language and construction. **Interpretation is complex because thresholds depend on education and age**; it has a **ceiling effect** and **tests executive function poorly**. Severity bands: **mild 20–24, moderate 10–19, severe below 9**.
12. **MoCA (Nasreddine, 2005)** — 30 points; adds **trail-making, cube copy, clock drawing, verbal fluency, abstraction and delayed recall**, so it detects **mild cognitive impairment and executive/subcortical dysfunction far better than the MMSE**. **Add 1 point if formal education is 12 years or less.**
13. **SLUMS (Saint Louis University Mental Status)** — 30 points; free of charge, with **separate cut-offs for those with and without a high-school education**.
14. **ACE-R / ACE-III** — 100 points across **attention/orientation, memory, verbal fluency, language and visuospatial function**; ACE-R **incorporates the MMSE and clock-face drawing**, and the **VLOM ratio helps separate Alzheimer's disease from frontotemporal dementia**.
15. **RUDAS (Rowland Universal Dementia Assessment Scale)** — designed to be **culturally and linguistically fair**, needing no literacy; highly relevant to multilingual, variably literate Indian populations.

Detailed and Domain-Specific Tools

16. **Domain mapping (Table 62.4):** premorbid ability — **NART**; screening battery — **MMSE, MoCA, RBANS, FAB**; attention — **digit span forward and backward**; language — **Boston Naming Test**; memory — **story recall, California Verbal Learning Test**; executive — **Trail-Making A and B, clock drawing**; visuospatial — **Rey-Osterrieth Complex Figure**; mood — **GDS-15**.
17. **Free and cued recall tests** — the **Grober and Buschke test** and the **CVLT** — separate mild Alzheimer's disease from normal ageing with **more than 90% precision**, even when MMSE scores are identical, because they demonstrate a **hippocampal amnestic pattern (cueing does not improve recall)**.

18. **Staging scales: Clinical Dementia Rating (CDR)** and the **Reisberg Global Deterioration Scale** combine cognition with ADL impact. The **Severe Impairment Battery** is used when impairment is too severe for standard testing.

Rules of Use

19. **Practical conduct:** obtain **consent**, explain the purpose, ensure **adequate lighting, hearing amplification, suitable seating and no distractions**, introduce questions **non-threateningly**, phrase feedback **positively**, and give the patient a chance to comment on their own performance at the end. Assess **premorbid intellectual status** first, and **always add a mood scale**.
20. **Two cardinal caveats:** - **Depression and delirium must be excluded before any score is attributed to dementia** — screening tools become unreliable in delirium, and depression is the commonest reversible mimic. - **No cognitive screening test is appropriate for determining decision-making capacity.** Screens of **executive function** such as the **clock-drawing test** or the **Executive Interview** correlate better with decisional capacity than the MMSE, but capacity requires its own task-specific assessment.

B. Comparison Table — Choosing the Right Tool

Clinical question	Tool of choice	Time	Notes
Is this delirium?	**CAM / 3D-CAM / CAM-ICU**	3–5 min	Sensitivity 94%, specificity 89%
Rapid screen in a busy clinic	**Mini-Cog**	3 min	Education-independent; memory + executive
Screen when the patient cannot be tested	**AD8 or IQCODE** (informant)	3 min	Detects change from baseline
General cognitive assessment	**MoCA**	10–15 min	Best for MCI; add 1 point if education 12 years or less
Severity grading in known dementia	**MMSE**	10 min	Mild 20–24, moderate 10–19, severe below 9
Free alternative with education cut-offs	**SLUMS**	10 min	Education-stratified
Differentiating dementia subtypes	**ACE-III**	20 min	VLOM ratio; Alzheimer's vs frontotemporal
Illiterate or multilingual patient	**RUDAS, HMSE, vernacular MoCA**	10 min	Culture- and literacy-fair
Detecting early Alzheimer's memory pattern	**Grober–Buschke, CVLT**	20–30 min	Cueing fails to improve recall
Frontal or subcortical deficit	**FAB, Trail-Making B, verbal fluency**	5–10 min	Subcortical screen
Global staging	**CDR, Reisberg GDS**	Interview	Combine cognition and function
Severe dementia	**SIB**	40 min	Below the MMSE floor

C. Latest Updates (2023–Present)

1. 2024 NIA-AA Revised Criteria define Alzheimer's disease **biologically** through **Core 1 biomarkers — plasma p-tau217, amyloid PET, or CSF p-tau181/Aβ42, t-tau/Aβ42 or Aβ42/40**. Cognitive tools now **stage the disease rather than diagnose it**.

2. Plasma p-tau217 is the practice-changing test. Models combining **plasma p-tau217, age and ApoE genotype** achieve **AUC about 0.94**. In the very elderly, **p-tau181, p-tau217 and GFAP discriminate probable Alzheimer's from normal cognition, while Aβ42, Aβ40 and the Aβ42/40 ratio do not** — so amyloid ratios should not be relied on in the oldest old.

3. Digital cognitive assessment. Mobile cognitive assessment systems show **diagnostic equivalence to MMSE and MoCA** in Alzheimer's screening. Future work is on **composite scores integrating digital tests, wearables (for example sleep fragmentation) and plasma p-tau217**, with cross-ethnic validation and regulatory frameworks still pending.

4. Mild behavioural impairment (MBI) — late-onset persistent neuropsychiatric symptoms — is now recognised as an early dementia-risk indicator that may **precede measurable cognitive decline**, and is being validated against plasma p-tau217.

5. Mandated inclusion in assessment frameworks. German S3 CGA guideline (2024): cognition and delirium is one of six core dimensions. **WHO ICOPE:** cognition is one of six intrinsic-capacity domains, with **Mini-Cog, MoCA, MMSE and GPCOG** as named step-2 tools. **Age-Friendly 4Ms:** cognition sits under **Mentation**. **ASCO 2023 Practical Geriatric Assessment** includes a cognitive domain for every cancer patient aged 65 and above.

6. Indian tools and data. LASI wave-1 found **impaired cognition in 9.3%** of those aged 60 and above. Because the MMSE penalises illiteracy heavily, Indian practice uses the **Hindi Mental State Examination (HMSE)**, **RUDAS**, **vernacular MoCA versions**, the **ICMR Neuro-Cognitive Tool Box**, and the **AIIMS Comprehensive Neuropsychological Battery in Hindi**.

D. Current Practice Update

Aspect	Pathy's 6th ed. (2022)	Current position (2023–2026)
What the tools do	Screen for and grade cognitive impairment	**Stage the disease** and **triage to biomarker testing**
Diagnosis of Alzheimer's	Clinical, supported by imaging and sometimes CSF	**Biological (2024 NIA-AA)** — Core 1 biomarkers
Blood tests	Not diagnostically useful	**Plasma p-tau217 in routine pathways**; GFAP adds value
Amyloid measures	CSF amyloid used in some centres	**Aβ42/40 unreliable in the oldest old**
Mode of testing	Paper-and-pencil, face to face	**Mobile and computerised testing equivalent to MMSE/MoCA**
Preclinical markers	Subjective cognitive decline, MCI	Adds **mild behavioural impairment**
Cross-cultural use	MMSE with an education caveat	**Literacy-fair instruments mandatory** in India — RUDAS, HMSE, vernacular MoCA

E. Exam One-Liners

- **Four groups of tools:** delirium instruments, brief screens, screening batteries, detailed batteries and staging scales.
- **CAM for delirium; Mini-Cog or AD8 to screen; MoCA or MMSE to assess; ACE-III to subtype; CDR or Reisberg GDS to stage.**
- **Mini-Cog = 3-word recall plus clock drawing**, and is relatively education-independent.
- **AD8 and IQCODE are informant-based** — they measure change from the person's own baseline.
- **MoCA detects MCI and executive dysfunction better than MMSE; add 1 point if education is 12 years or less.**
- **MMSE has a ceiling effect, is education-dependent, and tests executive function poorly.**
- **RUDAS, HMSE and vernacular MoCA are the literacy-fair choices for Indian patients.**
- **Grober–Buschke free and cued recall demonstrates the hippocampal amnestic pattern of Alzheimer's disease.**
- **ACE-R incorporates the MMSE and clock drawing.**
- **Exclude delirium and depression before interpreting any cognitive score.**
- **No cognitive screening test determines decision-making capacity** — executive tests correlate better than the MMSE, but capacity needs its own assessment.
- **2024 NIA-AA: plasma p-tau217, amyloid PET or CSF ratios define the disease; cognition defines the stage.**

QUESTION 6

Assessment of Decisional Capacity in an Older Person

A. 20 High-Yield Points

Concepts and Definitions

1. **Capacity and competence are not the same.** A **clinician evaluates a patient's capacity to make a decision**; **competence is a legal term** implying that a person **has been deemed competent or incompetent by a court of law**. Someone not competent to act on their own behalf **requires an agent to act for them**.
2. **Competence** refers to a person's ability to **act reasonably after understanding the nature of the situation being faced**.
3. **Capacity is decision-specific and time-specific.** A patient may have capacity for one decision and not another, and may regain capacity later.
4. **Capacity is presumed until proved otherwise.** A **diagnosis of dementia — even by type — is not a sufficient indicator of a person's ability to comprehend and express a meaningful preference**. Intellectual deficits are **spotty**: a person may get lost or forget things yet still make decisions **with appropriate prompting**.
5. **The ethical foundation is autonomy** — the capacity of each adult and cognitively competent individual to **process information and freely decide on a course of action that best suits their own values, preferences, goals and desires**. Respect for autonomy underpins **informed consent**.
6. **Preconditions of valid informed consent: competence to understand and decide**, and **voluntariness in deciding**. The **information element** is **disclosure of relevant information** about the condition and the proposed course of action.
7. **An unwise decision is not incapacity.** In a patient with capacity, autonomy means "*you may not do things to me without my permission*" — **even if a patient's decision to refuse treatment seems unwise, if they have capacity their refusal stands**, and the clinician's **duty of care does not diminish**; all other care continues without prejudice.
8. **Just as it is wrong to infantilise patients** by directing questions to others who answer faster, **it is equally wrong to prejudge their ability to participate in decisions about their own care**.

The Four Elements of Decisional Capacity

9. **Decisional capacity is predicated on four elements** — the single most examinable list: - **Understanding** — the ability to comprehend the disclosed information about the nature of the situation or medical problem, the procedures involved, and the risks and benefits of undergoing or not undergoing testing or treatment. - **Appreciation** — of the significance of the disclosed information and the potential risks and benefits **for one's own situation and condition**. - **Reasoning** — the ability to engage in a reasoning process about the risks and benefits. - **Choice** — being able to **express a choice** whether or not to undergo further testing or treatment.
10. **The four US legal standards for determining decisional capacity** (a parallel, equally examinable list): - The patient is **aware of the treatment options and expresses a treatment preference clearly and consistently**. - The patient can give a **conventionally understandable reason** for the decision that is **consistent with their past behaviour**. - The patient **remembers and can tell back the information** about diagnosis, prognosis and treatment options given by the practitioner. - The patient can **state what their decision means for their own state of health**.
11. **The sliding-scale principle (Figure 95.1):** the **standard of decisional capacity required rises with the risk of the intervention**. A **fully cognisant patient with good health literacy** can consent to high-risk options such as a **phase 1 clinical trial**; a **cognitively impaired patient lacking decisional capacity could not consent to experimental treatment** and, given reduced life expectancy in advanced dementia, would be unlikely to benefit from highly toxic therapy even if it is standard of care. **The area between is the domain of best clinical judgement.** Hence **"staging the ageing is as important as staging the cancer."**

Assessment in Practice

12. **Distinguish memory from understanding** — a person may fail a memory test yet understand the decision at hand.
13. **No cognitive screening test is appropriate to determine decision-making capacity.** Screening tools that focus on **executive function** — the **Clock Drawing Test** or the **Executive Interview** — are **more likely to be associated with decisional capacity** than the MMSE.
14. **Formal capacity instruments exist but are difficult for older adults**, because they require consideration of **hypothetical situations and complex abstract thinking**. Examples: **MacCAT-T (MacArthur Competence Assessment Tool for Treatment — the reference standard)**, **Aid to Capacity Evaluation (ACE)**, **Capacity to Consent to Treatment Instrument (CCTI)**, **Hopemont Capacity Assessment Interview**, **Understanding Treatment Disclosures**.
15. **A useful practical criterion** in routine informed consent is to **recheck with the patient after an interval** to be certain that they **understand the situation and consistently state the same preference**.

16. **Maximise capacity before declaring its absence.** Before deciding a person cannot decide: correct **sensory deficits** (a deaf patient may need a hearing aid, many older people need glasses), **treat delirium, depression, pain and infection**, review sedating drugs, use **simple language, repetition and rephrasing**, choose a **quiet, distraction-free environment**, and involve a familiar person. Written material must be legible — a leaflet is useless if **the typeface is too small, the colour contrast is poor, or there is no white space**.
17. **Formal assessment of mental state may be necessary**, but **no specific score is associated with an inability to make decisions about one's personal healthcare** — this is an important negative statement to write in an examination.
18. **Where capacity is absent:** consult any **advance care directive** and the **surrogate or proxy decision-maker**. A proxy may be formally appointed through an **enduring power of attorney**, or the patient's wishes may be recorded in an **advance directive**; if none exists, the lead clinician must decide in the patient's **best interests**, or apply for **guardianship**.
19. **Hierarchy of treatment decision-makers** (Australian model, quoted in the textbook): **enduring guardian with authority → guardian with authority → adult son or daughter → parent → sibling → primary unpaid carer → other person with a close personal relationship and frequent contact**. The clinician goes to the first person who is **18 or older, has full legal capacity, and is reasonably available and willing**.
20. **Communication and documentation:** - **Relatives must not be given the impression that the decision is theirs to make** — they may suffer significant distress from the emotional burden. Their role is to provide **valuable information about what would be in the patient's best interests**. - Where families cannot bear to decide, the humane option is **"informed assent"** — explicitly offering them the choice to **defer to the provider's judgement**, documented clearly in the record. - **Anticipate decisions early in admission** so the patient can be involved as much as possible and **proxy decision-making is avoided**. - Clinicians must disclose: **the condition being treated; the nature of the proposed treatment or procedure; anticipated results; recognised alternatives; and recognised serious risks, complications and benefits, including of non-treatment.** - **Document the assessment, the reasoning and the outcome.**

B. Structured Approach to a Capacity Assessment

Step	Action
1. Define the decision	Capacity is **decision-specific** — state exactly which decision is in question
2. Presume capacity	Start from presumption; a diagnosis alone never establishes incapacity
3. Optimise the person	Treat delirium, pain, depression, infection; correct vision and hearing; review sedatives; choose the best time of day and a quiet setting
4. Disclose	Condition, proposed treatment, expected outcome, alternatives, serious risks, and the consequences of non-treatment — in **plain language**
5. Test the four elements	**Understanding** ("tell me in your own words") · **Appreciation** ("what does this mean for you?") · **Reasoning** ("how did you weigh those up?") · **Choice** ("so what would you like to do?")
6. Apply the sliding scale	Higher risk demands a higher standard of capacity
7. Recheck	Re-ask after an interval to confirm **consistency** of preference
8. Conclude and act	If capacity present, the decision stands even if unwise. If absent, consult advance directive, then surrogate, then best interests or guardianship
9. Document	Record the specific decision, the disclosure made, the four elements, the conclusion and the reasoning

C. The Indian Legal Framework

1. **Mental Healthcare Act (MHCA), 2017** is the governing statute across India and was rewritten after India ratified the **UNCRPD in 2007**. Capacity has a **pivotal role**.
2. **Section 4, MHCA 2017:** every person is **presumed to have the capacity to make mental healthcare and treatment decisions** if they can **understand the information, appreciate the foreseeable consequences of the decision, or communicate the decision by speech, gesture or any other means**.
3. **Memory loss, cognitive deficits, or even a formal diagnosis of dementia do not imply incapacity automatically** — the Act emphasises **establishing capacity**, and gives **preference to the choices and wishes of a person who has capacity**.
4. **The opinion of the assessor or a third party that a decision is "unwise" must not influence the capacity assessment.** Capacity is **specific to the task and to the time**.
5. **Advance directives — Section 5(3):** an advance directive is **invoked only when the person becomes incapacitated** and **remains effective until they regain capacity**. The Act does not clearly distinguish advance statements from advance directives.

6. **Nominated representative:** decision-making by a nominated representative is **restricted to those lacking capacity for mental healthcare decisions**. **Supported decision-making** ranges from minimal support to complete support.
7. **Other relevant Indian law:** the **Maintenance and Welfare of Parents and Senior Citizens Act, 2007** (maintenance, protection, and transfer-of-property provisions), the **Rights of Persons with Disabilities Act, 2016** (limited guardianship), the **National Trust Act, 1999**, and **Elder Line 14567** for reporting abuse and neglect.
8. **Practical Indian caveat:** the **MacCAT-T, though the international reference standard, is not standardised for the Indian population**, and **family plays a central role in healthcare decision-making** in Indian and other Asian societies — creating real difficulties in operationalising individual autonomy and advance directives.

D. Latest Updates (2023–Present)

1. Indian evidence base is only now emerging. A 2025 descriptive cross-sectional study of mental capacity and advance directives in Indian persons with mental illness confirmed that **published Indian data remain very scarce**, that **the MacCAT-T is regarded as the gold standard but is not standardised for India**, and that the **central role of the family creates practical difficulty in determining advance directives** and enabling individual decision-making about future treatment.

2. Dementia and Indian law. A published analysis of the assessment of dementia under prevailing Indian laws confirms that under **Section 4 of MHCA 2017 a diagnosis of dementia does not itself establish incapacity**, and sets out the four components of the decision-making process as **understanding, appreciating, reasoning and communicating**. It also distinguishes **capacity** (clinical) from **competence** (legal — relating to valid contracts and financial and personal decision-making).

3. UK practice guidance (2024). NHS England guidance restates the functional test as the ability to **understand the relevant information, retain it long enough to make the decision, weigh up the arguments on each side, and communicate the decision** (by talking, signing or any other means). It provides a **practical checklist**: choose a quiet space free from distractions and noise, avoid jargon, **repeat and rephrase questions**, and **identify in advance what the "relevant information" for that specific decision is**. Essex Chambers publishes decision-specific guidance on what constitutes relevant information for different categories of decision.

4. High prevalence of impairment in institutional settings. Older adults evaluated in long-term care have **rates of capacity impairment between 44% and 69%** — an argument for routine, structured assessment rather than ad hoc judgement.

5. Convergence with capacity-based frameworks. The **German S3 CGA guideline (2024)** mandates cognition and delirium assessment as a core dimension; **WHO ICOPE** includes cognition and psychological well-being. Both feed directly into capacity evaluation, and the **Age-Friendly 4Ms** place **"What Matters"** — eliciting the person's own goals — as the first M, operationalising autonomy in routine care.

E. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Legal framework	Generic Western frameworks; Australian guardianship hierarchy quoted	**India: MHCA 2017 governs**, with statutory presumption of capacity and nominated representatives
Effect of a dementia diagnosis	A diagnosis is not a sufficient indicator of incapacity	**Statutorily reinforced** — Section 4 MHCA: dementia does not imply incapacity
Instruments	Formal tools exist but are hard for older adults	**MacCAT-T remains the gold standard but is not standardised for Indian populations**
Cognitive tests	No screening test determines capacity; executive tests correlate better	Unchanged and reaffirmed
Role of family	Consult relatives for best interests, but do not transfer the decision	**In India, family-centred decision-making is normative**, creating tension with individual-autonomy models
Documentation	Recommended	Now expected to be **decision-specific**, recording the relevant information disclosed
Autonomy in routine care	Ethical principle	Operationalised as **"What Matters"** in the 4Ms framework

F. Exam One-Liners

- **Capacity is clinical and decision-specific; competence is legal and determined by a court.**
- **The four elements: Understanding, Appreciation, Reasoning, Choice.**
- **Capacity is presumed** — a diagnosis of dementia never establishes incapacity by itself.
- **An unwise decision is not incapacity.** If the patient has capacity, their refusal stands, and the duty of care does not diminish.
- **Sliding scale:** the higher the risk of the intervention, the higher the standard of capacity required.

- **"Staging the ageing is as important as staging the cancer."**
- **No cognitive screening test determines capacity**; **clock drawing and the Executive Interview** correlate better than the MMSE.
- **No specific MMSE score defines incapacity.**
- **MacCAT-T is the reference instrument** — but is not standardised for India.
- **Maximise capacity first:** treat delirium, depression and pain; correct hearing and vision; simplify language; choose a quiet room and the best time of day.
- **Recheck after an interval to confirm the preference is consistent.**
- **Section 4, MHCA 2017 (India):** presumption of capacity; understand, appreciate consequences, communicate by any means.
- **Section 5(3), MHCA 2017:** advance directive is invoked only on incapacity and lapses when capacity returns.
- **Never make the family feel the decision is theirs** — offer **"informed assent"** where they cannot bear to decide.
- **Anticipate decisions early in the admission** so that proxy decision-making is avoided.

QUESTION 7

Geriatric Syndromes — An Overview

A. 20 High-Yield Points

Concept and Definition

1. **A geriatric syndrome is a clinical condition in older people that does not fit into a discrete disease category.** Geriatric syndromes are **highly prevalent, multifactorial, and associated with substantial morbidity and poor outcomes**.
2. **The defining feature is a many-to-one and one-to-many relationship: multiple contributing causes converge on a single presenting problem**, and **any one problem may arise from many different causes**. This is the opposite of the classical single-disease model.
3. **Because diagnoses often do not tell the whole story in geriatrics, it is more helpful to think in terms of presenting problems.**
4. **The underlying principle is homeostenosis** — the progressive decline in the **reserve capacity of all organ systems** with increasing age, so that **several small deficits combine to cross a threshold** and produce a syndrome that no single deficit would have caused.
5. **The classical list — "the series of I's": Immobility · Instability (falls) · Incontinence · Intellectual impairment · Infection · Impairment of vision and hearing · Irritable colon · Isolation (depression) · Inanition (malnutrition) · Impecunity · Iatrogenesis · Insomnia · Immune deficiency · Impotence.**
6. **Morley's "new geriatric giants"** add **frailty, sarcopenia, anorexia of ageing and cognitive impairment** — reflecting the modern emphasis on pre-disability states.
7. **Illustrative example (immobility):** it may be caused by a **fractured hip, congestive heart failure, a recent fall with fear of falling, or pain from degenerative joint disease** — any or all together. It is essential to **explore the underlying causes with the individual** so that appropriate interventions can be implemented; **pain and fear of falling must be addressed before engaging the person in an exercise programme**.

Shared Risk Factors — the Unifying Concept

8. **Four shared risk factors run across the five best-validated geriatric syndromes** (Tinetti, Inouye, Gill and Doucette, *JAMA* 1995; Inouye et al., *JAGS* 2007): - **Older age** - **Baseline cognitive impairment** - **Baseline functional impairment** - **Impaired mobility**
9. **The five syndromes in which these were demonstrated: pressure ulcers, incontinence, falls, functional decline and delirium.**
10. **Clinical corollary:** because the risk factors are shared, **multiple risk factor reduction is more effective than the regular single-disease medical model**, and **one intervention can prevent several syndromes at once**.
11. **Landmark proof-of-concept trials: Inouye's multicomponent HELP intervention (NEJM 1999)** for delirium prevention, and **Tinetti's multifactorial intervention (NEJM 1994)** to reduce falls in the community — both showing that **targeting shared risk factors works**.
12. **The number of risk factors present determines the total risk**, which rises **proportionally** as they accumulate — demonstrated by Tinetti for dizziness (five to seven significant risk factors).

Iatrogenesis — a Special Emphasis

13. **Iatrogenesis is an all too common problem, and the risk increases with exposure to the care system** — tests, surgical interventions, medications and treatments. In every interaction the **risk–benefit balance must be considered and explained** to the individual and their proxy.
14. **Medication management** needs particular deliberation, because older adults have **marked changes in absorption, metabolism and excretion**. Use **Beers criteria and STOPP-START**, review **anticholinergic burden**, and check **QTc risk with psychotropics**.
15. **Even more dangerous is the careless, hasty application of clinical labels.** A patient who becomes confused in hospital may **not** have dementia; a person with an occasional urinary accident is **not necessarily incontinent**. **Labelling a patient as demented or incontinent is too often the first step towards nursing-home placement — a setting that can make such labels self-fulfilling prophecies.**

Assessment and Management

16. **The clinical method for any geriatric syndrome:** - Treat the **presenting problem as a syndrome, not a diagnosis** - Enumerate **all contributing factors** rather than searching for one cause - Look specifically for the **shared risk factors** — cognition, function, mobility - Search for **reversible contributors**: a **new drug or dose change (including over-the-counter), an intercurrent acute illness, or a change in living conditions** - Intervene on **as many factors as possible simultaneously** - **Link assessment to a care plan and long-term follow-up**

17. **Comprehensive geriatric assessment is the definitive vehicle** for identifying and managing geriatric syndromes, because it is the only method that systematically covers all the contributing domains at once.
18. **Criteria for targeting CGA in diabetes (Table 86.6)** show how syndromes drive referral: **presence of a geriatric syndrome (confusional state, depression, falls, incontinence, immobility, pressure sores)**; pre-frailty or frailty; several coexisting morbidities with complex drug regimens; disability from lower-limb vascular disease or neuropathy requiring rehabilitation; and **absence of a terminal illness or dementing syndrome**.
19. **Cross-syndrome prevention principles: mobilise early ("bed is bad")**, **deprescribe**, **maintain hydration and nutrition**, **correct vision and hearing**, **avoid restraints and catheters**, **screen for cognition and mood**, and **treat pain**. Because pressure injuries, falls, delirium and functional decline share risk factors, **multifactorial interventions delivered by a multidisciplinary team** are effective across all of them.
20. **The major barrier is implementation, not evidence.** Preventive strategies of proven effectiveness for **delirium and falls** exist, but **major barriers have been identified in translating research advances into clinical practice and policy**.

B. The Major Geriatric Syndromes at a Glance

Syndrome	Key shared drivers	First-line action
Falls and instability	Gait/balance impairment, drugs, vision, cognition, environment	Multifactorial assessment; TUG, Tinetti; deprescribe; strength and balance exercise; home hazards
Immobility	Pain, disease, fear, iatrogenesis, environment	Treat pain and cause; early mobilisation; physiotherapy and occupational therapy
Delirium	Cognitive impairment, sensory deficits, drugs, infection, dehydration, immobility	**CAM**; HELP-type multicomponent prevention; treat precipitants
Dementia and cognitive impairment	Age, vascular risk, sensory deficits	Mini-Cog/MoCA; exclude reversible causes; caregiver support
Incontinence	Mobility, cognition, drugs, local pathology	Bladder diary; exclude retention, infection, impaction; timed toileting
Pressure injury	Immobility, nutrition, incontinence, low weight	Braden/Norton; pressure relief; nutrition; skin care
Frailty and sarcopenia	Disease, poor intake, sarcopenia, executive dysfunction	FRAIL screen; resistance exercise plus protein 1 g/kg/day; deprescribe if more than 5 illnesses
Malnutrition and anorexia of ageing	Social, sensory, gastric, hormonal factors	MNA; **MEALS-ON-WHEELS** mnemonic
Polypharmacy and iatrogenesis	Exposure to the care system	Beers, STOPP-START; medication reconciliation
Functional decline	All of the above	CGA and rehabilitation
Depression and isolation	Loss, disability, chronic disease, loneliness	PHQ-2 then GDS-15; social prescribing
Sensory impairment	Age-related	Snellen, whispered voice test; spectacles, cataract surgery, hearing aids
Insomnia	Pain, nocturia, drugs, depression, environment	Sleep hygiene; avoid hypnotics
Elder abuse and neglect	Dependency, caregiver burden, cognitive impairment	Direct enquiry; **Elder Line 14567** in India

C. Latest Updates (2023–Present)

1. The shared-risk-factor model is now the accepted organising principle. The Inouye/Tinetti framework — **four shared risk factors (older age, baseline cognitive impairment, baseline functional impairment, impaired mobility) across five syndromes (pressure ulcers, incontinence, falls, functional decline, delirium)** — remains the definitional basis, with current work focused on **synergistic interactions between risk factors** and on the **basic mechanisms** underlying multifactorial conditions.

2. Screening tools have been packaged. The **Rapid Geriatric Assessment (RGA)** bundles four syndromes — **frailty, sarcopenia, geriatric anorexia and cognitive decline**. Administered to **16,615 people aged 65 and over in Missouri between 2015 and 2024**, it showed that nearly **40% reported five or more illnesses (37.3%)**, linking syndrome screening to multimorbidity risk.

3. Multiple geriatric syndromes are the rule, not the exception. A Chinese community study of 706 adults aged 60 and above (2022–23) assessed **ten syndromes — depressive symptoms, cognitive impairment, pain, falls, sleep disturbance, constipation, polypharmacy, multimorbidity, malnutrition and frailty** — and defined **"multiple geriatric syndromes" as two or more in one individual**. A 2023–24 hospital CGA study in Shanghai similarly evaluated **pain, sleep, constipation, fall risk, urinary incontinence, polypharmacy, nutritional risk and dementia** in a single assessment, using **Mini-Cog, Snellen chart and Timed Up and Go** for in-depth evaluation of those screening positive.

4. Standardised syndrome-based CGA is now guideline-mandated. The **German S3 guideline (2024)** requires **six core dimensions — self-help ability, mobility, cognition/delirium, affect, nutrition and social situation** — which

map almost exactly onto the major geriatric syndromes. The **Italian guideline (2024)**, from 117 studies, showed CGA **reduces hospitalisation, mortality, institutionalisation and delirium risk** and **improves prescribing appropriateness**.

5. WHO ICOPE reframes syndromes as losses of intrinsic capacity. The six domains — **mobility, cognition, vitality/nutrition, vision, hearing and psychological well-being** — are essentially the geriatric syndromes re-expressed as **capacities to be preserved rather than deficits to be treated**.

6. Frailty is now the strongest single predictor of adverse syndrome outcomes. A pooled odds ratio of **9.82 for incident ADL disability in frail older adults** has been reported, and the **NEJM 2024 review by Kim and Rockwood** established **"frailty-guided clinical care"**, stratifying management across **robust, pre-frailty, frailty and end-stage frailty**.

7. Indian burden. LASI wave-1 (31,464 adults aged 60 and above) found **44.3% with no geriatric condition, 32.7% with one, 15.9% with two and 7.1% with three or more**. Individual prevalences: **underweight 26.9%, dizziness 14.5%, impaired vision 13.7%, impaired hearing 9.6%, impaired cognition 9.3%, major depressive disorder 8.2%, injurious falls 5.7%, incontinence 4.0%**, with **7.4% ADL dependency**. **Both a higher number of geriatric conditions and a higher number of chronic conditions predicted ADL dependency.** Frailty affects **29.2%** and pre-frailty **58.8%**. The most disabling multimorbidity combination is **hypertension plus arthritis plus high depressive symptoms**.

D. Current Practice Update

Aspect	Textbook position	Current position (2023–2026)
Definition	Descriptive list of "I's"; concept acknowledged as poorly defined	**Operationalised** around four shared risk factors across five validated syndromes
Number recognised	14 classical "I's" plus new giants	Studies now routinely screen **8–10 syndromes simultaneously** in one CGA
Screening	Clinician-led, opportunistic	**Packaged instruments (Rapid Geriatric Assessment)** and **guideline-mandated core domain sets**
Framing	Deficits and presenting problems	Complemented by **WHO intrinsic capacity** — the same domains framed as capacities
Frailty	One syndrome among many	The **central organising syndrome**, used to guide treatment intensity ("frailty-guided care")
Evidence gap	Multifactorial interventions effective for falls and delirium	Evidence secure; **the barrier is implementation and policy translation**
Indian data	Not addressed	**LASI provides national prevalence**; over half of Indian elders have at least one geriatric condition

E. Exam One-Liners

- **A geriatric syndrome is a multifactorial condition that does not fit a single disease category.**
- **The core principle is homeostenosis** — reduced reserve across all organ systems.
- **Many causes, one presentation; one presentation, many causes.**
- **The series of I's:** Immobility, Instability, Incontinence, Intellectual impairment, Infection, Impairment of vision and hearing, Irritable colon, Isolation, Inanition, Impecunity, Iatrogenesis, Insomnia, Immune deficiency, Impotence.
- **New geriatric giants:** frailty, sarcopenia, anorexia of ageing, cognitive impairment.
- **Four shared risk factors:** older age, baseline cognitive impairment, baseline functional impairment, impaired mobility.
- **Five validated syndromes:** pressure ulcers, incontinence, falls, functional decline, delirium.
- **Multiple risk factor reduction beats the single-disease model** — proved by Inouye (delirium, 1999) and Tinetti (falls, 1994).
- **Iatrogenesis rises with exposure to the care system.**
- **The careless application of a label is more dangerous than the syndrome** — "demented" or "incontinent" can become a self-fulfilling prophecy leading to institutionalisation.
- **CGA is the definitive vehicle for detecting and managing geriatric syndromes.**
- **India (LASI): 55.7% of elders have at least one geriatric condition; 7.1% have three or more; ADL dependency 7.4%.**
- **The evidence is settled; the barrier is implementation.**

End of Set 1.
